[4]Department of Neurology, Medical University of Graz, Graz, Austria

The role of genetic and environmental factors in specific cognitive abilities in the elderly is poorly understood. Here we estimated their contributions to variation in the cognitive domains memory, executive function and fine motor skills and tested the genetic correlations between these domains.

The study was conducted in the Austrian Stroke Prevention Study (ASPS), a population-based cohort study (n=479, mean age=64.6 years, 54.9% women) and in the ASPS-Family including relatives of the ASPS participants (n=376, 177 families, mean age=63.6 years, 60.1% women). The neuropsychological test battery included Bäumler's Lern-und Gedächtnistest, Trail Making B, Digit Span Backward, the Wisconsin Card Sorting and the Perdue Pegboard Test. Heritability was estimated by variance component analyses using SOLAR and by SNP genotypes using GCTA. Bivariate heritability was computed using SOLAR. We adjusted for age, gender, education and APOE.

Heritability of memory, executive function and fine motor skills using family structure were 60, 41 and 59%, and 11, 23 and 29% using SNP genotypes. Genetic and environmental correlations between memory and executive function were 53% and 20%, between memory and fine motor skills 41% and 14%, respectively. We found no genetic correlation between executive function and fine motor skills, the environmental correlation was 37%.

There is a substantial heritability of memory and fine motor skills and a moderate of executive functions. Half of the heritability of executive function and fine motor skills can be explained by common SNP. Our results support shared genetic factors for executive function and memory as well as fine motor skills.

MEMORY IMPAIRMENT CAUSED BY HIPPOCAMPAL ATROPHY BUT NOT BY CEREBRAL SMALL- VESSEL DISEASE IN HEALTHY ELDERLY PEOPLE

Y. Takashima[1], M. Hashimoto[1], R. Murakawa[1], A. Uchino[2], T. Yuzuriha[1], H. Yao[1]
[1]Clinical Research Division,
Center for Emotional and Behavioral Disorders National Hizen Psychiatric Center, Kanzaki Saga, Japan
[2]Department of Diagnostic Radiology,
Saitama Medical University International Medical Center, Saitama, Japan

Background: To estimate association hippocampal atrophy and memory impairment in normal elderly people, we investigated psychological tests and measured hippocampal volume of community-dwelling elderly people. Method: We examined 213 of healthy elderly community-dwelling subjects(age>or=58years,97men, 116women, mean age 68.6years)with no dementia or no psychiatry diseases. Memory impairment was assessed by Rivermead Behavioral Memory Test [RBMT]. Executive function was assessed by modified Stroop test, [MST] and apathy was assessed by apathy scale. A brain MRI examination was performed on a 1.5-Tscanner (Achieva; Philips) using theT1- and T2 - weighted images (WI), fluid-attenuated inversion recovery , T2*- WI. We used voxel-based specific regional analysis system for Alzheimer's disease (VSRAD). We used the Z-score which indicates severity of atrophy obtained from the averaged in the target volume of interest. Results: We operationally defined a total of individuals with Standard profile score (SPS)of RBMT less than 17 as having a memory impairment. In a multivariate analysis, there was a significant relationship between memory impairment defined by SPS and Z score(OR3.843, 95%CI 1.678 - 8.803, p=0.001). Impaired executive function defined by MST was related to existence of silent brain infarction (OR2.89,95%CI 1.019 - 8.214, p=0.046) and apathy defined by Apathy scale was related to existence of deep white matter lesions(OR2.077,95%CI 0.025 - 4.209, p=0.043)in a multivariate analysis. Conclusions: Memory impairment in healthy elderly people was caused by hippocampal atrophy but not by cerebral vascular diseases.

CHARACTERISTIC FEATURES OF COGNITIVE, AFFECTIVE, AND DAILY LIVING FUNCTIONS OF LATE-ELDERLY DEMENTIA

N. Hishikawa[1], Y. Fukui[1], K. Sato[1], S. Kono[1], Y. Ohta[1], T. Yamashita[1], K. Deguchi[1], K. Abe[1]

[1]Neurology, Okayama University, Okayama, Japan

Objectives: The world is rapidly aging, and is facing an increase of late-elderly dementia patients. **Methods**: We examined 1,554 dementia patients in our clinic, dividing into 3 subgroups according to the age; young- (≤64 years old [y.o.]), middle- (65-74 y.o.), and late-elderly (75 y.o.≤), and investigated the cognitive, affective, and activities of daily living functions (ADL), especially in late-elderly dementia comparing with young- (presenile) and middle-elderly dementia. **Results**: Among 1,554 dementia patients, Alzheimer's disease (AD) dominated 62%, followed by mild cognitive impairment due to AD (12%), vascular dementia (9%), but AD was age-dependently increased up to 69% in late-elderly dementia. Total scores of 4 cognitive tests were significantly worse with aging, with specific subscales of orientation, recall, visual retention, word fluency, etc. On the other hand, total scores of the affective tests showed only an increase in apathy scale in the late-elderly group. Each group showed depressive/depression in 63.2-55.2 %, and apathy in 44.2-54.8%. Furthermore, ADL especially in the instrumental ADL items deteriorated significantly in the late-elderly group, which statistically correlated with mini-mental state examination (MMSE) score. **Conclusions**: These results demonstrates that late-elderly dementia group is characterized as significant cognitive declines, increasing apathy, more than half in depressive/depression and apathy, and instrumental ADL decrease. The cognitive decline may be related to such an affective and ADL declines.

ADPD5-0786

TIME DELAY FROM FIRST MEMORY COMPLAINTS TO DIAGNOSIS OF AD. DATA FROM CZECH BRAIN AGING STUDY

K. Sheardova[1], O. Hromkova[1], D. Hudecek[1], R. Marciniak[2], M. Urbanova[2], B. Dvorakova[1], M. Vyhnalek[2], Z. Nedelska[2], J. Laczó[2], J. Hort[2]
[1]Department of Neurology, ICRC St. Anne´s University Hospital, Brno, Czech Republic
[2]Memory Center, ICRC St. Anne´s University Hospital, Brno, Czech Republic

Objectives: Czech Republic has 10.5 million inhabitants; average catchment area of 1500-1800 inhabitants per GP (15-20 dementia patients per GP), only 2-4 patients are actually referred to specialists who can prescribe ChEI. At the end of 2012, we have conducted educational campaign via media and lectures aiming on GPs and public about the importance of early diagnosis of Alzheimer´s disease (AD). We report the effect on early detection of patients with dementia and at risk of AD.
Methods: Subjects were examined at the Memory Center ICRC, St. Anne´s Teaching Hospital Brno. They underwent physical, neurological evaluation, neuropsychological testing covering: memory, attention/processing speed, language, executive and visuospatial functions. MRI scans were performed for vascular changes and hippocampal volume assessment.
Results: 348 subjects with memory complaints were examined, during the year 2013. 148 subjects had no objective cognitive deficit, 88 subjects were diagnosed with mild cognitive impairment (MCI), 100 were newly diagnosed with dementia (21 in moderate and 9 in severe stage of dementia). 54 of the dementia patients expressed long term memory complaints to their doctor and were neglected. 230 of the non-demented subjects were included in the Czech Brain Aging Study database. Current data about conversion rates after 1 year follow up will be presented.
Conclusion: Big proportion of patients with dementia and at risk of AD is not recognized by GPs or other physicians. Educational campaigns aiming on GPs and public help to bring subjects at risk earlier to specialized care.

NEUROLOGICAL SOFT SIGNS IN HEALTHY AGING, MILD COGNITIVE IMPAIRMENT, AND MILD ALZHEIMER´S DISEASE

N. Urbanowitsch[1], C. Degen[1], P. Toro[2], J. Schröder[3]
[1]Section of Geriatric Psychiatry, University of Heidelberg, Heidelberg, Germany
[2]Department of Psychiatry and Psychotherapy,
Universidad Catolica de Santiago de Chile, Santiago, Chile
[3]Section of Geriatric Psychiatry and Institute of Gerontology, University of Heidelberg, Heidelberg, Germany

Objectives: Neurological soft signs (NSS), i.e. minor motor and sensory changes, are a common feature in severe psychiatric disorders. Nevertheless, they have rarely been investigated in healthy aging or in patients with mild cognitive impairment (MCI) and Alzheimer's disease (AD).
Methods: NSS were examined using an abbreviated version of the Heidelberg NSS Scale in 226 'old' participants born from 1930 to 1932 (63 with MCI, 15 with AD, 148 healthy controls) and 231 healthy 'young' participants (born from 1950 to 1952) of the population-based Interdisciplinary Longitudinal Study of Ageing (ILSE). Subjects were examined at three examination waves (t1:1993/94; t2:1997/98; t3:2005/07). Years of school education were used as a proxy for cognitive reserve.
Results: NSS scores were significantly ($p<0.001$) higher in the AD patients (74.7±1.0) than in the healthy controls (73.9±1.0) while the MCI patients (74.2±1.0) took an intermediate position. This result was confirmed after years of school education were entered as a covariate which were inversely correlated ($r = - 0.27$; $p<0.001$) with NSS. Neither a history of major depression, ApoE and COMT genetic polymorphisms nor sex was significantly associated with NSS. Comparison of NSS scores between 'old' (2.8 ± 1.8) and 'young' (2.5 ± 2.0) controls yielded only minor, non-significant differences.
Conclusions: Our results demonstrate that NSS are frequently found even in mild AD. NSS refer to educational levels rather than sex, age, depression or important genetic polymorphisms. Since NSS primarily involve motor coordination it appears plausible that the respective deficits can be partly compensated for by cognitive reserve.

ASSOCIATION OF TELOMERE LENGTH ALTERATIONS WITH INCREASED RISK OF AMNESTIC MILD COGNITIVE IMPAIRMENT

R.O. Roberts[1], L.A. Boardman[2], R.H. Cha[1], V.S. Pankratz[1], R.A. Johnson[3], T.J.H. Christianson[1], L.R. Roberts[2], R.C. Petersen[4]
[1]Department of Health Sciences Research, Mayo Clinic, Rochester, USA
[2]Department of Internal Medicine, Mayo Clinic, Rochester, USA
[3]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, USA
[4]Department of Neurology, Mayo Clinic, Rochester, USA

Objective: To investigate the associations of peripheral blood telomere length with incident amnestic mild cognitive impairment (aMCI)**,** a putative precursor of AD, among Mayo Clinic Study of Aging participants. **Methods:** Using a nested case-control design, we matched 137 incident aMCI cases (mean age 81.1 years, [range 70.9-90.8]; 49.6% men) by age and sex to 137 cognitively normal controls. We measured peripheral blood telomere length (T/S ratio) in DNA from blood drawn at baseline using quantitative PCR. We investigated the association of peripheral blood telomere length with incident aMCI. **Results:** We observed a non-linear association of telomere length with aMCI ($p = 0.04$), with the lowest risk in the middle quintile. Compared to the middle T/S quintile (Q3), the risk of aMCI was elevated for subjects with the shortest (Q1: HR, 2.85, 95% Confidence interval [CI] 0.98, 8.25; $p = 0.05$) and the longest telomere lengths (Q5: HR, 5.58, 95%CI, 2.21, 14.11; $p = 0.0003$). **Conclusion:** In our elderly cohort, both short and long telomeres were associated with an increased risk of aMCI. The findings also suggest that both long and short telomeres are involved in the pathogenesis of aMCI and may be markers of increased risk of aMCI.

ADPD5-1997

THE ASSOCIATION BETWEEN AMYLOID PATHOLOGY TO CSF BIOMARKERS OF CONCOMITANT PATHOLOGY IN COGNITIVELY HEALTHY ELDERLY

K. Höglund[1], S. Kern[1], A. Börjesson[1], H. Zetterberg[1], K. Blennow[1], I. Skoog[1]
[1]Psychiatry & Neurochemistry, Neuroscience and Physiology, Mölndal, Sweden

Objectives: The objective of this study was to examine if amyloid pathology, measured by CSF Aβ42 < 550pg/mL, predicts concomitant pathology in cognitively healthy elderly from a Swedish population based sample. **Methods:** A total of 129 dementia free elderly participants from the Gerontological and Geriatrics Population Studies took part in a lumbar puncture in 2009/2010 and underwent a neuropsychiatric and neuropsychological examination. CSF levels of Aβ42, total tau, phospho-tau(p181), neurogranin and YKL-40 were assessed. Dementia was diagnosed in accordance with DSM-III criteria. The group was divided in two groups based on their CSF Aβ42 levels (cut off 550pg/mL) where levels below 550pg/mL are considered to reflect brain amyloid pathology. **Results**: Healthy elderly with CSF Aβ42 levels below 550pg/ mL (n=46) displayed significantly increased levels of total –tau (p<0,001), p-tau(p<0,001), neurogranin (p=0,011), and YKL40(p=0,044). **Conclusion**: This study indicates that amyloid pathology in cognitively healthy elderly individuals can predict neuronal damage (t-tau and neurogranin), tangle pathology (p-tau) and microglial activation (YKL-40).

ADPD5-2077

FIVE YEARS EVOLUTION OF MMSE SCORE AT DIAGNOSIS OF ALZHEIMER'S DISEASE: DATA FROM THE FRENCH ALZHEIMER DATABASE

K. TIFRATENE[1], P. ROBERT[2], C. PRADIER[3], J.F. DARTIGUES[4]
[1]Public Health EA Cobtek, CHU de Nice, Nice, France
[2]CMRR EA Cobtek, CHU de Nice, Nice, France
[3]Public Health, CHU de Nice, Nice, France
[4]U897, INSERM, Bordeaux, France

Objectives: To describe the 5 years evolution of the MMSE score at diagnosis of Alzheimer disease (AD) in French memory centers.
Methods: The French Alzheimer Database (BNA) collects the activity of 415 French memory centers. We included in the study patients newly diagnosed as AD between 2009 and 2013 within participating centers. The considered MMSE score was at diagnosis; in the absence of MMSE at diagnosis we used the closest MMSE within the limit of +/-1 year. MMSE scores at diagnosis were compared by variance analysis. Multivariate linear regression analysis was conducted to explore the association between mean MMSE score and year of diagnosis taking into account other factors.
Results: 65,270 AD patients were included in the analysis. Women accounted for 70.1% and the mean age at diagnosis was 81 years old (sd 7.3). The mean MMSE score at diagnosis was 20 for subjects diagnosed in 2009 and 17.6 for patients diagnosed in 2013. The decrease is linear. After taking into account age, sex, type of center (care vs care and research centers), and patients' education a significant decrease of MMSE score with time is still observed.
Conclusions: These results indicate that the level of MMSE at diagnosis of AD decreased between 2009 and 2013 in France. In the context of an observed decrease of the incidence and prevalence in some countries, these results would suggest that the diagnosis is performed at a more advanced stage than before.

[3]Clinical Pharmacology Neuroscience, Pfizer, Cambridge, USA
[4]Clinical and Translational Imaging Neuroscience, Pfizer, Cambridge, USA
[5]DevOps Neuroscience, Pfizer, Cambridge, USA
[6]Akili Interactive Labs, Akili Interactive Labs, Boston MA, USA

Objective
Subtle changes in Divided Attention (the ability to cope with distractions) have been reported in early Alzheimer's disease (AD).
As accumulation of amyloid in the brain, is both a biomarker and a risk factor for progression toward development of AD cognitive symptoms, it is hypothesized that amyloid carriers may have higher cognitive vulnerability and will thus benefit to a lesser extent from the learning associated with 28 days of dual-task cognitive training than non-carriers.
The primary study objective is to compare the effect of dual-task training on cognitive measures between amyloid carrier and non-carriers.
Method
A9001489 is a randomized double-blind, sponsor-open, parallel group, placebo controlled trial with repeated self-administration of Akili Interactive's EVO dual-task assessment in healthy elderly subjects. It is estimated that a total of approximately 100 subjects will be randomized in the study, at a ratio of no greater than 3:2 in each of the two amyloid groups (non-carrier:carrier).
Results
While A9001489 study is ongoing, a preliminary analysis of screening data revealed a lower rate of amyloid carrier status than expected in subjects of 60-80 years of age, thus challenging the feasibility of study conduct. These demographic and amyloid data are presented, along with mitigation strategies to enable study conduct.
Conclusion
Amyloid prevalence in the healthy elderly population needs to be carefully considered when planning a preclinical or early AD study. Selection criteria should be adjusted accordingly to allow study execution.

Objective

Aftins (**A**myloid-β **F**orty-**T**wo **In**ducers) is a family of molecules triggering robust up-regulation of extracellular/secreted Aβ-42 (1,2), similar to what is described in late onset Alzheimer's disease (AD). Our objective was to see whether such Aβ-42 inducers are found among products of common exposure ('human chemical exposome' (HCE)).

Methods

Cultures of cell lines, primary neurons and iPSCs derived neurons, ELISA, IP-MS.

Results

We screened 3500+ HCE products and detected a few Aβ-42 inducers, including some triazine herbicides. Among 37 commercial triazines, 6 triggered Aβ-42 production in various cell lines, primary neuron cultures and neurons derived from human iPSCs. Neurons derived from IPScs from AD patients (APP-K724N mutation) showed increased Aβ-42 production which was further enhanced by triazines or aftin-5. These results, initially obtained by ELISA, were confirmed by immunoprecipitation/mass spectrometry identification of the complete range of secreted Aβ fragments. To identify the molecular targets of triazines, we developed an affinity chromatography matrix of agarose-immobilized triazines.

Conclusion

(i) like Aftins, some triazines trigger a shift in the γ-secretase cleavage site preference at APP, leading to a relative increase in the production of longer, more aggregation-prone amyloids, **(ii)** the HCE contains products able to induce production of Aβ-42, **(iii)** these molecules may constitute new pharmacological tools to develop chemically-induced animal models of AD, **(iv)** such potentially 'Alzheimerogenic' products may contribute to the development of late onset AD, **(v)** identification of environmental Aβ-42 inducers may lead to a novel prevention approach to AD.

ACCESSIBILITY OF THE DOMINANT AND NONDOMINANT LANGUAGE IN VERBAL FLUENCY AND PICTURE NAMING IN BILINGUALS WITH MCI AND AD

M.E. Kowoll[1], S. Gladis[1], J. Schröder[2]
[1]Section for Geriatric Psychiatry, University of Heidelberg, Heidelberg, Germany
[2]Section for Geriatric Psychiatry/Institute for Gerontology, University of Heidelberg, Heidelberg, Germany

Background
Bilingualism leads to enhanced performance in a variety of executive function tasks (e.g. Bialystok et al., 2008). Neuropsychological differences between monolinguals and bilinguals with mild cognitive impairment (MCI) and Alzheimer`s disease (AD) as well as MCI- and AD- related effects on bilinguals' dominant and nondominant language have only rarely been analysed.
Methods
Neuropsychological performance was investigated in 41 lifelong bilinguals (mean age: 73.6 ± 11.5), and 45 monolinguals (mean age: 78.1 ± 10.9) subjects matched for age, education, sex, and severity of cognitive deficits. According to the results of a thorough psychiatric examination 22 and 47 subjects were diagnosed with MCI or AD, respectively, while 17 showed no cognitive deficits. Language dominance in bilinguals was determined using the objective method following Gollan et al. (2011).
Results
Both mono- and bilingual patients with MCI and with AD scored significantly lower than the healthy controls in nearly all neuropsychological domains tested. When compared between the dominant and the non- dominant language, bilingual patients with MCI had more severe deficits in their dominant than in their non- dominant language while a reversed pattern of deficits applied for the bilingual patients with AD.
Conclusions
Our findings demonstrate that bilinguals with MCI or AD do not differ from monolinguals in neuropsychological performance. The dominant language appears to be first compromised in bilingual patients while severe deficits of the nondominant language develop later in the course with manifestation of AD. This finding confirms previous studies describing language related deficits early in the course of AD.

MATERNAL EXPOSURE TO DIESEL EXHAUST NANOPARTICLES ENHANCES THE RISK OF ALZHEIMER'S DISEASE BY PROMOTE BETA-AMYLOID FIBRILLATION IN OFFSPRING

M. Sugamata[1], T. Ihara[1], M. Umezawa[2], K. Takeda[2]
[1]Department of Pathology, Tochigi Institute of Clinical Pathology, Tochigi, Japan
[2]Research Institute for Science and Technollogy, Tokyo University of Science, Chiba, Japan

Objective: Alzheimer's disease (AD) is one of amyloid diseases; the pathogenesis of AD is associated with β-amyloid (Aβ) fibrillation. Nanoparticles are being explored for their role in diagnosing, preventing, treating or even causing amyloid diseases. But the relations between nanoparticles and Aβ aren't proved at the present. We have already reported that Diesel exhaust particles (DEP; one of nanoparticles) exposure to animals exert severe influences on brains. In this study, we observed Aβ fibril formation in adult marine brain of maternal DEPs exposure.
Methods: Pregnant ICR mice were exposed to DEP and delivered of babies in clean air. At 12 and 40 weeks, brains were obtained from mice born from DEP-exposed and control mothers and examined by light and electron microscopy, compared between with and without DEP exposure. The storage of Aβ, which is characteristic of neurodegenerative diseases, was detected with immunohistochemical staining.
Results: All mice with DEP exposure showed swelling of astrocytes' endfoot, endothelial cell apoptosis, and diffuse obstruction of capillaries. Specifically, mice at 40 weeks have the neurofibrillary tangles, and showed positive for components of Aβ.
Conclusions: These findings suggest that maternal DEP exposure might effect fetal brain development, carry atrophy and promote Aβ fibrillation in the offspring. The damages of fatal brain make influences reach not only in infants and youths but also in adults, even if they live in clean environment after birth, the risk that suffers from Alzheimer's diseases etc. must be higher. The interaction between Aβ and nanoparticles may contribute to AD etiology.

[7]Center for Neuroscience Studies, Queen's University, Kingston, Canada

Alzheimer's disease (AD) is increasingly associated with peripheral metabolic disorders. Clinical/epidemiological data indicate increased risk of diabetes in AD patients. Here, we show that intracerebroventricular infusion of Ab oligomers (AβOs) in mice triggered peripheral glucose intolerance, a phenomenon further verified in a triple-transgenic mouse model of AD. AβOs failed to induce glucose intolerance when injected systemically, suggesting that brain regions involved in control of peripheral metabolism were targeted by AβOs. Accordingly, we show that AβOs bind to hypothalamic neurons and induce oxidative stress. AbOs further activated pro-inflammatory IKKβ/NF-κB signaling and instigated endoplasmic reticulum (ER) stress in the hypothalamus of mice and macaques given AbO infusions. AbOs failed to trigger peripheral glucose intolerance in tumor necrosis factor-a (TNF-a) receptor 1 knockout mice. Pharmacological inhibition of brain ER stress prevented glucose intolerance and the increase in sympathetic tonus induced by AbOs, indicating that oligomers act via a central route to affect peripheral glucose homeostasis. Results reveal a novel pathogenic action of AbOs in the brain, and indicate shared molecular mechanisms between hypothalamic dysfunction in metabolic disorders and AD.

ADPD5-0749
DEMENTIA AND ADIPOKINES

M. Bednarska-Makaruk[1], A. Graban[2], A. Wisniewska[1], W. Lojkowska[2], A. Bochynska[2], M. Gugala-Iwaniuk[2], K. Slawinska[2], D. Ryglewicz[2], H. Wehr[1]
[1]Department of Genetics, Institute of Psychiatry and Neurology, Warsaw, Poland
[2]First Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland

The aim of the study was to investigate the role of adipokines (hormones secreted by adipose tissue) in the development of Alzheimer disease and of other forms of dementia.
Material: The investigated group consisted of 327 individuals 120 men and 207 women, aged 72.7 ± 8.7 years, 68 of them diagnosed as probable Alzheimer disease (AD), 33 as dementia of vascular origin (VaD), 47 as mixed dementia (MD), 83 as mild cognitive impairment (MCI) and 96 persons without dementia which served as control group. Dementia was diagnosed using DSM IV criteria and the type of dementia on NINCDS-ADRDA and NINDS-AIREN scales and Hachinski score.
Methods: In blood serum the levels of adipokines: adiponectin, leptin and resistin were determined using ELISA methods. Fasting glucose and 2-hour post-load glucose levels were determined using enzymatic method. Insulin concentration was assayed using ELISA method and HOMA-IR (Homeostatic Model Assessment Index) illustrating insulin resistance was calculated.
Results: As compared with controls significantly higher adiponectin levels were stated in MD, higher resistin concentration in MD and VaD and tendency to lower leptin levels in MD group. Impaired glucose tolerance was observed in MD and VaD. In the whole group of dementia negative correlation of adiponectin and positive correlation of leptin and markers of glucose metabolism disturbances and obesity were observed.
It can be concluded that adipokines play an important role in those forms of dementia which are connected with vascular pathology and glucose intolerance.

ADPD5-0863

RESISTANCE TO DIET-INDUCED OBESITY IS ASSOCIATED WITH INTACT COGNITION IN AGING LOU/C/JALL RATS.

P. Gaudreau[1], G. Ferland[2], C. Menard[1]
[1]Medicine, University of Montreal, Montreal, Canada
[2]Nutrition, University of Montreal, Montreal, Canada

Objectives: Type 2 diabetes and obesity increase the risk of Alzheimer's disease (AD) and may favor memory deficits. Here, we investigated the effect of diet-induced obesity on cognition using the LOU/C/Jall (LOU) rat. This strain is considered a model of healthy aging due to its increased longevity, maintenance of low body fat mass throughout life, low incidence of age-related diseases and an absence of cognitive deficits.
Methods: We challenged 6- and 24-month-old LOU rats with a long-term high-fat high-glucose (HF/HG) diet (16 weeks, 60% calorie intake from high fat chow + 10% glucose in water). Body composition (echoMRI), recognition and spatial memory (novel object recognition and Morris Water Maze tasks) were assessed before and after the diet. BW, food/water consumption were measured regularly.
Results: Young and old rats on the 16-week diet had similar BW then controls. Interestingly, they reduced considerably HF intake to compensate for their elevated consumption of glucose water. Nevertheless, their glycemia remained low and their cognition was not affected. RNA-Seq analysis is currently performed to compare hippocampus gene expression signatures and unravel other characteristics of the LOU rat genome.
Conclusions: Taken together, our results suggest that the LOU rat strain is not only characterized by the maintenance of memory functions despite advanced age but is resistant to both age- and diet-induced obesity. Identification of molecular targets linked to this phenotype should help developing strategies to preserve or enhance cognitive abilities in aging and delay memory impairments associated with AD.

[3]Department of Neurobiology Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden

Several studies have shown that Diabetes Mellitus (DM) increases the risk of Alzheimer's Disease (AD). IDE is an enzyme cleaves small polypeptides including insulin, IGFs, amylin and amyloid beta. However up to date little is known about how DM affects IDE.

We performed *in vitro* experiments using rat primary neuronal cultures incubated with high glucose, lack of insulin or both conditions. *In vivo* experiments were performed using cortex of experimentally induced diabetic rats by injecting streptozotocin (STZ). IDE protein and mRNA levels were examined by western blot and RT-PCR respectively. In neurons from rat primary culture, IDE protein levels decreased in the lack of insulin group (18.78 %) and lack of insulin/high glucose group (29.11 %) compared to control group whereas IDE levels of high glucose group did not change. mRNA level of IDE decreased in lack of insulin group (16.28 %) and lack of insulin/high glucose groups (26.41 %) compared to control group. In neurons from diabetic rats, IDE protein levels decreased in diabetic group (41.22 %) compared to control group.

It is reported that in AD, IDE is reduced both in protein levels and activity. Our results suggest that DM lowers the levels of IDE. Thus, this could be one of the mechanisms by which DM confers high risk of AD development.

RISK FACTORS FOR COGNITIVE IMPAIRMENT IN PATIENTS WITH TYPE 2 DIABETES MELLITUS (DM2)

M. Rakusa[1], M. Rakusa[2], S. Gak[2], M. Cokolic[2]
[1]Neurology, University Clinical Centre Maribor, Maribor, Slovenia
[2]Endocrinology and Diabetes, University Clinical Centre Maribor, Maribor, Slovenia

Objectives:
Patients with DM2 may have an increased risk for Alzheimer's disease and vascular dementia. With our study we explored risk factors for cognitive impairment in Slovenian patients with DM2
Methods: The 427 patients were included (190 women). We evaluated cognitive impairment with Slovenian version of Clock Drawing Test (CDT). Patients who scored 3 out of 4 points or less were considered cognitive impaired. In logistic regression predictive model we included age, gender, duration of the DM2 and the years of education.
Results: Almost half of the patients (44%) scored less than 4 points. Cognitive impaired patients had significantly lower CDT score (1.97; SD 0.97 points vs. 4 points), were more common men, older (67.3; SD 10.2 years vs. 62.8; SD 12.4 years) with longer duration of DM 2 (13.1; SD 9.7 years vs. 10.9; SD 7.1 years) and less educated (10.9; SD 2.5 years vs. 11.7; SD 2.4 years). All variables were statistically significant in the logistic model. The highest prediction value had low education, followed by gender, age and DM2 duration.
Conclusion: Cognitive impairment is common among patients with DM2 in our group. We should be particularly alert to the men who are older than 63 years, with only primary education and suffer from the DM2 for more than 11 years.

IMPACT OF PHYSICAL ACTIVITY ON PROGRESSION OF ALZHEIMER'S DISEASE: A CREDOS STUDY

S. Choi[1], J. Kwon[2], E. Lee[2], S. Kim[2], D. Lee[3], J. Jeong[4]
[1]Neurology, Inha University School of Medicine, Incheon, Korea
[2]Neurology, Inha University Hospital, Incheon, Korea
[3]Clinical Trial Center, Inha University Hospital, Incheon, Korea
[4]Neurology, Ewha Womans University School of Medicine, Seoul, Korea

Objectives: There is a little information on the association of physical activity with progression of Alzheimer's disease (AD). The objective of this study is to evaluate an impact of physical activity on progression of AD.

Methods: A total of 343 AD patients enrolled from 31 memory clinics using the standard assessment and diagnostic processes were followed for progression of dementia for mean (SD) 14.9 (5.7) months. Demographic and vascular risk factors were evaluated and physical activity was investigated using Physical Activity Questionnaire of the Clinical Research Center for Dementia of South Korea (CREDOS) at baseline in all patients.

Results: In a univariate mixed model, an increment of Clinical Dementia Rating Scale-Sum of Boxes (CDR-SB) score was associated with older age (p=0.009), lower Mini-Mental State Examination (MMSE) score (p<0.001), lower Body Mass Index (BMI) (p=0.03), and less physical activity (p=0.001) at baseline. In a multivariate mixed model adjusted for age, BMI, and MMSE, AD patients who had done physical activity of moderate intensity such as quick walking and stretching over 90 minutes a week had a less increment of CDR-SB (Estimate=-1.42, 95% CI= -2.12 ~ -0.72, p=0.001) compared with those without physical activity. Changes of CDS-SB in AD patients with physical activity less 90 minutes a week or in those with physical activity of severe intensity such as running and climbing did not differ significantly with a change of CDR-SB in those without physical activity.

Conclusions: Physical activity of moderate intensity over 90 minutes a week may delay progression of AD.

Nagoya University Graduate School of Medicine, Nagoya, Japan
[3]Department of Comprehensive Community Care Systems,
Nagoya University Graduate School of Medicine, Nagoya, Japan
[4]Department of Biostatistics, Nagoya University Graduate School of Medicine, Nagoya, Japan

[Objectives] It has been suggested that cerebral white matter lesions and lifestyle-related diseases have interactive associations with cognitive decline, but there have been few reports based on longitudinal observation. In the current study we investigated the effects of white matter lesions and lifestyle-related diseases on the progression of cognitive decline in Alzheimer's disease and amnestic mild cognitive impairment subjects.

[Methods] A total of 80 subjects were enrolled in this study. All subjects underwent baseline brain MRI and neuropsychological assessments, and follow-up neuropsychological assessments were performed within 1 to 2 years. We performed Fisher exact test to examine the association between white matter lesions and lifestyle-related diseases and the multivariate regression analysis to examine the associations among white matter lesions, lifestyle-related diseases, and cognitive performance assessed prospectively.

[Results] Fisher exact test revealed a relationship between deep white matter hyperintensities (DWMH) and hypertension(p=.04), shown by a significantly higher prevalence of hypertension in subjects whose Fazekas rating were graded2. The multivariate regression analysis, making changes of cognitive scores from baseline as dependent variables, indicated a significant association of DWMH with lower scores on the MMSE (p=.03), and that of periventricular hyperintensities with lower scores on the initial letter fluency (p=.03). Meanwhile DWMH and existence of diabetes explained lower scores on the digit symbol (p=.02, .01).

[Conclusions] The present study suggested an involvement of hypertension with changes of some cognitive functions indicated by significant interactions between, whereas diabetes may influence the process by other mechanism different from hypertension.

ADPD5-0645

EFFECT OF POLYUNSATURATED FATTY ACIDS ON THE EVOLUTION OF COGNITIVE ABILITY IN ELDERLY PATIENTS WITH ALZHEIMER'S DISEASE PUFA, EPA

T. Yamazaki[1], K.E.N. Nagata[1], D. Takano[1], Y. Satoh[1], Y.U.M.I. Fujimaki[1], T. Maeda[1]
[1]Neurology, Institute for Brain and Blood Vessels, Akita, Japan

[Background] As the disease modifying therapy is not yet available for Alzheimer's disease (AD), the management of modifiable vascular risk factors (VRFs) including lipid metabolism is now considered to be the best strategy to minimize the impact of AD lesions, especially in elderly subjects. **[Objective]** To elucidate the effect of polyunsaturated fatty acids (PUFAs) on the cognitive ability, we investigated the relationship between the plasm PUFA profile and neuropsychological performance in elderly AD patients. **[Methods]** Present study was based on 133 elderly patients (51 men and 82 women) with probable AD, and their mean age was 78.6 years. Mini-mental State Exam (MMSE) and clock drawing test were used for neuropsychological evaluation. Blood samples were obtained for the measurement of PUFA profiles .Neuropsychological evaluation was repeated with one-year interval in 49 subjects, who were classified into two categories; stable group in which the MMSE score was unchanged or improved, and deteriorating group in which the MMSE score worsened. A receiver operating characteristic (ROC) curve was used to evaluate the relationship between the EPA/AA ratio and the evolution of cognitive ability. **[Results]** Total MMSE score correlated positively with the eicosapentaenoic acid (EPA)/ arachidonic acid (AA) ratio, and negatively with AA concentration. In the ROC curve analysis, the threshold EPA/AA ratio was estimated as 0.67 for the stable MMSE score with 66% sensitivity and 70% specificity [odds ratio (OR) = 4.43] . **[Conclusion]** The EPA/AA ratio can be regarded as a predictive marker for the preservation of cognitive ability in elderly AD patients.

[5]Departments of Medicine (Genetics Program), Neurology, Ophthalmology, Genetics & Genomics, Epidemiology, and Biostatistics, Boston University Schools of Medicine and Public Health, Boston, USA
[6]Department of Neurology, University of Louisville, Kentucky, USA

Objectives: Vascular risk factors and lack of formal education may increase the risk of Alzheimer's disease (AD). We aimed to determine the contribution of vascular risk factors and education to the risk of Mild Cognitive Impairment (MCI) and AD and estimate the risk for conversion from MCI to AD.

Methods: This door-to-door survey was performed by an Arab-speaking team in Wadi Ara villages in Israel. All consenting residents aged> 65 years were interviewed for medical history and underwent neurological and cognitive examinations. Individuals were cognitively classified as normal (CN), MCI, AD, vascular dementia (VD) or unclassifiable. MCI patients were re-examined at least one year later to determine conversion to AD. The contributions of age, gender, school years and vascular risk factors to the probability of conversion were estimated using logistic regression models.

Results: Of the 906 participants, 297 (33%) had MCI and 95 (10%) had AD. The risk of AD vs. CN was significantly associated with age (p

Conclusions: In this population, age, female gender, lack of formal education and hypertension are risk factors for both AD and MCI. Conversion risk from MCI to AD could be estimated using a formula as a function of age, time interval between examinations and hypertension.

CYTOMEGALOVIRUS INFECTION DOES NOT INCREASE THE RISK OF ALZHEIMER'S DISEASE

H. Lövheim[1], J. Gilthorpe[2], A. Johansson[3], S. Eriksson[1], G. Hallmans[4], F. Elgh[5]
[1]Geriatric Medicine, Umeå University, Umeå, Sweden
[2]Pharmacology and Clinical Neuroscience, Umeå University, Umeå, Sweden
[3]Odontology, Umeå University, Umeå, Sweden
[4]Public Health and Clinical Medicine / Nutritional Research, Umeå University, Umeå, Sweden
[5]Clinical Microbiology / Virology, Umeå University, Umeå, Sweden

1. Objectives
In recent years accumulating evidence has come to suggest a relationship between herpes simplex virus infection and the development of Alzheimer's Disease (AD). Another human herpes virus, Cytomegalovirus (CMV), has also during the last year been found to associate with an increased risk of AD in three epidemiological studies. The aim of this study was to confirm these observations using a nested case control material with very high diagnostic quality and long follow-up time.
2. Methods
The study included 360 AD cases and 360 closely age- and sex-matched dementia free controls. AD cases was diagnosed at the University Hospital Memory Clinic in Umeå, Sweden, and validated before inclusion in the study. Plasma samples taken on average 9.6 years before diagnosis was taken from the Medical Biobank in Umeå, for both AD cases and controls. Anti-CMV IgG and IgM antibodies were analysed using ELISA.
3. Results
There were 312/360 (86.7%) anti-CMV IgG positive persons among the AD cases and 318/360 (88.3%) in the control group. Presence of anti-CMV IgG antibodies did not increase the risk for AD (Odds Ratio 0.857, 95% Confidence Interval 0.549 – 1.338, p=0.497).
4. Conclusions
The present data does not support either a direct or an indirect relationship between CMV infection and the development of AD. Previously published findings could possibly explained by confounding factors or immune alterations in AD affecting CMV infection, rather than any relationship to the contrary.

ADPD5-1421

INFLAMMASOME GENE REGULATION FOLLOWING CHLAMYDIA PNEUMONIAE INFECTION OF THP-1 MONOCYTES HAS IMPLICATIONS FOR LATE-ONSET ALZHEIMER DISEASE

B. Balin[1], C. Hammond[2], J. Anzmann[1], S. Hingley[1]
[1]Bio-Medical Sciences, Philadelphia College of Osteopathic Medicine, Philadelphia, USA
[2]Division of Research, Philadelphia College of Osteopathic Medicine, Philadelphia, USA

Objectives: Neuroinflammation is often a major component of neurological diseases, including Alzheimer disease. Research focusing on the cause of late-onset Alzheimer disease suggests that chronic infection(s) may be key initiators or contributors to the pathogenesis. Our laboratory has shown that *Chlamydia pneumoniae* infects many different cell types *in vitro*, can survive intracellularly for long periods of time, and is detectable in Alzheimer disease brain tissues. In this study, we sought to determine how infection may influence gene regulation, including activation of inflammasomes, that may result in the neuroinflammation observed in Alzheimer disease.
Methods: THP-1 monocytes were infected with either AR-39 or CWL-029 respiratory strains of *Chlamydia pneumoniae* for 24, 48, or 72 hours and subsequently analyzed using commercial human inflammasome real time PCR Arrays. These arrays consist of 84 primers for gene transcripts known to be involved with inflammasome pathways.
Results: When compared with uninfected monocytes, *Chlamydia pneumoniae* infected monocytes revealed 21 of 84 total gene transcripts that were significantly up-regulated at least 4 fold or greater. CCL2 and IL-1beta gene transcripts showed up-regulation at 24, 48, and 72 hours. Interestingly, the AIM2 inflammasome gene transcript was significantly up-regulated in all infected cells.
Conclusions: Our data suggest that upon infection of THP-1 monocytes with *Chlamydia pneumoniae*, significant changes occur in the regulation of gene transcripts that correlate to the inflammatory signature observed in sporadic late-onset Alzheimer disease. Thus, gene regulation changes due to infection could lead to the neuroinflammation observed in Alzheimer disease.

ADPD5-0402

RELATIONSHIP OF NEUROINFLAMMATION ACCORDING TO AGING PROCESS AND PATHOGENESIS OF ALZHEIMER'S DISEASE

K. Lee[1], I. Song[1], J. Park[1], J. Kim[1]
[1]Neurology, The catholic University of Korea, Seoul, Korea

Background: Microglia are involved in immune surveillance in intact brains and become activated in response to inflammation and neurodegeneration. Microglia have different functions, neuroprotective or neurotoxic, according to aging in patients with PD. The clinical effect of microglia in patients with Alzheimer's disease (AD) is poorly defined. This prospective study was conducted to investigate the clinical effects of microglia according to the aging process in newly diagnosed AD.
Methods: We examined 532 patients with newly diagnosed AD and 119 healthy controls, and the differences in hs-CRP between these groups were investigated. The patients with AD was classified into 3 subgroups according to age of newly diagnosed AD to investigate the relationship between hs-CRP and the aging process in newly diagnosed AD.
Results: There were significantly higher serum high-sensitivity C-reactive protein (hs-CRP), levels in patients with AD compared with healthy controls. A post-hoc analysis of the 3 AD subgroups showed no significant differences in serum hs-CRP level between each group.
Conclusion: We assumed that neuroinflammation play a role in the pathogenesis of AD, but found no clinical evidence that microglia senescence underlies the microglia switch from neuroprotective in young brains to neurotoxic in aged brains. To clarify the role of microglia and aging in the pathogenesis of AD, future longitudinal studies involving a large cohort are required.

ADPD5-0745

DEMENTIA, VITAMIN D AND INDICES OF EXISTING INFLAMMATION

A. Graban[1], M. Bednarska-Makaruk[2], A. Wisniewska[2], W. Lojkowska[1], A. Bochynska[1], M. Gugala-Iwaniuk[1], K. Slawinska[1], D. Ryglewicz[1], H. Wehr[2]

[1]First Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland

[2]Department of Genetics, Institute of Psychiatry and Neurology, Warsaw, Poland

The aim of the study was to investigate the importance of vitamin D and inflammatory markers in the development of Alzheimer disease and other forms of dementia.

Material: The investigated group consisted of 327 individuals, 120 men and 207 women, aged 72.7 ± 8.7 years, 68 of them diagnosed as probable Alzheimer disease (AD), 33 as dementia of vascular origin (VaD), 47 as mixed dementia (MD), 83 as mild cognitive impairment (MCI) and 96 persons without dementia which served as control group. Dementia was diagnosed using DSM IV criteria and the type of dementia on NINCDS-ADRDA and NINDS-AIREN scales and Hachinski score.

Methods: In blood serum the levels of vitamin 25(OH)D, high sensitivity C-reactive protein (hsCRP) and high sensitivity interleukin 6 (IL-6) were assayed using ELISA methods. HDL cholesterol was determined after removing apoB containing lipoproteins by enzymatic method.

Results: Significantly higher IL-6 levels were stated in MD and VaD groups as compared to controls. In MD group a tendency to higher prevalence of serum vitamin 25(OH)D deficiency was observed. In the whole group of dementia negative correlation between 25(OH)D and IL-6 and hsCRP was observed. The positive correlation of 25(OH)D with HDL-cholesterol (anti-inflammatory marker) was also stated.

It can be concluded that vitamin D deficiency and inflammation could play an important role in dementia development, particularly in those forms of dementia which are connected with vascular pathology. The inverse association of 25(OH)D with IL-6 and hsCRP could suggest a potential anti-inflammatory role for vitamin D in dementia.

DIET, ELEVATED CHRONIC INFLAMMATION AND COGNITIVE DECLINE: DATA FROM THE AUSTRALIAN IMAGING, BIOMARKERS AND LIFESTYLE STUDY OF AGEING

S.R. Rainey-Smith[1], S. Gardener[1], N. Shivappa[2], H.R. Sohrabi[1], B.M. Brown[1], M. Weinborn[3], S.M. Laws[1], K. Taddei[1], J.R. Hebert[2], R.M. Martins[1]
[1]Centre of Excellence for Alzheimer's Disease Research and Care, Edith Cowan University, Joondalup, Australia
[2]Department of Epidemiology and Biostatistics Arnold School of Public Health, University of South Carolina, Columbia, USA
[3]School of Psychology, University of Western Australia, Crawley, Australia

Identification of lifestyle and dietary modifications which prevent or delay cognitive decline and Alzheimer's disease (AD) would confer significant socioeconomic benefit. Yet, there is a relative lack of large-scale longitudinal investigations of lifestyle-related factors impacting cognitive decline and AD-related pathology.
Inflammation is heavily implicated in AD pathology, with evidence suggesting it is both a reaction to the disease process and a contributor to neuronal damage. The relationship between diet and inflammation however, remains poorly understood, and a paucity of information exists which characterises the relationship between diet, inflammatory biomarkers and AD risk.
We report on data collected from 527 participants of the Australian Imaging, Biomarkers and Lifestyle (AIBL) Study of Ageing who were classified as healthy controls at baseline. Food Frequency Questionnaire data was used to construct an inflammatory dietary index (IDI) which categorises individuals' nutritional intake on a continuum from maximally anti-inflammatory to maximally pro-inflammatory. The IDI was subsequently analysed in conjunction with blood-based biomarkers of inflammation and comprehensive longitudinal neuropsychological assessment data.
Analysis over 54 months revealed that as individuals consume less anti-inflammatory dietary components (indicated by a higher IDI), levels of numerous inflammatory biomarkers increase. Further, multinomial logistic regressions used to calculate odds ratios revealed that high IDI was associated with increased likelihood ($OR=3.08$; $p<0.05$) of transitioning from healthy control classification at baseline to mild cognitive impairment or AD status after 54 months.
Taken together, our results suggest an interplay between diet and elevated chronic inflammation which may contribute to increased likelihood of cognitive decline and AD.

CD33-MEDIATED MICROGLIAL DEGRADATIVE PATHWAYS IN ALZHEIMER'S DISEASE

A. Griciuc[1], B.J. Innes[1], S.H. Choi[1], M.K. Oram[1], A.N. Lesinski[1], L. Bertram[2], B.T. Hyman[3], S.E. Hickman[4], J.B. El Khoury[4], R.E. Tanzi[1]
[1]Genetics and Aging Research Unit,
Massachusetts General Hospital and Harvard Medical School, Charlestown, USA
[2]Neuropsychiatric Genetics Group, Max-Planck Institute for Molecular Genetics, Berlin, Germany
[3]Alzheimer's Disease Research Laboratory,
Massachusetts General Hospital and Harvard Medical School, Charlestown, USA
[4]Neuroimmunology & Innate Immunity Laboratory,
Massachusetts General Hospital and Harvard Medical School, Charlestown, USA

Objectives: To define the cellular signature of CD33 activity in microglia. CD33 is a sialic acid-binding immunoglobulin-like lectin that regulates innate immunity. We have previously shown that CD33 activity in microglia promotes amyloid-beta (Aβ) pathology by inhibiting Aβ uptake and clearance (Griciuc et al., Neuron, 2013). Microglia can assume activation states in a spectrum from M1 (pro-inflammatory) to M2 (pro-phagocytic).
Methods: We assessed expression levels of M1-markers F4/80 and iNOS in 7-month-old WT, *APP/PS1*, *APP/PS1/CD33*$^{-/-}$ and *CD33*$^{-/-}$ brains by immunohistochemistry and western blotting. We isolated microglia from 14-month-old WT, *5xFAD*, *5xFAD/CD33*$^{-/-}$ and *CD33*$^{-/-}$ mice. Mouse forebrains were dissociated, and the cell suspension was labeled with CD11b/CD45 antibodies and underwent FACS. RNA extracted from microglia was used to determine M1/M2 marker abundance by RT-PCR.
Results: *CD33* knock-out led to reduced numbers of F4/80-positive microglia and to decreased iNOS protein levels in the *APP/PS1* brain. FACS experiments showed that the *5xFAD* brain exhibited a 1.9-fold increase in microglial numbers. *CD33* knock-out had no effect on CD11b/CD45-positive microglial numbers in both WT and *5xFAD* mice. Remarkably, *CD33* knock-out in a *5xFAD* background led to decreased levels of M1-markers, but increased M2-marker expression in adult microglia. *CD33* knock-out in a WT background did not alter M1/M2 marker levels.
Conclusions: Collectively, these observations raise the possibility that *CD33* knock-out results in skewing of microglia from M1 towards M2-activated state in brains that exhibit Aβ pathology. These findings suggest that therapeutic inhibition of CD33 may be considered as a means for curbing neuroinflammation in Alzheimer's disease.

AN IN VITRO MICROGLIA-LIKE MODEL FOR EXPLORING GENETIC-DRIVEN INNATE IMMUNE SYSTEM DYSFUNCTION IN NEURODEGENERATIVE DISEASES.

E. Bradshaw[1], K. Ryan[1], G. Chan[1], M. Olah[1], P. Winn[1], M. Chimpean[1], M. Frangieh[1], J. Imitola[2], W. Elyaman[1], P. De Jager[1]

[1]Neurology, Brigham and Women's Hospital/Harvard Medical School, Boston, USA

[2]Neuroscience, Ohio State University, Columbus, USA

In order to understand the functional consequences of disease-associated common genetic variation, we must be able to analyze the outcomes in the correct cell type. In terms of neurodegenerative diseases, such as Alzheimer's disease, Parkinson's disease and multiple sclerosis an increasing number of microglia-related genes have been associated with disease. However, these analyses cannot be performed at the scale required using primary human microglia as there is limited access to these resident innate immune cells of the central nervous system. We have validated an *in vitro* differentiation protocol using polarizing cytokines for converting monocytes to microglia-like (MDMi) cells, leveraging the plasticity of immune cells, using a recently defined unique microglia signature. Specifically, we see an increase in mRNA expression of PROS1, GAS6, GPR34, CD39, C1QA and TGFBR1 (all $p<0.001$) in MDMi cells compared to monocytes, confirming this *in vitro* system as a valid model for human microglia. We also observe an increase in TREM2 surface protein expression in the MDMi cells relative to monocytes ($p=0.001$). We are using this *in vitro* system to examine genotype-induced phenotypes. We have confirmed that the Alzheimer's disease-associated SNP, rs3865444, leads to differential CD33 protein surface expression ($p=0.001$) and uptake ability ($p=0.05$) in MDMi cells. Using monocytes isolated from 96 genotyped subjects from the PhenoGenetic cohort, we are assessing the functional consequences of 94 known neurodegenerative disease susceptibility loci in MDMi cells using the Fluidigm platform.

THE IMPACT OF PSYCHOTROPIC DRUGS ON THE RISK OF FALLS, ACUTE HOSPITALISATIONS AND MORTALITY AMONG PERSONS WITH DEMENTIA: A NATIONWIDE CASE-CONTROL STUDY

K. Johnell[1], G. Jonasdottir Bergman[2], J. Fastbom[1], B. Danielsson[2], N. Borg[2], P. Salmi[2]
[1]Aging Research Center, Karolinska Institutet, Stockholm, Sweden
[2]The Swedish National Board of Health and Welfare,
The Swedish National Board of Health and Welfare, Stockholm, Sweden

Objectives: To investigate whether psychotropics (i.e. antipsychotics, anxiolytics, hypnotics/sedatives and antidepressants) increase the risk of falls, acute hospitalisations and mortality in a large population of dementia patients.
Methods: We performed a nationwide matched (age, sex and case event day) case-control study between January 1st and December 31st 2011 based on several Swedish registers (n=45 914 dementia patients aged ≥65 years). We analysed the impact of use of psychotropics on the risk of falls, acute hospitalisations and mortality by multivariate conditional logistic regression adjusted for education, number of inpatient days, Charlson comorbidity index and number of other drugs.
Results: There was no association between use of psychotropics and falls. However, there was an increased risk of acute hospitalisations associated with use of anxiolytics (adjusted OR: 1.20; 95% CI: 1.10-1.31) and hypnotics/sedatives (adjusted OR: 1.15; 95% CI: 1.06-1.25), but a negative association for antidepressants (adjusted OR: 0.90; 95% CI: 0.83-0.97). Mortality was increased among those who used antipsychotics (adjusted OR: 1.50; 95% CI: 1.41-1.60), antidepressants (adjusted OR: 1.14; 95% CI: 1.08-1.21) and anxiolytics (adjusted OR: 1.33; 95% CI: 1.25-1.41). Additionally, a dose-response relationship was found between number of psychotropics and risk of acute hospitalisations (4 psychotropics vs 0: adjusted OR: 1.36; 95% CI: 1.14-1.62) and risk of death (4 psychotropics vs 0: adjusted OR: 1.99; 95% CI: 1.76-2.25).
Conclusions: Psychotropic drugs have an impact on the risk of acute hospitalisations and death in a dose-response manner among older dementia patients. Our findings emphasise the importance of reducing perfunctory psychotropic prescribing in dementia.

ADPD5-0361

A NOVEL TMP21 SNP AND ITS ASSOCIATION WITH ALZHEIMER'S DISEASE

W. Song[1], X. Zhang[1], K. Xia[2], W. Yili[1], F. Cai[1], K. Bromley-Brits[1]
[1]Department of Psychiatry, University of British Columbia, Vancouver, Canada
[2]The State Key Lab of Medical Genetics, Central South University, Changsha, China

Objectives

TMP21, a type I transmembrane protein of the p24 protein family is a trafficking protein. Recent studies suggest that TMP21 is a selective modulator of γ-secretase and its dysregulation may play a pivotal role in Alzheimer's disease (AD) pathogenesis. However, the genetic association between *Tmp21* and AD remains elusive. This study aims to identify the genetic link between TMP21 gene and AD and to further investigate the role of TMP21 in Alzheimer's pathogenesis

Methods

Genomic DNA was extracted from sporadic AD patients and healthy controls for targeted sequencing. Single nucleotide polymorphism (SNP) detection was performed. RT-PCR, Western blot analysis and luciferase assay were used to further define the effect of the identified SNP on TMP21 gene expression.

Results

In this study, we first identified that a novel T>C SNP located in intron 4 of *Tmp21* and is associated with AD patients by screening AD patients and controls. The SNP did not affect the splicing site recognition, but it significantly increased TMP21expression at both mRNA and protein levels. Furthermore, we found that this SNP significantly increased the splicing efficiency of *Tmp21* pre-mRNA, leading to the elevation of mature mRNA. However, the stability of *Tmp21* pre-mRNA and transcription activity of *Tmp21* was not affected.

Conclusions

Our study identified an AD-associated *Tmp21* SNP, and the results suggest that dysregulation of TMP21 may contribute to AD pathogenesis and that TMP21 may be a potential target for AD treatment.

Imaging Genetics Center and Laboratory of Neuro Imaging at the Mary S. Easton Center for Alzheimer's Disease Research, Los Angeles, USA

Objectives: To evaluate the association between genetics and donepezil responsiveness in mild cognitively impairment (MCI).
Methods: We conducted a candidate-gene secondary analysis of the vitamin E/donepezil trial using the genotyping data performed with the Illumina Human610-Quad Bead-Chip. We used linear regression models, adjusting for gender and APOE4 genotype, to test the influence of 24 SNPs - previously identified for their association with disease/endophenotypes or donepezil pharmacogenetics in Alzheimer's Disease (AD) - on changes in mini-mental state examination (MMSE) and Clinical Dementia Rating sum of boxes (CDRSB) scores at the end of the trial.
Results: We found a nominal association between three genetic loci associated with AD/MCI endophenotypes and non-response to donepezil when examining changes in MMSE and CDRSB after 3 years of therapy. The association between genotype and MMSE decline remained significant for the K-variant of BCHE (rs1803274; p=0.00062/corrected P=0.0149) after Bonferroni correction.The association between genotype and CRDRSB worsening remained significant for *ACOT11* (rs12752888; p=0.0032/corrected P=0.038) and *UBR5* (rs7840202; p=0.004/corrected P=0.043), after correction.
Conclusion: Our findings suggest that MCI subjects carrying genetic polymorphisms associated with AD are at risk of developing resistance to donepezil. This study represents a first effort at studying the pharmacogenetics of donepezil in MCI and calls for leveraging existing data sets to boost the statistical power and to replicate our findings. This study also reinforces the importance of examining donepezil pharmacogenetics and AD biological pathways as it can lead to the development of novel pharmacological compounds for the treatment of MCI/AD.

[3]Department of Neuroscience, Norwegian University of Science and Technology, Trondheim, Norway

Objective: A commonly known polymorphism of butyrylcholinesterase gene, the K-variant (BCHE-K) is found to be associated with reduced BuChE activity. Previous studies from our group suggest a possible interaction between APOE4 and BCHE-K. Our objective was to study the associations of BCHE-K and APOE4 with diagnosis and rate of cognitive decline in AD and DLB.

Method: Genomic DNA from 370 subjects (108 AD, 176 DLB and 86 Controls) from two studies in Norway, namely DemVest and TronderBrain were genotyped for BCHE-K and APOE4. The DemVest subjects were also followed annually for up to 5 years, including cognitive assessment with MMSE, and annual decline on MMSE was calculated.

Results: The controls had higher BCHE-K frequency, than DLB ($p=0.01$) and AD ($p<0.06$) (Table-1). The observed BCHE-K allele frequency in controls was even higher (51%) than the expected frequency (24%) calculated according to previous literature. Interestingly, in AD, $APOE4^-/BCHE\text{-}K^+$ patients had significantly slower annual MMSE decline than $APOE4^+/BCHE\text{-}K^-$ group ($p<0.01$) and $APOE4^+/BCHE\text{-}K^+$ group ($p<0.05$)(Figure-1). This pattern was observed in patients with mild AD, but not in moderate and severe AD.

Conclusion: These findings suggest that BCHE-K allele alone in absence of APOE4 may have a protective role, but when occurring along with APOE4, its protective contribution may be suppressed, most likely by the over-expression of APOE protein during the early stage of AD.

Table-1. Demographics of the study cohorts

DIAGNOSIS	DLB	AD	CONTROLS
No. of subjects	176	108	86
Females (%)	44.5	71.3	48.8
Age at inclusion (years)	76.3±7.6	74.5±7.9	73.9±5.9
MMSE	20.6±6.6	24±2.1	NA
APOE4 carriers (%)	53.1	63.9	25
BCHE-K carriers (%)	34.7	38	51.2

[4]Hussman Institute for Human Genomics, University of Miami, Miami, USA

Objectives: There is a strong genetic influence on late onset Alzheimer disease (LOAD). Large international efforts have identified numerous susceptibility loci for LOAD and yet the majority of the genetic risk remains unidentified. We are examining LOAD in the Amish (an isolated religious group of Swiss-German origin) of Indiana and Ohio because of their cultural and genetic isolation from the general population and their more homogeneous life style.

Methods: Individuals scoring below 87 on the 3MS were given a detailed neuropsychological battery; those scoring ≥87 were considered cognitively normal. We performed genome-wide SNP linkage and association studies on 921 individuals (109 with LOAD) using the Modified Quasi-Likelihood Score (MQLS) test and Merlin, respectively. We determined the overall burden of known LOAD loci by calculating a genetic risk score (GRS). Whole exome sequencing (WES) was performed on 166 cases and controls.

Results: Affected individuals have a significantly higher GRS score than unaffected individuals (P= 1 x 10-6); but a much lower burden than an equivalent general population dataset of affected individuals (P= 1.6 x 10-7). Linkage analysis identified four likely loci that do not overlap with the known loci. WES identified a number of novel rare variants that are nominally associated with LOAD, but none reach Bonferroni-corrected significance.

Conclusions: While the Amish clearly carry some of the same risk loci as the general population, the GRS, linkage, and sequencing data strongly indicate that there are different loci that also play a significant role in LOAD in the Amish.

[2]Taub Institute of Research on Alzheimer's Disease, Columbia University, New York, USA
[3]Institute for Computational Biology, Case Western Reserve University, Cleveland, USA

Objectives
Mutations in *APP*, *PSEN1* and *PSEN2* lead to early-onset Alzheimer disease (EOAD). These mutations account for ~11% of EOAD overall, leaving the majority of genetic risk for the most severe form of Alzheimer disease unexplained.
Methods
We performed Whole-Exome Sequencing (WES) in 50 Caucasian EOAD cases previously screened negative for *APP*, *PSEN1*, and *PSEN2* to search for rare variants contributing to risk for EOAD. Variant filtering for functional, damaging rare variants (MAF<0.1%) was performed. Genes with shared (2+ cases with the same variant), damaging variants were examined for interactions with known EOAD genes (*APP, PSEN1, PSEN2, SORL1, GRN*, *MAPT*) and *APOE* using STRINGdb.
Results
176 genes had rare functional variants shared in two or more cases. 46 of these genes were prioritized for their damaging potential, defined by their shared rare variants having a Combined Annotation Dependent Depletion (CADD) score in the top 10% of all variants. Gene network analysis of these 46 genes with known EOAD genes and *APOE* identified five top candidate genes: *HSPG2* (interacts with *GRN*, *APOE*, and *APP*), *CLSTN1* (interacts with *PSEN1* and *APP*), *DOCK3* (interacts with *PSEN1* and *PSEN2*), and the *APOE* interactors *SAR1B* and *STAT1*. 5 cases have a variant in *HSPG2*, a gene potentially involved in amyloidogenesis and tau aggregation in AD, while 4 cases have a variant in *DOCK3*, a gene expressed exclusively in the central nervous system and associated with neurofibrillary tangles in AD brains.
Conclusions
WES of EOAD cases identified several genes with potential roles in AD pathogenesis.

ADPD5-1662

EXOME SEQUENCING IN LATE ONSET FAMILIES IDENTIFIES ADDITIONAL CANDIDATE GENES FOR ALZHEIMER'S DISEASE SUSCEPTIBILITY

J. Lord[1], *C. Cruchaga*[1]
[1]*Psychiatry, Washington University, St. Louis, USA*

Using exome-sequencing in fourteen late-onset Alzheimer's disease (AD) families, we found that *PLD3* variant V232M segregated with disease status in two families, and confirmed its association with AD risk. However, on average eight variants per family segregated with disease status.

We followed up 400 AD cases and 1080 controls for all variants (in genes including *LRP4, CALCR, DMRT2, KIF1A, ZNF341, LRP4, PRKD2, EPHA2)* that segregated with disease status in the sequenced families. The most interesting genes were re-sequenced in an additional 800 cases and 400 controls. In order to analyze the association of the selected genes with disease risk we performed gene-based tests stratifying by minor allele frequency (MAF), and analyzing variants that were unique to cases or controls.

Analyses on variants with a MAF<1% had power to find gene-wide significant results. In addition we found analyses focused on variants unique to cases or controls lead to greater effect sizes (odds ratio; OR) but lower p-values due to the very low frequency of these variants. We hypothesize that this strategy may be used to prioritize genes for follow-up. From all the genes that were selected for the replication study, one showed a significant gene-based association (variants MAF<1%) with AD risk after correction for multiple testing, and a strong association when only "unique-variants" were included (OR=1.97, p=2.51x10^{-4})

Our analyses indicate that additional genes harboring low-frequency risk variants exist, and that family-based studies could help identify such genes and variants. Extensive additional sequencing and functional analyses to validate our findings are underway.

On the basis of prior evidence linking the COMT val158met polymorphism with cognition, mediated via prefrontal cortical dopamine, we hypothesised that the high activity val/val genotype would be associated with faster average annual decline in MMSE than the met/met or val/met genotypes. DNA from 237 people who were part of existing cohorts with clinically or pathologically diagnosed Alzheimer's disease were genotyped for the COMT val158met polymorphism. Average annual decline in MMSE was calculated based on at least two assessments in patients with an MMSE greater than 9 at first assessment to avoid floor effects. The sample was stratified by severity and mean annual MMSE decline was compared across the three COMT genotypes (val/val, val/met and met/met). One-way ANOVA showed that mild AD carriers of the val/val genotype had a significantly higher rate or annual MMSE decline than met/met carriers (4.2 points per year compared with 0.8 points per year; $p<0.01$). There was no difference across genotypes in the moderate AD group. This study presents the first evidence that the *COMT* val/val genotype is associated with more rapid cognitive decline in AD, suggesting reduced DA in the PFC may be an important target for treatment of cognitive decline among individuals with this genotype.

[5]University of Basel, Developmental Genetics, Basel, Switzerland

Objectives: Most cases of autosomal-dominant familial Alzheimer's disease (FAD) are due to mutations in the presenilin-1 (PSEN1) gene. PSEN1 mutations increase the proportion of the aggregation-prone Abeta42 peptides, and might impair crucial cellular processes such as calcium homeostasis. However, previous studies were frequently limited by the use of overexpression models that did not accurately reflect the heterozygous expression of PSEN mutations in FAD patients.
Methods: Specific mutations were incorporated into the endogenous PSEN1 gene in mouse embryonic stem cells by dual recombinase-mediated cassette exchange (dRMCE). dRMCE takes advantage of conditional mouse alleles containing recombinase recognition sites that allow to efficiently re-engineer the PSEN1 genomic locus.
Results: Mutations were successfully introduced into the conditional PSEN1 allele with a frequency of approximately 30%. RT-PCR and Western blotting verified that the re-engineered PSEN gene locus was fully functional and expressed at normal endogenous levels as compared to the unmodified wild type allele. To study the functional interaction between PSEN1 alleles with regard to endoproteolysis, we introduced the D385N mutation targeting an aspartate residue critical for enzymatic activity. Western blot analysis demonstrated that the catalytically inactive mutant accumulated as a full-length protein despite the presence of a second catalytically competent wild type allele.
Conclusions: Our genome editing approach provides an FAD model that accounts for the heterozygous expression of PSEN mutants and is suitable for stringently controlled biochemical experiments. Studies of the D385N mutation indicated that PSEN1 endoproteolysis did not occur in trans arguing against functional interaction of mutant and wild type PSEN alleles.

[4]Department of Neurology, Chungang University, Seoul, Korea
[5]Department of Neurology, Korea University, Seoul, Korea

Alzheimer's disease (AD) is the most common form of senile dementia, which occurs mostly in the elderly population. AD, under 65 years of age (early onset AD) represents a minority of all AD cases, but its genetic background is well understood. Three genes have been discovered, which are causative genes for EOAD: APP, PSEN1 and PSEN2. Up to 2010, Korean patients with EOAD were poorly studied, since only 4 mutations were discovered in PSEN1 gene. In 2011, we discovered a novel PSEN1 mutation, H163P in an EOAD patientwithout family history of dementia, and this study was published inNeuroscience Letters in 2012.

In our studies we screened several AD and dementia patients. We performed PCR – based mutation detection methods, such as SSCP and heteroduplex analysis. To validate the presence and absence of variants, all PCR products were sequenced.
As results, we reported novel and known mutations in PSEN1. Two known pathogenic mutations have been discovered in PSEN1, T116I and L226F, but both of them were reported in Asia for the first time. Patient with T116I had strong family history of dementia, but L226F seemed to be a *de novo* mutation. Our most recent data is a novel PSEN1 mutation, L232P, which might be involved in AD progression. Further analysis will be needed for this mutation.
Our findings supported that novel pathogenic variants might be possible in the PSEN1 gene. Genetic testing of EOAD patients could improve the disease diagnosis.

A 30-GENE RESEQUENCING ASSAY FOR PRECLINICAL DETECTION AND ELUCIDATION OF AETIOLOGICAL HETEROGENEITY OF ALZHEIMER'S DISEASE

K. Sleegers[1], K. Bettens[1], T. Van den Bossche[1], C. Van Cauwenberghe[1], C. Robberecht[1], M. Cruts[1], C. Van Broeckhoven[1], . BELNEU consortium[1]
[1]Neurodegenerative Brain Diseases Group of the Department of Molecular Genetics, VIB and University of Antwerp, Antwerp, Belgium

Background

Two outstanding challenges in the effort to bridge the translational gap in Alzheimer's disease (AD) research are preclinical detection and recognition of aetiological heterogeneity. Molecular genetic screening has the potential to address both challenges.

Methods

We developed an assay based on advanced PCR amplicon multiplexing (Multiplicom) and massive parallel sequencing (MiSeq, Illumina) targeting 30 validated genes involved in AD, frontotemporal lobar degeneration, Lewy body disorders, amyotrophic lateral sclerosis and Creutzfeldt-Jakob disease including 480 amplicons across 14 multiplexes. We screened 749 Belgian Alzheimer patients using this assay. Data processing was performed with rsBWA, GATK and GenomeComb.

Results

The assay achieved an average coverage of >600x, and for 94% of samples >80% was covered >50x. We identified ≥ 1 rare variants in 19% of patients, of whom 7% carried ≥ 2 variants. These include 5 predicted damaging *APP* mutations located outside the Abeta domain, 4 previously unreported *PSEN1* and *PSEN2* mutations and 3 carriers of a *PSEN2* mutation resulting in increased $Abeta_{42/40}$, but also numerous pathogenic *GRN* mutations, a compound heterozygous *PINK1* mutation, 27 *LRRK2* mutations of which 7 probable and 13 possible pathogenic, 3.5% heterozygous variations in recessive Parkinson genes and a pathogenic *CSF1R* mutation.

Interpretation

These data exemplify the relevance of genetic screening across the clinical boundaries of AD. This cost-effective neurodegeneration gene assay has an immediate clinical application in genetic diagnostics, and can be applied for genetic pre-selection in basic research (e.g. for whole genome sequencing studies) as well as clinical research to streamline biomarker and drug trials.

ADPD5-1482

NOVEL AND KNOWN MUTATIONS IN SORL1, PSEN1, AND PSEN2 GENES ARE FOUND IN MULTIPLEX ALZHEIMER'S DISEASE FAMILIES WITH VARYING AGE OF ONSET AND PATHOLOGICAL PRESENTATIONS

R.M. Carney[1], B.W. Kunkle[1], P.L. Whitehead[1], S. Rolatie[1], B. Vardarajan[2], G.W. Beecham[1], J.R. Gilbert[1], R.P. Mayeux[2], J.L. Haines[3], M.A. Pericak-Vance[1]
[1]John P. Hussman Institute for Human Genomics, University of Miami, Miami, USA
[2]Taub Institute of Research on Alzheimer's Disease, Columbia University, New York, USA
[3]Department of Epidemiology and Biostatistics, Case Western Reserve University School of Medicine, Cleveland, USA

Objectives
To identify causative AD-related mutations in 50 Caucasian multiplex families with at least one individual with early-onset Alzheimer's disease (EOAD).
Methods
Variants in the *SORL1, PSEN1, and PSEN2* genes were identified using an established whole-exome sequencing (WES) pipeline. Clinical characteristics of affected members were obtained via review of medical and research records.
Results
A novel *SORL1* mutation that is predicted to be damaging (T588I) was found in all 4 affected individuals in one family (age of onset [AOO] range 59-82; three with APOE genotype 3/4, one with 3/3). A second family carried a previously reported AD *SORL1* mutation (T749M), with 3 affected individuals with the mutation (AOO55-84, all APOE 3/3), and 1 affected individual without the mutation (AOO76, APOE 3/4).
A known *PSEN1* AD mutation (A79V) was identified in two families, with AOO54 years (APOE 3/4) and 56 years (APOE 3/4). A rare *PSEN1* variant (R269G) predicted to be damaging was identified in a third family (AOO50 years, APOE 3/3).
A single individual (AOO48, APOE 3/3) represented a compound heterozygote for 2 variants predicted to be damaging in *PSEN2* (R71W, M174V).
A large range of AOO was seen within the families, with some members classified as EOAD and other as LOAD. On autopsy, Lewy bodies were seen in an EOAD individual carrying *SORL1* T749M without clinical Parkinsonism.
Conclusions
Mutations were found in 6/50 families. The presence of an APOE-4 allele may account for disease status in one affected non-carrier (T749M). No prominent atypical clinical features were identified.

[5]Institute Born-Bunge University of Antwerp, Department of Neurology (Antwerp University Hospital) Edegem, Antwerp, Belgium

Objectives:
We analyzed next-generation sequencing (NGS) data obtained in early-onset or autosomal dominant Alzheimer disease (AD) patients for mutations in known causal and risk genes for AD. We identified a missense mutation in *PLD3*, a gene which was previously implicated in familial late-onset AD. To follow-up on this finding we screened an extended early-onset AD cohort for additional genetic variants in *PLD3*.
Methods:
We obtained whole genome sequencing data of 22 unrelated early-onset AD patients and whole exome sequencing of probands of 5 autosomal dominant AD families. Sanger sequencing was used to screen *PLD3* in an additional 261 early-onset AD patients and 319 control individuals. We included in the data analysis NGS data of 56 unrelated non-AD individuals. Gene-based rare variant burden analysis was used to calculate association with early-onset AD. Bioinformatics' prediction, cDNA sequencing and cloning were used to characterize a newly identified splicing variant in *PLD3*.
Results:
We detected rare genetic variants (N = 5) that were previously identified as well as novel variants (N = 8). However the variant frequency was comparable between patients (3.13%) and control individuals (3.13%). Besides missense mutations, we identified one novel splicing variant that leads to either exon 10 skipping or intron 10 retention.
Conclusions:
We did not identify a genetic association with rare variants in *PLD3* suggesting that this gene is unlikely contributing to disease etiology in early-onset AD patients.

[3]Biostatistics, Harvard School of Public Health, Boston, USA
[4]Neuropsychiatric Genetics, Max Planck Institute for Molecular Genetics, Berlin, Germany

Objectives: Over 200 rare and highly penetrant pathogenic variants in APP, PSEN1 and PSEN2 cause a subset of early-onset familial Alzheimer's disease (AD), while APOE-e4 and close to 60 other genomic loci are associated with late-onset forms of AD. In this study we performed a comprehensive and systematic analysis of whole genome sequencing data from 1440 subjects from 452 multiplex NIMH AD families.
Methods: WGS data was generated using the Illumina HiSeq 2500 platform. The genotypes were called using Freebayes; ultimately, a single large annotated GEMINI database was created for the purpose of downstream analysis. We used a multi-pronged approach to identify both, rare, highly penetrant functional variants, as well as, more frequently occurring functional variants acting as genetic risk-factors for AD.
Results: In addition to confirming previously known variants in the NIMH families, our analyses revealed several novel functional variants, comprised of both single nucleotide variants (SNVs) and insertion-deletion (Indels). Furthermore, our analyses have revealed several SVs showing association with AD risk.
Conclusions: Our WGS analysis approach yielded several novel genetic functional variants influencing risk for AD. These variants are predicted to significantly alter normal gene function, and associated molecular pathways. To our knowledge, this is the first WGS study reporting novel functional genetic variants influencing risk for AD.

ADPD5-0866
ROLE OF ABCA1 AND MICRORNAS IN ABETA METABOLISM
J. Kim[1], H. Yoon[1], J. Kim[1]
[1]Neuroscience, Mayo Clinic, Jacksonville, USA
1. Objectives
Dysregulation of Abeta metabolism is critical for Alzheimer's disease (AD). Several key proteins implicated in AD pathogenesis, such as APP, BACE1, and PSEN1, are membrane proteins and their trafficking and proteolytic activity are altered by cholesterol dysregulation. Due to its critical role in maintaining cholesterol homeostasis, ATP-binding cassette transporter A1 (ABCA1) has been considered as a promising therapeutic target. However, whether ABCA1 expression is regulated at the posttranscriptional level is largely unknown. Identification of a novel pathway that regulates ABCA1 expression may provide new strategy for regulating cholesterol metabolism and Abeta levels.
2. Methods
We used molecular and cellular biology methods, genetically modified microRNA mouse models, and an APP/PS1 transgenic mouse model to determine the role of microRNAs in regulating ABCA1 and Abeta levels.
3. Results
We identified several microRNAs that strongly downregulate ABCA1 and impair cholesterol metabolism in neuronal cells. In addition, these microRNAs impaired Abeta clearance and increased Abeta production.
4. Conclusions
Our data suggest that inhibition of microRNA function using antisense oligonucleotide may provide novel therapeutic strategy for treating AD.

[5]Research Department, National Neuroscience Institute, Singapore, Singapore

Amyloid precursor protein (APP) is a type I transmembrane glycoprotein proteolytically processed to release amyloid beta, a pathological hallmark of Alzheimer's disease (AD). APP is expressed throughout the developing and mature brain; however, the primary function of this protein is unknown. We previously demonstrated that APP deficiency enhances neurogenesis in the developing cerebral cortex, but the cellular and molecular mechanisms underlying this process are not known. Here, we showed that APP regulates the expression of microRNAs (miRNAs) in the cortical brain, and specifically miR-574-5p is repressed by APP. We also showed that the overexpression of miR-574-5p promotes the differentiation of neural progenitor cells (NPCs) into neurons but reduces the neural progenitor pool. In contrast, the reduced expression of miR-574-5p in NPCs inhibits neurogenesis and stimulates proliferation *in vitro* and *in vivo*. We further demonstrated that the inhibition of miR-574-5p in APP-knockout cells rescued the phenotypes associated with APP deficiency to enhance proliferation, inhibiting neurogenesis and migration *in vitro* and *in vivo*. Taken together, these results reveal a novel mechanism in which APP regulates the proliferation and differentiation of NPCs through miRNA-mediated post-transcriptional regulation.

Background: DNA methylation has been found altered in Alzheimer Disease (AD). At present, there are no DNA methylation studies in AD controlling the heterogeneity of the cellular composition between brain samples, which is a recently known confounding factor in epigenetic studies.

Objective: To perform DNA methylation analysis controlling the cellular heterogeneity in of Late Onset Alzheimer's Disease (LOAD) brain samples.

Methods: Analysis was performed in 36 human brains from the *Biobanco Navarrabiomed*, Navarra, Spain (19 LOAD cases and 17 controls), all patients were clinical and pathological diagnosis of LOAD. Using laser guided micro-dissection samples form pyramidal cortical layers Genome-wide methylation analysis was performed on the Infinium 450k platform. Analysis was done by using *limma* and *minfi* R bioconductor packages.

Results: We found highly significant differences on the DNA methylation pattern in several genes between cases and controls. These genes include Homeobox A3, a sequence-specific transcription factor rich in interaction networks; Endothelin Converting Enzyme-Like 1, related to a recently associated pathway with AD; Dendritic Cell Associated Lectin1; and MYOM2, which has recently been shown to be differentially methylated in an AD model. **Conclusions:** The differences in the methylation pattern observed in the present samples intended to control for cellular heterogeneity suggests that epigenetic changes are important in the pathophysiology of AD. These observations need to be corroborated by bisulfite sequencing analysis. Acknowledgements. This work was funded by grants from Colciencias (Contract # 401-2011).

Emerging evidence suggest that epigenetics plays an important role in neurodegenerative diseases, including Alzheimer's disease, Down's syndrome, dementia of Lewy bodies and Parkinson's disease. To face this challenging issue, we carried out a whole genome bisulfite sequencing on prefrontal cortex examining their DNA methylation profiles at base-pair resolution. We identified differentially methylated regions (DMR) and further analyzed the meaning of such alterations as well as the level of overlap between different diseases. Interestingly, we observed a protruding overlap of DNA methylation alterations, suggesting that these diseases might be just a consequence of alternative manifestations of similar phenomena. These data might constitute an important resource for future studies representing the most complete catalogue of DNA methylation differences between neurodegenerative diseases done so far.

CLINICAL SIGNIFICANCE BETWEEN TWO SUBGROUPS OF AMNESTIC MILD COGNITIVE IMPAIRMENT, ENCODING FAILURE AND RETRIEVAL FAILURE

M. Wang[1], S. Park[1], Y. Park[1], S. Kim[1]
[1]Neurology, Seoul National University Bundang Hospital, Gyeonggi-do, Korea

Object : We tried to estabilish whether a clinical significance exists between two subgroups of aMCI, encoding failure(aMCI-E) and retrieval failure(aMCI-R).
Methods : We retrospectively reviewed medical records of 96 subjects with aMCI who visited in Neurocognitive behavior center of Seoul University Bundang Hospital. They were divided to two subgrups, encoding failure and retrieval failure, by results of Seoul Verbal Learning Test (SVLT). We investigated basic characteristics including age, education, previous medical history and Apo E genotype. We also reviewed initial and follow up neuropsychological test to ascertain whether patients progressed or not.
Results : Among the 96 subjects, 65 (67.7%) subjects were classified into aMCI-R and 31 (32.3%) into aMCI-E. The baseline characteristics of two groups including previous medical history and Apo E genotype did not have any differences. There were no differences between two subgroups of aMCI on the initial neuropsychological test except immediate recall and recognition index of SVLT. On follow up neuropsychological test, KMMSE(p=0.0020) and CDR-SOB (p=0.005) scored lower in aMCI-E. The 14 subjects (45.2%) of aMCI-E progressed to dementia whereas 12 subjects (18.5%) of aMCI-R. The relative risk of progression was 2.97. Adjusted odds ratio of aMCI-E by a logistic regression was 5.688 (95% CI 1.905 to 16.982).
Conclusion : Our results showed that subjects with aMCI-E progress more likely than aMCI-R. This may suggest aMCI-E is independent prognostic factor for progression and clinicians might be better to consider more active therapeutic intervention to subjects with aMCI-E.

NEUROCOGNITIVE ASSESSMENT IN MILD COGNITIVE IMPAIRMENT: TRADITIONAL METHODS AND LATENT PROFILE ANALYSIS

B. McGuinness[1], S. Barrett[2], P. Passmore[1], G. Shorter[3]
[1]Centre for Public Health, Queen's University Belfast, Belfast, United Kingdom
[2]School of Psychology, Queen's University Belfast, Belfast, United Kingdom
[3]All Ireland Hub for Trials Methodology Research, University of Ulster, Belfast, United Kingdom

Background: Cognitive profiles can help delineate who is specifically at risk of conversion to dementia in mild cognitive impairment (MCI).
Objectives: To categorise patients by MCI subtype using a standard approach, to create latent profiles and to assess progression over time.
Methods: MCI participants (n=139) and controls (n=98) were recruited. Participants had a full neurocognitive assessment. Results were analysed 1) according to number of cognitive domains affected and 2) using latent profile analysis (LPA)
Results: Most MCI participants were in the amnestic multidomain (AMD) subgroup (46.8%); they were most at risk of conversion to dementia. LPA revealed a 3 profile solution. Profile 3 was the largest group (40.3%); the most neurocognitively impaired and most closely represented the AMD group. In both analyses age had a significant impact on risk of conversion to dementia.
Conclusions: Older MCI patients with multiple cognitive deficits are most at risk of conversion to dementia

Table 1 Classification of MCI Participants According to the Methods of Petersen and Morris (2005)

Group Categorisation by Petersen Criteria	Number of MCI patients (%)	Of the total MCI patients in each category, breakdown in each profile (from LPA)		
		Profile 1 Amnestic Single Domain N=51 (36.7%)	Profile 2 Cognitively Normal N=32 (23.0%)	Profile 3 Amnestic Multidomain N=56 (40.3%)
No impairment of clinical significance	25 (18.0%)	11 (44.0%)	14 (56.0%)	0 (0.0%)
Amnestic single domain	13 (9.4%)	12 (92.3%)	1 (7.7%)	0 (0.0%)
Amnestic multidomain	65 (46.8%)	17 (26.2%)	1 (1.5%)	47 (72.3%)
Nonamnestic single domain	26 (18.7%)	8 (30.8%)	15 (57.7%)	3 (11.5%)
Nonamnestic multidomain	10 (7.2%)	3 (30.0%)	1 (10.0%)	6 (60.0%)

THE PROFILE OF CSF BIOMARKERS AND ITS ASSOCIATION WITH APOE GENOTYPE IN PATIENTS WITH ALZHEIMER'S DISEASE

E. Grusauskiene[1], G. Psemeneckiene[1], A. Vaitkus[1], D. Rastenyte[1], K. Petrikonis[1]
[1]Department of Neurology, Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania

Objectives. There are still no published data on CSF and serum biomarkers of AD in Lithuanian population. Thus the aim of our study was to evaluate levels of main CSF biomarkers and its' relationship with age of onset, initial MMSE score, and to compare the differences in APOE ε4+ and APOE ε4- groups.
Methods. Patients diagnosed with early to moderate AD (n=30) were observed from 6 to 24 months. Cognitive decline was assessed by MMSE and Blessed dementia scale. Aβ42, t-tau, p-tau CSF concentrations and Aβ40 serum level were measured. Patients were grouped according APOEε4 allele, severity of dementia, age of AD onset.
Results. Main group consisted of AD patients (n=25, mean age 68.96 yrs, mean MMSE 20.44 pts), the rest of patients (n=5, mean age 61.80 yrs, mean MMSE 22 pts) during period of observation showed signs of another cognitive disease. Levels of CSF biomarkers differed significantly among groups of AD *vs* another dementia. Aβ42, but not tau nor serum Aβ40, differed in groups APOEε4+ *vs* APOEε4-. P-tau concentration was higher in group of moderate AD. No significant data estimated according to sex and age of AD onset.
Conclusions. AD patients have reduced CSF Aβ42 and increased t-tau and p-tau levels. Carriers of at least one APOEε4 allele have lower Aβ42 concentrations. Higher p-tau concentration is associated with deeper cognitive disturbance at the onset of disease. No significant differences in serum Aβ40 levels were found among groups. More extended research is needed to confirm these findings.

ALZHEIMER'S DISEASE AND THE TASTY SERIES
E. Kok-Mikkonen[1]
[1]*Forensic Medicine, University of Tampere, Tampere, Finland*

Understanding the mechanisms leading to the development of neuropathology in non-demented individuals will provide answers to the question as to why some individuals remain dementia-free even in the presence of large amounts of brain lesions. Additionally, by investigating plaques and tangles in this manner, we may begin to elucidate the pathways leading to their occurrence and develop therapies to reduce or abate their development.
At the University of Tampere we have, and are in the process of collecting a second larger cohort of brains (amongst a cardiovascular disease-based designed series) from individuals most closely representing the general population. Altogether 1600 cases with data on cardiovascular disease measurements, brain regions (frontal cortex, insula-putamen, hippocampus, substantia nigra, pons and the cerebellar cortex), blood, cerebrospinal fluid (CSF) samples, medical histories (from available hospital records) and surveys on lifestyle factors (answered by family members of the deceased) will provide a plethora of data in which to determine factors that confer risks as well as benefits in the prevalence of neuropathology.
Utilising genetics, proteomics, biomarker analyses and many other powerful tools, this study of non-demented individuals is an internationally unique opportunity to study these mechanisms. Please feel free to contact me for collaborative opportunities at eloise.mikkonen@uta.fi!

INVESTIGATING THE SYNERGISTIC RELATIONSHIP BETWEEN SLEEP QUALITY, EXERCISE AND LEVELS OF BRAIN BETA-AMYLOID

B.M. Brown[1], S.R. Rainey-Smith[1], V.L. Villemagne[2], J.J. Peiffer[3], V. Dore[4], P. Bourgeat[4], S.L. Laws[1], K. Taddei[1], C.C. Rowe[2], R.N. Martins[1]

[2]Department of Nuclear Medicine & Centre for PET, Austin Health, Melbourne, Australia

[3]School of Psychology and Exercise Science, Murdoch University, Perth, Australia

[4]ICT Centre, CSIRO, Melbourne, Australia

There is currently no effective treatment for Alzheimer's disease (AD), thus, attention has turned to preventative measures, such as lifestyle modifications, that have the potential to delay AD onset. Recently, higher levels of physical activity and good sleep quality have been separately linked to lower levels of brain beta-amyloid (Aβ). Furthermore, previous work suggests that active individuals are more likely to experience good sleep quality. However, to our knowledge, no previous research has investigated whether a synergistic link between sleep and exercise exists, and the effect of such a link on AD-related neuroimaging biomarkers. Thus, we aim to investigate whether the association between higher levels of physical activity and lower brain Aβ remains salient in individuals experiencing poor quality sleep. Similarly, we also aim to investigate whether the relationship between good sleep quality and lower brain Aβ is salient in sedentary individuals. Using data from the Australian Imaging, Biomarkers and Lifestyle (AIBL) study of Ageing, we investigated the interaction between sleep and exercise and its relationship with brain Aβ burden, measured by Pittsburgh Compound B positron emission tomography. The results from our analysis indicate that a synergistic relationship between exercise and sleep exists, and is related lower brain amyloid burden. Our results provide support for the hypothesis that both sleep quality and exercise levels are important in maintaining cognitive health, and through interpretation of AD-related neuroimaging results, may indicate reduced risk or delay in onset of AD.

REAL LIFE MOVING ABILITY CORRESPONDS TO SPATIAL NAVIGATION IMPAIRMENT IN EARLY ALZHEIMER'S DISEASE

I. Mokrisova[1], J. Laczo[1], M. Vyhnalek[1], I. Gazova[1], M. Parizkova[1], J. Hort[2]
[1]Memory Disorders Clinic Department of Neurology,
Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic
[2]International Clinical Research Center, St. Anne's University Hospital Brno, Brno, Czech Republic

Objectives: Spatial navigation (SN) impairment is present already in early stages of Alzheimer's disease (AD) – in patients with amnestic mild cognitive impairment (aMCI). Particulary in patients with AD dementia it interferes with their activities of daily living. The aim of our study was to assess to what extent SN impairment interferes with real life moving ability in patients with AD dementia and aMCI.
Methods: Subjects with aMCI (n=35), mild AD dementia (n=8), and age, gender and education matched controls (n=15) underwent neurological and neuropsychological examination and SN testing (body-centered [egocentric] and world-centered [allocentric] SN) in the real-space human analogue of the Morris Watter Maze. A life-space questionnaire with five levels of difficulty was used to evaluate subjects' real life moving abilities due to SN impairment.
Results: The control group outperformed AD dementia (ps<.001) and aMCI (ps≤.002) groups in egocentric and allocentric SN. The AD dementia (p=.009) and aMCI (p=.01) groups had a lower total score on a life-space questionnaire than the control group. In the egocentric navigation task the higher error score mildly correlated with lower score on level IV (visiting places outside the neighborhood) (r=-0.20; p=.027) and level V (visiting places outside the town) (r=-0.30; p=.001). In the allocentric navigation task the higher error score mildly correlated with lower score on level V (visiting places outside the town) (r=-0.25; p=.005).
Conclusions: Moving ability in real life is affected in patients with mild AD dementia and aMCI. The level of real life moving ability may reflect severity of SN impairment.

ADPD5-2079

CONVERSION OF MILD COGNITIVE IMPAIRMENT PATIENTS TO ALZHEIMER'S DISEASE IN CLINICAL SETTINGS

K. TIFRATENE[1], P. ROBERT[2], A. METELKINA[3], C. PRADIER[1], J.F. DARTIGUES[4]
[1]Public Health, CHU de Nice, Nice, France
[2]CMRR EA Cobtek, CHU de Nice, Nice, France
[3]I3S, UNS CNRS, Nice, France
[4]U897, INSERM, Bordeaux, France

Objectives: To describe the positive predictive value of Mild Cognitive Impairment (MCI) and factors associated with progression in daily practice.
Methods: A retrospective cohort study was conducted from the French National Alzheimer Database. Among 446 439 patients cared in the participating centres between January 2009 and January 2014, 45 386 (10.2%) were classified as MCI and 23 676 had a follow-up visit at least one time. Annual conversion rate was used to describe the progression of MCI patients to AD. Hazard ratios of AD were estimated using Cox regression model.
Results: Annual conversion rate (ACR) was 13.7 % persons-year (py) with higher rate for amnestic MCI (aMCI) (18.2%py) than for non-amnestic MCI (naMCI) (9.5%py). Separate regression models were performed for each MCI subtypes. Higher education, older age and lower Mini Mental State Examination score were associated with an increased risk of conversion for both subtypes. Male gender (adjusted Hazard Ratio [95% confidence interval]: 0.86 [0.78-0.95]) and anxiolytics (0.78 [0.66-0.91]) were protective factors for aMCI whereas antidepressant drugs (1.16 [1.04-1.29]) were associated with an increased risk. For naMCI prescription of antipsychotics (0.56 [0.33-0.95]) and having a full reimbursement for severe disease (0.66 [0.56-0.78]) were protective for progression.
Conclusions: In real life the positive predictive value of MCI diagnosis is in line with previous specific clinical studies and external validity of the concept strengthened. Distinguishing between aMCI and naMCI is particularly relevant.

ADPD5-0353

NEPRILYSIN DEFICIENCY INFLUENCES THE NEUROPATHOLOGICAL AND BEHAVIORAL PHENOTYPE OF 5XFAD MICE

M. Hüttenrauch[1], S. Baches[2], J. Gerth[3], T. Bayer[1], S. Weggen[2], O. Wirths[1]
[1]Molecular Psychiatry, University Medical Center, Göttingen, Germany
[2]Neuropathology, Heinrich-Heine-University, Düsseldorf, Germany
[3]Neurology, University of Bonn, Bonn, Germany

OBJECTIVE: By numerous *in vitro*, *in vivo* and reverse genetics studies, the metalloprotease neprilysin (NEP) has been shown to be the most potent Aβ-degrading enzyme (ADE) in the brain. 5XFAD mice represent a highly valuable AD mouse model showing accelerated plaque pathology and behavioral deficits. This project aimed on evaluating the effect of NEP deficiency on the 5XFAD mouse model.
METHODS: Expression levels of NEP and other ADEs were determined by qRT-PCR analysis. Spatial working memory of hemizygous 5XFAD/NEP$^{+/-}$ mice was evaluated by performing Y- and Cross Maze tasks. Amyloid-pathology and inflammatory processes as well as soluble Aβ levels in the brain were studied by immunohistochemistry and ELISA, respectively.
RESULTS: We found that 5XFAD mice per se show decreased NEP expression levels compared to WT mice, which is even aggravated upon hemizygous NEP depletion. 5XFAD/NEP$^{+/-}$ mice demonstrate impairments in spatial working memory and increased astrocytosis. In addition, NEP deficiency in aged mice led to an overall increased level of soluble Aβ42 as well as region-specific increases in extracellular Aβ deposition. Surprisingly, in young mice, a more abundant cortical Aβ plaque pathology could be observed in 5XFAD compared to 5XFAD/NEP$^{+/-}$ mice. Additionally, young 5XFAD/NEP$^{+/-}$ as well as NEP$^{-/-}$ mice show elevated levels of endothelin-converting enzyme 1 (ECE1), leading to the assumption of a mutual regulation of ECE1 and NEP at young ages.
CONCLUSION: We show that NEP deficiency aggravates the behavioral and neuropathological phenotype of 5XFAD mice and provide *in vivo* evidence that NEP mainly affects soluble Aβ species.

ADPD5-0407

PHYSICAL ACTIVITY AMELIORATES NEURON LOSS AND MEMORY DEFICITS IN TG4-42 MICE

O. Wirths[1], A. Braußß[1], A. Kurdakova[1], M. Hüttenrauch[1], T.A. Bayer[1]
[1]Dept. of Psychiatry, University Medicine Göttingen, Göttingen, Germany

Objectives: N-truncated Aß$_{4-42}$ is one of the most abundant Aß peptide species in the brain of sporadic AD patients. We have recently developed a transgenic mouse model (Tg4-42) expressing Aβ$_{4-42}$ without mutations under the control of the neuron-specific Thy1-promotor, which develops age-dependent deficits in spatial reference memory accompanied by robust CA1 pyramidal neuron loss. The impact of enhanced physical activity on hippocampal neuron loss and behavioral deficits was assessed using an enriched environment paradigm.

Methods: Tg4-42 mice were housed under standard conditions or in enriched cages equipped with various objects and running wheels. The number of CA1 pyramidal and dentate gyrus (DG) granule cell layer neurons was assessed using design-based stereological methods. In addition, spatial reference memory using the Morris Water Maze task, as well as neurogenesis in the subgranular zone (SGZ) were analyzed.

Results: In addition to CA1 neuron loss, homozygous Tg4-42 at 6 months showed a ~ 45% decrease in SGZ neurogenesis, accompanied by a ~20% neuron loss in DG. Housing under enrichment conditions maintained both neurogenesis and granule cell neuron loss and led to a partial rescue of CA1 neuron loss and spatial reference memory deficits.

Conclusion: We provide evidence that enhanced physical activity due to environmental enrichment leads to an amelioration of neuronal loss and behavioral deficits in a transgenic mouse model reflecting the sporadic form of AD. This might indicate the relevance of increased physical activity as a potential strategy in the prevention of dementia.

APP-CTFBETA IS ELEVATED IN A LINE OF APP TRANSGENIC MICE WITH COGNITIVE IMPAIRMENT AND SEIZURES, BUT NO DETECTABLE BETA-AMYLOID OLIGOMERS

S. Shapiro[1], M. Grant[1], M. Gastecki[1], K. Zahs[1], K.H. Ashe[1]
[1]Department of Neurology, University of Minnesota, Minneapolis, USA

Objectives: Premature death and seizures have been observed in many lines of APP transgenic (TgAPP) mice. Recently, seizures in a line of TgAPP mice were shown to be associated with the overexpression of APP rather than the overproduction of Abeta. Here, we examined a line of TgAPP mice, previously shown to exhibit premature death, cognitive impairment, and seizures – but no amyloid plaques – to determine whether total Abeta or Abeta oligomers were associated with these phenotypes.
Methods: Cognitive performance was assessed using a Corner Index Test as a measure of neophobia (Hsiao et al., Neuron, 1995). Mice were sacrificed and brains lysates were prepared and analyzed by Western blot.
Results: We found no Abeta oligomers in these mice. However, we did find that those animals with cognitive impairment and/or seizures had significantly more APP-CTFbeta than unimpaired/non-epileptic littermates.
Conclusions: Our findings support the hypothesis that seizures and premature death in some lines of TgAPP mice reflect the effects of APP or APP fragments (e.g., CTFbeta) other than Abeta.

SEX DIFFERENCES IN THE SEARCH STRATEGIES EMPLOYED BY TGCRND8 MICE DURING MORRIS WATER MAZE (MWM) PERFORMANCE

M.W. Granger[1], *M.W. Taylor*[1], *B. Franko*[1], *G.P. Taylor*[1], *S.A.L. Bennett*[1]
[1]*Biochemistry Microbiology and Immunology, University of Ottawa, Ottawa, Canada*

Objectives

To determine if there is a sex-specific impairment in searching strategies employed by the TgCRND8 mouse model of Alzheimer's disease

Methods

Navigation strategies were analyzed using a novel algorithm, MWM Visual, developed by our team for the efficient classification of spatial, systematic and repetitive looping search patterns in the MWM.

Results

TgCRND8 mice are impaired in MWM compared to NonTg littermates. This is due to a marked difference in searching strategies, notably a phenotypic tendency towards repetitive looping at the expense of spatial learning. Unlike NonTg mice, TgCRND8 mice are unable to learn a primarily spatial strategy over the test days. We show that females are more impaired than males at six months of age. Male TgCRND8 mice show an initial impairment in spatial navigation compared to NonTg mice but are capable of adapting their learning strategy over time, adopting a predominant spatial navigation profile. Females exhibit more robust learning impairments than males. Female TgCRND8 mice are capable of spatial navigation but this strategy never predominates with females unable to overcome their phenotypic preference for repetitive looping. Sex differences are not due to the visual impairments inherent in this mixed C57BL/6 x C3H/HeN line but rather inconsistencies in adopting a more efficient searching strategy.

Conclusions

These results identify subtleties in learning and memory impairment in TgCRND8 mice that model potential sex differences associated with disease severity.

ADPD5-0999
MUTATION OF AN AMYLOID BETA PROTEIN BINDING SITE ON ENDOGENOUS MYELIN BASIC PROTEIN IN MICE
J. Davis[1], F. Xu[1], M. Ou-Yang[1], W.E. Van Nostrand[1]
[1]Neurosurgery, Stony Brook University, Stony Brook, USA
Endogenous inhibitors of amyloid ß protein (Aß) assembly in brain may play an important role in suppressing amyloid formation and deposition in Alzheimer's disease and related disorders. Previously, we showed that myelin basic protein (MBP), a prominent component of the axonal myelin sheath, can strongly bind to Aß peptides and potently inhibit their assembly into fibrils. More recently, we identified residues K54, R55 and G56 in MBP as important in mediating its interaction with Aß. Here, we show that mutation of all three residues together completely disrupts MBP binding to Aß and blocks its inhibition of Aß fibrillar assembly in vitro. To investigate the in vivo consequences of this site on MBP we generated novel mice (MBP-KRG mice) where these three key residues in endogenous mouse MBP were mutated. MBP-KRG mice were fertile, viable and exhibited no overt behavioral abnormalities. Upon further examination by electron microscopy MBP-KRG mice appeared to exhibit a thicker myelin layer surrounding axons suggesting that this site on MBP may play a role in myelination. The MBP-KRG mice were bred with two lines of human AßPP transgenic mice: Tg-5xFAD mice that develop robust parenchymal amyloid plaque pathology and Tg-SwDI mice that develop extensive cerebral microvascular amyloid pathology. The bigenic MBP-KRG/Tg-5xFAD mice and MBP-KRG/Tg-SwDI are being evaluated to determine if mutation of this key site on MBP influences the onset and severity of amyloid pathologies.

ADPD5-1293
AGE-RELATED CHANGES IN SHORT-TERM AND LONG-TERM PLASTICITY IN TG2576 MICE
D. Fernandez Fernandez[1], C. Dorner-Ciossek[1], K.S. Kroker[2], H. Rosenbrock[1]
[1]CNS Research Germany, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach/Riss, Germany
[2]Drug Discovery Support, Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach/Riss, Germany
Objectives: TG2576 mice are one of the best characterized models to study amyloid-dependent synaptic dysfunction related to Alzheimer's Disease (AD). Several studies using this model previously described an impairment of long-term potentiation (LTP) in different regions of the hippocampus, although in each study only a single form of LTP was investigated. Here, we describe a series of experiments to study short-term and long-term plasticity by using paired-pulse facilitation (PPF) and both early and late forms of LTP, respectively. Additionally, we examined these different forms of plasticity during aging in wild-type and TG2576 mice.
Methods: Hippocampal slices from 3, 10 and 15 month old wild-type and TG2576 mice were used to measure the slope of fEPSPs in the CA1 region. Validated protocols were applied for the induction of PPF, early-LTP and late-LTP and its interaction with pharmacological manipulations.
Results: Our preliminary results show that in hippocampal slices from 10 months old TG2576 mice, early-LTP is compromised in contrast to late-LTP. Moreover, pharmacological investigation regarding the involvement of NMDA receptors and L-type voltage-gated calcium channels on late-LTP suggests a differential mechanism of induction among groups.
Conclusions: Our results indicate that early-LTP and late-LTP are differentially affected regarding wild-type and TG2576 during age. Furthermore, these differences can be partially explained under the scope of NMDA receptors and L-type voltage-gated calcium channels as a molecular background. New experiments are currently ongoing to create a wide-ranging framework of synaptic plasticity in TG2576 mice during aging.

[6]LANVIE - Laboratory of Neuroimaging of Aging,
University Hospitals and University of Geneva, Geneva, Switzerland
Objectives. Diffusion Tensor Imaging (DTI) is useful to detect alterations in mild cognitive impairment (Stahl et al., Radiology 2007) and Alzheimer's Disease (AD) (Liu et al, Neurobiol Aging 2011). Within the IMI-PharmaCog European Consortium (www.alzheimer-europe.org) we compared the diffusion profile of two mouse models of age-dependent amyloid deposition in order to detect markers of disease progression homologous to those found in human AD patients.
***Methods*.** Wild-type (WT), double (TASTPM) and triple (TauPS2APP) mice underwent DTI at 4, 8, 12, 18 and 24 months of age. Several regions of interest including corpus callosum, anterior commissure and hippocampus, were manually drawn and diffusion indices were extracted using FSL.
Results. Corpus callosum and anterior commissure of TASPM showed a decrease in anisotropy and axial diffusivity (index of axonal injury) concomitant to an increase of radial diffusivity (index of axonal demyelination). These alterations started at 12 months of age ($p < 0.001$). Greater hippocampal mean diffusivity was reported in older TauPS2APP mice relative to WT.
***Conclusions*.** Age-related deficits in the corpus callosum of TASTPM mice and in the hippocampus of TauPS2APP seems to reflect the human AD pathology (Acosta-Cabronero et al., PLoS One 2012; Kantarci et al., Neurology 2005). Treatments using amyloid lowering agents are on-going to validate these promising murine biomarkers.

BEHAVIORAL, BIOCHEMICAL AND IMAGING CHARACTERIZATION OF ALZHEIMER'S DISEASE MOUSE WITH APPSWEDI MUTATIONS AND NOS2 GENE KNOCK-OUT (CVN MOUSE)

J. Puoliväli[1], T. Ahtoniemi[1], O. Kontkanen[1], T. Heikkinen[1], J. Oksman[1], M. Cerrada-Gimenez[1], A. Nurmi[1]

[1]Discovery Services Finland, Charles River, Kuopio, Finland

CVN mouse, with APPSweDI mutations NOS2 knockout background, exhibits wide range of AD hallmarks including increased insoluble Aβ and plaque formation, inflammation, tau phosphorylation, hippocampal neuronal death and behavioral deficits (Wilcock et al 2008). Validation data from Charles River CVN mouse in-house testing colony shows reproducible AD defects, and positions CVN mouse as the most complete AD model available.

Wild-type and CVN mice were studied starting at age of 3 months. Behavioral battery included Open field, Barnes maze, Radial arm water maze, and Contextual fear conditioning. At 3,6,9 and 12 months of age, tissue were collected for biochemical analysis. Immunohistochemical stainings for Aβ1-40 and microglia were performed, and neuronal number was evaluated by CFV histological staining. MRI volumetric as well as spectroscopic (1H-MRS) analyses were performed.

CVN mice exhibited significant age-dependent behavioral deficits in Barnes maze, Radial arm water maze and Contextual fear conditioning. Robust biochemical changes, including increased number of dense amyloid plaques in hippocampus, thalamus and cortex, and increased levels of insoluble Aβ subtypes were evident. Significant inflammatory response detected by Iba-1 and CD45 immunoreactive microglia was heavily condensed around the plaques in all brain regions studied. The number of viable neurons in hippocampus was significantly decreased in aged animals. In 1H-MRS several translational AD-related metabolic changes were detected.

The CVN mouse provides a more complete tool to study novel therapies targeted for treatment of AD. Several desired AD-related end-points are present in this mouse line making it a valuable model for drug development.

MRNA PROFILING OF HIPPOCAMPAL NEURON LOSS IN THE TG4-42 MODEL EXPRESSING ABETA4-42

Y. Bouter[1], T. Kacprowski[2], R. Weissmann[3], K. Dietrich[1], A.W. Kuss[3], T.A. Bayer[1]
[1]Molecular Psychiatry, University Medical Center Göttingen, Göttingen, Germany
[2]Department of Bioinformatics, University Medicine Greifswald, Greifswald, Germany
[3]Human Molecular Genetics Institute for Human Genetics University Medicine Greifswald & Department for Human Genetics of the Institute for Genetics & Functional Genomics , Ernst-Moritz-Arndt University Greifswald, Greifswald, Germany

Objectives: N-truncated Aβ4-42 has been identified as a particular abundant Aβ species in the hippocampus and cortex of AD patients. Tg4-42 mice exclusively express N-truncated $A\beta_{4\text{-}42}$ and develop intraneuronal Aβ aggregation and behavioral deficits albeit without plaque formation. Strikingly, Tg4-42 mice develop a massive CA1 neuron loss. The gene expression profiles of Tg4-42 mice were compared to the widely used plaque-developing 5XFAD mouse model using next-generation sequencing.
Methods: Next generation sequencing was used to identify differentially expressed genes (DEGs) in an unbiased manner. DEGs were subsequently verified by quantitative PCR. Furthermore, mice were assessed for their ability to learn in the Morris water maze.
Results: Aged Tg4-42 displayed memory deficits similar to 5XFAD mice. Nineteen DEGs were identified in presymptomatic young 5XFAD mice, while no DEGs could be isolated in young Tg4-42 mice. In the aged cohort, 131 DEGs were found in 5XFAD and 56 DEGs in Tg4-42 mice. Intriguingly, 36 DEGs were identified in both mouse models.
Conclusions: The comparison of the Tg4-42 mouse model with 5XFAD model, revealed a remarkable overlap in the molecular signature. The pool of genes that showed differential expression exclusively in Tg4-42 is likely associated to soluble Aβ as no extracellular plaques are found in this model. Many of the DEGs specific to the 5XFAD model belong to neuroinflammatory processes typically associated with plaques. The jointly differentially expressed genes might indicate common pathways that are involved in the comparable memory decline and neuron loss apparent at twelve months of age in both transgenic models.

EARLY COGNITIVE DYSFUNCTION IN A HUMAN AMYLIN OVEREXPRESSING APP TRANSGENIC MOUSE MODEL OF ALZHEIMER'S DISEASE

T. Welt[1], F. Wirth[1], L. Kulic[1], C. Späni[1], R. Derungs[1], N. Krakoski[1], R.M. Nitsch[1]
[1]Division of Psychiatry Research, University of Zürich, Schlieren, Switzerland

Objectives
Recently, accumulating evidence points to a prominent role of type 2 diabetes (T2D) in age-related cognitive decline and neurodegenerative dementia including Alzheimer's disease (AD). Impaired glucose tolerance and insulin resistance have been associated with impaired cognitive performance both in human patients and in animal models of AD. To investigate the effects of amylin-induced impaired glucose tolerance on beta-amyloid-related pathology and cognitive dysfunction *in vivo*, we generated a novel mouse model of both T2D and AD-like neuropathology.
Methods
Human amylin (hIAPP) transgenic mice on an FVB background were crossbred with PSAPP bigenic mice overexpressing human APP carrying the Swedish mutation and the Presenilin1 delta exon 9 mutation. Metabolic parameters including fasting glucose, glucose tolerance and insulin secretion as well as spatial and object recognition memory were assessed in the four different genotypes PSAPP/hIAPP, PSAPP, hIAPP and WT at 4.5 months of age.
Results
Glucose tolerance was impaired both in the hIAPP single transgenic mice modeling T2D and in the PSAPP/hIAPP double transgenic mice modeling both T2D and AD-like pathologies. Interestingly, cognitive assessment on two hippocampus-dependent cognitive tasks revealed impaired memory performance only in the PSAPP/hIAPP double transgenic mice but not in the hIAPP nor in the PSAPP single transgenic mice.
Conclusions
The results of this study reveal that overexpression of human amylin exacerbates hippocampus-dependent cognitive dysfunction in the PSAPP transgenic mouse model of Alzheimer's disease and suggest that the PSAPP/hIAPP double transgenic mice may be a valuable model to study the role of amylin-related glucose intolerance in AD pathogenesis.

[2]College of Medicine, Seoul National Univ, Seoul, Korea

Amyloid-plaques and neurofibrillary tangles composed of Tau are the defining neuropathological features of Alzheimer's disease (AD). Recently, many studies report that amyloid-beta trigger Tau pathology in experimental systems. But the other studies had shown that tau pathology could trigger Abeta aggregation. To answer this controversy, we have crossed 5XFAD mice co-expressing human mutant APP695 with the Swedish, Florida, and London mutations and human mutant presenilin-1 (PS1) with the M146L and L286V mutations with the MAPT mice over-expressing human mutant tau with the P301L mutation. Our triple transgenic 5XFAD/MAPT mice have been characterized at 3, 5 and 7 months of age. Extracellular amyloid deposits were not changed in the 5XFAD/MAPT compare with 5xFAD at all ages. However, hyper-phosphorylated and accumulated tau pathology is dramatically increased in the hippocampus at 5 month old mice. Also memory deficit is observed compare with age-matched MAPT mice. These data suggest that tau pathology being downstream of amyloid pathology in our model mice. 5XFAD/MAPT mouse model shows a fast development of disease and aspects of AD neuropathology. It will be useful model for Abeta and tau interact study, also for pre-clinical intervention trials.

[3]Department of Functional Genomics,
Center for Neurogenomics and Cognitive Research (CNCR) Neuroscience Campus Ams terdam VU University Amsterdam, Amsterdam, Netherlands

Alzheimer's disease (AD) is characterized by progressive neuropathological changes and decline in cognitive function. Transgenic mice carrying AD-causing mutations in PS1 and APP have enhanced levels of toxic Aβ peptide species in the brain. These transgenic mice, as well as mice that are i.c.v. infused with toxic Aβ oligomers, show deficits in memory tasks, confirming the idea that Aβ oligomers play a critical role in AD. Strikingly, these memory deficits have been reported before the onset of pathological changes (e.g. plaques) and in the absence of neurodegeneration. To differentiate between the behavioral effects of toxic Aβ oligomers in the absence and presence of neuropathological changes, we longitudinally compared the behavioral profile of several mouse models of Aβ toxicity. Using an automated home-cage system and 24/7 video tracking and analysis we measured numerous spontaneous behavioral phenotypes including locomotor activity, feeding, sheltering and circadian rhythm. In addition, we measured cognitive performance in a novel automated 4-day discrimination and reversal learning task for cognitive flexibility in an automated home-cage. We observed highly significant behavioral changes in transgenic mice at 6 weeks of age, before neuropathology, whereas other behavioral features were only detected at 6-12 months of age, after onset of neuropathology. Moreover, we also detected highly significant age-dependent changes in wild type littermates in the majority of behavioral readouts. We conclude that longitudinal measurements are required to dissociate the effects of Aβ oligomer toxicity, neuropathological changes, and normal aging in mouse models of AD.

HIPPOCAMPAL PROTEOME ANALYSES REVEAL STAGE-SPECIFIC CHANGES IN A RAT MODEL OF ALZHEIMER'S DISEASE.

S. Do Carmo[1], G. Crynen[2], M.F. Iulita[1], A. Ducatenzeiler[1], F. Crawford[2], A.C. Cuello[1]
[1]Pharmacology and Therapeutics, McGill University, Montreal, Canada
[2]., Roskamp Institute, Sarasota, USA

Alzheimer's disease (AD) is characterized by progressive cognitive impairment associated with the accumulation of amyloid beta-peptide and neuronal degeneration in several brain regions and more importantly in the hippocampus. To elucidate the molecular changes occurring as the disease is triggered and progresses, we used the McGill-R-Thy1-APP rat model of AD-like amyloid pathology at 2 time-points: at 3 months of age when the amyloid pathology is only present in the intraneuronal compartment but cognitive deficits are already present; and at 12 months of age when extracellular plaques are abundant and cognitive deficits have progressed. Quantitative proteomics analyses of hippocampal tissue were carried out using isobaric tagging for relative and absolute quantitation (iTRAQ) with liquid chromatography/mass spectrometry analyses in a Q-Exactive Orbitrap to identify genotype and time-dependent changes in protein expression. After correction for multiple testing, expression levels of 64 proteins were found to be considerably different in transgenic versus wild-type rats at 3 months of age, as were 86 proteins in the 12 month age group. Interestingly, the proteins affected at the pre-plaque stage vary widely from the proteins impacted at the post-plaque stage, with only 9 proteins common to the two time-points. This minimal overlap supports the hypothesis that distinctive processes are at work in the hippocampus during the progression of AD. Oxidative stress processes are prominent at early stages while disturbances in amino acid metabolism develop later on. Further exploration of these changing molecular profiles could lead to identification of novel therapeutic targets for early intervention in AD.

[3]Physiology and Biophysics,
Zilkha Neurogenetic Institute University of Southern California, Los Angeles, USA

Objectives: Transforming growth factor-beta (TGF-beta) is a critical immunoregulatory cytokine with increased abundance in AD patient brains. Our group has previously shown that genetic ablation of TGF-beta-Smad 2/3 signaling in peripheral macrophages causes brain recruitment of these cells and resolution of cerebral amyloidosis, which does not come at the cost of damaging neuroinflammation. Currently, we are exploring whether pharmacological blockade of TGF-beta signaling in peripheral macrophages using next-generation nanoparticle technology can re-balance inflammation and mitigate AD-like pathology in our pre-clinical TgF344-AD rat model. These rats manifest the full spectrum of age-dependent AD pathologies and cognitive disturbance. **Methods:** To specifically target peripheral macrophages, we developed PEG-PLGA nanoparticles encapsulating SB505124 (a small molecule TGF-beta-Smad 2/3 inhibitor) and the non-toxic fluorescent tracker, Coumarin-6 (designated nano-C6/SB). In vitro experiments were performed to test whether nano-C6/SB target peripheral murine macrophages, inhibit TGF-beta-Smad 2/3 signaling, and alter Abeta uptake by these cells. Following long-term peripheral treatment with nano-C6/SB, aged TgF344-AD rats were behaviorally tested and their brains were analyzed for AD-like pathology. **Results:** Nano-C6/SB directly target peripheral macrophages, effectively inhibit TGF-beta signaling, and increase macrophage Abeta uptake. Moreover, peripheral nano-C6/SB treatment of TgF344-AD rats promotes 1) brain infiltration of C6-positive mononuclear phagocytes that 2) localize to amyloid plaques, 3) attenuates cerebral amyloidosis and 4) tauopathy, and 5) partially remediates cognitive deficits. **Conclusions:** PEG-PLGA nanoparticles encapsulating small molecule TGF-beta-Smad 2/3 inhibitors hold pre-clinical promise to directly target peripheral macrophages for cerebral amyloid clearance.

THALIDOMIDE RAPIDLY REVERSES SYNAPTIC PLASTICITY DISRUPTION IN A RAT MODEL OF ALZHEIMER'S DISEASE AMYLOIDOSIS

I. Klyubin[1], Y. Qi[1], A.C. Cuello[2], M.J. Rowan[1]
[1]Pharmacology and Therapeutics, Trinity College Dublin, Dublin, Ireland
[2]Pharmacology and Therapeutics, McGill University, Montreal, Canada

Pro-inflammatory mechanisms may play a key role in AD pathogenesis. Previously we reported that transgenic rats overexpressing mutant human APP (McGill-R-Thy1-APP) develop a deficit in long-term potentiation (LTP) as early as 3-4 month of age, long before the extracellular deposition of neuritic plaques.

Objectives:

Here we investigated if the immunomodulatory agent thalidomide reversed the deficit in LTP, at an age when these transgenic rats show signs of pre-plaque inflammatory processes in the brain (Hanzel, 2014).

Methods:

In vivo electrophysiology was carried out on either urethane (1.5 g/kg, i.p.) anaesthetized or chronically implanted freely moving male rats. Electrically evoked field excitatory postsynaptic potentials were measured at CA3 to CA1 synapses in the dorsal hippocampus. Our standard 200 Hz high frequency stimulation (HFS) protocol was used to induce LTP.

Results:

LTP was completely inhibited in transgenic rats aged 4 month and over ($p>0.05$, compared with pre-HFS baseline). Repeated i.p. treatment with thalidomide (50 mg/rat/day for 4 consecutive days) reversed the LTP deficit in 6 month-old animals under anesthesia (137±15%, $n=5$, $p<0.05$). The same treatment regime also enabled LTP induction in freely moving animals of similar age ($n=6$, $p<0.05$). Because of the anti-TNFalpha action of thalidomide, we tested the effects of the anti-TNF antibody infliximab (5X50 µg over 3 days, i.c.v.). To our surprise there was no improvement of LTP ($n=4$, $p>0.05$).

Conclusions:

These results support the development of thalidomide-like agents as potential candidates for early AD treatment. However, the beneficial effect of thalidomide may not be related to its ability to reduce TNFalpha production.

08b. Animal Models: transgenic rats

ADPD5-1310

NON-FIBRILLAR ABETA MEDIATES EARLY SYNAPTIC PLASTICITY DISRUPTION IN A RAT MODEL OF ALZHEIMER'S DISEASE AMYLOIDOSISS

Y. Qi[1], I. Klyubin[1], A.C. Cuello[2], M.J. Rowan[1]
[1]Pharmacology and Therapeutics, Trinity College Dublin, Dublin, Ireland
[2]Pharmacology and Therapeutics, McGill University, Montreal, Canada

Previously we reported that transgenic rats overexpressing mutant human APP (McGill-R-Thy1-APP) develop a deficit in long-term potentiation(LTP) as early as 3-4 month of age, long before the extracellular deposition of fibrillar Abeta in neuritic plaques.

Objectives:

Here, we applied an anti-Abeta antibody, a BACE1 inhibitor and a gamma-secretase inhibitor to investigate whether or not the LTP deficit in these transgenic rats is Abeta-dependent.

Methods:

In vivo electrophysiology was carried out on chronically implanted freely moving male rats. Electrically evoked field excitatory postsynaptic potentials were measured at CA3 to CA1 synapses in the dorsal hippocampus. A cannula was implanted in the lateral ventricle. Our standard 200 Hz high frequency stimulation (HFS) protocol was used to induce LTP.

Results:

LTP was completely inhibited in transgenic rats aged 4 month and over ($p>0.05$, compared with pre-HFS baseline). Repeated intracerebroventricular injection of the anti-Abeta antibody McSA1 (5X10 microg over 3 days) reversed the LTP deficit in 4 month-old animals (142.7±7.2%, n=5, $p<0.05$). Moreover, the BACE1 inhibitor LY2886721 (5X0.2 nmol over 3 days) reversed the LTP deficit in 4 month-old animals (140.3±16.1%, n=6, $p<0.05$). Similarly, the gamma-secretase inhibitor MRK-560 (5X0.19 nmol over 3 days) reversed the LTP deficit in 5 month-old animals (124.8±8.0%, n=7, $p<0.05$).

Conclusions:

These findings strongly indicate that the LTP deficit in this transgenic rat model is Abeta-dependent. Furthermore, the rapid reversal of the impaired LTP in the pre-plaque stage of amyloidosis provides encouragement for the development of therapeutic interventions early in AD pathogenesis.

TRANSLATIONAL APPROACH OF COGNITIVE EVALUATION IN THE PRIMATE MICROCEBUS MURINUS

N. Mestre-Frances[1], S. Trouche-Sabatier[1], C. Lautier[1], J.M. Verdier[1]
[1]biology and health, INSERM U710, Montpellier, France

Objective: The CANTAB battery is a computer-based cognitive assessment using a touch screen. It allows to assess cognitive abilities in humans. Among the tests developed, the Pairwise Discrimination (PD) test was confirmed to be sensitive to prefrontal pathologies. We have adapted this test to the lemurian primate *Microcebus murinus*. Our purpose was to differentiate healthy ageing from ageing-associated disorders such as Alzheimer's Disease (AD).

Methods: The subject has to discriminate two visual stimuli. The acquisition phase (PD) assesses the capability to succeed in a simple associative learning using working memory. The reversal phase (PDR) assesses the cognitive flexibility by measuring the capability to reverse the stimuli. When a subject reaches the criterion in PD (80% of correct responses in two consecutive sessions), it is tested in the PDR.

Results: We trained 32 old mouse lemurs. Seventeen were successfully trained and 12 reached the criterion in PD acquisition and 10 in PDR. Old healthy animals needed 9 sessions for PD and 11.5 sessions for PDR, whereas for AD-like animals, *i.e.* animals with risk to develop amyloid deposits, 10.25 sessions were necessary for PD and 20 sessions for PDR.

Conclusion: By using a computerized and standardized battery, we were able to distinguish between healthy old and AD-like animals. These observations highlight the usefulness of CANTAB tests for studying cognitive dysfunction in *Microcebus murinus*. Other tests are now developed to complete our approach that may help in diagnosing age-related disorders.

08c. Animal Models: primate models

ADPD5-1059
GENE ANALYSIS OF THE APP GENE IN THE GREY MOUSE LEMUR, A NONHUMAN PRIMATE WITH ALZHEIMER'S DISEASE-LIKE (AD-LIKE) PATHOLOGY

C. Lautier[1], C. Lemaire[1], J.M. Verdier[1]
[1]MMDN, INSERM U710, Montpellier, France

Objectives: The development of small nonhuman primate models for aging and neurodegenerative disease studies has considerable advantages in terms of costs, rapid colony growth and phylogenetic relationships to humans. The grey mouse lemur, *Microcebus murinus* (MIM), is a small primate with a short lifespan (6-8 years). Some of them develop the lesions of Alzheimer's disease (AD), such as amyloid deposits and/or cerebral atrophy. They are called 'AD-like'. Our objective is to look for APP mutations that might be linked to these lesions.
Methods: We selected 52 'AD-like' animals based on their genealogical tree showing a familial history of brain amyloid deposit and/or cerebral atrophy, and 41 wild-type (WT) as controls.
Results: The sequencing of the APP gene for the 93 animals led us to identify 86 single nucleotide variations (SNVs). Two of them are more frequently associated with the AD-like trait ($p<0,05$). By reconstruction of the LD-blocks for these 2 SNVs we found them on the block 10 (19 kbp), and on the block 15 (16 kbp) respectively. We found that the haplotypes 6 (H6) from the block 10 and the haplotype 2 (H2) from the block 15 are significantly associated to the AD-like phenotype ($p<0,002$). In addition, the genotype H1/H6 from the block 10 and the genotype H1/H2 from the block 15 were associated to AD-like animals ($p<0,002$).
Conclusion: Our results showed that some of the genetic variations observed in the APP gene are associated to the AD-like trait in our primate model MIM.

08d. Animal Models: drosophila

ADPD5-0571
EVALUATION OF ABETA43 TOXICITY IN VIVO USING DROSOPHILA MELANOGASTER
S. Burnouf[1], M. Gorsky[1], J. Dols[1], S. Grönke[1], L. Partridge[1]
[1]Biological Mechanisms of Ageing, Max Planck Institute for Biology of Ageing, Cologne, Germany
OBJECTIVES: Amyloid plaques observed in Alzheimer's disease (AD) brains are composed of a heterogeneity of Aβ peptides. Next to the well-studied $A\beta_{42}$ and $A\beta_{40}$ species, respectively highly pathogenic and rather harmless, $A\beta_{43}$ peptides were lately hypothesized to be instrumental in AD pathogenesis. Indeed, $A\beta_{43}$ is frequently found in AD brains in both dense and diffuse amyloid plaques and recent *in vitro* studies have stressed the ability of $A\beta_{43}$ to induce toxic effects on neuronal cultures. However, whether $A\beta_{43}$ directly triggers neurotoxicity *in vivo* has not been evaluated so far.
METHODS: We generated a new transgenic *Drosophila* line of human $A\beta_{43}$. Since eye roughening is a commonly-used readout to evaluate the extent of protein toxicity including Aβ peptides, we constitutively overexpressed human $A\beta_{43}$ in the fly eye-compound using the GMR-Gal4 driver.
RESULTS: We found that the specific overexpression of human $A\beta_{43}$ in the *Drosophila* eye-compound caused ommatidial disorganization together with the development of a rough eye phenotype.
CONCLUSIONS: Our data suggest that human $A\beta_{43}$ is toxic *in vivo* and delineate its contribution to the pathological events leading to neurotoxicity in AD.

08d. Animal Models: drosophila

ADPD5-0637
ROLE OF SARAH/NEBULA IN AMYLOID-BETA42-INDUCED NEUROLOGICAL IMPAIRMENT IN DROSOPHILA

K. Cho[1], S.M. Bang[1], S. Lee[1], Y.K. Hong[1]
[1]Biological Sciences, Konkuk University, Seoul, Korea

The Down Syndrome Critical Region 1 (DSCR1) protein, an inhibitor of Ca^{2+}-dependent phosphatase calcineurin, has been shown to be elevated in the brains of Down syndrome (DS) or Alzheimer's disease (AD) patients. Because DSCR1 has been implicated in the neuropathology of DS, an increased level of DSCR1 is believed to be deleterious to neuronal health. On the other hand, because hyper-activated calcineurin has been implicated in neuronal damage, calcineurin inhibitors such as DSCR1 are expected to exert beneficial effects against AD neuropathology. However, the role of DSCR1 in the pathogenesis of AD is still unclear. Here, we investigated the role of *sarah* (*sra*)/nebula, a *Drosophila DSCR1* ortholog, in the amyloid-β42 (Aβ42)-induced neurological phenotypes in *Drosophila*. Overexpression of the *sra* using the *UAS-GAL4* system exacerbated the rough eye phenotype, and decreased the survival rates of the *Aβ42*-expressing flies without modulating the *Aβ42* expression. Similarly, treatment with chemical inhibitors of calcineurin such as FK506 and cyclosporine A, or knockdown of *calcineurin* expression by RNAi, worsened the rough eye phenotype induced by *Aβ42*. Furthermore, the *sra*-overexpressing flies displayed significantly decreased mitochondrial DNA content, as well as increased susceptibility to oxidative stress compared to the control flies. Taken together, our results demonstrating that overexpression of *sra* has an augmenting role on Aβ42 cytotoxicity in *Drosophila* suggest that the *DSCR1* up-regulation or *calcineurin* down-regulation in the brains of DS or AD patients may accelerate neuropathogenesis of AD in humans as well.

ADPD5-1483

ROLE OF GLUCOSE METABOLISM IN Aß PATHOLOGY IN DROSOPHILA MELANOGASTER

T. Niccoli[1], M. Cabecinha[1], L. Partridge[1]
[1]Genetics Evolution and Enviroment, University College London, London, United Kingdom

Objectives

Reduced glucose metabolism in the brain is one of the main symptoms of Alzheimer Disease. This can precede the appearance of the clinical symptoms and is a strong predictors of who will go on to develop clinical AD. This suggests that glucose metabolism could play a role in the development of AD.
However, this relationship has not been extensively studied and a possible molecular mechanism is currently unknown.
The aim of this project was to establish whether modulation of glucose metabolism in neurons had an effect on Aß toxicity and how this was mediated.

Methods

Our laboratory has developed an adult-onset Drosophila model of AD which expresses a highly pathogenic form of human Aß (Arctic mutant) only in neurons of adult flies. These flies recapitulate some of the pathologies of AD such as defects in mitochondrial transport and synaptic dysfunction, leading to deficits in motor behaviour, thus making them a good model to investigate the role of Aß in neuronal dysfunction.
We altered glucose metabolism in this model by down-regulating and overexpressing a Glucose transporter (GluT1) to increase or decrease glucose transport in Aß expressing neurons.

Results

Overexpression of GluT1 improved several of the phenotypes of Aß expressing flies, including lifespan and motor ability, as well as a number of molecular phenotypes.

Conclusions

An increase in glucose metabolism can reduce the toxicity of Aß in Drosophila neurons. This suggests that targeting glucose metabolism could possibly provide a promising therapy for AD.

VALIDATION OF A NEW ZEBRAFISH MODEL FOR AMYLOID-BETA TOXICITY AS A FUTURE TOOL FOR DRUG DISCOVERY

M. Offenbartl[1], C.H. Andersson[1], R. Olsson[2], P. Kettunen[1]
[1]Neuroscience and Physiology, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden
[2]Chemical Biology & Therapeutics Experimental Medical Science, Lund University, Lund, Sweden

With our increased life expectancy, the number of people affected by AD and other neurodegenerative diseases will be substantially larger. There is a huge need to find novel treatments and disease preventions for AD. In this project we were interested in validating a new zebrafish model for Aβ-mediated memory disturbances as a tool for future AD drug discovery. We pretreated zebrafish embryos with the chemicals prior to the injection of Aβ into the brain ventricle. The next day, we tested learning as well as neuronal cell death levels in vivo. We tested a number of currently used AD medications as well as newly developed compounds, including nuclear receptor ligands. Our preliminary data show that both memantine and donepezil prevents against Aβ-mediated learning impairments in our model. This indicates that the zebrafish can serve as a tool to validate compounds that could be potential therapeutics for AD.

[4]Centre de Perharidy, ManRos Therapeutics, Roscoff, France

Objectives: The Aβ1-42-inducing aftins constitute unique chemical tools for both fundamental investigations and translational studies in sporadic Alzheimer's disease (sAD). Following the demonstration that aftin-5 triggers Aβ1-42 production in cultured neurons and various cell lines, our objective is to develop a chemically-induced sAD animal model.

Methods: Aftin-5 passage through the blood-brain barrier (BBB) was assessed *in vitro* in a cell-based BBB model. Pharmacokinetic (PK) parameters were then evaluated after intraperitoneal and oral administration of aftin-5 in mice. Due to short aftin-5 brain elimination half-life, C57Bl/6J mice were exposed sub-cutaneously to aftin-5 or vehicle during 28 days through an Alzet pump. Blood and brain tissue were collected at various times. Aftin-5 levels were measured by LC-MS/MS and Aβ1-42 was quantified using MSD technology. Data was analysed by one-way ANOVA and results were considered significant if $p<0.05$.

Results: Analysis of *in vitro* BBB permeability data and *in vivo* PK parameters confirm the ability of aftin-5 to cross the BBB. Our findings reveal that continuous subcutaneous infusion of aftin-5 in mice triggers a dose-dependent increase in the brain levels of Aβ1-42 (mean fold change ±SEM): at 3mg/kg/d (4.24±0.46 ; $p<0.01$) and at 30mg/kg/d (5.74±1.08 ; $p<0.001$). The mechanisms underlying *in vivo* Aβ1-42 induction remain to be identified.

Conclusions: Brain translocation of aftin-5 through the BBB is associated with a significant increase in Aβ1-42 production. Cognitive tests, molecular imaging and biochemical analysis, currently in progress, will determine whether aftin-5 could be used as a new pharmacological tool to develop chemically-induced sAD animal models.

STABILIZED LOW-N ABETA PEPTIDE OLIGOMERS INDUCE COGNITIVE DEFICITS ASSOCIATED WITH SYNAPTIC DYSFUNCTION IN RAT

T. Pillot[1], W. Watremez[2], N. Fischer[1], J. Neill[2], B. Grayson[2], V. Koziel[1], M. Harte[2]
[1]SYNAGING SAS, SYNAGING SAS, Vandoeuvre-lès-Nancy, France
[2]Manchester Pharmacy School, University of Manchester, Manchester, United Kingdom

Objectives

With current treatments for Alzheimer's disease (AD) only providing temporary symptomatic benefits and an ageing population, disease modifying drugs are urgently required. This approach relies on improved understanding of the early pathophysiology of AD. A new hypothesis has emerged, in which early memory loss is considered a synapse failure caused by low-n Aβ oligomers (AβO).
Our aim was to investigate synaptic markers and cognitive function following Intracerebroventricular (ICV) infusion of AβO in the rat.

Methods

Adult (male and female) hooded Lister rats received ICV administration of vehicle or AβO (n=10/group). Animals were tested in the novel object recognition (NOR) paradigm, to assess recognition memory at different time points following AβO administration (days 4-70). Following behavioral experiments brains were removed and analyzed for synaptic and neuronal markers. Data from vehicle and AβO groups were analyzed in SPSS using a one-way ANOVA.

Results

We found robust long lasting deficits in NOR in the AβO treated animals. This deficit was found in both male and female animals and was present at day 4 and up to 70 days post-administration of AβO. Post-mortem analysis revealed significant deficits in synaptic (SNAP25 and PSD 95) but not neuronal (n-acetyl aspartate) markers in AβO treated animals.

Conclusions

Taken together the results suggest that acute ICV administration of AβO may be a useful model to study the early mechanisms involved in AD and may provide us with a platform for testing novel therapeutic approaches that target the early underlying synaptic pathology.

THE CANINE MODEL OF ALZHEIMER'S DISEASE PROGRESSION: DISEASE PROGRESSION AMYLOID BIOMARKERS FOR EVALUATION OF NOVEL DISEASE MODIFYING THERAPEUTICS

J.A. Araujo[1], *C. de Rivera*[2]
[1]*InterVivo Solutions, Inc., Toronto, Canada*
[2]*Vivocore, Inc., Toronto, Canada*

Objectives
The current study sought to establish cross-sectional and longitudinal evidence of age differences in CSF concentrations of amyloid-beta in Beagle dogs.
Methods
CSF samples from N =130 (age range: 2.0 – 17.3 years) dogs were collected by cysterna magna puncture under short-term anesthesia. To determine reliability, a second sample was collected from a subset of 21 dogs, at the same time of day, four days later. Dogs were divided into four age groups (young, n=17, 2.00–2.58 years; middle-age, n=21, 6.33–7.25 years; old, n=57, 8.00–11.92; and senior, n=35, 12.00–17.33 years). Approximately 1.5 years later, an additional sample was collected from a subset of dogs to evaluate longitudinal changes. Amyloid-beta isoforms were quantified by ELISA. Percent amyloid-beta42 served as the dependent variable for the age analysis conducted by ANOVA.
Results
A significant effect of age [$p<0.002$] on %amyloid-beta42 was found, which reflected significantly higher levels in middle aged dogs compared to all other age groups ($p<0.05$ in all cases). Also, levels in senior dogs were significantly ($p<0.05$) lower than in old dogs. Analysis of the longitudinal data is ongoing.
Conclusions
Prior to the decline in %amyloid-beta 42 previously reported in canine aging, there is a significant increase in %amyloid-beta 42 from young to middle age. This supports the hypothesis that a threshold concentration of amyloid-beta42 is achieved during middle-age prior to brain amyloid deposition. Overall, CSF amyloid-beta42 levels should serve as a reliable and translational biomarker for preclinical aged canine studies.

AGED DOGS ARE NOT SUITABLE ANIMAL MODELS FOR STUDY OF ALZHEIMER'S DISEASE

T. Smolek[1], A. Madari[2], O. Kandrac[3], N. Zilka[1], M. Novak[1]
[1]Neuroscience, Institute of Neuroimmunology Slovak Academy of Sciences, Bratislava, Slovakia
[2]Small animals clinic, University of veterinary medicine and pharmacy in Kosice, Kosice, Slovakia
[3]study program - general veterinary medicine,
University of veterinary medicine and pharmacy in Kosice, Kosice, Slovakia

Objectives

Aged dogs develop many features of human aging and Alzheimer's disease (AD) such as disorientation, confusion, anxiety, changes in sleep cycle, and neuronal loss. Many studies have reported the presence of amyloid plaques in various brain areas of dogs. Therefore, dogs are proposed as suitable models for AD. We aimed to characterize the neuropathological hallmarks in aged dog brains.

Material and methods

Brains from clinically tested dogs were extracted postmortem and fixed in paraformaldehyde. Cortex and hippocampus were stained by immunohistochemistry using antibodies recognizing tau (AT 8), beta amyloid (4G8), phosphor TDP-43 (11-9), FUS (anti-FUS), alpha synuclein (4D6), neurofilament (SMI 31) and p62 (3/p62).

Results

Our results show that the senile plaques in dogs were exclusively in diffuse forms, which is sign of normal aging. We did not find any neuritic plaques in the aged dog brains. Furthermore, only one case out of 40 examined aged dogs showed very few NFT's pathology in the hippocampus. Other pathological lesions typical for human's neurodegenerative disorders such as Lewy bodies, FUS aggregates, TDP-43 aggregates and neurofilaments aggregates were not observed in any of the dog brains examined.

Conclusions

These results suggest that the pathological lesions in aged dog brains are different than those observed in AD brains. Therefore, aged dogs are suitable for studying aging process, but cannot be considered as an appropriate model for the study of human neurodegenerative diseases such as AD. ADPD5-1372
LYCOPENE ATTENUATES INSULIN RESISTANCE ASSOCIATED COGNITIVE DEFICITS IN RATS
A. Sachdeva[1], K. Chopra[1]
[1]Department of Pharmacology, University Institute of Pharmaceutical Sciences, Chandigarh, India
Objective: Alzheimer's is primarily a metabolic disease, which is characterized by glucose intolerance and central insulin resistance (IR). Excessive fructose consumption produces hippocampal insulin resistance. Lycopene is a natural polyphenol which has demonstrated neuroprotective effects in various preclinical and clinical studies. Thus, the present study was designed to elucidate the role of NF-κB pathway in neuroprotective effect of lycopene.
Methods: Six-week-old male Wistar rats were fed with 15% fructose in drinking water for 24 weeks. Body mass, food and water intake was measured regularly as well as plasma insulin, blood glucose, glycosylated heamoglobin, HOMA-IR, lipid levels and blood pressure were measured to ensure development of IR. Cognitive impairment was measured by Morris water maze test and elevated plus maze on 24th week. Lycopene treatment was initiated after 6th week and continued till 24th week.
Results: Insulin resistance was evident at 6th week and persisted till end of study (24th week) as demonstrated by significant increase in body weight, plasma insulin, blood glucose, glycosylated heamoglobin, HOMA-IR, blood pressure and a deranged lipid profile. Cognitive deficit was significantly evident at 24th week. Fructose-induced neuronal deficits were coupled with significant alterations in oxidative-nitrodative stress along with elevation of NF-κB and its downstream mediators as TNF-α, TGF β1, caspase-3 and IL 1β levels. Lycopene dose-dependently ameliorated emergence of insulin resistance induced memory impairment along with mitigation of cytokine levels.
Conclusion: These results provide a novel insight into the neuroprotective effects of lycopene and its possible therapeutic role in neuronal insulin resistance-induced memory impairment.

ANALYSES FOR LYSOPHOSPHATIDIC ACID RECEPTOR GENES IN MEDAKA TOWARD GENERATING FISH MODELS OF NEURODEGENERATIVE DISEASE

N. Fukushima[1], S. Ishii[1], T. Tsujiuchi[1], N. Kagawa[1]
[1]Life Sci, Kindai Univ, Higashi-Osaka, Japan

Neurite branches are fundamental for neuronal functions, and their collapse or degeneration might lead to neurological dysfunction observed in neurodegenerative diseases, such as Alzheimer's and Parkinson's diseases. Lysophosphatidic acid (LPA), a signalling phospholipid, has been shown to be involved in neurite retraction and branching, tau phosphorylation, and amyloid beta formation. However, how abnormal LPA receptor-mediated signaling is related with the onset or progression of neurodegenerative diseases remains still unclear. To address this issue, we attempted to generate genetically-engineered medaka fish (*Oryzias latipes*) for LPA receptor genes. Medaka is an experimental fish that can be easily maintained, propagated, and analyzed, and whose genome has been completely sequenced. Because there was limited information available regarding medaka LPA receptors. we first examine the genomic structures, expression, and functions of six LPA receptor genes, *Lpar1–Lpar6*. Our analyses reveal that the genomic structures of *Lpar1* and *Lpar4* are different from those deduced from the database. Functional analyses using a heterologous expression system demonstrate that all medaka LPA receptors except for LPA_{5b} respond to LPA treatment with cytoskeletal changes. These findings provide useful information on the structure and function of medaka LPA receptor genes to generate genetically-engineered medaka using a Crisper/Cas system. Our future study will generate and analyze these medaka to explore the pathophysiological significance of LPA signaling in neurodegenerative diseases.

ADPD5-1772
CHANGES IN BEHAVIOR AND BRAIN ELECTROPHYSIOLOGY IN A MOUSE MODEL OF DOWN SYNDROME

D. Brunner[1], T. Hanania[1], L. Thiede[1], M. Mazzella[1], H. Hain[1], E. Sabath[1], S. Gelman[1], G. Tombaugh[1], V. Alexandrov[1], A. Ghavami[1]
[1]PsychoGenics, New York, USA

Objective: Down syndrome is characterized by mental retardation, muscle hypotonia, and age-related Alzheimer-like disease neuropathology. The Ts65Dn mouse is the first trisomic Down syndrome model harboring an extra copy of a portion of the murine chromosome 16, including genes believed to cause many of the symptomatology of the disorder; these mice also show elevated expression of APP. The current investigation was focused on the relationship between behavioral deficits and changes in LTP.
Methods: PhenoCube® NeuroCube® and SmartCube® are high-throughput platforms that assess circadian, cognitive, motor behavior, anxiety, gait, and other domains using PGI's proprietary Computer Vision automated scoring system and machine learning algorithms to define phenotypic signatures. Other standard test follow published protocols. Extracellular fEPSPs were evoked in the CA1 region in hippocampal slices (13-14mo old mice). LTP was induced with tetanic stimulation (3 x 1 sec x 100 Hz trains; 5 min inter-train interval).
Results: We show that Ts65Dn mice are hyperactive especially during the night using our high throughput phenotypic platforms in addition to the expected learning deficits, reduced grip strength and weight. We also report deficient LTP following repeated tetanic stimulation (reduced by approximately 60% in Ts65Dn trisomic male mice compared to their disomic controls), suggesting impairment in the induction phase of LTP.
Conclusion: Cognitive changes are consistent with the observed decrease in LTP later in life. The observed functional changes suggest that these mice are a useful model for investigation of brain amyloid associated diseases occurring without formation of plaque pathology.

DEVELOPMENT AND CHARACTERIZATION OF AN AGED ONSET MODEL OF ALZHEIMER'S DISEASE IN DROSOPHILA MELANOGASTER

S. Mhatre[1], S. Michelson[1], J. Gomes[1], L. Philip Tabb[2], D. Marenda[1], A. Saunders[1]
[1]Biology, Drexel University, Philadelphia, USA
[2]Epidemiology and Biostatistics, Drexel University, Philadelphia, USA

Objectives: The biggest risk factor for developing Alzheimer's disease (AD) is age. Though many animal models of AD exist, very few are capable of analyzing the effect of older age on AD pathology. In an attempt to better model LOAD, we developed a novel “aged AD” model using Drosophila melanogaster.
Methods: In our model, we express low levels of the human AD proteins APP and BACE1 specifically in the fly's central nervous system by using the Gal4/UAS system and raising flies at 18°C. We assessed Aβ levels, neuroanatomy, climbing, learning, and memory in APP;BACE and control flies over the course of their lifespan.
Results: Expression of APP;BACE did not significantly alter lifespan. In flies expressing APP;BACE, significant increases in Ab levels were detected, compared to control flies, starting at day 30 and continuing until death. At the same age, degeneration of mushroom body axons, dendrites and cell bodies were also observed in these flies. Defects in climbing were observed in APP;BACE flies starting at day 42. Control and APP;BACE flies display normal learning across all ages, but day 80 APP;BACE flies have defective immediate recall memory.
Conclusion: This fly model of late onset AD displays numerous similarities to the disease course observed AD patients. The gradual accrual of gradual accrual of Aβ within the CNS leads to the onset of behavioral and neuropathological defects late in the life of these transgenic animals.

ADPD5-0527

DEMENTIA IN NATIVE POPULATIONS; MAKING THE CASE FOR CULTURALLY TAILORED DEMENTIA CARE WITH INDIGENOUS ELDERS AND FAMILIES

C. Browne[1], L.S. Kaopua[1]
[1]College of Health Science and Social Welfare, University of Hawaii, Honolulu, USA

An estimated 370 native peoples—whose ancestors first settled varied regions around the globe—reside in 70 Countries stretching across the vast expanse from the Arctic to the South Pacific Basin. Dementia rates for indigenous elders are presently unknown, but recent longevity improvements and greater prevalence for varying social and health disparities including diabetes and obesity place them at high risk for certain dementias such as Alzheimer's Disease. Objectives: Examine dementia and family care in native populations; identify culturally tailored health programs successful with native populations, and propose research and program approaches to promote culturally tailored psychosocial dementia care in native populations. Method: Using the case of indigenous populations in the U.S. (Native Hawaiians, Alaska Natives, and American Indians), we summarize results from a comprehensive literature review and study data on native eldercare conducted at the University of Hawaii. Results: We present summary data on dementia and psychosocial dementia care in native populations in the US, and provide examples of evidence-based culturally tailored programs that produce positive heath outcomes in breast cancer, obesity, and diabetes; and highlight potential practices for developing supportive family dementia care programs. Conclusion: Greater numbers of native elders are living longer. Dementia is associated with advanced age, and mounting evidence supports cultural variations in elder care preferences. As the family continues to be the major care provider, we argue for research and program development to increase family caregiver support by testing psychosocial dementia care approaches that incorporate cultural values and traditions prevalent in global indigenous elder populations.

[2]Special Coordination of Speech Language and Hearing Science,
Federal University of Santa Catarina, Bauru, Brazil
[3]Speech Language and Hearing Science,
Bauru School of Dentistry University of São Paulo, Bauru, Brazil

Objectives: The aim of this study is to present a website development containing information to patients with Alzheimer´s Disease (AD) and their caregivers focusing on the instructions of Speech and Language. **Methods:** The material production followed the stages of analysis and planning, modelling, implementation and evaluation. The website content will be evaluated by healthcare professionals, elderly and caregivers through an online questionnaire available on website. **Results:** Contents on the topic were designed and implemented, specifically on AD definition, what happens in the brain, the characteristic and disease´s steps, Speech and Language orientation, treatment, impacts on the communication and importance of the caregiver. Next step will be the evaluation of this website. This project was approved by Research Ethics Committee´s by number 20836813.0.0000.5417. **Conclusion:** It was sought to make available contents with simple, clear and objective language, providing knowledge to the general public who can have access to this material helping them to get a better understanding about AD.

ALZHEIMER'S DISEASE: QUALITY OF LIFE FOR ELDERLY AND THEIR CAREGIVERS.

M.L. Caldana[1], A.M. Arakawa[2], C.E. Santo[3], E.C. Franco[3], N.G. Carleto[3], N.C. Favoretto[3], M.R.B. Godoy[1], P.R.M. Damiance[3], R.J. Damasceno[3], J.R.M. Bastos[3]
[1]Speech Language and Hearing Science, Bauru School of Dentistry University of São Paulo, Bauru, Brazil
[2]Special Coordination of Speech Language and Hearing Science, Federal University of Santa Catarina, Bauru, Brazil
[3]Pediatric Dentistry Orthodontics and Public Health, Bauru School of Dentistry University of São Paulo, Bauru, Brazil

Objective: To investigate the differences on perceptions of each quality of life dimension of Alzheimer's Disease (AD) patients and their caregivers. **Methods:** Approval number by the Research Ethics Committee´s is 11599412.1.0000.5417. Sample consisted of elderly and their caregivers. Scale for the Assessment of Quality of Life in AD was applied - QOL-AD. There are three versions: one for the elderly to evaluate their own quality of life (QVi), another for the caregiver to evaluate the elderly (QVci) and for the caregiver self-assess (QVc). **Results:** Sample consisted of 70 individuals, 35 elderly, 71.42% women and 28.57% men; 35 caregivers, 88.57% women and 11.42% men. Age average of the elderly was 78.31 years old, 17.14% were illiterate, 65.71% had not concluded elementary school, 14.28% had completed elementary school and 2, 85% had finished secondary school. Caregivers' age average was 51.54 years. QVi presented a greater perception on the family and worse on the willingness and ability to do leisure activities. QVci pointed to a better perception on the mood and family and worse on memory. QVc presented a greater perception concerning family and worse on capability to leisure activities. There was no statistically significant difference between QVi, age and education level of the elderly, and caregiver age. Statistically significant difference was found between QVc and QVci. **Conclusion:** Perception on the QVi and QVci were similar regarding the greatest and poorest perception. In this context it has been found the family item as the aspect with greater perception in the three versions applied.

ADPD5-1561

CAREGIVER BURDEN OF DEMENTIA: CORRELATION WITH STAGES OF DEMENTIA AND BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS OF DEMENTIA

A. Biswas[1], A. Mukherjee[1], A. Roy[1]
[1]Neurology, Bangur Institute of Neurosciences, KOLKATA, India

Objective- To evaluate caregiver burden (CB) of dementia alongwith the correlation between caregiver burden with stages of dementia and behavioral and psychological symptoms of dementia (BPSD).
Methods- Study population consisted of 20 consecutive patients of dementia and their caregivers. Dementia was diagnosed by DSM-IV criteria. Patients were assessed using structured proforma of cognitive clinic of Bangur Institute of Neurosciences. Staging was done by Clinical Dementia Rating (CDR) scale. Standard criteria were used to delineate types of dementias. BPSD were assessed with Neuropsychiatric Inventory (NPI). CB was evaluated with Zarit Burden Interview (BI).
Results- Of the 20 patients included in the study, 14 were male and 6 female. Average age of patients was 66.2 years. 12 patients had Alzheimer Disease, 3 had Mixed dementia, 3 Frontotemporal Dementia, 1 Vascular dementia, 1 Dementia with Lewy Bodies. Average BI scores in Global-CDR groups were 11.5 for CDR-0.5, 37.9 for CDR-1, 57 for CDR-2 and 54 for CDR-3. Total NPI scores were: 3.3 for little-or-no burden, 19.7 for mild-to-moderate burden, 24.9 for moderate-to-severe burden, 41.2 for severe burden, respectively. CDR- sum of boxes scores were: 3.3 for little-or-no burden, 6.7 for mild-to-moderate burden, 13 for moderate-to-severe burden, 13.4 for severe burden, respectively.
Conclusions- CB was more with increasing severity of dementia. However, moderate-to-severe and severe burden groups had similar severity of dementia. Behavioral and psychological symptoms of dementia have immense effect on the caregiver burden; especially in moderate to severe dementia it seems to have greater effect than the stage of dementia itself.

09a. Patient Care & Support: caregiver support

ADPD5-2095

CARE OF PATIENTS WITH AD, WHEN THERE IS NO FORMAL CAREGIVERS: CASE DESCRIPTION IN CALI, COLOMBIA

Y. Ariza-Araujo[1], Y. Takeuchi[1]
[1]Facultad de Ciencias de la Salud, Universidad Icesi, Cali, Colombia

Background: With the worsening of AD, the patient is becoming increasingly dependent and therefore requires a 24 hours day caregiver to support it in performing activities of daily living. In Colombia, traditionally family caregivers are in charge of this work. Currently, the Health System does not include the cost of institutional care or nursing homes for these patients.
Objective: To describe the motivations and difficulties identified by a group of family caregivers of patients with AD in Cali Colombia.
Methods: A qualitative study was conducted. Family caregivers of patients with AD in moderate and severe degree were invited to participate. After obtaining informed consent, an anthropologist conducted in-depth interviews.
Results: 5/12 caregivers contacted, agreed to participate. Four of the respondents are female. All are first-degree relatives with the patient to whom they care. The most important motivation to assume responsibility for the care incorporates affective and religious references. The difficulties identified are related to patient care management and daily living, out-of-pocket expenses to support it, and self-care. The process is made more difficult by the limited emotional and financial support of other family members, as well as insufficient information on the care received from the Health System. However, it is clearly a reluctance to institutionalize the patient or to surrogate care to non-family caregivers.
Conclusions: In countries like Colombia, where care of these patients is not institutionalized, the system must consider strategies to support family caregivers. This would enhance the health care of patients and avoid negative impacts on caregivers

[2]Division of Neurology V/Neuropathology, Fondazione IRCCS Istituto Neurologico "Carlo Besta", Milano, Italy

[3]Department of Psychology, University of Milano-Bicocca, Milano, Italy

[4]Servizio Epidemiologia, ASL, Bergamo, Italy

Objectives. To determine the impact of a psychosocial intervention for caregivers of Alzheimer disease (AD) patients: a) on caregivers' burden, mood, health, social support, service use, and relationships with others; b) on patients' troublesome behaviours.

Methods. 145 home-dwelling dyads (AD patients and their primary caregivers) were enrolled in this randomized controlled study. 75 caregivers (CG, Control Group) received the care/treatment usually given at our center. The remainders (IG, Intervention Group) underwent 6 sessions of individual/family counselling over 4 months, based on the strategies developed both in the REACH program (Wisniewski et al., 2003) and at the NYU-ADRC (Mittelman et al., 1999). Both groups were reassessed at 6 and 12 months. Between and within group analyses were performed using t-test, Repeated-Measures ANOVA, and ANCOVA.

Results. The two groups were comparable at baseline for age, sex, education and patients' disease severity, but not for severity of depressive symptoms. Compared to CG, IG had better health ($p = 0.03$) and lower Hamilton Depression Rating Scale scores at 6 months, even after controlling for depression severity at baseline ($p = 0.03$). However, between group differences disappeared at 12 months.

Within the IG, health and relationships with others improved from baseline to month 6, while emotional distress, depressive symptoms and social support, as well as patients' troublesome behaviours, significantly improved from baseline to month 12. Conversely, within the CG, service use increased from baseline to month 12 ($p<0.05$).

Conclusions. These data support the long-term efficacy of a psychosocial intervention for caregivers of AD patients.

DRIVING PERFORMANCE IN INDIVIDUALS WITH MILD COGNITIVE IMPAIRMENT(MCI): THE ROLE OF DEPRESSIVE SYMPTOMS

I.N. Beratis[1], N. Andronas[1], D. Kontaxopoulou[1], S. Fragiadaki[1], A. Liozidou[1], A. Economou[2], J. Papatriantafyllou[3], G. Yannis[4], S.G. Papageorgiou[1]
[1]Neurology, ATTIKON UNIVERSITY HOSPITAL, ATHENS, Greece
[2]Psychology, National University of Athens, ATHENS, Greece
[3]Psychiatry, General Hospital of Athens G. Gennimatas, ATHENS, Greece
[4]Department of Transportation Planning & Engineering, National Technical University of Athens, ATHENS, Greece

Objectives: Studies focusing on the general population indicate that depression affects driving competence. Goal of the present research was to explore in drivers with MCI the association between depressive symptoms and various indexes of driving performance by applying a driving simulator experiment. **Methods:** A CDR score of 0.5 was required for the diagnosis of MCI. Additional inclusion criteria were the presence of a valid driver's license and regular car driving. The collection of the data included: (a) detailed clinical medical/neurological assessment, (b) extensive neuropsychological assessment, and (c) a driving simulation experiment. **Results:** Depressive symptoms were associated with various driving indexes that include longitudinal driving control measures, namely average speed (r=.570, p=.004), average headway distance (r=-.569, p=.004) and headway distance variation (r=-.564, p=.004) as well as lateral driving control measures, such as lateral position variation (r=.723, p<.001) and average wheel position (r=-.434, p=.034). Moreover, significant associations were present with measures linked to the possibility of a road accident, such as actual number of crashes (r=.584, p=.003), hits of side bars (r=.425, p=.039) and number of speed limit violations (r=.499, p=.013). Notably, the link between depressive symptoms and various driving indexes was evident even after controlling for sleepiness and cognitive functioning. **Conclusion:** The findings suggest that depressive symptoms influence the driving capacity of patients with MCI. Thus, their presence in the specific clinical group should be systematically assessed in order to implement proper therapeutic interventions that might help to improve the driving fitness of certain individuals with a diagnosis of MCI.

ADPD5-1381

THE RELIABILITY OF IPAD COGNITIVE TESTING IN THE HOME ENVIRONMENT: POTENTIAL USE IN CLINICAL TRIAL RESEARCH

D. Rentz[1], M. Dekhtyar[2], J. Sherman[3], R. Amariglio[4], K. Papp[4], S. Burnham[5], R. Sperling[1]

[1]Neurology, Harvard Medical School, Boston, USA
[2]Psychology, Boston University, Boston, USA
[3]Psychology, University of Chicago, Boston, USA
[4]Neurology, Massachusetts General Hospital, Boston, USA
[5]Computational Informatics, CSIRO, Wembley, Australia

Objectives: With the widespread use of mobile devices, can these technologies be reliably used in clinical trials? We sought to determine the reliability and validity of cognitive test data obtained at-home on an iPad in contrast to in-clinic assessments.

Methods: Forty-five clinically normal older subjects (CDR=0, age=72.9±7.3) were recruited from Massachusetts General Hospital. Subjects were required to make two in-clinic visits one week apart and perform five 30-minute alternate version assessments at-home on an iPad. A Reliability Analysis determined the consistency between the alternate iPad test versions. Correlational analyses examined the association between in-clinic vs. at-home assessments and between iPad vs. standardized paper and pencil tests.

Results: There was excellent reliability between alternate iPad versions (Cronbach alpha coefficient=0.906). Comparing subjects' single in-clinic score to their average at-home score, there was no significant difference in performance between test environments. The in-clinic and at-home scores were significantly correlated (r-squared=0.501, $p<0.001$) suggesting that the at-home tests could act as a proxy for supervised in-clinic assessments. There was also a significant correlation between standard paper and pencil tests and both in-clinic (r-squared=0.322, p=0.002) and at-home iPad assessments (r-squared=0.217, p=0.013).

Conclusions: The findings suggest that reliable cognitive data can be obtained from iPad assessments in the home environment without the assistance of a trained administrator. The at-home and in-clinic assessments were correlated with standard neuropsychological tests suggesting the validity of the at-home tests. IPad assessments performed in the home environment show promise for use in Alzheimer Disease prevention trials.

THE USE OF VIRTUAL REALITY FOR COGNITIVE STIMULATION IN PATIENTS WITH MILD COGNITIVE IMPAIRMENT AND ALZHEIMER'S DISEASE

V. Manera[1], E. Chapoulie[1], J. Bourgeois[1], R. Guerchouche[2], P.D. Petit[1], G. Drettakis[2], P. Robert[1]

[1]Medicine, CoBTeK Laboratory, Nice, France

[2]INRIA, INRIA, Sophia Antipolis, France

Objective. Virtual reality (VR) technologies hold great opportunities for the development of effective cognitive trainings, because they can provide realistic, familiar but highly controllable environments. In the present studies, we tested the acceptability of two VR solutions to stimulate autobiographical memory and attention in elderly participants and patients with Mild Cognitive Impairment (MCI) and early to moderate Alzheimer's disease (AD).

Methods. *Study 1*. 13 healthy participants (>60years) were administered an autobiographical memory stimulation task in two conditions: a classical stimulation condition, in which photographs of environments were used as prompts, and a VR condition, in which the prompts consisted in VR environments. At the end of each condition, the acceptability and the quality of the experiences were assessed employing standard questionnaires. *Study 2*. 25 patients with MCI and 25 patients with AD (>60years) performed an attention task, in which they needed to identify target characters hidden in a group. In the VR condition, the task was performed in a VR setting, while in the classical stimulation condition the task had a paper-pencil format. The acceptability and the quality of the experiences were assessed employing standard questionnaires.

Results. The results of the two studies confirmed that the VR setting were considered acceptable, interesting and motivating by both healthy participants and patients with MCI and AD.

Conclusions. Our results suggest that VR solutions are useful motivational tools. As apathy (a disorder of motivation) is very common among these clinical populations, having motivating tools is a key challenge in designing effective rehabilitation programs

PERFORMANCE IN MONTREAL COGNITIVE ASSESSMENT (MOCA) AND MINI-MENTAL STATE EXAMINATION (MMSE) OF ELDERLY SUBJECTS ON REGULAR MAH-JONG VERSUS PHYSICAL EXERCISE

W. Khoo[1], D. Chu[1], P. Noble[1], D. Dasig[1]
[1]Neurology, Makati Medical Center, Makati, Philippines

One of the many benefits that higher cognition brings is increased likelihood to achieve better economic outcomes even in older age. Although the prevention of dementia has emerged as a major health priority, there is paucity of potential preventive strategies. Identifying protective factor is essential to the formulation of effective interventions for dementia. Physical exercise has been proven to be a significant factor which can preserve cognitive function among elderly. Higher physical activity level is related to less impaired cognitive functions and less incidence of dementia. Mah-jong has been noted to produce consistent gains across all cognitive performance measures. Thus this cross sectional study explored the performance of elderly engaged in mah-jong versus physical exercise based on MoCA and MMSE. A total of 95 elderly were included: 31 played mah-jong, 30 engaged in physical exercise and 34 without any significant activity. One-Way ANOVA was done to assess whether there are significant differences among the study groups which resulted in the mah-jong group obtaining the highest mean score on MoCA and MMSE. Multiple comparison tests was done to identify which between physical exercise and mah-jong brought about better cognitive function which showed that despite both having a higher score compared to control group, there was no significant difference between physical exercise and mah-jong. This study therefore concludes that participation in mah-jong is associated with better MoCA and MMSE scores and can be a good treatment option for the prevention of cognitive decline especially for those with contraindication to physical activity.

COGNITIVE REHABILITATION: A STATE OF THE ART FOR LONG TERM MANAGEMENT OF ALZHEIMER DISEASE FOR INDIAN POPULATION

S. Bajpai[1], M. Tripathi[2], A. Nehra[1]
[1]Clinical Neuropsychology, All India Institute of Medical Science, Delhi, India
[2]Neurology, All India Institute of Medical Science, Delhi, India

Introduction: cognitive rehabilitation for dementia patients in India is a new approach to long term management of cognitive deficits. Unfortunately, there is no documented work on the same from India. This approach is essentially a highly individualised, personalised one, acknowledging the heterogeneity of underlying impairments, literacy level, culture specificity and individual situations and responses. While the individual focus is paramount, various formats and modalities may be adopted in the process of working towards achievement of rehabilitation goals.

Aim: to report 3 case series of cognitive rehabilitation on patients suffering from mild to moderate Alzheimer's Disease.

Methodology: a highly extensive and individualized cognitive rehabilitation was carried out for 8-10 weeks on these patients which included compensatory techniques focussed on retraining A-B-C of dementia, i.e., Activities of Daily Living, Behaviour and cognition.

Results: there was an evidence of improvement of 1.0 standard deviation in all the patients in their A-B-C domains post rehabilitation which were documented by conducting detailed standardized neuropsychological testing, pre and post cognitive rehabilitation.

Conclusion: Cognitive rehabilitation with a specific focus on individual strengths and limitation implemented with environmental modification is a promising method for long term management of Alzheimer's disease patients which can aid in optimizing not only the quality of life of the patients but also their caregivers'. However, well-designed studies with ample sample are required to obtain more definitive evidence.

ADPD5-2066

DEVELOPMENT OF RE-CREATE (REHABILITATION OF COGNITION USING RESTORATIVE EXERCISES & ACTIVITIES TARGETED FOR ELDERLY): COGNITIVE REHABILITATION FOR LOW LITERATE INDIANS

S. Bajpai[1], A. Nehra[1]
[1]Clinical Neuropsychology, All India Institute of Medical Science, Delhi, India

Objective: It is essential to use culturally appropriate, sensitive & specific assessment and interventions for true cognitive performance of individuals. However, studies have shown that several factors including education influence both the treatment and the management of dementia. Unfortunately, there is 37 million illiterate or low educated elderly Indians, thus, making management of dementia (understanding the concept of non pharmacological intervention) challenging. Hence, **Aim** was to develop & standardized a culture & education free cognitive rehabilitation intervention. **Methodology**: a culture specific picture based cognitive rehabilitation package was developed. It consisted of 112 category based pictures for 8 weeks which has been compiled for retraining attention, memory, abstract ability, perceptual tracking and verbal ability for dementia patients. It has been pilot try out on 20 healthy elderly between 60-85years of age with 0-15+ years of education**.** Later, it has been standardized on 50 healthy elderly matched on age, sex and education. **Results:** sample with 0-5 years of education (N=20) completed the whole intervention in 91.7±19.1 seconds; sample with 5-9 years of education (N=9) took 74.01±19.5 seconds; sample with 10-14 years of education (N=10) took 82.2±21.2 seconds while sample with 15+ years of education (N=11) took 77.5±21.8 seconds. Moreover, there was no significant difference between the education groups. **Conclusion:** RE-CREATE is found to be quite effectively working on dementia cases as it is free from any educational bias. Additionally, it helped us to extend non- pharmacological intervention to illiterate -low literate elderly to whom education was a barrier to their management.

LA TÊTE EN L'AIR - A GRAPHIC NOVEL AND ANIMATION FILM REPRESENTATION OF DEMENTIA AND ITS SYMPTOMS

F. Branco Germiniani[1], B.E. Scheffer[1], M. Piovezan[1], V. Zetola[1], H.A.G. Teive[1]
[1]Neurology Service Department of Internal Medicine, Hospital de Clínicas - Universidade Federal do Paraná, Curitiba, Brazil

Objective: To review the many symptoms of demented patients with Alzheimer's Disease living in nursery homes as represented in the graphic novel and animation film La Tête En L'Air (Roca, P, Éditions Delcourt, 2013).
Methods: La Tête En L'Air is both a graphic novel and animation film in which the main character, diagnosed with Alzheimer's Dementia, is instituted in a nursing home. The main character and additional characters present with several symptoms of AD and other conditions. All of these symptoms are presented in graphic form from the standpoint of the main character/patient and additional characters, acting as either patients or caregivers, thus presenting a layman's interpretation of dementia symptoms.
Results: By analyzing the different symptoms graphically represented in both the graphic novel and animation film, one can have a portrayal of the semiological features and the impact of dementia from the perspective of the main character/patient's viewpoint, as well as by the other additional characters, acting either as patients or caregivers.
Conclusions: In La Tête En L'Air, both a graphic novel and an animation film, the main character, diagnosed with Alzheimer's Dementia, is instituted in a nursing home and throughout the story different symptoms of AD and how they impact on caregivers are graphically represented from a layman's perspective.

ADPD5-0834

PREVALENCE AN TREATMENT OF „BEHAVIOURAL AND PSYCHOLOGICAL SYMPTOMS OF DEMENTIA" (BPSD) IN PATIENTS WITH ALZHEIMER´S DISEASE

M. Defrancesco[1], *E. Deisenhammer*[1]
[1]*General and social psychiatry, Medical University Innsbruck, Innsbruck, Austria*

Objectives: Alzheimer's disease (AD) is the most common cause of dementia among the elderly. Although cognitive deficits are the clinical hallmark of AD, various non-cognitive symptoms termed „behavioural and psychological symptoms of dementia" (BPSD) are common and can dominate disease presentation. BPSD have been observed in up to 60% - 98% of patients with dementia and include agitation, aggression, anxiety, delusions, sleep disturbances, and hallucinations among other symptoms.
Methods: We included 97 patients with AD within their regular visits at the outdoor memory clinic of the psychiatric department in Innsbruck between 2012 and 2014. All participants underwent a clinical examination, a neuropsychological testing, and patient's medication history was reviewed. Further, neuropsychiatric symptoms were assessed using the neuropsychiatric inventory (NPI). The association of neuropsychiatric symptoms, dementia severity and psychotropic medication was analysed by Pearson´s correlation.
Results: Clinically relevant neuropsychiatric symptoms (NPI score ≥ 4) were found in 76% of AD patients. The presents of neuropsychiatric symptoms positively correlated with dementia severity and more severe cognitive impairment. While the use of benzodiazepines (BZD) was associated with more sleep disturbances, the intake of neuroleptics was associated with more prevalent disruptive behaviours such as agitation and aggression. Further, we found a positive correlation between a higher NPI total score and the number of psychotropic medication.
Conclusion: Neuropsychiatric symptoms are very common in AD patients. Although good practice guidelines recommend a limited and caution use of BZD and neuroleptics in patients with AD, they are prescribed frequently to manage BPSD in AD patients.

LINK BETWEEN THE NEUROPSYCHIATRIC SYMPTOMS OF ALZHEIMER'S DISEASE AND THE DEPRESSION OF ELDERLY CAREGIVERS

M. Gantman[1], N.D. Selezneva[1], S.I. Gavrilova[1]
[1]Department of Alzheimer's disease and related disorders,
Mental Health Research Center of the Russian Academy of Medical Sciences, Moscow, Russia

Objective: To evaluate the link between the severity of the psychological and behavioural symptoms in Alzheimer's disease (AD) and the depression of the caregiver.
Methods: The sample of elderly caregivers of patients with AD (N=70) was investigated using Geriatric Depression Scale (GerDS). The behavioural disorders of the care-recipients and stress level of the caregiver were evaluated with Neuropsychiatric Inventory (NPI).
Results: Positive correlation between NPI disorders and stress subscales was significant, but did not reach strong level (Spearman's correlation coefficient 0.72, $p<0.05$). There was a positive link between GerDS score of the caregiver and the NPI disorders subscale score of the patient (Spearman's correlation coefficient 0.35, $p<0.05$). The similar link was revealed between the GerDS score and the NPI stress subscale score (Spearman's correlation coefficient 0.27, $p<0.05$). Caregivers with clinically significant depressive symptoms had higher NPI stress subscale score (Mann-Whitney test, $p=0.002$).
Conclusions: Caregiver's stress caused with behavioural and psychological symptoms of AD patient depends not only on severity of the disorders of the care-recipient, but on other factors, probably personal traits and affective status of the caregiver. More prominent neuropsychiatric symptoms of a care-recipient and caregiver's stress are positively linked with severity of depression among caregivers. The link between these measures may be bidirectional, but it is reasonable to suggest that stress is a risk factor for the depression. NPI can be used not only for evaluating a state of a patient with AD, but also for screening of stress in caregivers as a risk factor for depression.

ADPD5-1092
MODULATION OF PSA-NCAM TURNOVER BY NMDA AND INSULIN IS ASSOCIATED WITH EXPRESSION OF TAU, APP AND SNCA GENES.
H. Monzo[1], T. Park[1], M. Dragunow[1], M. Curtis[1]
[1]Centre for Brain Research, University of Auckland, Auckland, New Zealand
Objectives: Cellular interactions mediated by the neural cell adhesion molecule (NCAM) are critical in cell migration, differentiation and plasticity. Switching of the NCAM-interaction mode, from adhesion to signalling, is determined by NCAM carrying a particular post-translational modification, polysialic acid (PSA). Our objective was to determine the mechanisms for desialylation are also at play in mammalian cells and to measure if this would cause overexpression of key Alzheimer and Parkinson-related genes due to uncoupling of PSA from NCAM (causing increased NCAM interaction).
Methods: Cell culturing of human medulloblastoma and primary mouse cells using EndoN enzyme (that specifically cleaves PSA from NCAM) and exploiting the calcium dependence of polysialyltransferases allowed us to study the addition and removal of PSA to and from the cell surface, respectively.
Results: In TE671 cells, PSA-NCAM turnover requires internalization of the molecule into the cytosol. PSA-NCAM internalization was specifically triggered by nitric oxide and collagen in the extracellular matrix (ECM) and is blocked by insulin-like growth factor (IGF1) and insulin. Our results show that cultured-neurons treated with EndoN overexpress *Tau*, *App* and *SNCA*. Furthermore, addition of NMDA to the cultures resulted in a significant decrease in PSA-NCAM which was accompanied by overexpression of genes such as *Tau*, *App* and *SNCA*. However overexpression was prevented when NMDA culture medium was supplemented with insulin.
Conclusion: This data reveals an important role for PSA-NCAM in regulating the expression of genes associated with neurodegenerative diseases, and demonstrates a role for NMDA and insulin in the regulation of these genes.

PATH INTEGRATION IS A BEHAVIORAL MARKER FOR ALZHEIMER DISEASE

M. Pai[1], P. Chung[2]

[1]Neurology (Behavioral Neurology), National Cheng Kung University Hospital, Tainan, Taiwan

[2]Electrical Engineering, National Cheng Kung University, Tainan, Taiwan

Background: Many people with mild Alzheimer's disease (AD) have navigational impairment. The gene dosage of AD may play a role in the incipient deficit of path integration, which is related to hippocampal function and is important for navigation. Based on the gene dosage theory, among the F2, F1 and F0, the probability of AD-to-be is the highest in F2 and the lowest in F0. F1: the family with only one AD patient; F2: the family with two or more AD patients; F0: the family without AD patient.

Methods: We used the Pointing Test to evaluate path integration. Each participant was instructed to point to the start at 5 stops along a campus stroll of 660 meters. The dependent variables were absolute angle deviation and the presence of angle deviation over 22.5 degrees.

Results: 47 AD, 36 F2, 30 F1 and 42 F0 completed the study. In the Pointing Test, the F2 showed less angle deviations than AD at Point 3 ($p=0.023$); so did F2 and F0 than AD at Point 4 ($p=0.002$) and at Point 5 ($p<0.001$). When considering angle deviation at 22.5 degrees as a cut-off, non-AD groups outperformed AD at Point 4 ($p=0.003$) and at Point 5 ($p=0.038$), indicating a potential risk for AD to be lost.

Discussion: Path integration is a discriminator for AD from non-AD but the effect of gene dosage was not shown. It is worthwhile to follow non-AD with more angle deviations up to determine the predictive value of path integration in AD.

ADPD5-0847

THE POSITIVITY EFFECT ON INTENSITY OF EXPERIENCED EMOTION AND MEMORY PERFORMANCE IN MILD COGNITIVE IMPAIRMENT AND DEMENTIA

L. Gorenc-Mahmutaj[1], C. Degen[1], N. Urbanowitsch[1], P. Wetzel[1], J. Funke[2], J. Schröder[3]
[1]Institut for Gerontology, University of Heidelberg, Heidelberg, Germany
[2]Institut of Psychology, University of Heidelberg, Heidelberg, Germany
[3]Section for Geriatric Psychiatry/Institut for Gerontology, University of Heidelberg, Heidelberg, Germany

Objectives: In the course of a life a preference to positive stimuli is built whereas negative stimuli tend to be neglected. We investigated this “positivity effect” on memory performance in mild cognitive impairment (MCI) and dementia.
Methods: 81 patients (32 with MCI, 27 mild and 32 with moderate dementia) and 28 age-matched controls were presented 12 pictures showing positive, negative or neutral objects. At first, we investigated immediate and delayed (after 30´) recall and delayed recognition of the pictures. Moreover, the emotional valence of the pictures perceived and the emotions evoked in the subjects were evaluated.
Results: Irrespective of the condition, patients with mild and moderate dementia recalled fewer pictures than those with MCI or the healthy controls (main effects diagnosis $12.5<F<14.8$*). Across groups, the positive pictures were better memorized than the negative or neutral ones (main effects valence $9.3<F<18.2$*). In delayed recognition a significant interaction between “diagnosis” and “valence” arose. In all diagnostic groups pictures were experienced as expected. However, the positive pictures induced a higher arousal than the negative and neutral ones.
Conclusions: Our findings indicate that the positivity effect does not only apply to healthy elderly but also to patients with MCI or mild and moderate dementia. This effect does not refer to the compliance of the patients investigated since they perceived and experienced the pictures in the expected way. Since arousal levels were highest for positive pictures the positivity effect may rather correspond to a higher reactivity with greater arousal induced by the positive pictures.

ADPD5-0873

FUNCTIONAL EFFECT OF RARE CLU VARIANTS ASSOCIATED WITH ALZHEIMER DISEASE RISK.

K. Bettens[1], S. Vermeulen[1], B. Asselbergh[2], C. Van Broeckhoven[1], K. Sleegers[1]
[1]Neurodegenerative Brain Diseases Group of the Department of Molecular Genetics, VIB and University of Antwerp, Antwerp, Belgium
[2]Microscopy Unit of the Department of Molecular Genetics, VIB and University of Antwerp, Antwerp, Belgium

Objectives The role of rare variants in Alzheimer disease (AD) susceptibility was emphasized by our finding of genetic association with rare non-synonymous and small insertions/deletions (indels) in clusterin (*CLU*). Applying a multidisciplinary approach, we attempted to untangle the effect of these rare variants on the pleiotropic CLU protein.
Methods The effect of 11 coding *CLU* variants was determined on protein localization and secretion using immunocytochemistry, live cell imaging, ELISA's, Western blot and immune-detection. For variants located at the interface between alpha and beta protein domains, the effect on hetero-dimerization is assessed by yeast-two-hybrid experiments (Hybrigenics). The novel SwithSENSE technology (Dynamic Biosensors) is used to investigate the influence on Abeta40 interaction and conformational changes.
Results Three variants in the beta-chain (p.I303NfsX13, p.R338W and p.I360N) caused an alteration of the subcellular localization of CLU. While the relative amount of CLU-EGFP signal was reduced in Golgi, it was almost exclusively present in endoplasmic reticulum. Further, we observed a significantly decreased CLU secretion in cell medium compared to an increased presence of full length CLU protein in cell lysate for p.R338W and p.I360N variants.
Conclusion Our data suggest a reduced secretion of the CLU protein as one of the modes of action for the rare variants identified in the beta-chain. Additional research will address whether beta-chain variants lead to conformational changes like altered protein folding or interaction with the Abeta40 peptide.

[5]AIBL, Howard Florey Research institute, Parkville, Australia
[6]Academic Unit for Psychiatry of Old Age, University of Melbourne, Kew, Australia
[7]CSIRO, CSIRO, Parkville, Australia
[8]AIBL, CSIRO Howard Florey NARI McCusker Austin, Melbourne and Perth, Australia
Of 1112 subjects recruited (211 AD, 133 MCI, 768 HC), 824 (74%) returned at 36 months and 718 (65%) at 54 months. Nearly 60% of the MCI subjects at baseline progressed to dementia due to AD by 54 months, but under 4% of healthy controls developed MCI or AD by 54 months. Having AD or MCI at baseline was associated with increased death and drop out rates. The low level of progression to cognitive impairment among those who were healthy at baseline reflects a low average age (70) and good education and general health in this group.

10c. Other: preclinical research

ADPD5-0996
EVIDENCE FOR AFFECTIVE SYMPTOMS AS AN EARLY MANIFESTATION OF COGNITIVE CHANGE

F. Guillo-Benarous[1], J. Sidhu[1], P. Patel[2], S. Naqvi[2], M. Thu[3], S. Ghimire[2], J. Xu[4], B. Reisberg[2]
[1]Department of Psychiatry and Center for Cognitive Neurology, New York University School of Medicine, New York, USA
[2]Department of Psychiatry, New York University School of Medicine, New York, USA
[3]Center for Cognitive Neurology, New York University School of Medicine, New York, USA
[4]Department of Population Health, New York University School of Medicine, New York, USA

'Subjective Cognitive Impairment' (SCI) persons have the subjective belief that memory is impaired, but show normal performance on psychometric tests. In this study, we aim to assess the nature of cognitive and affective symptoms of SCI, and develop tools to identify early predictors of cognitive decline in the evolution towards MCI and AD. METHOD: 136 healthy subjects, aged ≥ 50 years, presenting at the NYU Alzheimer's Disease Center were evaluated through self-reported scales : A Visual Analog Scale (VAS), (Guillo Benarous, 2013), the Brief Questionnaire Regarding Severity of Memory & Emotional Problems (BQRS-M&E =S1), (Reisberg, 2013), and the Memory Complaint Questionnaire (MAC-Q). Alternating subjects were evaluated on time related scales: the ADNI Cognitive Change Index =S2 (Saykin, 2012), the Sahlgrenska Academy Self-Reported Cognitive Impairment Questionnaire (SASCI-Q = S5) or on a severity based questionnaire SEVCOG =S3 and an Emotional Questionnaire =S4; on depression and anxiety scales: Geriatric Depression Scale, Hamilton; and on psychometric measures: MMSE, Logic1, Digit Span F&B, TMT, DSST, Paired Associates Recall and the Boston Naming Test. The evaluations at baseline were studied.

Table1: Baseline Characteristics

ADPD5-1339

COGNITION IS ASSOCIATED WITH TIME TO CLINICAL ONSET, SPECIFIC GENES AND COGNITIVE RESERVE IN AUTOSOMAL DOMINANT ALZHEIMER'S DISEASE

O. Almkvist[1], A. Ståhlbom[1], S. Thordardottir[1], M. Viitanen[1], C. Graff[1]
[1]NVS, Karolinska Institutet, Stockholm, Sweden

Objective. Cognitive decline is reflected by time to clinical onset (TCO) in familial Alzheimer's disease (fAD). However, it is not known how specific AD-causing mutations (APP vs. PSEN1), APOE and cognitive reserve (CR) influence the relationship between TCO and cognitive decline.

Methods. Cognitive functions covering five domains were assessed in 38 mutation carriers (n=24; APP_{SWE}, and APP_{ARC}, and n=14; $PSEN1_{M146V}$, $PSEN1_{H163Y}$ and $PSEN1_{I143T}$) and 43 non-carriers (n=22; APP-families and n=21; PSEN1-families). CR was estimated by years of formal education. Carriers and non-carriers were comparable in TCO (-7.3 vs. -7.4; carriers vs. non-carriers), proportion of at least one e4 allele (0.53 vs. 0.36; carriers vs. non-carriers), age, gender distribution and CR (10.9 vs. 10.6; carriers vs. non-carriers)(all p's>0.1).

Results. A 4-way ANOVA on episodic memory as dependent variable and with APOE, CR, mutation status and type of AD-gene (APP vs. PSEN1) as factors showed strongly significant main effects of CR (the higher the better), mutation status (in favor non-carriers) and type of AD-gene (in favor of PSEN1), but no significant effect of APOE. A similar pattern of significant effect main effects (CR, mutation status and AD-gene) was obtained for visuospatial and executive functions, but not for verbal and immediate memory. The interaction between CR and mutation status was significant in 3 out of 5 cognitive functions showing a strong impact of high CR for mutation carriers but not for non-carriers.

Conclusion. Cognitive reserve has a strong favorable influence on cognition for mutation carriers but not for non-carriers.

ADPD5-1688
ISORHYNCHOPHYLLINE IMPROVES LEARNING AND MEMORY IMPAIRMENTS INDUCED BY SCOPOLAMINE IN MICE

Z.X. LIN[1], Y. Xian[1], J.C.Y. Wu[2], S.P. Ip[1]
[1]School of Chinese Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong China
[2]Hong Kong Institute of Integrative Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong China

Objectives: The present study aimed to investigate whether isorhynchophylline (IRN, Fig. 1), an alkaloid isolated from Chinese herb *Uncaria rhynchophylla*, could reverse scopolamine (SCOP)-induced learning and memory impairments in mice and to evaluate its action mechanisms.
Methods: The cognitive-enhancing effect of IRN on amnesic mice induced by SCOP was investigated by the Morris water maze test. To elucidate the underlying mechanisms of memory enhancing effects of IRN, the activity of acetylcholinesterase (AChE) and neuroinflammatory parameters were measured.
Results: The results showed that IRN significantly improved the learning and memory functions in SCOP-treated mice. Mechanistically, IRN significantly decreased the protein and mRNA levels of interleukin (IL)-1β and the activity of AChE, but markedly accentuated the protein and mRNA levels of IL-10 and the level of acetylcholine in the brain of the SCOP-treated mice. Moreover, IRN also significantly suppressed the production of prostaglandin E2 and mRNA expression of cyclooxygenase-2 while markedly enhanced the protein level of phosphorylation of ERK1/2 in the brain of the SCOP-treated mice.
Conclusions: These results amply demonstrated that IRN was able to improve the learning and memory impairments induced by SCOP in mice, and the underlying mechanisms involved the inhibition of AChE activity and the amelioration of the neuroinflammatory processes via protecting ERK activity in the mice with SCOP-induced cognitive impairments.

PRECLINICAL PHARMACOKINETIC STUDIES OF TRITIUM LABELLED D-ENANTIOMERIC PEPTIDE D3 FOR THE TREATMENT OF ALZHEIMER'S DISEASE

N. Jiang[1], L. Leithold[1], J. Kutzsche[1], D. Jürgens[1], K.J. Langen[2], A. Willuweit[2], D. Willbold[1]

[1]Structural Biochemistry, Institute of Complex Systems Forschungszentrum Jülich, Jülich, Germany

[2]Medical Imaging Physics,

Institute of Neuroscience and Medicine Forschungszentrum Jülich, Jülich, Germany

Objectives: We are developing small D-enantiomeric peptides for elimination of toxic Aβ oligomers during causal treatment of Alzheimer´s disease (AD). D-enantiomeric peptides composed of D-amino acids have theoretical advantages over all L-amino acid peptides, such as resistance to proteases and reduced or non-existent immunogenicity. We previously developed D3, an all D-peptide, which specifically binds to Abeta, inhibits aggregation into toxic species and shows diagnostic and therapeutic potential in vitro and in vivo. Only little information is known about pharmacokinetic properties of D-peptides. Therefore, we conducted experiments with a tritium labelled D-peptide D3 (^{3}H-D3) in mice with different administration routes to study its distribution in plasma and organs, as well as its bioavailability by i.p. and p.o. administration. We also tested its metabolic stability in mouse brain, liver and kidney homogenate, plasma and liver microsomes.

Methods: Tritium labelled D3 was administered i.v., i.p., p.o. as bolus dose and through osmotic pump i.p. implantation. Plasma and organs were sampled at different time points after administration. Radioactivity in the plasma or organ homogenate was measured by liquid scintillation counting. Stability tests were performed through incubation of ^{3}H-peptides with plasma or organ homogenates, using thin layer chromatography combined with ^{3}H-autoradiography. PK parameters were calculated with non-compartmental analysis using WinNonlin.

Results: D3 showed resistance to proteases, long plasma half-life and adequate brain-plasma ratio, as well as high oral bioavailability.

Conclusions: Our results indicate that D3 and its derivatives may be promising drug candidates for AD treatment.

AMYLOID-BETA-OLIGOMER INDUCED ALZHEIMER'S DISEASE MODELS FOR TARGET VALIDATION AND DRUG DEVELOPMENT

T. PILLOT[1], D. RIMET[1], N. FISCHER[1], A. ALLOUCHE[1], E. DORARD[1], V. KOZIEL[1]
[1]SYNAGING SAS, SYNAGING SAS, Vandoeuvre-lès-Nancy, France

Objectives

Amyloid-β peptide oligomers (AβO) are the likely initiator of synaptic failure associated with early Alzheimer's dementia (AD). SynAging has successfully industrialized the preparation of stabilized AβO with the aim to offer preclinical models facilitating drug development for AD.

Methods

In vitro, rodent primary neurons challenged with AβO preparations resulted in well characterized and highly reproducible synaptic degeneration and neuronal death facilitating target validation, hit selection and lead optimization. Recently, microfluidic devices, separating the dendritic and soma from the axonal compartment have been established, enabling compound's mode of action investigations.
In vivo testing of compounds is performed in rodents injected with minute amounts of AβO ICV. Recently, intra-peritoneal injection of AβO in mice resulted in memory loss in the novel object recognition (NOR). Indeed, Y-maze, Morris Water Maze and NOR assays are fully validated and used in drug development.

Results

Reproducibility of AβO neurotoxicity in AD assays has been verified e.g. in Y-maze assay. While normal mice exhibited an alternation behavior of 65.8±2.4%, the AβO-injected mice showed an average of 53.9±1.5% of alternation behavior over many months. Humanin is used as positive control and customer compounds where successful in full protection of mice from AβO induced cognitive decline.

Conclusion

AβO induced AD models are thought to:

- Have better translatability than transgenic models
- Induce AD symptoms in rodents of all ages and large group sizes
- Show high convergence of *in vitro* and *in vivo* results
- Be faster, more reproducible and versatile than transgenic models

THE VALIDITY AND RELIABILITY OF THE MINI-MENTAL STATE EXAMINATION-2 FOR DETECTING MILD COGNITIVE IMPAIRMENT AND ALZHEIMER'S DISEASE IN A KOREAN POPULATION

M. Baek[1], H. Kim[1], Y. Park[2], Y. Chang[3], S. Kim[2]

[1]Clinical Neuroscience Center, Seoul National University Bundang Hospital, Gyeonggi-do, Korea

[2]Department of Neurology, Seoul National University Bundang Hospital, Gyeonggi-do, Korea

[3]Department of Neurology, Kangnam General Hospital, Gyeonggi-do, Korea

The Mini-Mental State Examination, 2nd edition (MMSE-2) is developed as a reliable cognitive screening measure to provide finer discrimination than the MMSE in recent years. The goal of this study was to examine the validity and reliability of the MMSE-2 for assessing the patients with mild cognitive impairment (MCI) and Alzheimer's disease (AD) in a Korean population. Two hundred and twenty six patients with MCI, ninety seven patients with AD, and 91 healthy older adults were recruited. All participants accepted examination by the MMSE-2, the MMSE, and other detailed neuropsychological assessments. The MMSE-2 performed well in discriminating participants across Clinical Dementia Rating (CDR) stages and CDR-Sum of Boxes (CDR-SOB) and showed excellent internal consistency, high test-retest reliability, and high interrater reliability and good concurrent validity with the MMSE and other detailed neuropsychological assessments. Also, the MMSE-2 was performed into two factors in normal cognitive aging and the patients with AD, but the MMSE-2 was factored into three factors in the patients with MCI. The sensitivity and specificity of three versions of the MMSE-2 were relatively high in discriminating normal cognitive aging and the patients with MCI and AD. The MMSE-2 is a valid and reliable cognitive screening instrument for assessing the cognitive impairment in a Korean population, but its ability to detect the patients with MCI from normal cognitive aging may not be as highly sensitive as expected.

ADPD5-0238
DISCRIMINATION ABILITY OF SHORT TEST OF MENTAL STATUS (STMS) COMPARED TO MMSE IN THE SPECTRUM OF NORMAL COGNITION-MCI-AD: THE TURKISH STANDARDIZATION STUDY

M. Cebi[1], G. Babacan Yildiz[2], H. Gürvit[3], N. Tarhan[1]
[1]Faculty of Humanities and Social Sciences, Uskudar University, Istanbul, Turkey
[2]Faculty of Medicine Department of Neurology, Bezmiâlem University, Istanbul, Turkey
[3]Faculty of Medicine Department of Neurology, Istanbul University, Istanbul, Turkey

Identification of mild cognitive impairment and its discrimination from normal cognition and Alzheimer's disease is a crucial process in clinic. The Mini Mental State Examination (MMSE) developed by Folstein is the most commonly used bedside mental examination test. In spite of its widespread use, on the other hand, the discriminative ability of MMSE in the spectrum of controls, mild cognitive impairment (MCI) and Alzheimer's disease (AD) is below the required level. Therefore, the lack of an ideal cognitive screening test, which is easy to apply and able to differentiate normal cognition from mild cognitive impairment, is a well-acknowledged fact. This prompted Emre Kökmen to develop STMS (Short Test of Mental Status) in Mayo clinic (1987). As a time-saving, economic and practical test, STMS can be more advantegous in differentiating normal people from MCI and, MCI from AD, compared to MMSE. The aim of the present study was to create standardization of the STMS in the general Turkish aging population and to find its disciminative ability in the spectrum of normal cognition, MCI, and AD. According to our results, STMS was found to be significantly better then MMSE both in discrimination of normal cognition from MCI and MCI from AD, with cut-off scores high in both sensitivity and specifity.

ADPD5-0289

ECOLOGICAL ASSESSMENT OF AUTONOMY IN INSTRUMENTAL ACTIVITIES OF DAILY LIVING USING AN AUTOMATIC VIDEO MONITORING SYSTEM

A. König[1], C.F. Crispim Junior[2], A.G. Covella[2], F. Bremond[2], A. Derreumaux[1], R. David[1], P. Aalten[3], F. Verhey[3], P. Robert[1]

[1]Centre Mémoire de Ressources et de Recherche, Insitut Claude Pompidou, Nice, France

[2]STARS, INRIA, Sophia Antipolis, France

[3]Maastricht University Medical Center, School for Mental Health and Neuroscience, Maastricht, Netherlands

Objectives: To investigate the use of a video monitoring system for automatic event recognition for the assessment of autonomy in Instrumental Activities of Daily Living (IADL) in dementia patients.

Methods: Three groups of participants (healthy control, Mild Cognitive Impairment and Alzheimer's disease) had to carry out a standardized scenario consisting of directed tasks (single and dual task) and IADLs such as preparing pillbox. During this time they were recorded by 2D video cameras capturing all their activities. The performance quality of each participant was manually annotated and assessed based on the amount of successfully carried out activities. Recorded data was processed by a platform of video signal analysis in order to extract kinematic parameters detecting activities undertaken by the participant. We developed a classifier based on the extracted video features for diagnostic prediction and further autonomy performance prediction.

Results: Overall activities were correctly automatically detected. The most accurate detected activities were: using the phone with 91% accuracy and preparing pillbox with 88% accuracy. The diagnostic group classifier based on the automatically extracted video features obtained accuracy of 71.79 % when combining directed tasks and IADLs. Autonomy group classifier obtained an accuracy of 84.61% when combining directed tasks and IADLs.

Conclusions: The results suggest that it is possible to assess autonomy with the help of an automatic video monitoring system (AVMS) and that the use of such technologies could provide clinicians with diagnostic relevant information to improve autonomy assessment in real time and decrease observer biases.

ADPD5-0368

SERUM MIR-206 AND MIR-132 AS POTENTIAL CIRCULATING BIOMARKERS FOR MILD COGNITIVE IMPAIRMENT

B. Xie[1], H. Zhou[1], R. Zhang[1], M. Song[2], L.L. Yu[2], L. Wang[2], D.S. Cui[1], X.Y. Wang[2], S.J. Xu[1]

[1]Central Laboratory, 1st Hospital of Hebei Medical University, shijiazhuang, China

[2]Department of Mental Health, 1st Hospital of Hebei Medical University, shijiazhuang, China

Abstract

Objectives: Circulating microRNAs (miRNAs) are reportedly potential diagnostic biomarkers for many diseases due to their stable, content-rich, easy quantitative detection and non-invasive advantages. This study investigated the potential role of circulating miRNAs as diagnostic biomarkers for mild cognitive impairment (MCI).

Methods: We collected 66 patients with MCI and 76 normal controls from our previous cross-sectional cohort study. Seven miRNAs (miR-206, miR-132, miR-193b, miR-130b, miR-20a, miR-296, and miR-329) related to Alzheimer's disease (AD) were detected using a quantitative real-time PCR (qRT-PCR) method. Each miRNA's diagnostic performance was evaluated by receiver operating characteristic (ROC) curves and the areas under curves (AUC) analysis.

Results: The miR-206 and miR-132 levels in MCI patients' serum were significantly elevated compared to normal controls. Combining miR-206 and miR-132 had the highest AUC of 0.981, followed by miR-206 (AUC = 0.880) and miR-132 (AUC = 0.912). Importantly, miR-206 and miR-132 were respectively correlated with the Montreal Cognitive Assessment (MoCA) score in MCI patients.

Conclusions: The results revealed that circulating miR-206 and miR-132 as novel miRNAs over expressed in MCI and suggested that serum levels of miR-206 and miR-132 were potential predictive biomarkers for MCI.

Figure. 1. **Receiver-operator characteristic (ROC) curve analyses.** ROC curves of miR-206, miR-132, and combined miRNAs were established to distinguish MCI from normal controls.

ANTIBODIES AGAINST SYNTHETIC FRAGMENTS OF ABETA RECEPTORS AS NOVEL BIOMARKERS IN BLOOD SERA OF PATIENTS WITH ALZHEIMER'S DISEASE

A. Kamynina[1], S. Gavrilova[2], D. Koroev[1], E. Ponomareva[2], O. Volpina[1]
[1]Laboratory of synthetic vaccines, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russia
[2]Department for Study of Alzheimer's Disease and Its Related Disorders, Research Center of Mental Health RAMS, Moscow, Russia

Pathogenic Abeta binds to many receptors on the cell surface leading to cell death. Degradated proteins appear in blood sera and must be eliminated by antibodies. We detected the level of antibodies against fragments of these proteins in sera of patients with Alzheimer's disease (AD) and control donors.

We have formed a pannel of several fragments from extracellular regions of different Abeta receptors such as alpha7-type of acetylcholine receptor (AChR), prion protein, neurotrophin receptor p75 and receptor for advanced glication end products (RAGE). As control we used peptide fragments from tumor assosiated proteins such as survivin and nucleophosmin. To investigate the level of antibodies towards these peptide fragments, more than 30 patients with AD and more than 10 control individuals were taken.

The ELISA revealed that the level of antibodies against one peptide from AChR and one fragment from p75 receptor differs in the control group and in patients with AD. Moreover, the level of antibodies against the AChR peptide was statistically lower in the group of patients than in the blood sera of control individuals, whereas the level of antibodies against the p75 peptide on the contrary was higher in patients' sera. The antibody titers against other fragments were shown to have almost no difference between control sera and blood samples from AD patients.

Thus, detection of the level of antibodies against two fragments from AChR and p75 in blood samples of patients with AD is a novel approach for easy diagnostics of AD.

Supported by grant RFBR 14-04-31232.

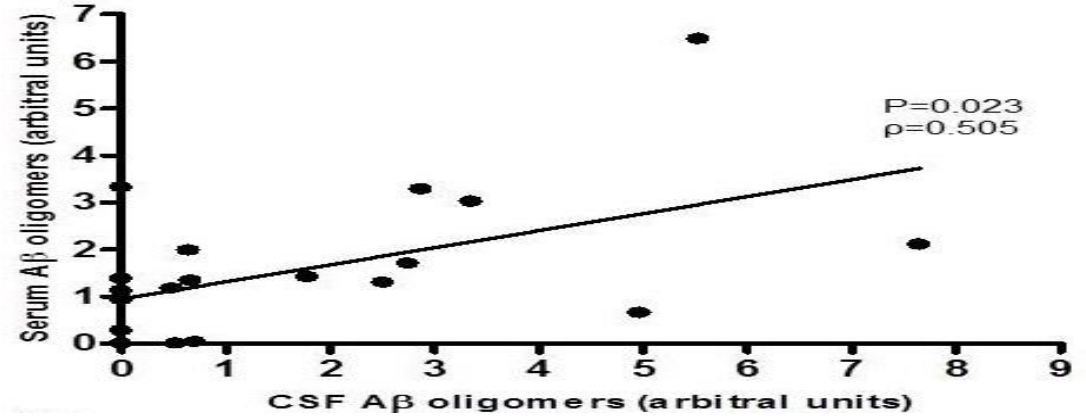
ADPD5-0385

CORRELATION OF ABETA OLIGOMER LEVELS IN MATCHED CSF AND SERUM SAMPLES.

T. Kasai[1], T. Tokuda[2], M. Taylar[3], D. Allsop[3], M. Nakagawa[4], T. Mizuno[1]
[1]Neurology, Kyoto Prefectural University of Medicine, Kyoto, Japan
[2]Molecular Pathobiology of Brain Diseases, Kyoto Prefectural University of Medicine, Kyoto, Japan
[3]Biomedical and Life Science, Lancaster Univesity, Lancaster, United Kingdom
[4]North Medical Center, Kyoto Prefectural University of Medicine, Kyoto, Japan

Objectives. We recently developed an ELISA for amyloid-beta (Abeta) oligomers in CSF, in which the same Abeta monoclonal antibody, BAN50, was used for both capture and detection for selective detection of oligomers. However, the invasive CSF sampling procedure, limits its use in routine clinical practice. In this study, firstly we determined whether the BAN50 SAS-ELISA can detect Abeta oligomers in serum. Secondly, we examined the possible relationship between the levels of Abeta oligomers in matched samples of CSF and serum collected at the same time.
Methods. Twenty subjects with no dementia who were required to give CSF and serum at the same time were enrolled. We measured Abeta oligomers by the BAN50 SAS-ELISA and Abeta1-40/1-42 by commercially available kits in each sample.
Results. Our ELISA could detect signals in 60% of serum samples and in 80% of CSF samples obtained from the subjects. Heterophilic antibodies that are a primary confounding factor in this type of ELISA did not affect the signals obtained. Although the levels of serum Abeta oligomers were unexpectedly high, suggesting the possible detection of non-pathological Abeta complexes associated with serum carrier proteins, they did show a significant positive correlation with the levels obtained from matched CSF samples (Figure).



Coclusions. This correlation between CSF and serum Abeta oligomer levels implies that the levels of serum Abeta oligomers measured with our ELISA might be useful as a marker for AD that reflects an intact system of Abeta transport across the blood brain

barrier (Figure).

ADPD5-0420

TECHNICAL VALIDATION OF A FULLY AUTOMATED ROCHE ELECSYS IMMUNOASSAY FOR THE QUANTITATIVE DETERMINATION OF AMYLOID-BETA1-42 IN HUMAN CEREBROSPINAL FLUID

T. Bittner[1], C. Rabe[1], E. Manuilova[1], A. Leinenbach[1], U. Kobold[1], T. Nikolcheva[2], P. Heiss[1]

[1]R&D, Roche Diagnostics GmbH, Penzberg, Germany

[2]Biomarker, Hoffmann-La Roche, Basel, Switzerland

Objectives:

Cerebrospinal fluid (CSF) amyloid-beta1-42 peptide (Abeta42) is a well-established biomarker for Alzheimer's Disease. Several immunoassays for Abeta42 are on the market as research use only (RUO) assays in the US. Their technical qualification as in vitro diagnostics (IVD) worldwide is hindered by imprecision, lot-to-lot variability, and lack of standardization to either a reference method or material. The fully automated Roche Elecsys Abeta42 immunoassay has been developed to overcome these technical hurdles.

Methods:

Technical validation of the assay was performed according to CLSI guidelines. Imprecision was assessed by CLSI EP05 over 21 days with two runs per day. Lot-to-lot variability was evaluated based on a comparison of 90 native CSF samples from individual patients measured with three assay lots. The assay was standardized based on the mass spectrometry-based reference method from Leinenbach et al. 2014 to ensure that assay values are traceable to SI units.

Results:

The measuring range of the assay is 200-1700 pg/mL with a limit of quantification (LoQ) < 6 pg/mL. Imprecision studies yielded within-run coefficients of variation (CVs) of 0.4-1.5%, between-day CVs of 1.2-2.0%, and intermediate CVs of 1.9-4.0%. Lot-to-lot comparison of three lots showed excellent correlation, with a coefficient of r>0.99 (Pearson).

Conclusion:

The Roche Elecsys Abeta42 immunoassay is a technically validated assay for the quantitative determination of Abeta42 in human cerebrospinal fluid. The technical performance of the assay shows high lot-to-lot comparability, high precision, and traceability of the results to an IFCC-endorsed reference method.

[3]Statistics Neuroscience, Eli Lilly & Co, Indianapolis, USA
[4]Medical Dept., Lilly Italia S.p.A., Sesto Fiorentino (FI), Italy

Introduction: Understanding the pattern of decline in cognitive functioning in Alzheimer's disease (AD) could assist primary care physicians in explaining AD progression to patients and caregivers. The objective of this analysis is to determine if there is an identifiable order in which cognitive abilities are lost within the progression of AD.
Methods: GERAS is an 18-month observational study on AD. Patients diagnosed with probable AD and Mini Mental State Examination (MMSE) ≤26 were enrolled. Proportional odds logistic regression model was applied to model MMSE subscales of orientation, registration, attention and concentration (spelling and counting), word recall, language and copying. The model converted ordinal scores of each subscale to corresponding probabilities of cognitive impairment at each MMSE total score level where the probabilities were estimated based on start of and complete cognitive impairment.
Results: 1495 patients were analyzed. Figure 1 shows the probability estimates of start of and complete impairment for each subscale. The first aspect of cognition to become impaired is word recall, followed by orientation in time. The last abilities to fully deteriorate are orientation in place, language, and registration.
Conclusions: The process of cognitive decline was visualized by means of probability estimates of key aspects of cognition. This might be useful to set expectations on disease progression for patients/caregivers.

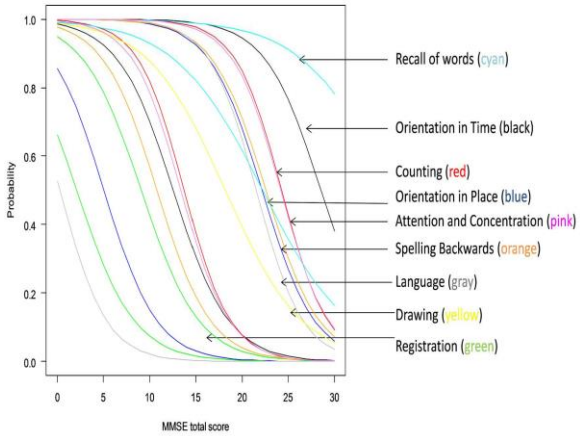

Figure 1 Leftmost curve for each color denotes the probability of complete impairment (individual subscore=0). Rightmost curve denotes the probability of start of cognitive impairment (first error on each individual subscore).

ADPD5-0439

SIMPLE BAJA SCORING OF THE CLOCK DRAWING TEST FOR MILD ALZHEIMER DISEASE

A. Bartos[1], M. Janousek[2], M. Hohinova[2], D. Ripova[3]
[1]AD Center, Prague Psychiatric Center, Prague, Czech Republic
[2]AD Center, AD Center, Prague, Czech Republic
[3]AD Centre, Prague Psychiatric Center, Prague, Czech Republic

Objectives
Our goal was to develop a simple, but unambiguous scoring of the clock drawing test (CDT) that is able to reliably distinguish serious from minor errors and to assess its diagnostic potential for mild dementia due to Alzheimer disease (ADD).
Methods
We administered the Mini-Mental State Examination (MMSE) and CDT with 11:10 to 30 ADD patients (MMSE 24±4 points) and to 30 matched normal seniors (NOS) (MMSE 29±1). We prepared our own Baja scoring system ranging from 0 to 9.5 points. It contains 9 items to evaluate separately quality of a watch face, its hands and the required time. We compared it with a 5-point scoring of CDT in the Addenbrook´s cognitive assessment (ACE).
Results
Both groups did not differ in CDT scores according to ACE rules (p=0.8). Patients even with mild ADD made significantly more mistakes and thus had higher scores than the controls (average ± SD: 7±2 vs 8±1 points, p=0.0023). We found an optimal Baja cut-off for CDT ≤ 7.5 points associated with sensitivity (Se) 60 %, specificity (Sp) 77 % and area under curve (AUC) of receiver operating characteristic 0.71. Similar variables for MMSE are ≤ 27 points, Se and Sp equally 93 %, AUC 0.86.
Conclusion
Our newly developed scoring Baja is a brief and easy instrument to screen mild ADD. MMSE is better, but requires longer time for screening.
The study was supported by grant IGA No. NT 13183 and PRVOUK 34/LF3.

ADPD5-0589

THE EFFECT OF NEURODEGENERATION ON VISUOMOTOR INTEGRATION IN ALZHEIMER AND PARKINSON

C. de Boer[1], J.J.M. Pel[1], A.J.W. Boon[2], F. Mattace-Raso[3], J. van der Steen[1]
[1]Neuroscience, Erasmus MC University Medical Center, Rotterdam, Netherlands
[2]Neurology, Erasmus MC University Medical Center, Rotterdam, Netherlands
[3]Internal Medicine, Erasmus MC University Medical Center, Rotterdam, Netherlands

Objectives:
Alzheimer's disease (AD) and Parkinson's disease (PD) both affect visuomotor integration areas (frontal-parietal brain regions). Eye - and hand responses to visual stimuli are a good model to objectively quantify the efficiency of visuomotor integration. The goal of this study is to assess eye - and hand responses across a series of visuomotor tasks to investigate disease specific effects of AD and PD on visuomotor integration.
Methods:
39 AD patients, 59 PD patients and 54 healthy controls performed a series of three visually guided reaching tasks, two counterpointing tasks and one memory guided reaching task. Subjects performed these tasks on a touch screen while their eye movements were recorded using an eye tracking system and their hand movements were recorded using a motion detection system. Outcome parameters describing task performance, response latencies to visual stimuli and task execution speed were calculated and compared between groups.
Results:
AD patients had delayed hand latencies and increased task execution times compared to controls in two of three visually guided reaching tasks and in the memory guided reaching task. PD patients performed worse than controls in one counterpointing task and displayed increased task execution times in two visually guided tasks.
Conclusions:
Parameters describing performance, latencies and execution times across a series of eye-hand coordination tasks provide a quantitative description of disease specific deficits in visuomotor integration. A combination of eye - hand coordinated tasks may serve as an additional tool to diagnose AD and PD and to monitor disease progression.

ADPD5-0717

ANALYTICAL PERFORMANCE EVALUATION OF A FULLY AUTOMATED CHEMILUMINESCENT HUMAN TAU ASSAY ON THE LUMIPULSE G1200 SYSTEM

A. Vandersteen[1], S. Pereson[1], K. De Vuyst[1], K. Gorteman[1], W. Vandezande[1], F. Dekeyser[1], P. Vandeponseele[1], M. Dauwe[1], G. Jannes[1]
[1]R&D, Fujirebio Europe N.V., Ghent, Belgium

Objectives: Cerebrospinal fluid (CSF) β-amyloid$_{(1-42)}$ peptide and tau protein are important biomarkers supporting Alzheimer's disease diagnosis and disease state. Today there is a growing need for reliable and automated tests to quantify both biomarkers. Analytical performance was evaluated for a novel total tau assay for the LUMIPULSE G1200 instrument, a fully automated chemiluminescent enzyme immunoassay system.
Methods: The LUMIPULSE G1200 system uses single, ready-to-use cartridges composed of three wells and has a throughput of 120 tests/hour. Sequential immunoreaction steps are carried out at pre-determined intervals while the cartridge is transported through the system. Quantitative results are available within approximately 25 minutes. The total tau assay was developed using established monoclonal antibodies to human tau and analytical performance parameters e.g. limit of detection (LoD), limit of quantitation (LoQ), linear measuring interval, reproducibility and correlation with INNOTEST hTAU Ag were evaluated according to well-defined protocols.
Results: Within-run reproducibility is <5% for CSF and control samples. Based on 20 measurements of the blank, the LoD is <37 pg/mL. LoQ with 10% coefficient of variation is 66.5 pg/mL. The linear measuring interval, allowing a deviation of 10% is between 190 and 1100 pg/mL. Analysis of CSF tau showed a correlation coefficient of >0.95 compared to INNOTEST hTAU Ag assay.
Conclusions: The fully automated LUMIPULSE G1200 instrument rapidly quantifies biomarkers for neurodegeneration in biological samples in a highly standardized manner. The Lumipulse human tau assay quantifies tau in CSF samples, displays good precision and correlates well with the established INNOTEST hTAU Ag assay.

ADPD5-0721

ANALYTICAL PERFORMANCE EVALUATION OF A FULLY AUTOMATED CHEMILUMINESCENT BETA-AMYLOID(1-42) ASSAY ON THE LUMIPULSE G1200 SYSTEM

M. Dauwe[1], F. Dekeyser[1], A. Vandersteen[1], P. Van Hecke[1], K. De Vuyst[1], T. Dumont[1], P. Vandeponseele[1], G. Jannes[1]

[1]R&D, Fujirebio Europe N.V., Ghent, Belgium

Objectives: Cerebrospinal fluid (CSF) β-amyloid$_{(1-42)}$ peptide (Aβ$_{1-42}$) and total tau protein are important biomarkers supporting Alzheimer's Disease (AD) diagnosis and disease state. Today there is a growing need for reliable and automated tests to quantify both biomarkers. Analytical performance was evaluated for a novel Aβ$_{1-42}$ assay on the LUMIPULSE G1200 instrument, a fully automated chemiluminescent enzyme immunoassay system.

Methods: The LUMIPULSE G1200 system uses single, ready-to-use cartridges composed of three wells and has a throughput of 120 tests/hour. Sequential immunoreaction steps are carried out at pre-determined intervals while the cartridge is transported through the system. Quantitative results are available within approximately 25 minutes. The Aβ$_{1-42}$ assay was developed using established monoclonal anti-Aβ antibodies and analytical performance parameters e.g. limit of detection (LoD), limit of quantitation (LoQ), linear measuring interval, precision and correlation with INNOTEST β-AMYLOID$_{(1-42)}$ were evaluated according to well-defined protocols.

Results: Within-run reproducibility was <5% for controls and CSF samples. Based on 20 measurements of the blank, the LoD was determined to be <25 pg/mL. LoQ with a coefficient of variation of 10% was <30 pg/mL. The assay was found to be proportionally linear over the clinically relevant range and correlated well (r>0,90) with the reference device INNOTEST β-AMYLOID$_{(1-42)}$.

Conclusion: The fully automated LUMIPULSE G1200 instrument has the potential to rapidly quantify biomarkers for neurodegeneration in biological samples in a highly reproducible manner. The Lumipulse Aβ$_{1-42}$ assay fulfils current needs for quantification of AD biomarkers: superior sensitivity and precision and good correlation with the established INNOTEST β-AMYLOID$_{(1-42)}$ assay.

ADPD5-0762
AUTOMATIC SPEECH ANALYSIS FOR THE ASSESSMENT OF PRE-DEMENTED AND ALZHEIMER PATIENTS

A. König[1], A. Satt[2], A. Sorin[2], A. Derreumaux[1], R. David[3], F. Verhey[4], P. Aalten[4], P. Robert[1]
[1]CobteK, Institut Claude Pompidou, Nice, France
[2]Speech Lab, IBM Research, Haifa, Israel
[3]CHU de Nice, Centre Mémoire de Ressources et de Recherche, Nice, France
[4]School for Mental Health and Neuroscience,
Alzheimer Center Limburg Maastricht University Medical Center, Maastricht, Netherlands

Background: Various types of dementia and MCI are manifested as irregularities in human speech and language, which have proven to be strong predictors for the disease presence and progression. Therefore, automatic speech analysis is expected to be an useful tool in providing indicators for assessment and detection of early stage Alzheimer's disease (AD) and MCI.
Method: 15 Healthy elderly subjects (HC), 23 MCI patients and 26 AD patients were recorded while performing several short vocal cognitive tasks, including verbal fluency, picture description and counting down, during a regular consultation.
Voice recordings were processed in two steps: first vocal markers were extracted using speech signal processing techniques; second, vocal markers were tested to assess their 'power' to distinguish between HC, MCI and AD. The second step included training automatic classifiers for detecting MCI and AD, based on machine learning methods, and testing the detection accuracy.
Results: classification accuracy of automatic audio analyses were as follows: between HC and MCI: 79 ± 5%, between HC and AD: 87 ± 3%, and between MCI and AD: 80 ± 5%.
Conclusions: Decline in cognitive functioning affects speech production in different ways. Preliminary analysis indicates the potential value of vocal cognitive tasks for accurate automatic differentiation between HC, MCI and AD. This can provide the clinician with meaningful information for assessment and early diagnosis purposes, based on non-invasive, simple and low-cost method. Investigations of new and improved vocal tasks, signal processing tools and pattern recognition tools, are planned.

LOW CSF AMYLOID-BETA LEVELS CORRELATE WITH POOR PERFORMANCE IN CERAD-NB SUBTESTS MEASURING DELAYED MEMORY IN WOMEN

F. Haapalinna[1], E. Solje[1], J. Penttinen[1], M. Rautiainen[2], T. Hänninen[2], A. Koivisto[2], P. Hartikainen[2], A. Remes[2], T. Paajanen[3], S. Herukka[1]
[1]Neurology, University of Eastern Finland, Kuopio, Finland
[2]Neurology, Kuopio university hospital, Kuopio, Finland
[3]Development of work and work organizations, Finnish Institute of Occipational Health, Helsinki, Finland

The relationship between The Consortium to Establish a Registry for Alzheimer's Disease Neuropsychological Battery (CERAD-NB) and CSF biomarkers for Alzheimer's disease (AD) have been evaluated only in few studies. Our aim was to study the correlation of pathological changes in the CSF biomarkers with various CERAD-NB subtests.
This study consisted of 80 subjects (53.8 % women, 46.2 % men) with mean age of 70,4 years. 65 had undergone an assessment of cognitive status with CERAD-NB and a CSF biomarker analysis due to a suspected memory disorder and 15 were controls with no memory complaint. A total of 23 subjects were diagnosed with AD, 19 with Mild Cognitive Impairment (MCI) and 38 with another memory problem.
We found a significant correlation between CSF amyloid-beta ($Abeta_{1-42}$) and several subtests measuring delayed recall in women. Word list recall correlated with all markers: $Abeta_{1-42}$ (r=0,323, p=0,035), tau (r=-0,304, p=0,050) and hyperphosphorylated tau (p-tau) (r=-0,331, p=0,046). No such correlations were found in men. Moreover, within the group diagnosed with MCI $Abeta_{1-42}$ correlated with a memory compound score measuring delayed recall (r=0,568, p=0,022).
CSF biomarkers, particularly $Abeta_{1-42}$, correlate with delayed memory score in CERAD-NB and women may have more actual AD pathology at the time of the investigations than men who may be likely to have other reasons behind the memory deficit.

[3], ADx, Gent, Belgium

Objectives
Numerous technologies are available to quantify CSF biomarkers for Alzheimer's disease diagnosis, resulting in different biomarker concentrations and cut-off values for a specific intended use. If a laboratory wants to use a new generation assay, cut-off values need to be re-established. It is a common practice to test available samples 'side-by-side' with the old and new assay and to transfer the cut-off by means of a linear regression formula. We evaluate the effect of this transfer method on the biomarker's performance and introduce an alternative, Bayesian methodology.
Methods
We simulated two sets of data that mimic the structure of CSF $A\beta_{1-42}$ values: a 'cut-off' dataset used to derive the cut-off for the current assay and a 'transfer' dataset containing biomarker values measured with the current and new assay, without the availability of diagnostic information. The cut-off for the new assay was transferred with the linear regression approach. Additionally, we applied a Bayesian method, which consists of using the 'cut-off' data as prior information for estimation of the biomarker's distributions in the 'side-by-side' dataset.
Results
We show that the Bayesian method results in less variable cut-off values and associated sensitivities and specificities. We show the effect of increasing sample sizes of the 'cut-off' and 'transfer' dataset on the precision of the new cut-off.
Conclusions
The Bayesian transfer method results in a more precise cut-off than the linear regression approach. Hence, the Bayesian approach is preferred for a cut-off transfer and will result in a faster integration of the new assay.

ADPD5-1003
FALSE RECOGNITION MEMORY IN REY AUDITORY-VERBAL LEARNING TEST FOR MILD COGNITIVE IMPAIRMENT

M. Konishi[1], H. Tabuchi[1], B. Yamagata[1], D. Ito[2], M. Mimura[1]
[1]Neuropsychiatry, Keio University, Tokyo, Japan
[2]Neurology, Keio University, Tokyo, Japan

Objectives: Patients with Alzheimer's disease (AD) and with Mild Cognitive Impairment (MCI) often show false recognition errors on neuropsychological assessment of memory. We retrospectively examined the qualitative difference in false recognition memory in Rey auditory-verbal learning test (RAVLT) for MCI patients.
Methods: Forty-two out patients (male=17, female=21; mean age=72.7 (SD=6.9); Clinical Dementia Rating Scale=0.5) were recruited from Memory Clinic at Keio University Hospital. We classified MCI patients into those who progressed to AD (MCI-p, N=19) and those who did not (MCI-np, N=23) according to the CDR after mean 38.8 (SD=10.4) months.
Results: There was a tendency for MCI-p group to produce more false recognition errors than for MCI-np group ($p = .054$). Moreover, MCI-p group showed significantly more false recognition errors phonetically close to target words than MCI-np group [MCI-p: 0.42 (SD 0.69); MCI-np: 0.09 (SD 0.29), ($p < .05$)]. Regarding false recognition errors semantically close to or non-related target words, both MCI-p and MCI-np groups showed equivalent false recognition errors.
Conclusions: MCI patients tend to produce false recognition errors in the auditory-verbal learning task, and it was revealed that phonetically close words to target words might intrude into auditory-verbal memory for MCI patients who progressed to AD in 3 years. It implies that the qualitative aspect of false recognition memory is important for the prediction of the progression to AD for MCI.

[7]Psychiatrie et Neurologie-CMRR Grenoble Arc alpin, Centre Hospitalier Universitaire, Grenoble, France
[8]Neurologie-CMRR, Centre Hospitalier Universitaire, Saint-Etienne, France

Objective: Our present objective is testing if the CSF concentrations of CSF non-Phosphorylated Tau (non-P-Tau) can be useful to detect Alzheimer's disease (AD) from different others neurodegenerative diseases. This study is supplementary to another presented work during this event on the analytical validation of CSF non-P-Tau determination with a novel ELISA (AJ Roboscreen, Leipzig, Germany).
Methods: Non-P-Tau concentration was measured in CSF from patients with AD (n=61) from patients with frontotemporal dementia (FTD; n=33), from patients with Lewy body dementia (LBD; n=30). Patients with neuropsychiatric disorders without alteration in the CSF biomarkers (n=19) were chosen as controls. 'Classical CSF Alzheimer biomarkers', Aβ1-42 and/or Aβ42/40 Ratio, Tau, and pTau181, were available for each patient tested. The diagnostic accuracy and receiver operating characteristic (ROC) of the non-P-Tau were evaluated in this study.
Results: Patients with AD presented significantly higher non-P-Tau levels than either controls ($p<0.001$) or all the other neurodegenerative non-Alzheimer patients ($p<0.001$). Interestingly, the sensitivity and the specificity of the discrimination of AD patients from FTD patients were 87% and 86% , respectively, resulting in the area under the ROC curve of 0.918.
Conclusions: our results suggest for the first time, that CSF non-P-Tau could be taken account as a reliable candidate biomarker of Alzheimer's Disease at the dementia stage.

ADPD5-1035

CLOCK DRAWING TEST IN SCREENING FOR ALZHEIMER'S DEMENTIA AND MILD COGNITIVE IMPAIRMENT IN CLINICAL PRACTICE

M. Vyhnalek[1], T. Nikolai[1], J. Laczó[1], E. Rubinova[1], H. Markova[1], R. Andel[1], K. Sheardová[1], J. Hort[1]

[1]Neuro 2, FNUSA - ICRC, Brno, Czech Republic

Objectives: The Clock Drawing Test (CDT) is widely used for brief evaluation of cognitive impairment in elderly. The aim of the study is (1) to describe the diagnostic accuracy and inter-rater agreement of subjective CDT ratings by different specialists and (2) to compare it with complex rating performed by a neuropsychologist in patients with amnestic mild cognitive impairment (aMCI) and Alzheimer's dementia (AD).

Methods: Three cognitive neurologists, three neuropsychologists and six medical residents with no experience in cognitive neurology rated 200 CDTs (50 mild AD, 50 aMCI, 50 healthy elderly and 50 patients with subjective memory complaints) using a binary (yes - no) classification to evaluate impairment in the CDT. An experienced neuropsychologist rated the CDTs using a 17-point scoring system. All raters were blinded to the diagnosis.

Results: When using the binary classification, neuropsychologists had highest sensitivity (89%) in differentiating mild AD patients, followed by neurologic residents (80%) and cognitive neurologists (79%). When differentiating aMCI patients, the sensitivity was 84% for neuropsychologists, 64% for cognitive neurologists and 62% for residents. All groups of raters showed moderate agreement (kappa = 0.4 - 0.6). The sensitivity using the 17-point scoring system was 92% in mild AD patients and 69% in aMCI patients.

Conclusions: A binary classification of CDT shows high sensitivity for mild AD even in non-experienced raters. However, neuropsychologists outperformed residents and neurologists in differentiating aMCI patients from cognitively healthy elderly. The diagnostic accuracy was not substantially improved by using a complex scoring system.

ADPD5-1062
COGNITIVE IMPAIRMENT RELATED WITH DEPRESSION PRESENTING AS "FRIDGE SIGN"

J. Han[1], S. Park[1], M. Wang[1], Y. Park[1], M. Baek[1], S. Kim[1]
[1]Department of Neurology, Seoul National University Bundang Hospital, Seongnam si Gyounggi-do, Korea

Objectives
The 'Fridge sign', defined as the behavior of putting wrong things in the refrigerator, is considered as a warning sign indicating dementia in public. Here we demonstrate its value in cognitive assessment by examining initial neuropsychological data between the 'Fridge sign' group and the mild cognitive impairment (MCI) or suspected early stage Alzheimer's disease (AD) group with later AD progression.
Methods
We reviewed the medical charts of 23 patients showing 'Fridge sign' and 10 AD patients whose initial status was MCI or early stage of AD (CDR 0.5). We analyzed the demographic data, initial neuropsychological test and diagnosis of the two groups.
Results
The diagnosis and neuropsychological test of 'Fridge sign' group significantly differed from initial profile of AD. 78% of patients were confirmed as subjective or objective cognitive complaints related to depression (13 patients (56.5%) as cognitive impairment related with depression (CIRD), 5 patients (21.7%) as subjective memory impairment with depression). 3 patients (13.0%) were MCI and 2 patients (8.7%) were AD. On initial neuropsychological test, the scores of 'Fridge sign' group were higher in most items, however, the digit span forward, phonemic word fluency and word stroop test scores did not differ from AD progression group.
Conclusion
In contrast to common belief, the 'Fridge sign' group keeps favorable outcome in many domains except attention and frontal lobe function compared to AD group. It is probable that depression may be associated with attention deficit and frontal lobe dysfunction, thus causing the 'Fridge sign'. Further longitudinal study is needed.

POST-LUMBAR PUNCTURE HEADACHE EXPERIENCE IN THE STUDY FOR ALZHEIMER'S DISEASE

J. Han[1], S. Park[1], M. Wang[1], Y. Park[1], J. Lee[2], S. Kim[1]
[1]Department of Neurology, Seoul National University Bundang Hospital, Seongnam si Gyounggi-do, Korea
[2]Department of Radiology, Seoul National University Bundang Hospital, Seongnam si Gyounggi-do, Korea

Objectives
Headache worsened by standing and improved after lying down is a frequent complication of lumbar puncture (LP). We performed LP in our study for searching biomarker of Alzheimer's disease (AD) to the target of AD patient and normal control. We analyzed the incidence and the risk factor for post-lumbar puncture headache (PLPH).
Methods
We retrospectively collected data from 47 participants who underwent LP. Twenty AD patients and twenty-seven normal control aged 51-88 underwent LP and drainage of cerebrospinal fluid with Quincke 20G needle. Data included needle characteristics, CSF pressure assessed by LP, degree of small vessel disease and hippocampal atrophy on MRI, clinical scale for cognition and basic demographic factors including age, sex and BMI. One to two weeks after the procedure, we checked PLPH in participants.
Results
PLPH was reported in 23 (48.94%) subjects, among which noted severe in 15 (65.22%) subjects. The incidence of PLPH was significantly high in younger normal control subjects. Risk factors for PLPH were examined using logistic regression. Only young-age is associated with increased risk for PLPH (p value=0.047).
Three of young-aged subjects who were excluded from this study had lumbar puncture performed with atraumatic spinal needle, and none of them suffered from headache.
Conclusions
Young age is a strong risk factor for PLPH. But it may be possible to reduce PLPH by using atraumatic spinal needles. Further study is needed.

ADPD5-1080
SOLUBLE FULL-LENGTH AND HETEROMERS OF AMYLOID PRECURSOR PROTEIN IN THE CEREBROSPINAL FLUID

J. Saez-Valero[1], I. López-Font[1], A. Boix-Amorós[1], G. Brinkmalm[2], K. Blennow[2], J.L. Molinuevo[3], I. Cuchillo-Ibáñez[1]
[1]Molecular Neurobiology, Instituto de Neurociencias Universidad Miguel Hernández, Sant Joan d'Alacant, Spain
[2]Clinical Neurochemistry Lab,
Inst. of Neuroscience and Physiology University of Gothenburg, Mölndal, Sweden
[3]Alzheimer's Disease and Other Cognitive Disorders Unit, Hospital Clinic, Barcelona, Spain

Objective: The aim of this study is to assess the presence of soluble full-length amyloid precursor protein (sAPPf) in cerebrospinal fluid (CSF), the oligomerization state of sAPP and how heteromers affect with the quantitation of sAPPα and sAPPβ by ELISA.
Methods: sAPPf and sAPP heteromers were characterized in CSF and brain extracts by co-immunoprecipitation, ultracentrifugation in sucrose density gradients and native gel electrophoresis. Alzheimer's disease and non-disease CSF were assayed for sAPPα and sAPPβ by ELISA following immunoprecipitation with different anti-APP antibodies.
Results: sAPPf co-exists in CSF with sAPPα and sAPPβ, and all forms are capable of assembling into heteromers. These CSF heteromers differ from APP membrane-dimers in brain extracts. ELISA determination of the levels of sAPPα and sAPPβ in CSF samples was affected by previous immunoprecipitation of the CSF by APP C-terminal or sAPPβ antibodies.
Conclusions: Quantitation of CSF sAPPα and sAPPβ in CSF by ELISA is affected by presence of sAPPf and assembly of all sAPP species into heteromers. This should be taken into consideration when exploring their potential role as CSF biomarkers.

Alzheimer's disease (AD) is a progressive neurodegenerative disease, and represents the most prevalent cause of dementia. Specific biomarkers for diagnose of AD at the early stage are essential to prevent and treat the disease. To find such biomarkers, we analyzed 579 plasma metabolites of age-matched healthy controls (n=60, 68.2 year old), mild cognitive impairment (MCI) patients (n=35, 75.2 year old), and AD patients (n=31, 73.5 year old) by capillary electrophoresis/mass spectrometry. The average plasma levels of 136 metabolites, which were 20% of total 579 detectable metabolites, were relatively low in all plasma samples and exhibited a high measurement deviation. Such 20% metabolites were excluded from the statistic analysis. Of the remaining 463 metabolites, a significant part of the metabolites was not detected in the samples. This gave a high individual deviation as biomarkers. Therefore, 70 metabolites detectable in more than 80% of all participants were selected and further subjected to t-test statistical analysis. Our results revealed that plasma levels of 6 and 7 metabolites significantly changed in MCI and AD, respectively, compared with the controls. Receiver Operating Characteristic (ROC) analyses of these metabolites enabled us to diagnose MCI and AD with high accuracy. The ROC Area Under the Curve (AUC) values for MCI and AD were 0.930 and 0.927, respectively. This study was supported a research program by the National Institute of Biomedical Innovation (NIBIO).

[3]Institute of Molecular Bioimaging and Physiology (IBFM), CNR, Cefalù-Segrate, Italy
[4]Department of Medical Sciences and Community Health, University of Milan, Milan, Italy

Objectives: Cerebrospinal fluid (CSF) biomarkers have been recently described for the improvement of AD diagnosis, even though, to date, diagnosis remains mainly based on neuropsychological tests. The objective of the present effort is to transfer MALDI profiling technology to the study of lipid profile in CSF samples, to assess a MALDI specific CSF lipid profile and identify new biomarkers.
Methods: Total lipids from CSF samples (AD n=10; *idiopathic* normal-pressure hydrocephalus (iNPH)=10; controls=10) were extracted according to Bligh and Dyer modified method and analyzed by MALDI. Profiles were analyzed by ClinProTools software. For sphingolipids and phospholipids characterization, lipid extracts were separated by HPTLC and directly analyzed by MALDI (Torretta E. et al, Electrophoresis 2014).
Furthermore, for a direct MALDI CSF lipid analysis, crude CSFs diluted in distilled water (1:2) were analyzed by MALDI and peaks searched against NIST database.
Results: Profiling preliminary results of lipid extracts from CSFs of 10 controls, 10 iNPH and 10 AD indicated a characteristic quantitative lipid CSF profile able to differentiate controls and iNPH vs AD.
Sphingolipids and phospholipids semiquantitative pattern provides a characteristic pattern in AD vs iNPH and controls.
Furthermore qualitative lipid characterization can be obtained by analyzing directly the crude CSF by MALDI in patients vs control samples for the identification of new lipid targets.
Conclusions: MALDI profiling of CSF lipid extracts contributed to the detection of specific lipid profile and possible biomarkers for an early AD diagnosis. HPTLC-MALDI and direct lipid analysis offered a hint for the identification of new lipid markers.

CSF AND SERUM MALDI PROFILING FOR THE IDENTIFICATION OF NOVEL BIOMARKERS IN DEMENTIA PATIENTS

C. Gelfi[1], C. Fania[1], B. Arosio[2], M. Casati[2], M. Vasso[3], C. Gussago[4], E. Torretta[1], E. Ferri[4], D. Mari[2]

[1]Department of Biomedical Sciences for Health, University of Milan, Segrate (MI), Italy

[2]Geriatric Unit, Fondazione Ca' Granda IRCCS Ospedale Maggiore Policlinico, Milan, Italy

[3]Institute of Molecular Bioimaging and Physiology (IBFM), CNR, Segrate (MI) - Cefalù (PA), Italy

[4]Department of Medical Sciences and Community Health, University of Milan, Milan, Italy

Objectives: In elderly, the increase of dementia incidence and the lack of effective therapies have stimulated the search for early markers for discrimination and prevention of this pathology. In this contest we profiled the CSF protein content in old patients with cognitive impairment affected by Alzheimer's disease (AD) and idiopathic Normal Pressure Hydrocephalus (iNPH) compared to controls.

Methods: 10 CSF from AD, 10 from iNPH patients and 12 from controls were profiled by MALDI-MS for the detection of small proteins discriminating the two forms of dementia from healthy subjects. Statistics (Wilcoxon test $p<0.01$, PCA analysis and ROC AUC>0.800) and classification models were performed by ClinProTools Software. For the identification of putative biomarkers (peaks discriminating the different classes), an in-gel approach (SDS-PAGE separation) coupled to MALDI-MS was adopted.

Results: MALDI Profiling allowed to discriminate iNPH (resulting similar to controls) from AD patients through the presence of 28 differentially changed peaks in the acquisition range of 4-34 kDa. Among them, 6 were selected (on the base of the corresponding p-values, ROCs and box-plots) and combined to build models to classify a blind set (n=50) of CSFs.

SDS-PAGE coupled to MALDI-MS allowed peak identification corresponding to a protein involved in lipid transport.

Conclusions: CSF MALDI profiling can be adopted to identify protein differences in various types of dementia in order to obtain a specific pattern to support clinical and biochemical diagnosis. This approach can also provide new putative biomarkers to couple to the existing molecules, whose expression is currently evaluated in clinical practice.

[8], VU University Medical Center, Amsterdam, Netherlands

[9], Finland

Objectives: It is important to detect which patients with mild cognitive impairment (MCI) have a high risk for dementia in order to identify those who could benefit from treatment and preventive measures. We evaluate the feasibility of combining MCI cohorts and test how well our prediction model performs when different cohorts are used as training and test sets. This is a vital issue when evaluating clinical utility.

Methods: We combined data from four large cohorts of MCI patients: ADNI, AddNeuroMed, DESCRIPA and Kuopio MCI to predict progression to Alzheimer's Disease. All patients had age and gender corrected MRI data, MMSE and the APOE genotype available and additionally some results on neuropsychological tests and CSF. Altogether 875 patients were included in the analysis. We used the Disease State Index to classify patients as stable or progressive MCI.

Results: We tested each cohort and their combination using 10-fold cross-validation and compared the result to inter-cohort bootstrapping analysis done by testing each cohort separately with a model built from the other three cohorts. The cohorts differed in several aspects, including age, years of education and MMSE score. The AddNeuroMed study had a fixed follow-up time of 1 year, while the other three cohorts had mean follow-up times of over 2 years. Despite the differences between the cohorts, the intra-cohort prediction efficiency of the combined cohort (AUC=0.76) was close to the average of the individual cohorts.

Conclusions: It is feasible to combine different cohorts but for accurate predictions they need to be sufficiently similar.

WHAT IS THE WORSE IN HEALTHY ELDERLY INDIVIDUALS: HAVING BRAIN AMYLOID OR REFERRING TO A MEMORY CLINIC WITH A SUBJECTIVE-COGNITIVE-DECLINE?

A. Perrotin[1], S. Egret[1], F. Mezenge[1], B. Landeau[1], V. De La Sayette[2], B. Desgranges[1], F. Eustache[1], G. Chetelat[1]

[1]Inserm-EPHE-UCBN U1077, Cyceron, Caen, France

[2]Inserm-EPHE-UCBN U1077, CHU Caen, Caen, France

Objectives. Both healthy elderly individuals with amyloid deposition in the brain or with a subjective cognitive decline (SCD) have higher risks of developing Alzheimer's disease (AD). The objective was to identify which condition in cognitively normal (CN) individuals is the most associated with an AD-like pattern of neurodegeneration.

Methods. We compared structural-MRI and FDG-PET data in i) a group of 15 CN individuals with SCD recruited from a memory clinic to 45 matched controls without SCD recruited from the general population, and ii) a group of 10 CN individuals with amyloid-positive Florbetapir-PET scan to 29 matched controls with amyloid-negative scan.

Results. Regarding structural-MRI, highly significant gray matter atrophy in the hippocampal region was found in the SCD compared to the controls with no SCD. This result was not related to amyloid deposition since both groups did not differ in the proportion of amyloid-positive individuals. By contrast, the amyloid-positive individuals did not show any sign of brain atrophy relative to the amyloid-negative controls. Regarding FDG-PET, no significant hypometabolism was found either in the SCD or in the amyloid-positive groups.

Conclusions. Our findings showed that only CN individuals with SCD who refer to a memory clinic, but not CN individuals with amyloid deposition in the brain, have greater AD-like hippocampal atrophy. Thus, even if they are still asymptomatic, the short-term prognosis in individuals with SCD could be worse than that of individuals having amyloid deposition in the brain. These results emphasize the critical interest for SCD in preclinical AD.

ADPD5-1322
AUTOMATIC EVALUATION OF PARKINSON'S DISEASE TREMOR WITH SUPPORT VECTOR MACHINES

A. Koçer[1], A. Oktay[2]
[1]Neurology, Istanbul Medeniyet University, Istanbul, Turkey
[2]Computer Engineering, Istanbul Medeniyet University, Istanbul, Turkey

OBJECTIVE: In this study, we propose a system to automatically assess the Hoehn Yahr Score (HYS) of patients with Parkinson's disease. Our main objective is determine the HYS from 0 to 4 with a low-cost accelerometer for assisting the Parkinson's Disease clinical assessment.
MATERIAL: The resting tremor data of subjects are gathered with the accelerometer of the Nintendo Wii (Wiimote). Instead of determining the amplitude and frequency of the tremor data, we extract various features like maximum, minimum, average and standard deviation values with a windowing technique from the acceleration values. The clinical disability of the PD was graded by the Hoehn and Yahr staging (HYS) and tremor was recorded twice from the more affected side in each patient and from the dominant extremity in each control for a 60 seconds period.. The HYS are learned using Support Vector Machines (SVM) which is a popular machine learning technique. The system is evaluated and tested on a dataset containing 55 subjects where 20 of them were healthy (HYS 0) and 35 of them were patients (HYS:1-4).
RESULTS: Leave-one-out technique is used for training the SVM and the system has average 0.89 accuracy rate (Range: 81-100% changing according to grading by HYS) which is promising for the proposed system.
CONCLUSION: Resting tremor related features were much studied by using different accelerometer methods, but a Wiimote accelerometer with a machine learning system was not assessed previously. The subjects was automatically diagnosed as having PD or normal in the present study.

ADPD5-1549
EVENT-RELATED POTENTIALS IN DIAGNOSIS AND ASSESSMENT OF TREATMENT OF ALZHEIMER'S DISEASE

W. Derkowski[1]
[1]*EEG Laboratory, Neurological Clinic, Kluczbork, Poland*

To improve the efficiency of the patient in the treatment of Alzheimer's disease are used acetylcholinesterase inhibitors, e.g. donepezil, which leads to increase the amount of acetylcholine in the cortex of the brain and enhances cognitive processes, including memory and thinking efficiency, especially in the initial stage of the disease, delaying the moment of the failure. The aim of this study was to evaluate the usefulness of event-related potentials system for monitoring patients with Alzheimer's disease treated with oral inhibitors of acetylcholinesterase. Material consisted of event-related potentials findings of 30-patient during routine treatment of Alzheimer's disease using inhibitors of acetylcholinesterase, madein the EEG Laboratory of our Neurological Clinic. Tests were performed before inclusion and during therapy. The control group consisted of the 30 healthy subjects of the similar age. The results revealed that event-related potentials in patients with Alzheimer's disease had in some cases prolongation of P300 wave in comparison with healthy controls. Patients treated with acetylcholinesterase inhibitors showed a marked improvement in cognitive functioning, that seen with the Mini Mental State test. In the course of acetylcholinesterase inhibitors treatment in some cases there was a shortening of P300 wave latency. The obtained results allow to hope that finally there is the possibility of supplementing subjective psychological tests for early diagnosis and monitoring of Alzheimer's disease progression and treatment with new, this time objective kind of electroneurophysiological tests.

ADPD5-1564
BRAIN-ENRICHED MICRORNAS CIRCULATING IN PLASMA AS BIOMARKERS FOR MILD COGNITIVE IMPAIRMENT, ALZHEIMER'S AND PARKINSON'S DISEASES

S. Umansky[1], K. Sheinerman[1], V. Tsivinsky[1], A. Keegan[2], F. Crawford[2]
[1]Not applicable, Diamir LLC, Princeton, USA
[2]Not applicable, Roskamp Institute, Sarasota, USA

Objectives: There is a great need in an accurate and minimally invasive assay for early detection and differentiation of neurodegenerative diseases. We will present analysis of plasma levels of brain-enriched microRNA biomarker pairs comprised of (i) microRNA enriched in brain regions affected by the pathology (hippocampus in AD, midbrain or frontal cortex in PD) and present in neurites and synapses, and (ii) microRNA enriched in brain regions/cells not involved in the pathology.
Methods: Plasma levels of pre-selected microRNAs are measured by individual RT-qPCR; statistical analysis is performed as described in Sheinerman, Aging 2013, 5:12. Clinical data and plasma samples of PD patients and healthy controls used in the present work include those obtained from the BioFIND Study.
Results: Independent cohorts of plasma samples from PD, MCI, and AD patients and healthy controls have been analyzed. Correlation between levels of microRNAs in plasma was considered in selection of effective microRNA biomarker pairs. Differentiation of MCI and AD from PD and of MCI and PD from control by selected microRNA pairs with up to 95% to 100% accuracy has been achieved.
Conclusions: The analysis of brain-enriched circulating cell-free microRNAs as biomarkers for detection and differentiation of neurodegenerative diseases demonstrates validity of this approach, which could also be complementary to neuroimaging and CSF biomarkers.
This work is supported in part by grants from the NIH/NIA and The Michael Fox Foundation for Parkinson's Research. BioFIND is funded by The Michael Fox Foundation for Parkinson's Research and the National Institute Neurological Disorders and Stroke.

MAGNETIC-NANOPARTICLE-BASED ULTRA-HIGH-SENSITIVITY QUANTITATIVE DETECTIONS OF PLASMA A-BEAT-40, A-BETA-42, AND TAU PROTEIN FOR DIFFERENTIATING MILD COGNITION IMPAIRMENT FROM EARLY-STAGE ALZHEIMER'S DISEASE

E. Yang[1], S.Y. Yang[1], M.J. Chiu[2], H.E. Horng[3], D.F. Chen[2], Y.K. Tzen[4]
[1]R&D, MagQu Co. Ltd., New Taipei City, Taiwan
[2]Department of Neurology, National Taiwan University Hospital, Taipei, Taiwan
[3]Institute of Electro-optics, National Taiwan Normal University, Taipei, Taiwan
[4]Nuclear Medicine, National Taiwan University Hospital, Taipei, Taiwan

Magnetic nanoparticles biofunctionalized with antibodies against A-beta-40, A-beta-42, and tau protein, which are promising biomarkers related to Alzheimer's disease (AD), were synthesized. We characterized the size distribution, saturated magnetizations, and stability of the magnetic nanoparticles conjugated with antibodies. In combination with immunomagnetic reduction technology, it is demonstrated such biofunctionalized magnetic nanoparticles are able to label A-beta-40/-42 and tau protein specifically. The ultra-low-detection limits of assaying A-beta-40/-42 and tau protein *in vitro* using the magnetic nanoparticles via immunomagnetic reduction are determined to a concentration of ~10 pg/mL. Further, immunomagnetic reduction signals of A-beta-40/-42 and tau protein in human plasma from normal samples and patients with mild cognition impairment due to AD and early-stage AD were analyzed, and the results showed a significant difference between these three groups. These results show the feasibility of using antibody-functionalized magnetic nanoparticles as reagents for assaying low-concentration A-beta-40/-42 and tau protein through immunomagnetic reduction, and also provide a promising new method for early diagnosis of mild cognition impairment due to AD and early-stage Alzheimer's disease from human blood plasma.

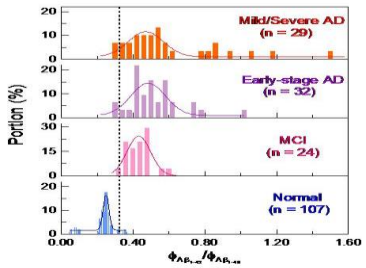

Fig. 1. Statistic results of the ratio of plasma A-beta-42 to A-beta-40 for normal controls and patients.

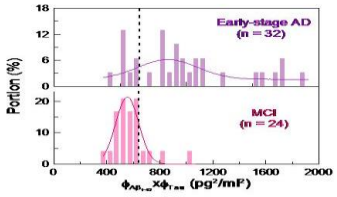

Fig. 2. Statistic results of the products of plasma A-beta-42 and tau protein for patients with mild cognition impairment due to AD and early-stage AD.

ADPD5-1719

INTEREST OF CSF HYPOCRETIN-1 LEVEL IN AN EARLY STAGE OF ALZHEIMER DISEASE.

A. Gabelle[1], S. Lehmann[2], I. Jaussent[3], Y. Dauvilliers[4]
[1]Neurologie, CHRU Gui de Chauliac Montpellier, montpellier, France
[2]Biologie, IRB INSERM U1040, montpellier, France
[3]Epidémiologie, INSERM U1061, montpellier, France
[4]Neurologie, CHRU Gui de Chauliac, montpellier, France

Objective: To study cerebrospinal fluid (CSF) Alzheimer' disease (AD) biomarkers and hypocretin-1 levels relationships in patients with cognitive troubles including patients in an early stage of AD patients and hypocretin-deficient narcolepsy-cataplexy (NC) diagnostic accuracy.
Methods: Ninety-one cognitive patients (37 AD, 16 mild cognitive impairment (MCI due to AD), 38 others dementia) and 15 old patients with NC were recruited. Diagnoses were performed blinded with CSF results. CSF Ab_{42}, total Tau, Phospho-Tau_{181}, hypocretin-1 were measured.
Results: A higher hypocretin-1 levels were found in MCI due to AD patients compared to other dementias. CSF hypocretin-1 was significantly and independently associated with AD/MCI due to AD with an OR of 2.70 after full-adjustment, greater than $A\beta_{42}$. A positive correlation was reported between $A\beta_{42}$ and hypocretin-1 levels ($r=0.43$, $p=0.001$) in the AD/MCI due to AD group only. No association was found between sleep problems and any of CSF biomarkers. None of patients with NC achieved pathological cut-offs of $A\beta_{42}$, with respectively one and four patients with NC above Tau and P-Tau cut-offs, without any correlation between hypocretin-1 and other biomarkers.
Conclusions: Our results suggest a pathophysiological relationship between $A\beta_{42}$ and hypocretin-1 in AD process especially in an early stage of the disease. Further longitudinal studies are required to validate these biomarker interactions, and to precise the cause-effect relationship and the role of wake/sleep behaviour in the regulation of the amyloid plaque formation.

SACCADIC EYE MOVEMENTS IN ALZHEIMER´S DISEASE
P. Walecki[1], K. Pasgreta[2], E.J. Gorzelanczyk[2], M. Kunc[3]
[1]Department of Bioinformatics and Telemedicine,
Jagiellonian University Medical College, Krakow, Poland
[2]Department of Theoretical Basis of Bio-Medical Sciences and Medical Informatics,
Collegium Medicum of Nicolaus Copernicus University in Torun, Bydgoszcz, Poland
[3]Airedale NHS Trust Steeton, University of Leeds, Leeds, United Kingdom

Introduction: There are abnormalities in eye movements in individuals with Alzheimer´s disease,
which are related to oculomotor frontal-subcortical circuit dysfunctions.
Objectives and aims: The aim of the study is to compare the parameters of saccadic eye movements in individuals with Alzheimer´s disease with those in older adults without dementia.
Methods: 31 individuals with mild and intermediate Alzheimer´s dementia (AD) (MMSE> 13) (26
women, mean age 76.8 ± 6.41 and 5 men, mean age 79.1 ± 5.21) and 30 individuals without
symptoms of dementia (matched for age) were examined.
The parameters of saccadic eye movements were measured with the use of Saccadometer Advanced.
Two experiments were performed: Latency Trials (LAT) and Reflexive with Gap (RXG). Saccadic
latency [ms], promptness [Hz], duration [ms], amplitude [deg], peak velocity [deg/s] and the number of executed saccades were measured.
Results: Statistically significant differences in the number of saccades (p = 0.000024), latency (p = 0.039), promptess (p=0,01), duration (p = 0.000035) between patients with AD and control group.
Conclusions: It was found that the level of oculomotor efficiency in mild and intermediate Alzheimer´s disease is significantly lower in relation to older people without dementia.

INFORMANTS ARE BETTER IN DISTINGUISHING BETWEEN SMC AND MCI IN MCNAIR FREQUENCY OF FORGETTING QUESTIONNAIRE. FINDINGS FROM CZECH BRAIN AGING STUDY.

D. Hudecek[1], K. Sheardova[1], O. Hromkova[1], R. Marciniak[1], M. Urbanova[1], B. Dvorakova[1], M. Vyhnalek[1], J. Laczo[1], J. Hort[1]

[1]Neuro 2 programme, ICRC St. Anne´s University Hospital, Brno, Czech Republic

Objectives: Subjective memory complaints (SMC) and Mild cognitive impairment (MCI) as pre-dementia stages of cognitive decline could be diagnosed and differentiate by using clinical examination, neuropsychological cognitive evaluation and subjective memory questionnaires. McNair Frequency of Forgetting Questionnaire (MFFQ) is one of the instruments, which are used in this field. MFFQ consists of two identical lists of possible memory failures, first for participants and second for informants.
We tried to find out which part of MFFQ is more sensitive for distinguishing between SMC and MCI.
Methods: Subjects, participants of Czech Brain Aging Study (CBAS), were examined at the Memory Center ICRC, St. Anne´s University Hospital Brno. They underwent clinical examination, neuropsychological testing and self-assessment, including MFFQ. Results acquired from both parts of MFFQ were compared to neuropsychological conslusions.
Results: 151 subjects, with memory complaints were examined, during the year 2013 and 2014. Difference in MFFQ scores between subjects and informants was 9,25 points and was stastically significant. Informants discriminated good between SMC and MCI (stastically significant difference in MFFQ scores), while subjects themselves not.
Conslusion: Subjects showed overestimation in self-assessment of memory impairment and their evaluation was not able to discriminate between SMC and MCI. In opposite, informants distinguished these stages successfully.

ADPD5-1952

RELATIONSHIP BETWEEN EEG POWER AND EARLY DIAGNOSIS AND COGNITIVE FUNCTION OF ALZHEIMER'S DISEASE AND VASCULAR DEMENTIA

Q. Xu[1], W. Xu[1], Y. Zhang[1], Q. Du[1], C. Lu[1], X. Jiang[1], Y. Wu[1], J. Zhu[1], P. Li[1], C. Jin[1]
[1]Department of Geriatric Psychiatry,
Wuxi Mental Health Center Affiliated to Nanjing Medical University, Wuxi, China

Objective: To explore the relationship between electroencephalography (EEG) power and early diagnosis and cognitive function of Alzheimer's disease (AD) and vascular dementia (VaD) in a Han Chinese.
Methods: 30 AD patients, 30 VaD patients and 30 healthy controls were recruited in the present study. All participants were measured and evaluated using quantitative EEG and visual EEG. We recorded all four wave frequencies including δ (0.8-4.0Hz), θ (4.0-7.8Hz), α (7.8-12.8Hz) and β (13.0-20.0Hz) from different brain regions, and calculated the value of δ+θ/α+β as the final evaluation index. The differences in δ+θ/α+β ratio and EEG scores were analyzed among three groups.
Results: The value of δ+θ/α+β and EEG scores were significantly increased in AD patients group compared with healthy controls in the measured brain regions ($P < 0.05$). Additionally, the similar consistent results were also observed in VaD patients compared with healthy controls, except for right temporal lobe and right central regions ($P < 0.05$). Importantly, δ+θ/α+β ratios in left hemisphere were significantly higher to those in opposite regions of right hemisphere in VaD group compared with AD or control group. Moreover, we found that MMSE scores were negatively related to δ+θ/α+β ratio and EEG scores in AD or VaD groups (all $P < 0.05$).
Conclusions: The present study suggested that quantitative EEG may contribute to early diagnosis for AD or VaD, and it may be an effective method for distinguish AD and VaD.

ADPD5-1969
CATEGORIZATION PROCESSES IN MILD AND MODERATE STAGES OF ALZHEIMER DISEASE

C. Mello[1], V. Duarte[2], O.F.A. Bueno[2]
[1]Educaçao e Saude, UNIFESP, Sao Paulo, Brazil
[2]Psychobiology, UNIFESP, Sao Paulo, Brazil

The concept that the progression of Alzheimer's disease (AD) leads to a sequence of cognitive losses corresponding to the inverse order of the normal sequence of ontogenetic cognitive acquisition is called retrogenesis. In this way, specific developmental markers would contribute to identify early changes in cognitive losses. Semantic memory processes, one of the first systems impaired in AD, develop progressively in typical development. Children become more able to associate semantic related stimuli in more complex, taxonomic, ways. Objective: In this study, we investigated if AD-related deterioration of semantic memory involves a decrease in categorization skills with progression of the disease, according to the retrogenesis hypothesis. Methods: We compared the performance of AD patients at mild and moderate stages, and of groups of 7, 10 and 14-year-old children in tasks of free association of semantically related stimuli. Results: ANOVAS showed a decrease in taxonomic associations and an increase in diffuse associations between mild and moderate stages, corresponding to the inverse order shown by children groups. At the moderate AD stage, the pattern was similar to that of 7-year-old children. Conclusions: These results corroborate the hypothesis of an involution of the processes of semantic processes in the course of the disease. The identification of the early cognitive signs of the progression of Alzheimer's disease (AD) may contribute to early interventions.

[7]Statistics, SAIL Statistics, Barcelona, Spain

[8]Clinical Research Program, Pasqual Maragall Foundation, Barcelona, Spain

Objective: To describe normative data of a Spanish version of the Memory Binding Test (MBT), a novel test that has been developed with the aim to detect pre-symptomatic memory impairment suggestive of Alzheimer's disease. ***Method:*** Participants were 472 healthy and cognitively unimpaired subjects, 45 to 65 years old. Raw scores of the variables of the test were transformed to scaled scores (SS) on which multivariate regression analysis was applied adjusting by age, gender and education level. A standard linear regression was employed to derive the scaled score adjusted (SSA). Sociodemographic corrections were applied when needed and an adjustment table was constructed. ***Results:*** The performance of the subjects was heterogeneously influenced by sociodemographic factors. Mainly, age influenced negatively the free recall. Education had an overall effect in the performance of the test, resulting in lower performance with lower education level. Women outperformed men especially in the initial learning, influencing the results in some subsequent variables. The only variables unaffected by sociodemographic factors were those related to semantic proactive interference (SPI) and to the retention of learned material. Our results shown that, a certain level of vulnerability to SPI is within the psychometrically normal range, independently of any sociodemographic variable. Regarding retention, close to 100% of the learnt material was maintained across the delay interval. ***Conclusion:*** This study describes normative data for the MBT providing the necessary adjustments for sociodemographic characteristics. This data may prove to be useful for detecting asymptomatic at risk candidates for secondary prevention studies of AD.

SFIDA – PLATFORM TECHNOLOGY FOR EARLY DIAGNOSTICS OF PROTEIN MISFOLDING DISEASES

O. Bannach[1], T. Bujnicki[1], Y. Herrmann[1], M. Hülsemann[1], K. Kühbach[1], A. Kulawik[1], K. Kravchenko[1], K. Wang[1], C. Zafiu[1], D. Willbold[1]
[1]ICS-6, Forschungszentrum Jülich, Jülich, Germany

Protein misfolding is a common hallmark of many neurodegenerative diseases such as Alzheimer's disease (AD), Parkinson's disease (PD) and prion diseases. Mounting evidence argues that especially smaller aggregates, so called oligomers, are the pathological culprits in these proteinopathies. Therefore these oligomers might be the most direct and reliable biomarker of the respective disorder. To quantify oligomers in body fluids like blood plasma and cerebrospinal fluid (CSF), however, two major technical challenges have to be addressed: i) the extremely low concentration of oligomers and ii) the ubiquitous presence of an excess of monomers.
We have developed a method designated sFIDA (surface-based fluorescence intensity distribution analysis) for detecting single oligomers of amyloid beta, alpha-synuclein and prion protein, respectively. In sFIDA, protein aggregates are fixed on a capture-coated glass surface and loaded with at least two antibodies carrying two different fluorescence dyes. Single protein aggregates are detected by high-resolution imaging like laser scanning and total internal reflection fluorescence microscopy. The use of the same epitope for capturing and probing renders the assay insensitive against monomeric proteins. By sFIDA analysis of CSF samples, a small cohort of AD-affected patients could be distinguished from an age-matched control group.
Here we present recent advancements of the sFIDA technology including application of standard molecules for calibration and quantification, assay automatization as well as novel data obtained on patient samples. The sFIDA assay will be employed for biomarker-based monitoring of therapeutic success in drug trials and further adapted for differential diagnostics of other protein misfolding diseases.

TARGETING THE GENERATION OF MONOCLONAL ANTIBODIES TO PROTEIN POST TRANSLATIONAL MODIFICATIONS IN THE DIAGNOSIS OF ALZHEIMER DISEASE

R. Kascsak[1], C. Chen[1], H. Hong[1], V. Sapienza[1], R.J. Kascsak[1]
[1]Monoclonal Antibody Facility, New York State Institute for Basic Research, New York, USA

I It has become increasingly clear that post translational modifications of two key proteins, beta amyloid and tau, play a major role in the neurodegeneration process in Alzheimer disease. The IBR Monoclonal Antibody Facility has for many years focused on the generation of mAbs to these two proteins for diagnostic and therapeutic intervention in this disease. In the past, focus has been placed on the production of mAbs to either linear or conformational epitopes of these proteins. It has become increasingly clear that the post translational modifications of these proteins play a key role in the modulating the progression of disease and should be our immunogenic targets. Hybridoma clones have been generated to several pyroglutamate modified sites on beta amyloid and also to several phosphorylation modified sites on tau. Several strategies for the generation of these hybridomas were employed. One highly successful approach was the process of inducing tolerance in newborn mice to the non-modified immunogen followed by immunizatioin of these mice as weanlings with the modified form of the same protein. These monoclonal antibodies which will be discussed in our presentation have the ability to detect diagnostic biomarkers as well as the potential to serve as therapeutic tools.

ADPD5-2101

ALZHEIMER'S DISEASE OUTPATIENT REFERRALS TO A DEMENTIA CENTRE: DIAGNOSTIC CHALLENGES

I. Dimitrov[1], A. Kaprelyan[2], N. Usheva[3], B. Ivanov[4]
[1]Dept. of Nursing, Medical University Varna Sliven Affiliate, Varna, Bulgaria
[2]Dept. of Neurology, Medical University Varna, Varna, Bulgaria
[3]Dept. of Social Medicine and Health Care Organization, Medical University Varna, Varna, Bulgaria
[4]Dept. of Clinical Medical Sciences, Medical University Varna, Varna, Bulgaria

Objectives: For the last several years, since partial reimbursement for acetylcholinesterase inhibitors and memantine has been introduced in Bulgaria for AD cases, referrals from general practitioners and neurologists to university hospital based dementia centers have increased. According to the National health insurance fund, only patients with probable AD according to NINDS-ADRDA criteria are eligible for reimbursement. Nevertheless, patients with significant other disorders which could cause cognitive impairment, who do not conform to the criteria, are often sent for administration of treatment with a diagnosis of AD. The objective of our study is to reevaluate cases of outpatients who have been referred with a diagnosis of AD and assessed at the dementia center of First neurology clinic, Sveta Marina university hospital in Varna, Bulgaria, for a one-year period, and point out the main diagnostic challenges faced by referring physicians.
Methods: Retrospective review of medical records.
Results: A total of 150 records were identified. Repeat visits were not counted. Eighty-six cases (57.3%) were compliant with NINCDS-ADRDA criteria for probable AD, and 52 (34.7%) for possible. Twelve patients were classified as not having AD, cognitive decline being due to vascular or psychiatric disorders.
Discussion: Even if AD is the most prevalent among dementing disorders, it may be a difficult diagnosis to establish, especially in cases with comorbidities. Further training on AD diagnosis, differential diagnosis and respective criteria could be useful for physicians who manage AD outpatients in our region, in order to improve diagnostic accuracy.

ADPD5-2117

A COMPARATIVE ANALYSIS OF A NOVEL PSYCHOMETRIC TOOL FOR ALZHEIMER'S DEMENTIA WITH THE MODIFIED ADAS-COG

V.P. Grewal[1]

[1], *Windsor University School of Medicine, Houston, USA*

Objectives:

To examine the accuracy of the Montreal Cognitive Assessment (MoCA) in evaluating Alzheimer's Disease (AD) and Mild Cognitive Impairment (MCI).

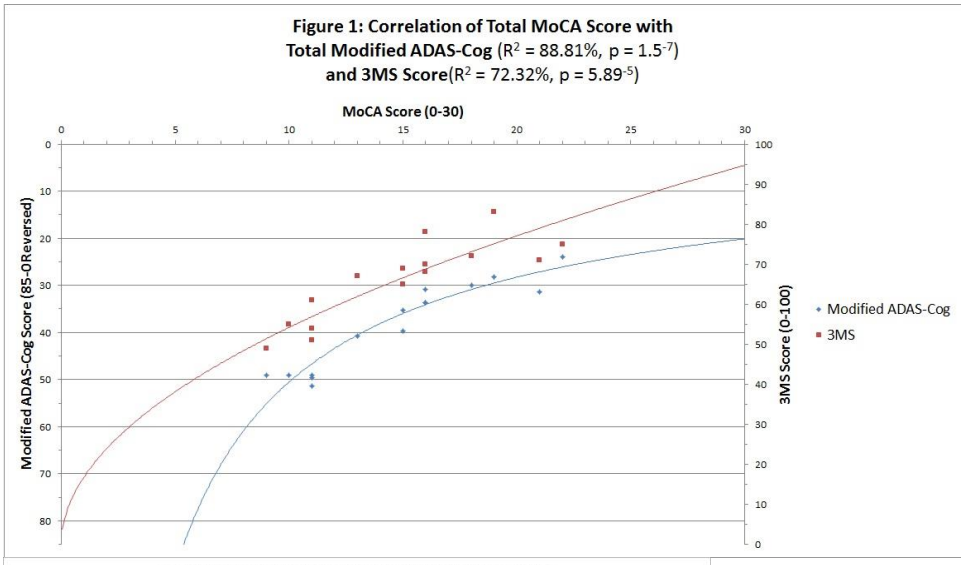
Methods:

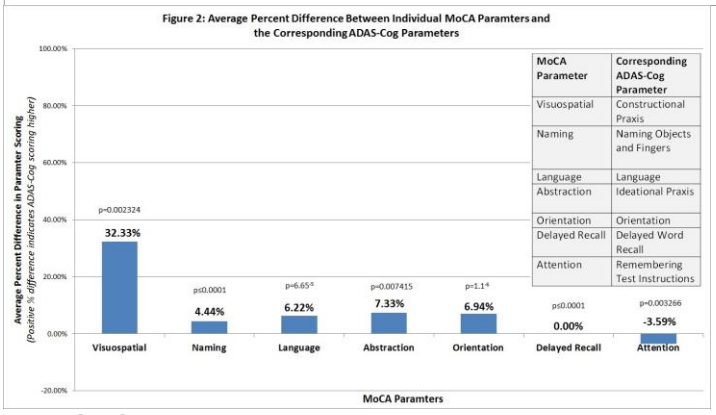
A sample of 15 patients in a dementia facility in Texas, were selected based on a clinical diagnosis of AD or MCI. Patients averaged 83.3 (SD=4.8) years of age.

A Modified Mini-Mental (3-MS) score of ≤ 85 and ≥ 48 was used as an inclusion guideline. MoCA was then administered, followed by Modified ADAS-cog. The sample had a mean 3-MS score of 65.9 (SD=10.0), MoCA score of 14.9 (SD=4.0), and ADAS-Cog score of 38.4 (SD=9.2).

The individual parameters of the MoCA and ADAS-cog were converted into a percentage, and corresponding parameters were compared.

Results:





Conclusion:

The use of formal mental status testing by primary care practitioners for diagnosing dementia was estimated to be only 58%, with the main reported barrier being a lack of time.

The MoCA correlated significantly with both the 3-MS and ADAS-Cog ($p<0.001$), and all individual parameters had a statistically significant correlation with the ADAS-Cog parameters ($p\leq0.01$).
The relative ease of MoCA administration, may allow it to serve as an adequate assessment tool of dementia for primary care practitioners.

ADPD5-2134

ILLITERACY AND LOW SCHOOLING: IMPACT ON COGNITIVE TEST SCORES

M. Yassuda[1], L. Cassimiro[1], P. Pellegrino[2], R. Nitrini[1]
[1]Neurology, University of São Paulo, Sao Paulo, Brazil
[2]Geriatrics, Paulista Institute of Geriatrics and Gerontology (IPGG), Sao Paulo, Brazil

Schooling significantly impacts cognitive performance and is usually regarded as a proxy measure of cognitive reserve. The effect of illiteracy and minimum schooling on cognition is poorly understood. Objectives: To investigate the impact of illiteracy and low schooling on a set of cognitive tests commonly used in dementia diagnosis.
Methods: 164 non-demented community-dwelling women - 60 were illiterate, 52 had 1-2 years of schooling and 52 had 3-4 years of schooling - were assessed in an outpatient geriatric facility with the Mini Mental State Examination (MMSE), Brief Cognitive Screening Battery (BCSB) – episodic memory test of 10 pictures of common objects (Incidental, Immediate and Delayed Recall), Verbal Fluency animal category (VF), Clock Drawing Test (CDT), Digit Span Forward and Backward (DSF, DSB), Raven´s Coloured Progressive Matrices (CPM), Wisconsin Card Sorting Test (WCST).
Results: The groups were equivalent as to age, number of diseases, medications taken daily, depression and anxiety symptoms (Table 1). There were schooling effects in all tests with the exception of the BCSB memory test. For FV, CDT, CPM, DSB and number of categories completed in the WCST, illiterates and those with 1-2 years of schooling had equivalent scores but lower than those with 3-4 years. For the MMSE, DSF and the other WCST parameters, minimum schooling generated higher scores (Table 2).
Conclusions: Minimum schooling generates a significant increase in cognitive test scores. The BCSB memory test does not seem to be influenced by schooling and could be recommended for cognitive screening among seniors with heterogeneous educational backgrounds.

Table 1 – Characteristics of the sample stratified in levels of schooling (N = 164)

Variables	Illiterates		1-2 years		3-4 years		
	Median	25/75 percentile	Median	25/75 percentile	Median	25/75 percentile	p value*
Age	70	(67-73)	69	(68-72,5)	70	(66,5-73)	0,940
Number of diseases	3	(3-4)	3	(2-4)	3	(2-4)	0,145

The impact of genetic risk loci in Parkinson's disease on age at onset

C.M. Lill[1], J. Hansen[2,3], T. Liu[4], J.H. Olsen[2], B. Ritz[3], L. Bertram[1,5]
[1]Platform for Genome Analytics,
Institutes of Neurogenetics & Integrative and Experimental Genomics,
University of Lübeck, Lübeck, Germany
[2]Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark
[3]Dept. of Epidemiology and Environmental Sciences, School of Public Health,
University of California, Los Angeles, California, USA
[4]Max Planck Institute for Human Development, Berlin, Germany
[5]School of Public Health, Faculty of Medicine, The Imperial College of Science,
Technology, and Medicine, London, UK

Genome-wide association studies (GWAS) in Parkinson's disease (PD) have identified 27 independent loci associated with disease risk. The aim of the current study was to assess whether the polymorphisms associated with PD risk also explain age at onset (AAO) variability in PD patients. To this end, we genotyped 24 independent single nucleotide polymorphisms (SNPs) in a sample of 1,526 well-characterized Danish patients with idiopathic PD and tested for association with AAO. Statistical analyses were based on single and multi locus models. The latter entailed constructing a weighted genetic risk score (wGRS) for each individual. The most significant single locus finding was observed with SNP rs12726330 (located in the GBA [glucosidase, beta, acid] locus). Carriers of the minor allele of this SNP on average showed a reduction in onset age of 3.5 years per risk allele (beta = -3.536, p = 3.2 x10-5). In addition, carriers of the risk allele of SNP rs34311866 (located in the TMEM175/GAK locus) also showed a significantly earlier PD onset age (beta = -1.199, p = 3.8 x10-3). No other nominal AAO associations were observed in the single locus analyses. Combining all tested risk alleles in the wGRS showed significant association with reduced AAO (p = 1.9x10-4), although the variance in AAO explained by the wGRS was small (0.8%). Overall, our study shows that genetic variation in two PD risk loci, i.e. GBA and TMEM175/GAK, also significantly alter AAO in PD, while, in this sample, the cumulative impact of the currently known risk loci only make a minor contribution to AAO variability.

PREPARATION OF DNA APTAMERS THAT SPECIFICALLY RECOGNIZE HIGHER-ORDER ABETA STRUCTURES

K.M. Nelson[1], S. Sreevatsan[2], K.H. Ashe[3], M.A. Walters[1]
[1]Institute for Therapeutics Discovery and Development, University of Minnesota, Minneapolis, USA
[2]Department of Veterinary Population Medicine, University of Minnesota, Minneapolis, USA
[3]N. Bud Grossman Center for Memory Research and Care, University of Minnesota, Minneapolis, USA

Objectives: Alzheimer's disease (AD) is the most common neurodegenerative disorder worldwide, characterized by the hallmark accumulation of neurotoxic oligomers and fibrils of the amyloid-beta peptide (Abeta). While it is accepted that oligomers are more neurotoxic than fibrils, *typical immunohistochemcial methods used to characterize Abeta oligomers are not entirely reliable*. The development of more accurate, reliable reagents for detecting and identifying Abeta oligomers is critical to the study of the pathogenesis of AD.
Methods: Following literature precedence, we have prepared two Abeta fibrils that contain structural motifs that may be present in Abeta oligomers: in-register parallel or antiparallel beta-sheets. We will use these structures as templates for the development of DNA aptamers, single-stranded oligonucleotides that can selectively recognize structural variants of proteins. We will use solid state NMR to decipher the structural basis for the binding of the aptamers to the two types of fibrils.
Results: Two distinct quaternary structures of Abeta have been produced and validated using biophysical techniques. These structures have been used as templates for DNA aptamer development. Sensitivity and selectivity data will be presented.
Conclusions: We have used stable, structurally defined, Abeta fibrils to begin developing a toolkit of DNA aptamers that bind selectively to different classes of Abeta assemblies. This toolkit may be used to probe the quaternary structure of Abeta oligomers in humans with AD and transgenic mice that model AD. Structure-specific aptamers may provide mechanistic insights into the neurotoxicity of Abeta oligomers, aiding the development of diagnostic tools and therapeutic reagents.

Abeta+	n	14	31	11			
	CSF Abeta level (pg/mL)	436±75	411±98	439±83			
	Hippocampus (mm^3)	3620±594	3258±566	2740±430	.003	.000	.009
	Amygdala (mm^3)	1422±264	1329±240	1157±187	.019	.002	.077
Abeta-	n	62	22	1			
	CSF Abeta level (pg/mL)	940±240	675±97	633	.000		

Conclusions. A specific ApoE4 dose effect is associated with decreased of CSF Abeta level and of several subcortical volumes in MCI patients. ApoE4 genotype and abnormal CSF Abeta level seems to act synergistically to increase volume loss in the hippocampus and amygdala.

ADPD5-0365

DIFFERENCES OF DEPRESSION SYMPTOMS IN PATIENTS WITH EARLY-ONSET ALZHEIMER'S DISEASE BY WHITE MATTER HYPERINTENSITIES

Y. Kim[1], B. Yoon[1], K. Lee[1], S. Na[1], Y. Shim[2], D. Yang[3]
[1]Department of Neurology, Konyang University, Daejeon, Korea
[2]Department of Neurology,
Bucheon St. Mary's Hospital College of Medicine The Catholic University of Korea, Bucheon, Korea
[3]Department of Neurology,
Seoul St. Mary's Hospital College of Medicine The Catholic University of Korea, Seoul, Korea

Depression which is frequently combined with dementia shows higher incidence in early-onset Alzheimer's disease (EOAD) than late-onset AD. It has hypothesized that vascular component or small vessel disease influence depression. However, the influence on EOAD remains uncertain. We investigated the differences in incidence and characteristics of depression by white matter hyperintensities (WMHs) in EOAD patients.

We enrolled 412 EOAD patients. The 15-item Korean version Geriatric Depression Scale (GDS-15) was administered to 412 subjects. We subdivided into mild WMHs (353, 85.7%) and moderate WMHs (59, 14.3%) groups by visual rating scale. Factor analysis was used to assess GDS-15 factor structure. We compared the incidences of individual GDS-15 items between two groups.

Mean age, scores of K-MMSE, CDR were 58.4 years(SD 5.1), 18.8(SD 5.0), and 0.9(SD 0.5). There was no statistical differences in mean scores of GDS-15 (mild 6.1±4.4 vs moderate 7.1±4.7;P=0.75) and incidence of depression by cut-off value (mild 38.4% vs moderate 48.3%,P=0.326) between 2 groups. Three factors were generated in EOAD, which were hopelessness/negative thoughts (items 6,8,12,14,15), unhappiness/unsatisfaction (items 1,3,5,7,11), and monotony/lack of energy (items 2,4,9,10,13). Regardless of WMHs, items 2,10,13 were reported most frequently. Moderate WMHs demonstrated more empty feeling (item 3,P=0.019), a preference to stay at home (item 9,P=0.042), and loss of energy (item 13,P=0.049).

WMHs severity itself did not influence incidence of depression in EOAD and frequent depressive symptoms were similar. However, moderate WMHs showed trends complaining more depressive symptoms. In particular, based on factor analysis, symptoms related to monotony/lack of energy were significantly increased.

ADPD5-0417

REAL-WORLD EVALUATION OF COMPLIANCE AND PREFERENCE (RECAP) IN ALZHEIMER'S DISEASE: ANALYSIS OF PROSPECTIVE DATA FROM SOUTH KOREA

J. Lee[1], S. Cho[2], B. Kim[3], J. Lee[4], M. Park[4], K. Lee[5]
[1]Neurology, Asan Medical Center, Seoul, Korea
[2]Psychiatry, Gachon University of Gil Hospital, Incheon, Korea
[3]Neurology, Chonnam National University Hospital, Gwangju, Korea
[4]Medical, Novartis Korea, Seoul, Korea
[5]Psychiatry, Inje University Ilsan Paik Hospital, Goyang, Korea

Objectives: To examine caregiver preference and treatment compliance in Korean patients with mild-to-moderate AD under “real-world” settings.
Methods: This was a 24-week prospective, non-interventional, multi-center study. Eligible patients were grouped into two treatment cohorts based on the baseline AD therapy: oral (donepezil, galantamine, memantine, rivastigmine capsule) and transdermal (rivastigmine patch). Primary effectiveness variables were caregiver preference and patient compliance for AD treatment. Secondary variables included physician’s preference for treatment and adverse events.
Results: A total of 398 patients (65.8% women; mean age 76 years) were enrolled in the study, of which 192(48.2%) were in the transdermal therapy cohort. For patients who were exposed to both oral and transdermal therapies, results showed a significant preference by caregivers for transdermal therapy (65.9%) at week 24. Patient compliance (range: 0-10) to treatment was good and similar in both groups at week 24 (mean scores: oral therapy, 8.8; transdermal therapy, 8.9). Of the 15 physicians who participated in the study, eight physicians preferred transdermal therapy at week 24. A total of 133 patients (33.4%) reported at least one adverse event during the study period: 29.1% in the oral cohort and 38.0% in the transdermal cohort. Nausea (1.9%) and depression (1.9%) were most frequent adverse events in the oral cohort and pruritus (9.9%), rash (4.7%), and dizziness (3.6%) were most frequent in the transdermal cohort.
Conclusions: The RECAP study in patients with mild-to-moderate AD showed a caregiver and physician preference and a good patient compliance for transdermal therapy.

ADPD5-1422

INVESTIGATING THE VALUE OF REPEATED MEASURES ANALYSIS IN EVALUATION OF TREATMENT EFFECTS IN SMALLER STUDIES IN ALZHEIMER'S DISEASE

J. Gray[1], W. Barth[2], A. Muhs[2], D. Fleet[3]
[1]R&D, Neuroglobe Ltd, Zug, Switzerland
[2]R&D, ACImmune SA, Lausanne, Switzerland
[3]Statistics, Data Magik Ltd, Salisbury, United Kingdom

1. Objectives:
To examine the usefulness of Repeated Measures Analysis in the evaluation of data from small studies in Alzheimer's disease.

2. Methods
Literature reviews as well as modelling were performed using cognitive data from a double-blind, placebo controlled Phase II study of a putative neuroprotective agent, ACI-91 in 62 patients with mild to moderate probable Alzheimer's disease.
Primary analysis of cognitive/clinical variables used an ANCOVA model at end-point (52 weeks) with log change from baseline as explanatory variable and Treatment as fixed effect, log Baseline as covariate, and Treatment by log Baseline as interaction term. Additionally change from baseline at weeks 12,24,36 and 52 was assessed using a repeated measures mixed model ANCOVA, with Treatment as fixed effect, Baseline as covariate, Time as repeated measure effect and Patient as random effect.

3. Results
Where consistent effects were seem over time, repeated measures analysis highlighted the differences observed. For example, for ADAS-cog-12 in the per protocol population the overall LS mean difference (95% CI) was 3.72 (0.61, 6.83) (p value 0.020) incorporating results at weeks 12,24,36 and 52, compared with an LS mean difference (95% CI) of 3.79 (-1.53, 9.11) for the ANCOVA 52 week analysis (p=0.122).

4. Conclusions
In certain situations the repeated measures analysis can be used to 'add value' to the ANCOVA endpoint analysis. With appropriate caution, this can be used to demonstrate consistency of the treatment effect over time, increasing confidence in the result, increasing the power and thereby significance of the outcome (smaller p value).

ADPD5-1427

A SENSOR-BASED SYSTEM TO SUPPORT DIAGNOSIS AND ASSESSMENT OF PEOPLE WITH DEMENTIA

A. Karakostas[1], T.H. Stavropoulos[1], G. Meditskos[1], T.H. Tsompanidis[1], I. Kompatsiaris[1], M. Tsolaki[2]

[1]Information Technologies Institute, Centre for Research and Technology Hellas, Thessaloniki, Greece

[2]School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

The objective of this research is the development of a complete system providing personal health services to people with dementia, as well as medical professionals and caregivers, by using a multitude of sensors, for context-aware, multi-parametric monitoring of lifestyle, ambient environment, and health parameters.

The system consists of three parts:

1. a group of wearable (physiological, motion) and ambient (audio, video, motion, electric) sensors to record the patients' activities
2. Semantic Interpretation of the recorded data and
3. end-user applications which allow the clinicians to manipulate the sensors and view the results.

The evaluation of the system is conducted in two phases. The first phase involves short-term tests (between 1 to 1 1/2 hours) in Alzheimer' s day care center. 90 participants will be monitored in lab conditions and the goals of this pilot are (a) to provide a brief overview of the participants' health status (cognition, behaviours and function), (c) to assess the system's wearable and ambient technology in aspects such as suitability, accuracy, security, fault tolerance, operability and attractiveness and (c) to correlate the system results with the typical clinical assessment tools. The second phase will be based on the findings of the first phase and will include long-term tests (2-6 months) involving 4 participants in their homes.

Acknowledgment

This work has been supported by the EU FP7 project Dem@Care: Dementia Ambient Care – Multi-Sensing Monitoring for Intelligent Remote Management and Decision Support under contract No. 288199.

THE EFFICACY OF CENTRAL REVIEW MODALITIES IN THE QUALITY CONTROL OF ADAS-COG FOR AD CLINICAL TRIALS

C. Randolph[1], S. Negash[2], P. Böhm[3], L. Garzio[4]
[1]Neurocognition, MedAvante, Hamilton, USA
[2]Penn Memory Center, University of Pennsylvania, Philadelphia, USA
[3]Neurocognition, MedAvante, Munich, Germany
[4]Research, MedAvante, Hamilton, USA

Objectives: Despite the urgent need to find therapies for Alzheimer's disease (AD), the success rate of AD trials has been very limited. One likely contributor to this variability in endpoint measurement within AD trials. It has been reported that the ADAS-Cog, the most widely used endpoint in AD trials, is prone to high error rates that may contribute to unwanted variance (e.g., Shafer et al., 2011). The recognition of these high error rates has led to the use of centralized oversight methodologies to identify and correct scoring errors. The goal of this study was to compare two such approaches: Review of audio recordings of assessments and review of paper source documents alone.
Methods: Aggregated data from 3 double-blind, placebo-controlled AD clinical trials were reviewed. Each trial included assessments using the ADAS-Cog, reviewed via either audio recordings (N = 3,148) or worksheet review alone (N = 2,578). The percentage and rate of errors identified by the two modalities were compared.
Results: There were a higher percentage of assessments that were identified as having at least one error by audio recording review (52%) than by worksheet alone (14%). In addition, the overall rate of errors identified by review of audio recordings was approximately five times higher than those identified by worksheet alone.
Conclusions: Central review of audio recordings of ADAS-Cog administrations is far more effective in identifying scoring errors than review of worksheets alone. The findings are discussed in the context of additional approaches to improving measurement reliability in AD clinical trials.

ADPD5-1524

DISCORDANCE BETWEEN OBJECTIVE AND INFORMANT RATED MEASURES OF COGNITION: RESULTS FROM THE PREDICTORS STUDY

B. Rothman[1], M. Farrell[1], A. Khan[1], S. Cosentino[2], J. Stern[2]
[1]Research & Training, ProPhase LLC, New York City, USA
[2]Neuropsychology, Columbia University, New York City, USA

Background/Objectives: The literature has identified informant report as a valid assessment of patient symptomatology in AD. Despite this, discrepancies in specific areas suggest that informants may be biased by a variety of factors. Little is known about the characteristics of informants that may over or under-report symptoms when compared to objective measures of patient cognitive performance. Our aims were to examine the validity of informant report in the context of a longitudinally dataset and to identify characteristics of informants that predict discordance with objective assessment.
Methods: The sample included participants from the PREDICTORS study, which examined biological/lifestyle markers of AD progression. Informant insight was determined by comparing informant ratings and patient neuropsychological testing results (assessed via bivariate correlation and ANOVAs). Linear regression identified variables associated with informant ratings independent of patient cognition, including: caregiver demographics, time spent with patient, burden, caregiving satisfaction, caregiver-rated patient depression, and presence of cognitive complaint.
Results: Informant-rated cognitive impairment moderately correlated with objective measures ($r = 0.25$, $p < .05$). Notably, 20% of informants denied memory deficit in a population with known AD. Higher informant-rated impairment was associated with higher burden, lower caregiver satisfaction, and higher caregiver-rated patient depression. These variables were more strongly associated with informant ratings than patient cognitive performance.
Conclusions: These results challenge the notion of informant report as a gold score in clinical trials for AD, and underscore the importance of examining the integrity of informant ratings and the characteristics of informants prior to accepting their reports at face value.

METHODOLOGICAL PROCEDURES IN CLINICAL REHABILITATION OF ALZHEIMER'S DISEASE PATIENTS

V. Vieira[1], S.M.D. Bruck[1], A.L.C.M. Martins[1], M.O. Oliveira[1], L.G. Vasconcelos[1], F. Canali[1], B.G.S. Bittencurt[1], L.J.T. Leite[1], P.H.F. Bertolucci[1], O.F.A. Bueno[1]
[1]Psychobiology, Federal University of Sao Paulo, Sao Paulo, Brazil

Introduction: longitudinal studies of cognitive aging enable detection of the initial stages of Alzheimer's disease (AD), in which intact cognitive abilities and potentialities are being found, thus supporting the development of methodology for non-pharmacological intervention in the early stages.

Objective: Present a clinical rehabilitation program focusing on family guidance and introducing compensatory strategies, thus enabling maintenance of functionality, diminished psychiatric symptoms, and enhanced quality of life for patients and caregivers.

Methodology: 12 patients (6 female), average age 75.42 (06.22), and 9:58 (5.6) years of schooling. Fulfilled NINCDS / ADRDA criteria and were taking maximum anticholinesterase dose. Cognitive profile was evaluated using MMSE, ADAS-Cog, Wechsler Memory (Information and Orientation), Personal Data and Temporal Orientation. Caregivers responded to the NPI and Functional Activities Questionnaire (FAQ). After Initial testing (T1), retesting after 8 months of rehabilitation program (T2). Comprised two sessions per week and Family Guidance every fortnight. Techniques used: Reduced clues, spaced learning, reminiscence therapy, and reality orientation, guided by errorless learning. Patients filled out Personal Data (PD) and Temporal Orientation (TO) every day. **Results**: MMSE (T1: 23.25 (1.82)/ T2: 23.42(2.81); ADAS-Cog (T1: 17.11 (6.73)/ T2: 2.21 (8.59), WMS Information (T1: 4.33(1.89)/T2: 4,58(1,73); WMS Orientation (T1: 3,75(1,29)/T2: 3,67(0,89); DP-StreetT1: 3,00(0,00)/T2: 2.92 (0.29); District T1: 3,00(0,00)/T2: 3,00(0,00);TelephoneT1: 2.75(062)/T2: 2.75 (0.62), NPI-(T1: 23.42(23.38)/T2: 19.83(17.73); FAQ-(T1: 10.67(7.24)/ T2: 13.92(6.92).

Conclusion: These results show that external supports adapted to patients conditions may help maintain functionality for longer periods when introduced in the initial phase of the disease.

ADPD5-2302
ARE PEOPLE WITH DEMENTIA AND THEIR CARERS HAPPY FOR RESEARCHERS TO ACCESS ELECTRONIC HEALTH RECORDS TO SCREEN FOR RESEARCH STUDIES?

P. Kotting[1], A. Smith[1], Z. Qadir[1]
[1]Dementia Research Centre, University College London, London, United Kingdom

Identifying suitable patients for clinical studies in dementia is a pressing issue for researchers. Creating registers of people who have given consent to be contacted and for their data to be used to screen them against study criteria has the potential to increase speed of cohort creation, reduce costs and increase equality of access to clinical research for people with dementia.

Objectives

To investigate whether people with dementia and their carers are willing to give consent for researchers to access their Electronic Health Records (EHR) for the purpose of screening them to assess their suitability to be contacted about specific studies.

Methods

A survey was conducted of the first 310 people registered on the new national dementia consent for approach register in the UK.

Results

124 people (40%) responded to the survey. 115 (93%) responded to the question about EHR data linkage. 67% said they would consent for researchers to access their EHR, 23% were unsure and 10% said they would not provide consent. Of the 'not sure' respondents the primary reason given was that more information was required to make a decision.

Conclusions

The majority of people joining the consent for approach register will consent to researchers accessing their EHR to screen them for studies. Provision of clear information about the use of data will increase consent. Developing links between the UK dementia consent-for-approach register and EHRs will be acceptable to a large majority of potential registrants and increase the value of the register to researchers and patients.

ADPD5-0535

IMPROVEMENT OF INTESTINAL MICROFLORA BY FEEDING OF PREBIOTICS DELAYS ONSET OF LEARNING AND MEMORY DISORDER IN SENESCENCE-ACCELERATED MODEL MICE (SAM)P8

S. Nakamura[1], *K. Tanabe*[2], *T. Oku*[1]
[1]*Institute of Food Nutrition and Health, Jumonji University, Saitama, Japan*
[2]*Graduate School of Human Health Science, University of Nagasaki Siebold, Nagayo, Japan*

Objectives:

Senescence-accelerated mice (SAM) P8 is a model of deflect in learning and memory, emotional disorder and age-related impairment, and resemble to symptoms in human senescence. Gastrointestinal microflora (GIM) changes and harmful microbiota markedly increases in accordance with the host aging. Consecutive ingestion of prebiotics affects antioxidant potentials, anti-inflammation via improvement of GIM. In this study we investigated that daily feeding of prebiotics affects the progressing of senescence and delays the onset of learning and memory disorder via the improvement of GIM using SAMP8.

Method:

We raised 45 male SAMP8 (4 weeks old) and 10 male SAMR1 as normal senescence mice individually until 42 weeks old. SAMP8 were fed 2 kinds of diet; control (AIN93) and replaced sucrose by 5% fructooligosaccharide (FOS). The assessment for the ability of learning and memory was performed using passive avoidance test (PA test). GIM were measured by molecular biological method. Inflammatory cytokines in sera and amyloid-beta concentration in brain were measured using kit, respectively.

Result:

GIM was significantly different and *Bifidobacterium* genus was significantly increased by the feeding of FOS ($p<0.05$). The assessment by PA test was significantly better in FOS group than that in control group ($p<0.05$). Serum TNF alpha, IL-6 and amyloid-beta in brain were significantly lower in FOS group than those in control group ($p<0.05$).

Conclusion:

These results demonstrate that daily intake of prebiotics delays the onset of senescence related symptoms via the improvement of GIM. These findings can contribute to support the treatment and care for senile patients.

ADPD5-1951
MODULATION OF SYNAPTIC COMPLEXITY AND METABOLIC ACTIVITY PREDICTS COGNITIVE DECLINE OR DELAY TO DEMENTIA: A MATHEMATICAL APPROACH

O. Sotolongo-Costa[1], L.M. Gaggero-Sager[1], F. Maestu[2], J.T. Becker[3], O. Sotolongo-Grau[4]
[1]Departamento de Física,
Facultad de Ciencias.Universidad Autónoma del Estado de Morelos, Cuernavaca, Mexico
[2]Laboratory of Cognitive and Computational Neuroscience,
Centre for Biomedical Technology, Madrid, Spain
[3]Department of Psychology Department of Neurology Department of Psychiatry,
School of Medicine University of Pittsburgh, Pittsburgh, USA
[4]Research, Fundació ACE. Institut Català de Neurociències Aplicades ., Barcelona, Spain

Objectives: Aging associated cognitive decline often results in some kind of irreversible dementia. The goal of this work is to generate a simple mathematical description of the process of cognitive decline to dementia. The synthesis and compactness of such a formulation could help to refine and focus models and analyses that need to take into account the multitude of factors associated with normal and pathological cognitive aging.
Methods: We formulate the energetic balance of the functional network to describe the cognition variations as functions of metabolic activity and the new defined 'synaptic complexity', which characterizes the connections between several functional networks.
Results: The model predicts that the neuronal network is exposed to an irreversible fall into poor cognition state due to losses of metabolic activity or synaptic complexity. However, this fall will be delayed if the combination of both variables remains high enough. Even after the irreversible fall occurs a little improvement of cognition could be reached by raising the metabolic activity of the brain.
Conclusions: This is a first catastrophe theory approach to cognitive decline. The cognitive decline appears as irreversible, as a consequence of the involved energy and the loss of synaptic complexity. Two important things emerge from the model. First, any kind of treatment must be applied as soon as possible to avoid the irreversible fall. Second, a combined treatment improving synaptic complexity and metabolic activity must be taken into account in dementia therapy.

RELATIONSHIP BETWEEN HALLUCINATIONS AND DEPRESSION IN ALZHEIMER'S DISEASE
M. El Haj[1], S. Raffard[2], F. Laroi[3], P. Antoine[4]
[1]departement of Psychology, University Lille3, Villeneuve d'Ascq, France
[2]departement of Psychology, University Montpellier3, Montpellier, France
[3]departement of Psychology, University of Liège, Liège, Belgium
[4]departement of Psychology, University of Lille3, Lille, France
Objectives: We investigated links between hallucinations and depression in patients with Alzheimer's Disease (AD).
Method: Thirty participants with probable AD and 32 healthy-older-adults voluntary participated in this study. We assessed the Launay–Slade Hallucination Scale (LSHS, Launay & Slade, 1981), evaluating auditory hallucinations (e.g., "I have been troubled by hearing voices in my head") and visual hallucinations (e.g., "Sometimes, I have seen objects or animals even though there was nothing there"). Participants were also administered The Hospital Anxiety and Depression Scale (HADS, Zigmond & Snaith, 1983), a widely used screening instrument for anxiety and depression in patients with AD. Participants were also administered neuropsychological battery, tapping episodic memory and executive functions.
Results: Hallucinatory experiences were significantly higher in AD participants compared to control participants. AD-related hallucinatory experiences were significantly correlated with depression.
Conclusion: Our outcomes suggest significant relationship between hallucinations and depression in AD, a relationship that is likely to be mediated by affective disturbances.
Keywords: Alzheimer's disease; hallucinations; inhibition

NEURO-COGNITIVE-PSYCHOLOGICAL CHARACTERISTICS OF WANDERING IN PATIENTS WITH DRUG-NAÏVE ALZHEIMER'S DISEASE

Y. Yang[1], J. Kang[1], J. Han[1], D. Kim[1]
[1]Neurology, Seoul Veterans Hospital, Seoul, Korea

Background: Wandering represents one of a major problem occurring in patients with Alzheimer's disease (AD). To find the disproportionate neuropsychological deficit and behavioral psychological symptoms in dementia(BPSD) of AD patients with wandering compared to AD patients without wandering, this study examined the set of neuropsychological tests and caregiver-administered neuropsychiatric inventory (CGA-NPI). **Methods:** Psychotropic-naïve(drug-naïve) probable AD patients with wandering(64) and without wondering(278) were assessed with the Seoul Neuropsychological Screening Battery, which included measures of memory, intelligence, and executive functioning. **Results:** Patients with wandering had lower scores in the Rey-Osterrieth Complex Figure copy, Fist-edge-palm, Alternating hand movement tests compared to patients without wandering. The degree of wandering in AD patients was significantly related with CGA-NPI subdomains of aggression, disinhibition, depression, and delusions. **Conclusions:** This study showed that 1) AD patients with wandering have disproportionately cognitive deficit suggesting frontal and right parietal dysfunctions, 2) wanderings are related with specific BPSD. Considering these results, AD patients with wandering may have specific neuronal anatomic substrates related with pathology of Alzheimer.

A 2.8 YEAR ANALYSIS OF THE PROGRESSION OF AMNESTIC MILD COGNITIVE IMPAIRMENT: CLINICAL RESEARCH CENTER FOR DEMENTIA DATABASE

S. Yoon[1], S. Jo[1], S. Choi[2], K. Park[3], H. Han[4], E. Kim[5], B. Kim[6]
[1]Neurology, Eulji University Hospital, Daejeon, Korea
[2]Neurology, Inha University Hospital, Incheon, Korea
[3]Neurology, Dong-A University Hospital, Pusan, Korea
[4]Neurology, Kwandong University Hospital, Koyang, Korea
[5]Neurology, Pusan University Hospital, Pusan, Korea
[6]Neurology, Chonnam University Hospital, Gwangjoo, Korea

Background & Objectives
Amnestic mild cognitive impairment (a-MCI) is a risk factor of Alzheimer's dementia (AD). Our objectives are to determine which type of a-MCI is more significant in predicting AD conversion, as well as the other important predictors of AD conversion in a-MCI patients.
Methods
We recruited 183 a-MCI patients from the Clinical Research Center for Dementia (CRCD) database, who underwent at least three times annual detailed neuropsychological tests. All patients underwent blood tests and brain MRI, as well as several questionnaires. We defined verbal a-MCI as patients whose verbal memory is impaired but visual memory is intact; and vice versa for visual a-MCI. Additionally, we defined both a-MCI as patients who have deficits in both verbal and visual memory.
Results
We enrolled 43 verbal a-MCI, 44 visual a-MCI, and 96 both a-MCI patients. The mean age was 70 years and the mean MMSE score was 24 $\pm$ 1. More male patients were classified as verbal a-MCI and more female patients as visual a-MCI. Among the 183 a-MCI patients, 60 a-MCI patients (14 verbal a-MCI, 7 visual a-MCI, and 39 both a-MCI) converted to AD and 99 patients remained a-MCI during a 2.8 year follow up period. Twenty-five of the 45 converted a-MCI patients had at least one Apo e 4 allele.
Conclusion
Within 3 years, more than 30% of a-MCI patients converted to AD: most frequently seen in both a-MCI, then verbal a-MCI, and least in visual a-MCI.

MASS SPECTROMETRIC MEASUREMENT OF AMYLOID BETA IN CSF: A CANDIDATE REFERENCE MEASUREMENT PROCEDURE

J. Pannee[1], A. Leinenbach[2], T. Dülffer[2], A. Huber[2], T. Bittner[2], U. Andreassson[1], J. Gobom[1], H. Zetterberg[1], U. Kobold[2], E. Portelius[1], K. Blennow[1]
[1]Psychiatry and Neurochemistry, Neuroscience and Physiology, Mölndal, Sweden
[2]-, Roche Diagnostics GmbH, Penzberg, Germany

Objectives
There is a major need in the Alzheimer's disease (AD) community for an assay that with a high sensitivity, specificity and reproducibly can measure biomarkers with an excellent stability over time. The assays used today are antibody-based and struggling with lot-to-lot variability and matrix effects that influence analyte concentrations depending on sample handling. To overcome the variability and the possible matrix effects that appear with antibody-based amyloid β (Aβ) assays, we have developed an antibody-independent mass spectrometry-based candidate reference measurement procedure (RMP) for $A\beta_{42}$.
Methods
The method uses solid-phase-extraction (SPE) in a 96-well format and differently isotope-labeled $A\beta_{42}$ peptides for calibration in human CSF and as internal standard. Extracted samples were injected on a reversed phase column and analyzed on a high resolution quadrupole-Orbitrap hybrid mass spectrometer.
Results
The candidate RMP method is validated for CSF $A\beta_{42}$ measurements from 150 to 4000 pg/mL with a recovery within 100±15%, intra- and inter-assay imprecision of 5% and 6.4% respectively and an expanded uncertainty of 15.7%.
Conclusion
The candidate RMP will help set the value of CSF $A\beta_{42}$ in a certified reference material, which could be used to harmonize $A\beta_{42}$ assays and facilitate the introduction of cut-off concentrations in clinical practice.

A NORWEGIAN PILOT STUDY OF THE TYM TEST (TEST YOUR MEMORY)

M. Breitve[1], L. Chwiszczuk[2], M. Hynninen[3]
[1]Old age department, Haugesund Sykehus, Haugesund, Norway
[2]Neurological department, Haugesund Sykehus, Haugesund, Norway
[3]Old age psychiatry department / Department of clinical psychiatry, NKS Olaviken / University of Bergen, Bergen, Norway

Background
The elderly population is growing and we need short cognitive instruments to screen for dementia. The widely used MMSE has some limitations and better instruments should be aspired for. The TYM was designed to take minimal operator time to administer, test a reasonable range of cognitive functions, and be sensitive to mild AD.
Aim
The aim of this pilot study was to investigate the sensitivity and specificity of the Norwegian version of TYM (TYM-N), and compared it with MMSE.
Method
Patients (n=16) who were referred to dementia assessment at the neurology department and old age psychiatry department at Haugesund hospital filled out the TYM test, in addition to MMSE. The test results were compared with the final diagnosis based on ICD-10.
Results
Mean age 66.5 y (range 52-89), mean completion time 13.3 minutes (range 6-30), mean score 32.2 point (14-47). Using 42 points as cut off, TYM-N had a specificity of 56 % for AD (64 % positive predictive value). For all cases of dementia the specificity was 100 % (100 % positive predictive value). Sensitivity was 100 %. Interrater reliability was also 100 %.
Conclusion
We found high sensitivity and specificity for detecting dementia or pseudodementia, but lower specificity for AD than in previous studies. The study sample was small, which limits the generalizability of results. TYM may, however, be a good alternative to MMSE as it has the advantage of measuring more cognitive domains, takes short time to administer, and is not influenced by hearing loss.

ADPD5-1874

THE LOAD AND DISTRIBUTION OF AMYLOID-BETA PATHOLOGY IN SUBTYPES OF LEWY BODY DISEASE.

W.D.J. van de Berg[1], D.H. Hepp[1], D.L.E. Vergoossen[1], E. Huisman[1], H.W. Berendse[2], A.W. Lemstra[2], A.J. Rozemuller[3], E.M. Foncke[2]
[1]Anatomy and Neurosciences, VU University Medical Center, Amsterdam, Netherlands
[2]Neurology, VU University Medical Center, Amsterdam, Netherlands
[3]Pathology, VU University Medical Center, Amsterdam, Netherlands

Objectives: Lewy body disease (LBD) is the umbrella term for Dementia with Lewy bodies (DLB), Parkinson's disease (PD) and other related disorders. These movement disorders differ in clinical presentation, but pathologically share the same hallmarks, Lewy body pathology. Concomitant pathology is very common in LBD. The aim of the present study was to determine the load and burden of amyloid-beta (Abeta) plaques and neurofibrillary tangles (NFT) pathology in cortical and subcortical areas in subtypes of Lewy body disease.
Methods: Donors with Lewy body pathology at post-mortem evaluation collected by the Netherlands Brain Bank in the period 1999-2013 were included (n=410). Patients were retrospectively diagnosed according to the current diagnostic criteria. PD(D) patients were categorized further into tremor dominance, no-tremor dominance, early-onset and late-onset subtypes. The prevalence, distribution and burden of Abeta pathology was determined in 9 brain regions using morphometric analysis (n=120). In addition, Thal phases were used to evaluate NFT pathology.
Results: DLB patients had higher Thal phases and higher mean Abeta burden in all investigated areas than PD(D) patients. In contrast, PD, PDD and the other PD subtypes did not differ in mean Abeta burden or Thal phases. Longer disease duration and delay of dementia onset was associated with less Abeta pathology in cortical regions in LBD.
Conclusions: This study suggests that Aβ pathology contributes to differences between DLB and PD(D). Abeta pathology may be involved in the timing of dementia with respect to parkinsonian symptoms and progression of the disease.

01c. Protein Misfolding & Aggregation: alpha-synuclein

MINOR SALIVARY GLAND BIOPSY AS A EARLY PATHOLOGICALLY DIAGNOSTIC TOOL FOR SPORADIC PARKINSON'S DISEASE

T. Feng[1], L.Y. Gao[1]

[1]Department of Neurology, Beijing Tian Tan Hospital Capital Medical University China, Beijing, China

Objective: To confirm the presence of Lewy pathology in the minor salivary glands of Par kinson's disease (PD) patients and evaluate the diagnostic value of minor salivary gland s biopsy for the detection of PD.

Methods: Thirteen PD cases and 13 age-matched controls were recruited. PD patients were evaluated with the Hoehn and Yahr s tage and UPDRS III. We performed immunohistochemical staining for Lewy-type alpha-synucleinopathy in minor salivary glands using antibodies against α-synuclein. All the subjects underwent the 11C-CFT DAT-PET scan.

Results: Abnormal accumulation of α-SYN can be found aroud the gland cells in 9 out of 13 PD patients, but none of the contr ol subjects. We found that the α-SYN inclusions were located in the periacinar space. The 11C-CFT uptake in the caudate, anterior and posterior putamen was reduced at different leve ls in 12 the PD patients, but decreased in only one of the controls. When we compared with the DAT-PET results, the sensitivity, specificity, positive predictive value and negative predictive v alue of our biopsy results were 75%, 100%, 100% and 25% respectively. There was no s ignificant difference between the α-SYN inclusions positive group and α-SYN inclusions negative group when compared mean age, mean age of PD onset, mea n disease duration, mean Hoehn & Yahr stage and mean UPDRS-III total score.

Conclusions: These results suggest that minor salivary glands biopsy may be a feasible biomarker of PD, and it may help us improve the clinical diagnostic accuracy of this dise ase.

MODULATION OF ENDOGENOUS ALPHA-SYNUCLEIN BY SMALL MOLECULES

M. Chermenina[1], E. Chorell[2], H. Antii[2], A. Olofsson[2], F. Almqvist[2], P. Wittung-Stafshede[2], I. Strömberg[1]

[1]IMB, Umea University, Umeå, Sweden

[2]Department of Chemistry, Umea University, Umeå, Sweden

Objective: To investigate effects of the small molecules affecting alpha-synuclein aggregation *in vitro* on the oligomerization of the endogenous alpha-synuclein in mice.

Methods: Two compounds, FN075 and MS382, known to template and inhibit aggregation of alpha-synuclein *in vitro,* respectively, were stereotaxically injected into the striatum or the substantia nigra of C57B1/6 mice. In order to evaluate the effect of these compounds, 3 behavioral tests (adhesive removal test, cylinder test, and pole test) sensitive to impairment in the nigrostriatal system were performed in mice that had received the compounds. Cell counts of TH-positive neurons in the substantia nigra were performed in mice injected with the compounds into the striatum at 6 months and in mice with the nigral injection at 3 months postinjection.

Results: No acute toxicity of the injected compounds was detected. Behavioral tests revealed impairment in sensorimotor functions without significant reduction in the number of TH-positive neurons in the substantia nigra after the striatal injection of FN075 compared to MS382 and the control mice. In contrast, injection of FN075 into the substantia nigra demonstrated a significant reduction of TH-positive neurons already at 3 months. TH-negative inclusion-like structures were found in dopamine neurons in mice injected with FN075.

Conclusions: Most animal models for Parkinson's disease involving alpha-synuclein are focused on alpha-synuclein overexpression or administration of exogenous alpha-synuclein while here is demonstrated that the use of small molecules that can affect the aggregation of endogenous alpha-synuclein may provide a powerful animal model for Parkinson's disease to elucidate the aggregation of alpha-synuclein.

IMPAIRMENT OF THE UNFOLDED PROTEIN RESPONSE ACCELERATES PROGRESSION OF PD

C. Hansen[1], J.Y. Li[1]
[1]Molecular Neurobiology, Wallenberg Neuroscience Center, Lund, Sweden

Accumulation of α-synuclein relies both on the rate of synthesis and degradation of the protein. The unfolded protein response (UPR) is signaling system the serves keep protein homeostasis in balance. In old α-syn overexpressing transgenic animals, we observed that expression of the UPR chaperone BiP was lowered compared to control animals.

We speculated that if the protein homeostasis is not maintained by the UPR system, then this might allow an acceleration of accumulation and aggregation of toxic misfolded proteins. To address this we crossed our α-syn overexpression model with mice that had an impaired UPR system (the T51A eif2alpha heterozygous mice), and found that mice with an impaired UPR system displayed much faster progression of PD symptoms than did the littermate controls in behavioral tests. These mice also had increased levels of phosphorylated and total α-syn compared to control mice. In cell culture, we observed that if we instead increased phosphorylation of eif2alpha by treating the cells with the clinically approved phosphatase inhibitor Guanabenz, then we could lower the expression of α-syn. Furthermore, treating α-syn overexpressing animals with guanabenz also resulted in a behavioral improvement, suggesting a beneficial effect of guanabenz of restoring the UPR system. In summary, we demonstrate that impairment of the UPR system leads to accumulation and aggregation of α-synuclein and that this in turn accelerates disease progression. These results suggest that modulating UPR activity could be a novel avenue for treatment for PD patients.

Introduction

The aggregation of alpha-synuclein is considered the key pathogenic event in many neurological disorders such as Parkinson's disease (PD), dementia with Lewy bodies and multiple system atrophy, giving rise to a whole category of neurodegenerative diseases known as synucleinopathies. Although the molecular basis of alpha-synuclein toxicity has not been precisely elucidated, a great deal of effort has been put into identifying compounds that could inhibit or even reverse the aggregation process.

Aim

The aim of the present study was to assess the anti-aggregating effect of gallic acid (GA) (3,4,5-trihydroxybenzoic acid), a benzoic acid derivative that belongs to a group of phenolic compounds known as phenolic acids.

Methods

An array of biophysical and biochemical techniques and a cell-viability assay was used.

Results

GA was shown not only to inhibit alpha-synuclein fibrillation and toxicity but also to disaggregate preformed alpha-synuclein amyloid fibrils. Interestingly, GA was found to bind to soluble, non-toxic oligomers with no β-sheet content, and to stabilize their structure. The binding of GA to the oligomers may represent a potential mechanism of action. Additionally, by using structure activity relationship data obtained from fourteen structurally similar benzoic acid derivatives, it was determined that the inhibition of alpha-synuclein fibrillation by GA is related to the number of hydroxyl moieties and their position on the phenyl ring.

Conclusion

GA may represent the starting point for designing new molecules that could be used for the treatment of PD and related disorders

ALPHA-SYNUCLEIN AMINO TERMINUS REGULATERS MITOCHONDRIAL MEMBRANE PERMEABILITY
G. Gao[1], J.M. Shen[1], H. Yang[1]
[1]Department of Neurobology, Capital Medical University, Beijing, China
Objectives:
A functional characterization of the alpha-Syn N-terminal domain and investigation of its effect on mitochondrial membrane permeability were undertaken in this study.
Methods:
A functional characterization of the alpha-Syn N-terminal domain and investigation of its effect on mitochondrial membrane permeability were undertaken in this study.
Results:
A decrease in cell viability was observed in cells transfected with alpha-Syn/N but not alpha-Syn/delN. In addition, an alpha-Syn/N-induced increase in the level of intracellular reactive oxygen species, alteration in mitochondrial morphology, and decrease in mitochondrial membrane potential were accompanied by the activation of mitochondrial permeability transition pores (mPTP). These changes were also associated with a decline in mitochondrial cardiolipin content and interaction with the voltage-dependent anion channel and adenine nucleotide translocator in the mitochondrial membrane. The activation of mPTPs and reduction in cell viability were partially reversed by bongkrekic acid, an inhibitor of adenine nucleotide translocator (ANT), suggesting that the interaction between alpha-Syn and ANT promoted mPTP activation and was toxic to cells.
Conclusions:
These results suggest that the N terminus of alpha-Syn is essential for the regulation of mitochondrial membrane permeability and is a likely factor in the neurodegeneration associated with PD.

[2]School of Advanced Medicine, Macquarie University, Gold Coast, Australia
[3]Eskitis Institute for Drug Discovery, Griffith University, Brisbane, Australia

Objectives: Intracellular aggregates of alpha-synuclein are the major pathological hallmark of Parkinson's disease (PD) and dementia with Lewy bodies (DLB) and are linked to neurotoxicity. Multiple triggers of alpha-synuclein aggregation have been implicated, including raised copper. The potential protective role of the endogenous copper- and zinc-binding proteins, metallothioneins (MT), was investigated in relation to copper-induced alpha-synuclein aggregation. As endogenous MT induction has been observed in alpha-synuclein disease[1], current studies are exploring MT levels and distribution across different brain regions in DLB tissue compared to normal controls and also examine copper-MT in plasma/urine samples from PD and unaffected cases as a potential biomarker. **Methods:** Up-regulation of endogenous MT expression was induced in SHSY-5Y cells by the synthetic glucocorticoid analogue, dexamethasone, and beta-thujaplicin. After treatment with dexamethasone/beta-thujaplicin to induce endogenous MT expression, immunofluorescence confocal microscopy was used to quantify protein aggregates in cells with and without 100μM copper treatment. **Results:** Dexamethasone treatment resulted in a significant (*p*, 0.01), dose-dependent up-regulation of MT expression and a significant reduction in copper-dependent alpha-synuclein intracellular aggregates (*p*, 0.01). Ubiquitous (MT-2) and brain-specific (MT-3) isoforms were investigated by transient transfection of the GFP-fusion proteins, resulting in equal alpha-synuclein aggregate suppression by each isoform. **Conclusions:** MTs show neuroprotective capability against copper-induced alpha-synuclein aggregation as up-regulation or over-expression yielded reduced alpha-synuclein aggregation and may be a useful disease biomarker.

[2]BioArctic Neuroscience, BioArctic Neuroscience, Stockholm, Sweden

[3]German Center of Neurodegenerative Diseases, University of Tübingen, Tübingen, Germany

[4]Department of Immunology Genetics and Pathology, Uppsala University, Uppsala, Sweden

Objectives: Aggregated alpha-synuclein is the main component of Lewy bodies, intraneuronal deposits observed in Parkinson's disease and dementia with Lewy bodies. However, it is not completely elucidated which parts of the protein are involved in the aggregation process. The objective of the study was to map epitopes of alpha-synuclein aggregates *in vitro* and *in vivo*.

Methods: Polyclonal chicken antibodies were raised against short linear peptides spanning the alpha-synuclein molecule. Monomeric alpha-synuclein was expressed recombinantly and oligomers and fibrils were generated. An indirect ELISA was performed to identify surface exposed epitopes of the *in vitro* generated alpha-synuclein aggregates. The antibodies were used for immunohistochemical analysis of brain tissue from transgenic mice overexpressing human alpha-synuclein and from Parkinson's disease patients to determine exposed epitopes.

Results: In addition to the C-terminal part, two epitopes in the N-terminal and one in the hydrophobic mid-region of alpha-synuclein were found to be exposed in the *in vitro* generated oligomeric and fibrillar alpha-synuclein. Similarly, the antibodies specific for those epitopes labelled neuropil threads and neuronal cell bodies in brain from transgenic mice and Lewy bodies in Parkinson's disease patients' brains.

Conclusions: The regions exposed in the *in vitro* generated oligomer and fibrils are similar to those exposed in Lewy bodies *in vivo*. These findings can help to improve the detection of various alpha-synuclein species in biological tissues and fluids for diagnostic purposes.

ADPD5-0780

ALPHA-SYNUCLEIN: CAUSE OR CONSEQUENCE OF CYTOPATHOLOGICAL LESIONS OBSERVED IN VITRO MODELS OF PARKINSON'S DISEASE.

N. Callizot[1], M. Combes[1], P. Poindron[1]
[1]Neuropharmacology, Neuro-Sys, Gardanne, France

Parkinson's disease (PD) is characterized by loss of dopaminergic neurons in substantia nigra pars compacta and intraneuronal protein aggregates (Lewy bodies (LB)). Mitochondrial involvement has been postulated based on observations with mitochondrial toxins causing Parkinson's like syndromes. α-synuclein (α-syn) mutations, major LB component, cause autosomal dominant familial PD. Additionally, α-syn-null mice demonstrate increased resistance to MPTP, whereas transgenic α-syn animals treated with MPTP present morphological abnormal mitochondria. Studies have demonstrated that extracellular LB and nigral aggregates immunoreactive to a-syn were often surrounded by activated microglia or inflammatory mediators. Altogether, these observation raise the question of the α-syn role in PD. To investigate this point, we used rat primary mesencephalic neurons enriched or not with microglial cells and injured with mitochondrial toxins, or with α-syn enriched oligomer preparations. Tyrosine hydroxylase (TH) neuron survival, a-syn protein and ATP pool levels were assessed. First, we showed that respiratory chain impairment significantly increased α-syn levels and aggregation. Second, consequently to respiratory impairment, some ATP pool disturbance appeared and was correlated with α-syn level increase. In parallel, we showed on microglia / mesencephalic neuronal culture that α-syn oligomeric form preparation induced significant TH neuronal death dose and time dependent. Interestingly, no toxicity was observed when a-syn was applied on cultures deprived of microglial cells. Additionally, α-syn preparation without any oligomeric fractions did not display any toxicity. In conclusion, we showed that a massive oxidative stress induced α-syn aggregation and that oligomeric fraction of this protein induced a large TH neuronal death involving microglial cells.

Objectives: Alpha-synuclein (α-syn) species in cerebrospinal fluid (CSF) are candidate biomarkers for PD, where total α-syn levels are reduced, as opposite to the increase of oligomeric and phosphorylated forms. In this study we investigate the levels of different α-syn species in AD.

Methods: Using our developed ELISA assays, we studied the levels of α-syn species, total (t-α-syn), oligomeric (o-α-syn) and phosphorylated at serine 129 (p-S129-α-syn) in a well characterized cohort of AD patients (n=225) showing at baseline a typical AD profile for the three classical CSF biomarkers - amyloid beta peptide 42 (Aβ42), total tau (t-tau) and phosphorylated tau (p-tau).

Results: The AD patients were compared with cognitively intact patients diagnosed with other neurological disease (n=68) and having a normal CSF profile for the three biomarkers. T-α-syn CSF levels were significantly increased in the AD group ($p < 0.001$ for t-tau; $r = 0.30$, $p < 0.001$ for p-tau) and negatively with the baseline MMSE score ($r = -0.21$, $p < 0.01$).

Conclusion: The increased levels of CSF t-α-syn in AD and the unchanged levels of the other α-syn species suggest a different role of α-syn in AD.

FAMILIAL PD MUTATIONS RAISE THE SUSCEPTIBILITY TO PRION-LIKE AGGREGATION BY DESTABILIZATION OF THE ALPHA-SYNUCLEIN NATIVE TETRAMER

J. Sanderson[1], N. Kim[1], A. Newman[1], U. Dettmer[1], D. Selkoe[1], T. Bartels[1]
[1]Neurology, Brigham and Women's Hospital Harvard Medical School, Boston, USA

Pathogenic aggregation of α-synuclein (αS) is implicated in familial and sporadic PD and other human synucleinopathies. Our lab has provided several lines of evidence that αS normally exists in neurons principally as a helically-folded tetramer which resists aggregation. We hypothesize that destabilization events which lead to an equilibrium shift toward unfolded monomeric αS precede the initiation of pathologic aggregation, analogous to what occurs in transthyretin-based amyloidosis. Our new experiments suggest that tetrameric αS from varying sources is unable to trigger pathological fibril formation by itself and is also resistant to prion-like misfolded protein propagation seeded by fibrillar αS from either recombinant or human tissue. This resistance is in stark contrast to αS monomer, which was susceptible to recombinant or human fibrillar material. Further, recent work in our lab has shown that single or compound fPD mutations destabilize the native tetramer, leading to increased relative amounts of the aggregation-prone monomer (Dettmer et al, this meeting). In accord, we tested the impact of fPD mutants on susceptibility to spontaneous or stimulated prion-like aggregation using biochemical approaches. We observed that this shift in the tetramer:monomer equilibrium leads to enhanced propensity towards the ß-sheet-rich aggregation pathway in human neuronal cells. Collectively, our data suggest that the helical, tetrameric form of αS appears devoid of a pathogenic function. Therefore, stabilizing αS in this physiological state represents a new therapeutic strategy aimed at a very early event in idiopathic PD and certain other synucleinopathies: the conversion of physiological oligomers into aggregation-prone monomers.

[6]Department of Experimental Medical Sciences, Wallenberg Neurosccience Center Lund Univerisy, Lund, Sweden
[7]College of Science Engineering and Technology, HBKU Qatar Foundation (QF), Education City Doha, Qatar

Objectives: To develop and characterize novel conformation-specific monoclonal antibodies directed against α-synuclein pathology.
Methods: Monoclonal antibodies (mAbs) were generated by fusion of Sp2/O myeloma cells and splenocytes from Balb/c mice immunized with α-syn. Positive hybridomas were screened by ELISA and purified by protein G affinity chromatography. mAbs were characterized by inhibition ELISA, dot blot and immunohistochemical analysis
Results: The antibodies described herein recognize specifically a conformational epitope present only in a-syn aggregates, given that they did not recognize the fibrils generated from other proteins of the synuclein family, namely b- and γ-syn, nor cross-reacted with fibrils generated from other amyloidogenic proteins including b-amyloid (Ab), tau protein, islet amyloid polypeptide (IAPP) and ABri. By employing a library of overlapping linear peptides spanning the entire sequence of a-syn, it was shown that the aforementioned antibodies do not recognize peptides with linear sequence of a-syn confirming further that they only detect the aggregated forms of the protein. In extensive immunohistochemical studies of PD, DLB and MSA cases, these antibodies detected a variety of histopathological features including LBs, LNs, GCIs and extracellular accumulations of α-syn, while they did not stain the brain tissue of the age-matched controls. Furthermore, employing one of our conformation-specific antibodies in a sandwich based ELISA, we observed an increase in levels of a-syn oligomers in brain lysates from DLB compared to Alzheimer's disease (AD) and control samples.
Conclusion: The conformation-specific antibodies portrayed herein represent a useful tool for research, biomarker development, diagnosis and even therapy for PD and related pathologies.

ADPD5-0931
UNFOLDING THE SECRETS OF ALPHA-SYNUCLEIN – STRUCTURE, FORMATION AND PATHOPHYSIOLOGICAL EFFECTS
L. Nilsson[1], I. Iakovleva[1], A. Olofsson[1]
[1]Medical Biochemistry and Biophysics, Umea University, Umeå, Sweden
PD is a neurodegenerative disorder characterized by the accumulation of α-synuclein (asyn) into Lewy body inclusions and the loss of dopaminergic neurons in the substantia nigra. asyn is a 14 kDa natively unfolded protein present in high amounts in presynaptic terminals. Its function is not known but it is suggested to control neurotransmitter release through its effects on the SNARE complex. It is increasingly accepted that it is the asyn oligomers, and not the fibrils, that are responsible for the cytotoxic effect. However, structural information about both fibrils and oligomers remains scarce due to their size and tendencies to aggregate.
Our aim is to probe the structure and the formation of both fibrils and oligomers using peptide antibodies covering the complete sequence of asyn. The setup in a unique manner enables the details of both fibrils and oligomers to be evaluated. We can today show that the fibrils in a significant manner differs from the oligomeric assemblies. Apart from pinpointing these differences it is our goal to define the features of oligomers found *in vivo* in PD patients.

01c. Protein Misfolding & Aggregation: alpha-synuclein

ADPD5-1008
NEUROTOXIC EFFECTS OF ALPHA-SYNUCLEIN VARIANTS ENGINEERED TO ABOLISH NATIVE MULTIMERS

V. von Saucken[1], *A.J. Newman*[1], *U. Dettmer*[1], *D. Selkoe*[1]
[1]*Neurology, Brigham and Women's Hospital/Harvard Medical School, Boston, USA*

There is disagreement on what the major physiological structure of alpha-synuclein (aS) is in healthy, intact cells. Our work suggests that aS exists principally as a helically folded tetramer of ~60 kDa and related multimers. We hypothesize that if native multimers are triggered by various genetic or environmental factors to destabilize, unfolded monomers will accumulate in neurons, resulting in toxic aggregates characteristic of Parkinson's disease. To assess the determinants of stability of aS multimers in intact cells, we introduced strategic point mutations in the canonical aS repeat motifs (KTKEGV). We essentially abolished physiological aS multimers by certain (but not all) in-register repeat substitutions, as assessed by intact-cell methods: crosslinking and YFP complementation (see abstract by Dettmer *et al*.). We then searched for evidence of neurotoxicity from those aS variants that shifted aS equilibrium from multimers to monomers in cells. Trypan blue staining of M17D human neuroblastoma cells transfected with untagged aS showed multimer-abrogating variants (KLKEGV, KTKKGV, KTKEIV, KTKEGW) to be more neurotoxic: viability was significantly reduced versus cells expressing wild-type aS or multimer-permissive variants (GTKEGV, KTEEGV, KTKEGR). Strikingly, multimer-abrogating variants yielded SDS-stable assemblies suggestive of beta-sheet-rich aggregates, as shown by immunoblotting and immunocytochemistry. Further, we searched for differences in apoptosis-driven neurotoxicity and detected substantially greater levels of the apoptotic marker, cleaved PARP, for all multimer-abrogating variants, similar to the effect of the control pro-apoptotic protein Bax. In support of our overall model of PD pathogenesis, these data suggest strong neurotoxic effects from abolishing stable aS multimers in intact neural cells.

NEUROPROTECTANT TREHALOSE LEADS TO INHIBITION OF AUTOPHAGIC FLUX AND INCREASES TRANSMISSION OF ALPHA-SYNUCLEIN

E. Cho[1], K. Lee[2], Y. Yoon[1], S. Lee[3], H. Lee[1]
[1]School of Medicine, Konkuk University, Chung-ju, Korea
[2]IBST, Konkuk University, Seoul, Korea
[3]College of Veterinary Medicine, Konkuk University, Seoul, Korea

Abnormal accumulation of α-synuclein and formation of intraneuronal inclusions known as Lewy bodies are major pathological features of PD. Abnormal proteins and damaged cellular components accumulated in cells are major targets of quality control system, such as autophagy/lysosome pathway or proteasomal pathway, to maintain cellular homeostasis. In our recent study, we have shown that autophagic failure leads to the acceleration of α-synuclein aggregation and increase of α-synuclein exocytosis and transmission. To further demonstrate the relation between the activity of autophagy/lysosome system and transmission of α-synuclein, we have utilized trehalose, a novel mTOR-independent autophagy enhancer which is shown to be neuroprotective. Interestingly, trehalose-exposed cells were not only inducing the autophagosome formation but also interrupted autophagic flux, causing accumulation of autophagosomes and disruption of substrate clearance through lysosomal fusion. Trehalose-treated cells showed accumulation of intracellular α-synuclein aggregates and α-synuclein secretion was significantly elevated. These results suggest that in contrary to what is known to date, an autophagy inducing agent trehalose actually causes inhibition of autophagic flux and impairment of autophagy/lysosomal pathways, leading to accumulation /secretion of toxic substrates that may not be beneficial to cells.

Objectives: To develop novel immunoassays capable of detecting the pathogenic forms of alpha-synuclein (α-syn) that might likely serve as diagnostic tools for PD and related disorders.

Methods: We developed, thoroughly validated and optimized novel enzyme-linked immunoadsorbent assays (ELISAs) capable of specifically quantifying different species of α-syn namely total (t-α-syn), oligomeric (o-α-syn) and phosphorylated at serine 129 (p-S129-α-syn) in biological samples. Next, we examined whether our assays could effectively differentiate PD patients from control subjects based on CSF α-syn levels.

Results: Interestingly, our novel ELISA assays highlighted the importance of CSF o-α-syn for diagnosis and early detection of PD. Moreover, combining the measurements of different CSF α-syn species, we observed marked differential CSF patterns between PD and control subjects

Conclusion: Our assays can be promising tools for exploring the potential use of α-syn in diverse biological samples

CHARACTERIZATION OF VARIOUS STRUCTURES OF ALPHA SYNUCLEIN PROBED BY HIGHLY EFFICIENT HYDROGEN EXCHANGE MASS SPECTROMETRY
W. Lim[1], H. Shin[2]
[1]Molecular Biology, Pusan National University, Busan, Korea
[2]Division of Energy and Bio-engineering, Dongseo University, Busan, Korea
Alpha Synuclein (aSyn) is the major component of intracellular inclusions responsible for several neurodegenerative disorders including Parkinson's disease. The physiological structure of aSyn has been controversial from natively unfolded structure(s) to a stable helical tetrameric structure. aSyn has also been known to exist as membrane bound forms, dimer/oligomers, and amorphous/amyloid aggregates. Here we examined structures of aSyn in the presence of various additions including trichloroacetic acid. The structures were analyzed by deuterium hydrogen exchange mass spectrometer with highly efficient online fungal protease xiii HPLC system. About 110 peptides covering whole 140 residues was successfully produced. C-terminal domain of aSyn shows high exchange rate, indicating that it constitutes random disordered structure. In contract, N-terminal and NAC domains have slower exchange rate depending on the concentration. It seems to form molten globule-like structure at low concentration, and highly structural forms at high. This result suggests that aSyn could potentially form such highly organized structure(s) as a helical tetramer.

IMPACT OF THE GOLGI-LOCALIZED, GAMMA EAR-CONTAINING, ARF-BINDING (GGA) PROTEIN FAMILY ON ALPHA SYNUCLEIN OLIGOMERIZATION AND SECRETION

B. von Einem[1], J. Eschbach[1], A. Wahler[1], D.R. Thal[2], A.C. Ludolph[1], C.A.F. von Arnim[1], K.M. Danzer[1]

[1]Institute of Neurology, University Ulm, Ulm, Germany

[2]Laboratory for Neuropathology - Institute of Pathology, University Ulm, Ulm, Germany

Aggregation of alpha-synuclein (a-syn) and resulting cytotoxicity is a hallmark of sporadic and familial Parkinson's disease (PD) as well as dementia with Lewy bodies. Rising evidence points to oligomeric and pre-fibrillar forms as the pathogenic species, and oligomer secretion seems to be a crucial event in the spreading and progression of PD pathology. Recent studies implicate that dysfunction in endolysosomal/autophagosomal pathways increase secretion of a-syn via endosomal pathways. Furthermore, mutation in the retromer complex protein VPS35, which is involved in retrograde transport from endosomes to Golgi, was suggested to cause familial PD. GGA proteins (Golgi-localized, Gamma-adaptin ear homology, ARF-binding) regulate vesicular traffic between the trans-Golgi-network (TGN) and endosomes. Several studies reported that GGA proteins might work as an antagonist for retromer complex mediated transport. The aim of this study was to investigate the role of the GGA proteins in the a-syn oligomerization and/or secretion process. Using a novel protein fragment complementation assay where a-syn is fused to non-bioluminescent amino-or carboxy-terminus fragments of humanized Gaussia Luciferase we demonstrate here that GGA proteins alter a-syn oligomers secretion and a-syn oligomer mediated toxicity. Specifically, we determine that GGA3 modifies extracellular a-syn species in an exosome-independent manner. Our data suggest that GGA3 drives a-syn oligomers in endosomal compartments and thus facilitates a-syn oligomer secretion. Preventing the early events in a-syn oligomer release may be a novel approach to halt disease spreading in PD and other synucleinopathies.

REAL-TIME ANALYSIS OF CELL-TO-CELL TRANSMISSION OF ALPHA-SYNUCLEIN AGGREGATES IN VITRO AND IN VIVO

D. Kim[1], H. Lim[1], K. Ichiro[2], Y. Shim[2], H. Lee[3], S. Lee[1]
[1]Department of Biomedical Science and Technology, Konkuk University, Seoul, Korea
[2]Department of Bioscience and Biotechnology, Konkuk University, Seoul, Korea
[3]Department of Anatomy School of Medicine, Konkuk University, Seoul, Korea

Cell-to-cell transmission of protein aggregates is the underlying mechanism for pathological spreading in the brains of progressive neurodegenerative diseases. Under the basis that cell-to-cell transmission of aggregates is associated with the progression of PD, understanding the mechanism of transcellular transmission of aggregates would be a promising strategy to slow down the progression of disease. The greatest impediment to this goal is the lack of experimental systems in which both protein transfer and co-aggregation can be accurately and quantitatively analyzed. In this study, we describe a system in which cell-to-cell alpha-synuclein transmission in mammalian cells and *C. elegans* can be assessed in real-time with high accuracy using a novel dual-cell bimolecular fluorescence complementation (BiFC) technique. Using these models, we demonstrated in live cells and animals that the transferred alpha-synuclein co-aggregated with the endogenous protein, and especially in animals, transcellular transmission of aggregates is associated with nerve degeneration, behavioral deficits, and reduced life span. These models represent *in vitro* and *in vivo* systems by which genetic and chemical modifiers of protein aggregate transmission can be screened and analyzed.

ADPD5-1446

REGULATION OF AMYLOID FORMATION BY A HAIRPIN MOTIF IN ALPHA-SYNUCLEIN

W. Hoyer[1], H. Shaykhalishahi[1], E.A. Mirecka[1], A. Gauhar[1], C.S.R. Grüning[1], M.W. Wördehoff[1], A.N. Klein[2], M. Stoldt[2], T. Härd[3], D. Willbold[2]
[1]Institute of Physical Biology, Heinrich Heine University, Duesseldorf, Germany
[2]ICS-6, Research Centre Juelich, Juelich, Germany
[3]Department of Molecular Biology, Swedish University of Agricultural Sciences (SLU), Uppsala, Sweden

Objectives: The beta1-beta2 region of alpha-synuclein (amino acid residues 35 to 60) contains most of the reported disease-related point mutations. Here we investigate the impact of hairpin conformations in the beta1-beta2 region on the aggregation of alpha-synuclein and other amyloidogenic proteins.
Methods: Protein aggregation and toxicity are monitored under conditions which stabilize hairpin conformations in the beta1-beta2 region. Stabilization is achieved either by engineered beta-hairpin-binding proteins (beta-wrapins) or by introduction of an intramolecular disulfide bond.
Results: Sequestration of a beta-hairpin in the beta1-beta2 region by beta-wrapins inhibits alpha-synuclein aggregation and toxicity at substoichiometric concentrations, indicating impeded nucleation of aggregation. Promotion of intramolecular beta1-beta2 contacts by introduction of a disulfide bond results in an aggregation-incompetent alpha-synuclein variant that potently inhibits aggregation and toxicity of wild-type alpha-synuclein, Abeta, as well as islet amyloid polypeptide.
Conclusions: The beta1-beta2 region is a critical regulator of alpha-synuclein aggregation. Hairpin conformers interfere with aggregation nucleation of alpha-synuclein as well as of other disease-related amyloidogenic proteins.

01c. Protein Misfolding & Aggregation: alpha-synuclein

ADPD5-1913
ALPHA-SYNUCLEIN IS PRESENT AS A MONOMER IN CSF
H. Tatebe[1], T. Tokuda[2], R. Ishii[3], T. Kasai[3], M. Yamawaki[4], T. Mizuno[3]
[1]Zaitaku(Homecare), Kyoto Prefectural University of Medicine, Kyoto, Japan
[2]Molecular Pathobiology of Brain Diseases, Kyoto Prefectural University of Medicine, Kyoto, Japan
[3]Neurology, Kyoto Prefectural University of Medicine, Kyoto, Japan
[4]Medical Education and Primary Care, Kyoto Prefectural University of Medicine, Kyoto, Japan
Recent studies have suggested that α-synuclein (α-syn)(molecular weight: 14 kDa) exists predominantly as a tetramer (~58 kDa) in solution. However, a subsequent report has shown that brain- and RBC derived α-syn is present as a natively unfolded monomer. Therefore, the native structure of α-syn remains controversial.

To determine a structure of the α-syn in the biological fluid, we analyzed cerebrospinal fluid (CSF) fractionated using ultrafiltration (UF) and size-exclusion chromatography (SEC) , as well as Western blot (WB) and ELISA. We also expressed A140C α-syn variant, which forms dimers, and wild-type α-syn in Escherichia coli, which were then analyzed after fractionation. Recombinant α-syn proteins were subsequently compared with native α-syn in CSF.

When α-syn was evaluated with SEC columns, α-syn in CSF migrated as 50- to 60-kDa proteins; however, in denaturing gels, they migrated as 15-kDa proteins. The similar result was obtained in recombinant wild-type α-syn. The disulfide-linked dimer (A140C) and oligomer migrated slower than either the unfolded recombinant α-syn or the native α-syn in SEC. We also confirmed by UF in the presence of 8M urea. The recombinant α-syn proteins or CSF in these conditions were fractionated by centrifugal UF membrane devices with different molecular weight cut-offs: 30 and 100kDa. Neither the unfolded recombinant α-syn nor the CSF α-syn was passed through the 30KDa membrane of both normal and 8M Urea conditions.

These results suggest that α-syn detected in about 60kDa fraction in the SEC was a monomeric protein, implying that α-syn in CSF exists as a monomer, not a tetramer.

Introduction

Compelling evidence indicates that alpha-synuclein aggregation plays a central role in the pathogenesis of Parkinson's disease (PD) and other synucleinopathies. Identification of compounds that inhibit or reverse the aggregation process may thus represent a viable therapeutic strategy against PD and related disorders. Ginseng is a well-known medicinal plant that has been used in East Asia for more than two thousand years to treat several conditions. It is now understood that the pharmacological properties of ginseng can be attributed to its biologically active components, the ginsenosides, which in turn have been shown to have neuroprotective properties.

Aim

To determine for the first time, the potential of the most frequently used and studied ginsenosides, namely Rg1, Rg3 and Rb1, as anti-amyloidogenic agents.

Methods

The effect of Rg1, Rg3 and Rb1 on alpha-synuclein aggregation and toxicity was determined by an array of biophysical, biochemical and cell-culture-based techniques.

Results

Among the screened ginsenosides, only Rb1 was shown to be a potent inhibitor of alpha-synuclein fibrillation and toxicity. Additionally, Rb1 exhibited a strong ability to disaggregate preformed fibrils and to inhibit the seeded polymerization of alpha-synuclein. Interestingly, Rb1 was found to stabilize soluble non-toxic oligomers with no β-sheet content, that were susceptible to proteinase K digestion, and the binding of Rb1 to those oligomers may represent a potential mechanism of action.

Conclusion

Thus, Rb1 could represent the starting point for designing new molecules that could be utilized as drugs for the treatment of PD and related disorders.

ADPD5-2026

INHIBITION OF THE DEUBIQUITINASE UCHL-1 RESULTS IN ALPHA-SYNUCLEIN CLEARANCE AND MICROTUBULE STABILIZATION IN OLIGODENDROCYTES: IMPLICATIONS FOR MULTIPLE SYSTEM ATROPHY

C. Richter-Landsberg[1], *K. Pukaß*[1]
[1]*Department of Neuroscience, Universität Oldenburg Fak VI, Oldenburg, Germany*

Objectives
UCH-L1 is a deubiquitinating enzyme (DUB) belonging to the subfamiliy of ubiquitin-carboxy-terminal hydrolases. UCH-L1 transfers ubiquitin to alpha-synuclein (a-syn) and its overexpression inhibits microtubule formation. In neurons it is required for maintaining the structure and function of synapses, and colocalizes with Lewy bodies in Parkinson's disease. We investigated whether UCH-L1 is a constituent of oligodendrocytes, and is present in glial cell inclusions (GCIs) of patients with multiple system atrophy, which is considered a primary oligodendrogliopathy.
Methods
The presence of UCHL1 was determined in primary cultures of rat brain oligodendrocytes by immunoblot procedure, indirect immunofluorescence and RT-PCR, and in MSA brain sections by immunohistochemistry. To investigate whether UCHL-1 is involved in protein aggregate formation, a specific UCHL-1 inhibitor, namely LDN-57444 (LDN) was used and an oligodendroglial cell line stably expressing a-syn and GFP-LC3 (OLN-GFP-LC3), to monitor autophagy and the autophagic flux.
Results
The data show that UCHL-1 is expressed in oligodendrocytes and colocalizes with a-syn in GCIs of MSA brain sections. After treatment with LDN, small a-syn aggregates, which are constitutively present in OLN-GFP-LC3 cells, are removed. LDN induces the autophagic pathway as indicated by an increase in free GFP and GFP-positive autophagic vesicles. Furthermore, the microtubule network is altered, microtubules appear elongated and more bundled, and an increase in tubulin detyrosination is observed.
Conclusions
UCHL-1 inhibition in oligodendroglial cells results in microtubule reorganization, induction of autophagy and the clearance of a-syn aggregates. UCHL-1 is present in GCIs of MSA brains which further points to a role in aggregate formation during pathogenesis.

SMALL MOLECULE-MEDIATED STABILIZATION OF VESICLE-ASSOCIATED HELICAL ALPHA-SYNUCLEIN INHIBITS PATHOGENIC MISFOLDING AND AGGREGATION

L. Fonseca-Ornelas[1], S. Eisbach[2], M. Paulat[1], K. Giller[1], C. Fernández[3], T. Outeiro[2], S. Becker[1], M. Zweckstetter[1]

[1]NMR-based Structural Biology, Max Planck Institute for Biophysical Chemistry, Göttingen, Germany

[2]Department of Neurodegeneration and Restorative Research, University Medicine Göttingen, Göttingen, Germany

[3]Neurobiología estructural y molecular, Instituto de Biología Molecular y Celular de Rosario, Rosario, Argentina

Alpha-synuclein (aSyn) is an abundant presynaptic protein that is important for regulation of synaptic vesicle trafficking and misfolds into insoluble protein deposits in the course of Parkinson's disease. Native brain aSyn exists in equilibrium between a disordered soluble state and an alpha-helical vesicle-bound conformation.

Objectives. To find small molecules that stabilize the helical structure of vesicle-bound aSyn.

Methods. Aggregation of soluble and vesicle-bound aSyn in the absence and presence of different small molecules was monitored using an integrated approach based on circular dichroism, fluorescence spectroscopy and electron microscopy. NMR spectroscopy in combination with site-directed mutagenesis and cell toxicity measurements were employed to obtain insight into the molecular mechanism of inhibition of the aggregation of vesicle-bound aSyn.

Results. Several small molecules, which delay aggregation of aSyn in solution, including the Parkinson's disease drug selegiline, fail to interfere with misfolding of vesicle-bound aSyn. In contrast, the porphyrin phtalocyanine tetrasulfonate directly binds to vesicle-bound aSyn, stabilizes its helical conformation and thereby delays pathogenic misfolding and aggregation [1].

Conclusions. Our results enable a better understanding of the pathogenic aggregation of aSyn and show that stabilization of helical, vesicle-bound aSyn might enable specific targeting of Parkinson's disease and related synucleinopathies.

OLIGOMERIC ALPHA-SYNYCLEIN-MEDIATED SYNAPSIN LOWERING IMPAIRS MEMORY

S. Lesne[1], M. Larson[1], S. Greimel[1], F. Amar[1], M. Sherman[1], Z. Zeidler[1], M. LaCroix[1], H. Schley[1], J.A. Schneider[2], R. Kayed[3], D.A. Bennett[2]
[1]Neuroscience, University of Minnesota, Minneapolis, USA
[2]Rush Alzheimer's Disease Center, Rush University Medical Center, Chicago, USA
[3]Neurology, University of Texas Medical Branch, Galveston, USA

Objectives:
We recently reported that soluble monomeric intracellular αSyn might modulate Alzheimer's disease (AD) pathophysiology in absence of αSyn cytopathology. In the present studies, we hypothesized that oligomeric αSyn species were the likely effector of the changes described and sought to determine the causality and effect relationship of these events.
Methods:
To address this hypothesis, we used biochemical and imaging analyses of human and transgenic mouse brain tissues combined with a custom-made enzyme-linked immunosorbent assay (ELISA) designed to detect various oligomeric forms of αSyn. Mouse behavior was also used as a functional outcome for our *in vivo* genetic manipulations. Finally, we performed *in vitro* cell delivery of isolated αSyn species to identify the effector(s) involved in primary neurons.
Results:
We found an abnormal accumulation of oligomeric αSyn species in AD brains by ELISA, size-exclusion chromatography and non-denaturing/denaturing immunoblotting techniques. However, only a subset of these assemblies was elevated intracellularly. Importantly, the abundance of low molecular weight αSyn oligomers in human brain tissue correlated with cognitive impairment. Further, the overexpression of *SNCA* in an AD mouse model exacerbated amyloid-beta-induced cognitive deficits and triggered a selective decrease in synapsins, reminiscent of the reduction noted in humans. Following isolation of various monomeric or oligomeric αSyn assemblies from transgenic mice, we found that *in vitro* delivery of oligomeric αSyn but not monomeric αSyn was causing a lowering in synapsin expression.
Conclusions:
Our results demonstrate that endogenous αSyn oligomers can impair memory by selectively lowering synapsin expression.

ADPD5-1213
EXTRACELLULAR ALPHA-SYNUCLEIN-EVOKED PARKIN DEREGULATION PROMOTES TAU PHOSPHORYLATION AND DOPAMINERGIC PC12 CELLS DEATH.

A. Adamczyk[1], A.M. Lenkiewicz[1], A. Wilkaniec[1], M. Gassowska[1]
[1]Department of Cellular Signaling, Mossakowski Medical Research Centre, Warsaw, Poland

Objectives: alpha-Synuclein (ASN), the major component of Lewy bodies and Parkin, a multifunctional E3 ubiquitin ligase, play an important role in pathogenesis of PD. Parkin dysfunction leads to the accumulation of misfolded, aggregated proteins and Tau phosphorylation that results in a progressive neurodegeneration and cell death. In these studies, we examined the effect of extracellular ASN on expression and post-translational modifications of Parkin in rat pheochromocytoma (PC12) dopaminergic cells. Moreover, Tau modification in ASN treated cells was analyzed.
Methods: The experiments were performed using spectrophotometrical, spectrofluorometrical and immunochemical methods and real time PCR analysis.
Results: Exogenously added ASN led to free radicals generation and activation of stress response genes in PC12 cells. ASN-dependent nitrosative stress induced Parkin S-nitrosylation, its inactivation and loss of function. Moreover, ASN evoked significant decrease in Parkin immunoreactivity without changes in mRNA level. Then we analyzed Tau modification in PC12 cells with impaired Parkin E3 ligase function evoked by extracellular ASN. In these cells we observed significant increase in Tau phosphorylation on Ser396. In addition, nitrosative stress caused Tau translocation and nuclear accumulation. ASN-evoked Tau changes led to increase in the amount of free tubulin and concomitantly reduced the amount of polymerized tubulin leading to cells death.
Conclusions: We suggest that ASN-induced cellular stress affects Parkin function and impairs its E3 ligase activity, leading to Tau-dependent a microtubule destabilization and cells death. These findings may thus provide a molecular link between ASN liberation and Parkin dysfunction in sporadic PD.

ADPD5-0254
MUTATED ALPHA-SYNUCLEIN SPECIES ENHANCE AMYLOID-BETA PRODUCTION IN SH-SY5YS

H.L. Roberts[1], D.R. Brown[1]
[1]Biology and Biochemistry, University of Bath, Bath, United Kingdom

Objectives:
To determine the effect of wildtype and mutant alpha-synuclein over-expression on the amyloidogenic processing of the amyloid precursor protein (APP) in human SH-SY5Y cells.
Methods:
Stable transgenic lines of SH-SY5Y were generated that over-express wildtype or mutant human alpha-synuclein. The mutants either mimicked point mutations identified in familial early-onset Parkinson's disease (A30P, E46K, A53T), or were truncations of the N-terminus, C-terminus, or 'NAC' region of alpha-synuclein. Secretion of amyloid-beta-40 and amyloid-beta-42 peptides by the cells was quantified with an MSD sandwich immunoassay. Levels of APP amyloidogenic processing were also determined indirectly through a luciferase reporter assay, which detects the liberation of Gal4-tagged APP intracellular domain (AICD) through the action of endogenous beta- and gamma-secretases. A similar luciferase-reporter assay was performed that specifically detects gamma-secretase activity alone. The major enzyme responsible for beta-secretase cleavage of APP is BACE1, and its expression was investigated through Western blotting, and BACE1 promoter-luciferase reporter constructs.

Results:
Overexpressed wildtype alpha-synuclein does not produce a statistically significant effect on APP amyloidogenic processing. However, amyloidogenic processing is significantly enhanced when disease-associated point mutations are present. These mutant alpha-synuclein cells also have elevated BACE1 protein levels, which could account for the increased beta-cleavage of APP. Gamma-secretase activity was apparently unaltered.

Conclusions:
Mutant forms of alpha-synuclein increase the amyloidogenic processing of APP in human neuroblastoma cells. The mechanism for this requires further elucidation, but may involve the increased activity of BACE1.

A STUDY OF A-SYNUCLEIN OLIGOMERS IN HUMAN RED BLOOD CELLS AS A POTENTIAL BIOMARKER FOR PARKINSON'S DISEASE

T.A.O. Feng[1], *F. Li*[1]

[1]*neurology, Beijing Tiantan Hospital Affiliated to capital medical, Beijing, China*

Objective We evaluated the value of α-syn oligomers and the ratio of α-syn oligomers /total protein in human red blood cells (RBCs) as a potential biomarker for PD.

Methods Patients with PD and MSA were recruited according to the United Kingdom Brain Bank (UKBB) Criteria and Quinn Criteria.The total levels of protein in the RBCs were quantified by BCA Protein Assay Kitset. For further detection, α-syn oligomers were tested with a special ELISA.

Results α-syn oligomers were detectable in RBCs of PD, MSA and age-matched control group. The levels of RBCs α-syn oligomers and the ratio of RBCs α-syn oligomers / total protein in PD patients (3954.9 ± 2463.3ng/ml and 29.0± 19.8ng/mg) and in MSA patients(3843.7±1887.2ng/ml and 22.3±13.8ng/mg)were higher than those in control subjects(2716.9± 890.2 ng/ml and 15.4± 7.4 ng/mg.p<0.001). Age, duration, the Hoehn and Yahr stage,age at onset,UPDRS motot scale and motor progression weren't correlated with α-syn oligomers levels in RBCs. In PD group, area under ROC curve of the levels of a-synuclein oligomers was 0.65(p=0.039) and a cut-off value was 3802.5mg/ml with a sensitivity of 41% and a speci-city of 31%. While the area of the a-syn oligomers levels/protein was 0.76(p=0.033) and the cut-off value was 15.03ng/mg with a sensitivity of 79% and a speci-city of 44%.

Conclusions Our observations offer new opportunities for developing diagnostic tools for PD. Elevated Levels of a-syn oligomers and the ratio of α-syn oligomers/total protein in RBCs make them potential biomarkers for PD, especially the latter.

Parkinson's disease (PD) is characterized by intracellular protein deposits known as Lewy bodies, mainly containing α-synuclein protein (α-syn). Deregulation of α-syn and impaired neuronal trafficking, are largely considered as one of the early key factors contributing to PD (Ebrahimi-Fakhari et al., 2012). The primary lysosomal protease involved in α-syn degradation is Cathepsin-D (CD), a lysosomal aspartic endopeptidase synthesized in rough endoplasmic reticulum as pro-Cathepsin-D (proCD) (Cullen et al., 2010). The transport of proCD to endosomes is mediated by the cation independent Mannose 6-Phosphate Receptor300 (MPR300). Upon final delivery to lysosomes proCD is cleaved, at the low lysosomal pH, to form the mature CD (Bonifacino et al., 2003). We looked at the α-syn trafficking from mice and human models of PD, by employing confocal cell microscopy technologies and biochemical assays, and we found that α-syn overexpression induces the missorting of MPR300, leading to its increased degradation and secretion outside neurons. Such missorting seems to be related to an alteration in the endosome-lysosomal pathway and it is partially counteracted by lysosome's inhibitors. In turn, improper sorting of MPR300 affects CD maturation, leading to the increase of the CD precursor form and to the decrease of CD mature fragment. All these events result in the further accumulation and secretion of α-syn and consequently to neuronal degeneration.

Our results advice about a new possible mechanism influencing a-syn degradation and accumulation and may suggest MPR300 as new molecular target to address PD in humans.

THREE-DIMENSIONAL STUDY OF CORTICAL LEWY BODIES AND SENILE PLAQUES IN DLB

N. Nomoto[1], A. Nakamura[1], K. Hirokawa[2], T. Uchihara[3]
[1]Laboratory of Structural Neuropathology, Tokyo Metropolitan Institute Science, Tokyo, Japan
[2]Department of Pathology, Nakano General Hospital, Tokyo, Japan
[3]Tokyo Metropolitan Institute of Medical Science,
Laboratory of Structural Neuropahology, Tokyo, Japan

Triple labeling of brainstem Lewy bodies and neurites has demonstrated a shared three-layered structure with ubiquitin (Ub) at the core, neurofilament (NF) at the periphery with a-synuclein (aSyn) in between (Brain Pathol 2008:18:415-422). To examine whether similar structure is shared with aSyn deposits (Lewy bodies, Lewy neurites and those in senile plaques) in the cerebral cortex, thick floating sections were containing abundant aSyn deposits were obtained from four cases of dementia with Lewy body. Three-dimensional observation of cortical Lewy body on confocal demonstrated similar three-layered structure. Although colocalisation of aSyn and NF was extremely rare on axons, NF-positive segments were sometimes in continuity with aSyn-positive segments or Lewy bodies or with Ub-positive swelling in the senile plaques. Such axonal connections with aSyn and Ub were more abundant in the senile plaques, which provides structural and functional link of these proteins in the cortex of DLB.

MUTATIONAL ANALYSIS OF THE FERRIREDUCTASE ACTIVITY OF ALPHA SYNUCLEIN

J.S. McDowall[1], J. Horne[1], C.R. Pudney[1], D.R. Brown[1]
[1]Biology and Biochemistry, University of Bath, Bath, United Kingdom

Alpha synuclein (a-syn) is the predominant protein found within Lewy bodies which are characteristic of Parkinson's Disease (PD) and other synucleinopathies. It has recently been discovered that a-syn has ferrireductase activity. This is extremely important due to the large number of processes in which iron plays a role within the brain. The objectives of this study were to further investigate the ferrireductase activity of a-syn and to link this activity to structure.

Fe(II) production from a-syn was measured using an *in vitro* ferrozine assay. This was performed using both recombinant protein and cell lysates of SHSY5Y cells over-expressing wild type (WT) and mutant forms of a-syn. Recombinant protein was purified using ammonium sulphate precipitation followed by anion exchange chromatography. Circular dichroism was used to assess the conformational state of a-syn and respective mutants in the presence/absence of NADH.

PD mutations of a-syn result in the reduction of K_m for NADH and for Fe(III) resulting in ferrireductases which are less efficient Fe(II) producers compared to the wild type. Metal binding/truncation mutants showed variable effects in terms of activity. Loss of the C-terminal section did not seem to affect activity unless in conjunction with the N-terminal section.

In conclusion, this study has produced an in-depth analysis of the ferrireductase activity of a-syn and has shown that disease mutations of a-syn show altered ferrireductase activity compare to the WT enzyme.

ADPD5-1038

APOMORPHINE ATTENUATES THE A53T-INDUCED MICROGLIAL REACTIVITY

C. Hoenen[1], P. Heuschling[1], T. Heurtaux[1]

[1]Laboratory of Neurobiology, University of Luxembourg, Luxembourg, Luxembourg

INTRODUCTION - Parkinson's disease (PD) is an age-related motor disorder characterized by a progressive loss of dopaminergic neurons and the presence of proteinaceous insoluble inclusions called Lewy bodies containing high concentration of α-synuclein (α-syn). It has been described that α-syn released is phagocyted by microglia, the resident immune macrophages. Microglia can exhibit a pro-inflammatory phenotype. Microglial overactivation can give rise to the progressive neurodegenerative processes related to PD.

OBJECTIVES - Given the role of neuroinflammation in the development of PD, further studies are necessary to understand the precise role of α-synuclein in the microglial reactivity. We have focused attention on the role of microglia in the neurodegenerative PD process, but also on the role of dopamine receptors as potential regulators of activated microglial cells.

METHODS - Primary microglia were stimulated with synuclein preparations and apomorphine, a non-selective dopamine agonist. The effects of these treatments were established by immunocytochemistry, real-time PCR, western-blots and ELISA assays.

RESULTS - Microglial cultures were exposed to synuclein preparations. Synuclein peptides induced pro-inflammatory states, which appear to be peptide-dependent. The strongest response was observed with the A53T mutant. An apomorphine co-treatment reduced this pro-inflammatory state. Thereafter, we have dissected the A53T-induced microglial reactivity and highlighted the recruitment of MAP kinases and transcription factors.

CONCLUSIONS - These results support the hypothesis that activation of microglia in PD may be due to the presence of synuclein peptides. Furthermore, we have shown for the first time that the microgliosis intensity during PD could be diminished with an apomorphine treatment.

Objective: In several neurodegenerative diseases, pathological modes of action of alpha-synuclein (asyn) comprise a complex interplay of factors influencing oligomer formation. In this study, cellular models applying bimolecular fluorescence complementation (BiFC) were developed to investigate the physiological relevance of *in vitro* findings on asyn aggregation on the cellular level.
Methods: Single particle fluorescence techniques were applied to monitor oligomer formation of fluorescently labeled human asyn as well as interactions with small unilamellar vesicles of different lipid compositions. qRT-QuIC was used to analyze the aggregation characteristics of wild-type asyn as well as the pathological mutants A30P, E46K, and A53T. Lentiviral transduction of asyn-hemiVenus constructs inducible by a Gal4-UAS system was performed on LUHMES and H4 cells. asyn aggregation and subcellular localization were analyzed by fluorescence microscopy and sucrose gradient centrifugation.
Results: Exposure to physiological concentrations of Fe^{3+} induced the rapid formation of specific asyn oligomers exhibiting a pathological gain of function in binding to neutral lipid surfaces. Additionally, aggregation was altered in the pathological asyn mutants A30P, E46K, and A53T. In both H4 and LUHMES cells, transduction with asyn-hemiVenus constructs yielded a model of inducible asyn pathology. In accordance with our *in vitro* findings, fluorescence intensity was augmented by aggregation inducers and decreased upon exposition to known inhibitors of asyn oligomer formation (baicalein, anle138b/c) in the BiFC assay.
Conclusions: Inducible asyn cellular models are suitable both for evaluating the pathophysiological relevance of factors modifying asyn oligomer formation *in vitro* and for validating inhibitors of asyn aggregation identified by high-throughput screening assays.

LYSOSOMAL DEGRADATION OF ALPHA-SYNUCLEIN: ANALYSIS IN VIVO

A. Tran Nguyen[1], O. Scudamore[2], B. Ferger[2], T. Ciossek[2]
[1]CNS, Van Andel Research Institute, Grand Rapids, USA
[2]CNS, Boehringer Ingelheim Pharma GmbH Co &KG, Biberach an der Riss, Germany

Misfolded and aggregated structures of alpha-Synuclein are the main components found in Lewy bodies and are characteristic pathological features in parkinsonian brains. Therefore, down-regulating of alpha-Synuclein levels by enhancing its degradation represents an interesting therapeutic target. Recently, alpha-Synuclein has been demonstrated to be a substrate of the chaperone-mediated autophagy (CMA), a pathway in which proteins are directly translocated into the lysosome lumen via the lysosomal membrane receptor LAMP2A. Mutation of the CMA-motif (delta-CMA) of alpha-Synuclein slows down its turnover in inducible cells overexpressing a-Synuclein. A53T pathogenic mutation of alpha-Synuclein has been shown to act as blockers of LAMP2A and its overexpression increases toxicity in cells. The impact of these mutations *in vivo* regarding CMA remains unexplored. In this study, two conditional transgenic mouse lines expressing C-terminal truncated (deltaCT, 1-120) alpha-Synuclein (construct 1: A53T-deltaCT, construct 2: A53T-deltaCMA-deltaCT) were generated. Expression of alpha-Synuclein was regulated by the expression of tetracyclin-regulated transactivator (tTA) driven by the Pcp2 promoter. We found that alpha-Synuclein was highly expressed in presynaptic areas, cell bodies and neurites of Purkinje cells (PCs). Despite this overexpression, there was no loss of PCs or obvious pathology observed in cerebella of transgenic lines up to 24 months compared to control lines. Interestingly, transgenic mice showed impairments in motor behavioral tests (pole-climbing test and open-field). However, the fact that both lines showed similar motor behavior and alpha-Synuclein protein steady-state levels suggesting that mutation of the alpha-Synuclein CMA motif did not play a significant pathological role in our *in vivo* model.

ALPHA-SYNUCLEIN REDUCES NMDA RECEPTOR-MEDIATED INWARD CURRENT BY PROMOTING RECEPTOR INTERNALIZATION IN NEURONS

S. Yu[1], Y. Chen[1], W. Yang[1], X. Li[1], A. Baskys[2]
[1]Department of Neurobiology, Xuanwu Hospital of Capital Medical University, Beijing, China
[2]Memory Disorders Program & Riverside Integrative Health Academy, School of Medicine University of California Riverside, Riverside CA, USA

Objective: To explore the effect of alpha-synuclein on NMDA receptor (NMDAR)-mediated inward current in neurons. **Methods:** NMDAR-mediated inward current was recorded in primary cultures of rat brain neurons by whole cell patch clamp recording method. The internalization of NMDAR from the surface membrane of the neurons was measured by Western blotting using an antibody specific for NMDAR NR1 subunits. **Results:** Recombinant alpha-synuclein added to the culture medium entered into the neurons, which was detected in the cytoplasm within 30 min. Patch clamp recording revealed that the NMDA-induced inward current (that could be blocked by NMDAR antagonist MK801) was dramatically reduced in alpha-synuclein-treated neurons in a manner dependent on the alpha-synuclein concentration. Alpha-synuclein treatment also induced internalization of NMDAR from the neuron surface as was revealed by decrease in NR1 subunits in the membrane fraction. **Conclusion:** Alpha-synuclein can reduce the NMDAR-mediated inward current by promoting the internalization of NMDAR.

HUMAN ALPHA-SYNUCLEIN 5' UNTRANSLATED REGION CONTAINS AN INTERNAL RIBOSOME ENTRY SEGMENT

P. Koukouraki[1], *E. Doxakis*[1]
[1]*Basic Science, Biomedical Research Foundation Academy of Athens, ATHENS, Greece*

Genetic and biochemical studies have established a central role for alpha-synuclein (asyn) accumulation in the pathogenesis of Parkinson disease. Uncovering and subsequently interfering with physiological mechanisms that control asyn expression is one approach to limit disease progression. Several physiological and pathophysiological conditions that lead to lower levels of the predominant cap-dependent translation in cells such as oxidative stress, hypoxia and nutrient deprivation often drive an alternative mode of translation which is dependent on Internal Ribosome Entry Site (IRES) sequences in the 5´UTR of specific mRNAs. IRESes are hairpin structures that attract eukaryotic ribosomal translation initiation complexes promoting translation initiation independent of the presence of the commonly utilized 5'-m7G cap structure.
Methods: In order to investigate whether the 5'UTR of asyn mRNA has IRES activity, the bicistronic pRF reporter construct was used. Relative luciferase expression was determined after transfection of the pRF reporter into HEK293 cells. Protein and mRNA levels of asyn were determined by Western blot and RT-PCR respectively, in lysates or RNA from various cell lines treated with rapamycin or oxidative compounds.
Results: We show that asyn 5'UTR exhibits IRES activity and the middle part of asyn 5'UTR is probably critical for this activity. Moreover, under specific stress conditions, the asyn IRES activity is induced to promote asyn accumulation and asyn can be translated in a cap-independent manner in the presence of rapamycin.
Conclusions: Asyn can be translated in a cap-independent manner and this mechanism might contribute to asyn accumulation observed in pathological conditions, such as Parkinson disease.

ACTIVATION OF THE E3 UBIQUITIN LIGASE PARKIN
W. Springer[1], T.R. Caulfield[1], F.C. Fiesel[1], E.L. Moussaud-Lamodiere[1], M. Ando[1]
[1]Neuroscience, Mayo Clinic, Jacksonville, USA
OBJETIVES
The PINK1/Parkin-directed mitochondrial quality control pathway ensures the selective degradation of damaged mitochondrial proteins and of whole organelles. Loss of either gene function abrogates this protective pathway and results in early-onset PD. Upon mitochondrial stress, PINK1-dependent phosphorylation activates the E3 ubiquitin ligase Parkin from its 'closed', auto-inhibited structure to enable its translocation to and enzymatic functions at mitochondria. While the molecular mechanisms remain unknown, several therapeutic opportunities may exist along a sequential activation process that eventually results in the 'open', active Parkin conformation.
METHODS
We combined structural computational with functional cell-biological and biochemical methods to discover novel genetic and chemical modulators of Parkin activity.
RESULTS
We provide an all atom resolution model of Parkin and the first molecular dynamics simulation for its activation upon PINK1-dependent phosphorylation. We could show a sequential release of Parkin's intertwined domains towards its opening conformations that could enable binding of a charged E2 co-enzyme and ubiquitin transfer. Using virtual high throughput screening and cell-based high content imaging, we identified small molecule activators of Parkin and genetic regulators of its enzymatic functions.
CONCLUSIONS
With our structure-function approach, we provide the basis for a dissection of Parkin's regulation and a targeted drug design to develop small molecule activators of this broadly neuroprotective E3 ubiquitin ligase.

ADPD5-1479

A SPECIFIC SUBSET OF E2 UBIQUITIN-CONJUGATING ENZYMES REGULATE PARKIN ACTIVATION AND MITOPHAGY DIFFERENTLY.

F. Fiesel[1], E.M. Moussaud-Lamodiere[1], M. Ando[1], W. Springer[1]
[1]Neuroscience, Mayo Clinic, Jacksonville, USA

Objectives
PINK1, a mitochondrial kinase and Parkin an E3 ubiquitin ligase functionally cooperate to label damaged mitochondria for degradation via the proteasomal and autophagic/lysosomal pathway. Although several other key proteins have been identified, the regulation(s) and the exact molecular mechanisms remain elusive. We set out to identify the specific E2 co-factors of Parkin required for mitophagy.
Methods
Using siRNA against 11 of the 35 human E2 enzymes we have screened for effects on mitochondrial translocation of Parkin using High Content Imaging and validated effects using Western blots of mitochondrial substrates and Ubiquitin charging of Parkin.
Results
We have identified several E2 enzymes (UBE2D, L3 and N) that are necessary for Parkin translocation and subsequent degradation of mitochondrial proteins in a cooperative and additive fashion. UBE2D and L3 are able to charge Parkin with ubiquitin. UBE2D, L3 and N are being discharged in response to CCCP. We found that knockdown of UBE2R1 enhances clustering of Parkin and mitochondria.
Conclusions
Parkin uses several different E2 enzymes for the ubiquitination of mitochondrial substrates upon depolarization of the mitochondrial membrane potential. UBE2D and L3 are necessary for the activation of Parkin, whereas UBE2N might be necessary to build K63-linked ubiquitin chains that are required for an efficient clustering of the mitochondria.

STRUCTURAL AND CELLULAR STUDIES WITH CDNF
D. Raymundo[1], C. Latgé[1], K.M.S. Cabral[1], M.S. Almeida[1], D. Foguel[1]
[1]Instituto de Bioquimica Medica, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil
Neurotrophic Factors (NTFs) are a heterogeneous group of soluble polypeptides that promote survival, differentiation, maintenance and regeneration in the central and peripheral nervous system, acting via specific receptors. Traditionally, there are three families of NTFs: neurotrophins, GLFs (GDNF ligands factors) and neuropoietic cytokines. Another family was recently described and named CDNF/MANF. It comprises NTFs that are not structurally related to the classical families, suggesting a completely novel mechanism of action and therapeutic potential for the treatment of neurodegenerative diseases.
CDNF (Cerebral Dopamine Neurotrophic Factor) was first identified by bioinformatics and then biochemically characterized. This protein is able to protect and restore the function of dopaminergic neurons in the rat Parkinson's disease model, it has potential as a therapeutic protein or a basis for the development of drugs for the treatment of PD. We performed MTT assay to identify the domain necessary to the neuroprotective activity of CDNF in N2A differentiated cells. N-terminal domain appears to be responsible for the protection observed to date for this neurotrophic factor.
Its structure and molecular dynamics in solution suggests sites to interact with molecular targets. We design two mutants in hydrophobic aminoacids based on our NMR results to identify the site interaction of CDNF. However, these mutants were not well structured when visualized by 2D–[15N, 1H] HSQC.
Based on these results we assume that the N-terminal of CDNF is necessary to protect dopaminergic neurons to injuries like 6OHDA and alpha-synuclein.

ADPD5-2080

UNRAVELLING THE DJ-1 INTERACTOME IN CONTROL AND OXIDATIVE STRESS CONDITIONS

M. Repici[1], *F. Giorgini*[1]
[1]*Department of Genetics, University of Leicester, Leicester, United Kingdom*

Mutations in DJ-1 (*PARK7*) cause autosomal recessive Parkinson's (Bonifati et al., 2003). DJ-1 is known to protect cells from oxidative stress. However, exactly how DJ-1 functions as an "upstream" oxidative stress sensor and how it exerts its role in many other important cellular processes relevant to Parkinson's, is still to be elucidated.
In the present study we used affinity purification and mass spectrometry to gain insight into DJ-1 interacting proteins in normal and disease-relevant conditions. Proteins interacting with endogenous DJ-1 in HEK293T cells were pulled down using Dynabeads and subsequently identified by liquid chromatography mass spectrometry/mass spectrometry (LC-MS/MS). In parallel, DJ-1 protein partners were pulled down using the GFP Trap technique in HEK293T cells transfected with tagged WT DJ-1 constructs (Repici et al., 2013). Pull-down experiments were performed in normal and oxidative stress conditions. Fragment ion spectra generated by LC-MS/MS were searched using the MASCOT search tool against an updated copy of the UniProt protein database using appropriate parameters. Promising interaction partners were validated by co-immunoprecipitation and co-localization experiments.
We were able to detect 166 candidate proteins interacting with endogenous DJ-1 and 155 proteins specifically interacting with WT DJ-1 overexpressed in HEK293T cells, and not with the control. Candidate proteins identified in both experimental conditions fall into 6 functional categories: transcription regulation/splicing, translational control, mitochondrial proteins, chaperones, cytoskeletal proteins, and proteins involved in endolysosomal trafficking. Our results highlight an approach for detailed investigation of DJ-1 function in Parkinson's and of molecular mechanisms relevant to neurodegeneration.

ADPD5-0351

DROSOPHILA LRRK REGULATES THE DYNAMICS OF DENDRITIC GOLGI OUTPOSTS IN NEURONS

C.H. Lin[1], H. Li[2], Y.N. Lee[2], Y.J. Cheng[2], R.M. Wu[1], C.T. Chien[2]
[1]Neurology, National Taiwan University Hospital, Taipei, Taiwan
[2]Molecular Biology, Institute of Molecular Biology Academia Sinica, Taipei, Taiwan

Construction of dendritic arbor in neurons requires dynamic movements of Golgi outposts, the prominent component in the dendritic secretory pathway. Golgi outposts move in both anterograde and retrograde directions (toward dendritic distal ends and cell bodies, respectively), although the majority of them remain stationary. It is not clear how the dynamic profile of Golgi outposts is regulated in dendrites. Here, we show that Leucine-rich repeat kinase (Lrrk), the Drosophila homolog of Parkinson's disease (PD)-associated LRRK2, regulates dynamic behaviors of Golgi outposts in dendrites. Live imaging shows that Lrrk colocalizes with the pool of stationary Golgi outposts in dendrites and Lrrk-absent Golgi outposts are dynamic. Lrrk regulates directionality and movement of dynamic Golgi outposts: Lrrk loss-of-function mutation enhances anterograde movement and Lrrk overexpression promotes retrograde movements. Regulation of Golgi outpost dynamics is consistent with the activity of dendrite arborization, with an increase in dendrite complexity in Lrrk mutants and a reduction in Lrrk overexpression. Genetic and immunoprecipitation assays suggest that Lrrk interacts with the golgin Lava lamp (Lva) through coiled-coil Lva3 and Lva5, the domains that interact with the dynein/dynactin complex. The kinase activity of Lrrk is also crucial in these processes as kinase-dead mutant exhibits dominant-negative effects on Golgi outpost dynamics and dendritic arborization. Notably, overexpression of the LRRK2 PD mutation G2019S enhances retrograde movement of Golgi outposts, consistent with that G2019S has severe suppressive effect on dendrite arborization and implying that regulation of Golgi outpost dynamics might be altered in the most common PD-associated LRRK2 mutation G2019S.

ADPD5-0408

ABERRANT LRRK2 MODIFIES EXCITATORY INPUTS TO DORSAL STRIATAL MEDIUM SPINY NEURONS AT EARLY POSTNATAL AGES.

B.A. Matikainen-Ankney[1], N. Kezunovic[1], R.E. Mesias[1], F.M. Williams[1], G.W. Huntley[1], D.L. Benson[1]

[1]Neuroscience, Icahn School of Medicine at Mount Sinai, New York, USA

Objectives: Mutations in the gene encoding leucine-rich repeat kinase 2 (LRRK2) strongly predispose humans to an autosomal dominant form of Parkinson's Disease (PD). LRRK2 is enriched in medium spiny neurons (MSNs) of the dorsal striatum, the principal target of dopaminergic neurons that degenerate in PD, but paradoxically, LRRK2 expression in striatum peaks during synaptogenesis in early postnatal life. We hypothesize that LRRK2 influences the formation of striatal input-output synaptic circuits such that PD-causing LRRK2 mutations lead to aberrant striatal synaptic development. Methods: We evaluated synaptic physiology, anatomy, and molecular organization in dorsal striatum of mice expressing an endogenous G2019S mutation (the most prevalent mutation seen in PD patients and known to cause an increase in kinase activity), mice lacking LRRK2, and mice expressing an endogenous D2017A mutation rendering LRRK2 kinase-dead. Results: At postnatal day 21, MSNs from mice lacking LRRK2 or expressing the G2019S mutant form of LRRK2 display a significant increase in the frequency of spontaneous excitatory postsynaptic currents in comparison with control mice (wild type and D2017A mice); additionally, they have an increased density of excitatory postsynaptic markers in dorsal striatum relative to the controls. Conclusions: These data suggest that excitatory synapse development is abnormally accelerated in the absence of LRRK2 or when LRRK2 activity is too high. These experiments further characterize the impact of LRRK2 activity on the generation and function of striatal circuits and synapses and reveal early dysfunction that may predispose the system to degeneration later in life.

ADPD5-0431

FUNCTIONAL PROPERTIES OF LRRK2 MUTATIONS IN TAIWANESE PARKINSON'S DISEASE

K. Chang[1], C. Chen[1], G. Lee-Chen[2], Y. Wu[1]
[1]Department of Neurology, Chang Gung Memorial Hospital, Taoyuan, Taiwan
[2]Department of Life Science, National Taiwan Normal University, Taipei, Taiwan

Background: LRRK2 (leucine-rich repeat kinase 2) is a large protein encoding multiple functional domains. Mutations within different LRRK2 domains have been considered to be involved in the development of Parkinson's disease (PD) by different mechanisms. Our previous study found three *LRRK2* mutations, R767H, S885N and R1441H, in the Taiwanese patients with PD.
Methods: We evaluated functional properties of these mutations by overexpressing them in human embryonic kidney HEK-293 and neuroblastoma SK-N-SH cells. The common G2019S mutation in the kinase domain was included for comparison.
Results: In 293 cells, overexpressed R1441H but not R767H, S885N or G2019 increased GTP binding affinity to prolong the active state. Overexpressed R1441H and G2019S LRRK2 generated aggregates in 293 cells. In SK-N-SH cells, the α-synuclein was immunoreactive to wild type and mutated R767H, S885N, R1441H and G2019 LRRK2 proteins. Part of the perinuclear aggregates formed by R1441H and G2019S were colocalized with α- synuclein. Additionally, reduced interaction between LRRK2 with ARHGEF7, a putative guanine nucleotide exchange factor for LRRK2, was demonstrated by S885N, R1441H and G 2019S mutations, while this interaction is well preserved in R767H mutation.
Conclusions: Although being a pro-aggregation mutant, the non-aggregated R1441H protein may compromise its GTP hydrolysis by increasing its affinity for GTP.

ADPD5-0640

THE PARKINSON DISEASE-ASSOCIATED GENES LRRK2 AND RAB7L1 DEFINE AN EVOLUTIONARILY-CONSERVED REGULATORY MODULE ESSENTIAL FOR LYSOSOMAL INTEGRITY

T. Kuwahara[1], K. Inoue[2], D. MacLeod[2], T. Iwatsubo[1], A. Abeliovich[2]
[1]Department of Neuropathology, Graduate School of Medicine The University of Tokyo, Tokyo, Japan
[2]Department of Pathology Cell Biology and Neurology, Columbia University, New York, USA

Objectives: Mutations in leucine-rich repeat kinase 2 (LRRK2) are the major genetic cause of familial PD. We previously identified RAB7-like variant 1 (RAB7L1) as an interactor of LRRK2: RAB7L1 modulates neurite morphology, intracellular trafficking and PD risk in coordination with LRRK2. But the detailed physiological roles as well as genetic relationships between LRRK2 and RAB7L1 are still unclear.
Methods: We examined the nematode *C. elegans* mutants deficient in orthologues of LRRK2 or RAB7L1, and explored the phenotypic associations.
Results: LRRK2 and RAB7L1 deficiency in *C. elegans* caused similar defects in neurite morphology and lysosomal integrity. Genetic epistasis analyses demonstrated that LRRK2 functions downstream of RAB7L1 in a linear pathway. We further identified a retromer and a lysosomal adaptor protein complex that link RAB7L1/LRRK2 dysfunction to lysosomal and neurite abnormalities.
Conclusions: These data underscore the evolutionarily conserved role of RAB7L1-LRRK2 pathway in the context of lysosome-related functions in diverse cellular contexts.

ADPD5-0978

MONITORING THE OUTCOME OF VIRAL ENCEPHALITIS IN LRRK2 MUTANT MICE: A ROLE FOR LRRK2 IN MICROBIAL SUSCEPTIBILITY OR HOST RESPONSE

I.E. Harmsen[1], M. Hakimi[1], J. Majithia[2], J.J. Tomlinson[1], E. Brown[1], M.G. Schlossmacher[1]

[1]Neuroscience, Ottawa Hospital Research Institute, Ottawa, Canada

[2]Biochemistry Microbiology & Immunology, University of Ottawa, Ottawa, Canada

Objective

Leucine-rich repeat kinase-2 (LRRK2) has been implicated in modulating the risk of Parkinson's, Crohn's disease and leprosy. A proposed LRRK2 function lies within the innate immune system. To better study its role in complex diseases, we employed a recently described infection model using a neurotropic, respiratory-enteric-orphan (REO) virus, serotype-3-Dearing (Gauvin et al., 2013). We hypothesized that LRRK2 modulates disease severity.

Methods

After nasal administration of REO-virus to suckling lrrk2 knock-out mice and wild-type littermates (Tong et al., 2009), we used holocranomicroscopy (ie, whole skull mounts) to monitor infection from rhinitis to terminal encephalitis. To probe for genotypic differences, we quantified anti-REO antibody positivity by Aperio-ImageScope software examining serial, 4 micrometer-thin sections. We juxtaposed these data with available viral titres of select organs.

Results

The rate of neuronal infection at the time of euthanasia (day 11) was higher in knock-out mice for three regions examined. Mean percentage counts for anti-REO antibody-positive neurons in knock-out (versus wild-type) mice of thalamus, midbrain, and cerebellum measured 4.72(3.12), 8.20(2.00) and 0.37(0.20), respectively; corresponding p-values for the differences (0.17-6.20%) were calculated at 0.0871, 1.75x10(-8) and 0.1895, respectively. These neuropathological results were associated with preliminary findings of higher viral titres in the liver, lungs and brain of knock-out (versus wild-type) mice three days post inoculation.

Conclusions

REO-T3-Dearing virus-infected lrrk2 knock-out mice show significantly greater rates of neuronal infection in the midbrain by day 11 when compared to wild-type animals. We conclude that LRRK2 modulates host susceptibility and/or response after nasal exposure to a neurotropic pathogen.

ADPD5-1050

ROLE OF LRRK2 IN THE CONTROL OF DOPAMINE RECEPTOR TRAFFICKING

C. Iaccarino[1], M.G. Del Giudice[1], M. Rassu[1], M. Galioto[1], S. Sanna[1], C. Crosio[1]
[1]Biomedical Sciences, Universita di Sassari, Sassari, Italy

Objectives: To date, the molecular mechanism of LRRK2 toxicity is largely unknown. Different lines of evidences suggest a potential role of LRRK2 in the control of neuronal vesicle trafficking. Our objective is to analyse the LRRK2 involvement in the control of dopamine receptor trafficking and to understand the molecular mechanisms involved in this process. The dopamine receptor levels into the membrane are the sum of new synthesized receptors reaching the membrane and those cycling between the membrane and the vesicle compartments. Moreover the vesicle contents can be either recycled to the membrane or degraded.
Methods: SHSY5Y cell lines stably expressing the Dopamine D1 (DRD1) or D2 receptors (DRD2) transduced by recombinant adenovirus expressing LRRK2WT or different pathological mutants or dead kinase. 48 hours after transduction the cells were treated by dopamine and the receptor trafficking was analysed by biotin protection assay (BPA) at different time points.
Results: The expression of LRRK2 pathological mutants affects the DRD1 trafficking in a dose dependent manner. In particular, the expression of mutant LRRK2s alter the DRD1 physiological equilibrium between the vesicle and membrane pool. The alteration in DRD1 cell trafficking parallels an alteration in ERK signalling. No significant effect was observed analysing both trafficking and signalling of DRD2 in the presence of LRRK2 pathological mutants.
Conclusions: Taking into account the relevance of dopamine receptor trafficking in the dopaminergic system physiology, our results highlight a important mechanism of toxicity due to the expression of LRRK2 pathological mutants.

ADPD5-1052

IN VIVO STUDY OF THE POTENTIAL NEUROTOXICITY OF FUNCTIONAL DOMAINS OF LRRK2 USING A VIRAL VECTOR APPROACH

N. Cresto[1], M. Gaillard[1], E. Diguet[1], D. Bellet[1], L. Legroux[1], N. Déglon[1], K. Cambon[1], P. Hantraye[1], A. Bemelmans[1], E. Brouillet[1]

[1]DSV Molecular Imaging Research Center (MIRCen), CEA CNRS URA2210, Fontenay aux Roses, France

Mutations in the leucine-rich repeat kinase 2 gene (LRRK2) are the most common genetic causes of autosomal dominant PD, which is characterised by a progressive loss of dopaminergic neurons (DAn) in the substantia nigra pars compacta (SNc). The neurotoxicity of mutant forms of LRRK2, especially the G2019S mutation, is at least in part, related to an increase in its kinase catalytic activity. Transgenic mouse models of LRRK2 mutations despite their interest for studying PD pathogenesis, show limited neurodegeneration of DAn in the SNc with no motor symptoms, which precludes rapid testing of neuroprotective interventions (e.g. LRRK2 inhibitors). As an alternative to transgenesis, we used lentiviral (LV) and adeno-associated viral (AAV) vectors to overexpress the C-terminal part of wild type (WT) or G2019S mutant LRRK2. These vectors were stereotaxically injected in the rat SNc. Histological evaluation showed that 20-60% of the tyrosine-hydroxylase-(TH)-positive DAn were transduced, and expressed high levels of the kinase containing domains. Longitudinal evaluation (10 and 25 weeks post injection) of the rats injected with LVs and AAVs coding the wild type RCK-WD40 fragment or its mutant form (G2019S) showed: 1) no performance change in motor tests, and 2) no loss of TH-positive DAn in G2019S group as compared to wild type and sham-operated controls. We are currently testing the hypothesis that the addition of Ser^{1292} to our constructs could reinforce the G2019S-induced increase in kinase activity of LRRK2, potentially leading to neurotoxicity and motor dysfunctions.

ADPD5-1204

LRRK2 KINASE INHIBITION REDUCES ENDOGENOUS LRRK2 PROTEIN LEVELS IN VIVO

E. Lobbestael[1], S. Deman[1], T. De Wit[1], J.M. Taymans[1], V. Baekelandt[1]
[1]Neurosciences, KU Leuven, Leuven, Belgium

LRRK2 (Leucine-rich repeat kinase 2) kinase inhibitors are proposed as potential PD drugs. Still many ambiguities exist concerning their therapeutic effects. For example, LRRK2 kinase inhibition reduces cellular LRRK2 phosphorylation to the same extent as several pathogenic LRRK2 mutations. Moreover, it has recently been shown that the beneficial effect of LRRK2 kinase inhibition on LRRK2-induced toxicity can be attributed to reduced LRRK2 protein levels rather than inhibition of kinase activity (Skibinski et al. 2014 J Neurosci 34(2):418-433). To further define the molecular consequences of LRRK2 kinase inhibitor treatment, we have explored the 'long-term' effects of pharmacological LRRK2 kinase inhibition.

Treatment of LRRK2 (WT or G2019S) overexpressing SH-SY5Y cells with different LRRK2 kinase inhibitors induced LRRK2 dephosphorylation via recruitment of PP1 (Lobbestael et al. 2013 BJ 456:119-128) prior to reduction of its protein levels. We confirmed these data for endogenous LRRK2 from rodent brain, where we observed LRRK2 dephosphorylation and reduced LRRK2 protein levels after systemic administration of LRRK2 kinase inhibitor. Treatment of an inhibitor-resistant LRRK2 variant did not affect LRRK2 phosphorylation and stability, indicating that our findings result from LRRK2-specific inhibitor effects.

Our findings shed light on the 'long-term' effects of LRRK2 kinase inhibition and have important implications regarding the use of these inhibitors as therapeutic agent. Currently, we are investigating the effects of kinase inhibition on other LRRK2 mutants as well as the mechanisms of the inhibitor-induced reduction of LRRK2 levels. Further insight in the relation between LRRK2 kinase activity and LRRK2 stability, may point to new therapeutic targets.

ADPD5-1857

HG-11-31-01 RESCUES IN VIVO DOPAMINE RELEASE DEFICITS IN LRRK2 G2019S KNOCK IN MICE

M. Yue[1], P. Davies[1], J. Zhang[1], H. Melrose[1]
[1]Neuroscience, Mayo Clinic, Jacksonville, USA

The physiological and pathological roles of LRRK2 are yet to be fully determined, but evidence points towards the autosomal dominant Parkinsonism LRRK2 mutations causing a gain in kinase function, impacting neuronal maintenance, vesicular dynamics and neurotransmitter release. We created G2019S knock-in (KI) mice and have performed comprehensive in this model up to 24 months of age. We find elevated brain kinase activity in heterozygous and homozygous mice. Although normal at 6 months, by 12 months of age, *in vivo* basal and amphetamine-induced extracellular release of dopamine (DA) is reduced in both heterozygous and homozygous mice and we speculate that exocytotic release from the vesicular pool is impaired.

The aim of this study was to administer brain-permeable kinase inhibitor HG-11-31-01 to G2019S KI mice and measure amphetamine-stimulated extracellular DA levels using *in vivo* microdialysis. Our data indicates that LRRK2 inhibitor HG-11-31-01 significantly restores amphetamine-stimulated dopamine release in G2019S homozgous KI mice to levels that are similar to wild-type mice treated with vehicle. As expected, HG-11-31-01 had no effect in wild-type mice, but interestingly no effect was noted in heterozgous G2019S KI mice. This is most likely explained by the mutant G2019S-specific preference of this compound and/or alterations in accessability of compound binding due to mutation-induced protein conformational changes. We conclude that restoration of DA levels in homozgous LRRK2 G2019S KI mice by HG-11-31-01 suggests a direct *in vivo* link between LRRK2-mediated phosphorylation and dopamine release.

ADPD5-2253

NEURONAL AND NON-NEURONAL IMPLICATIONS OF LRRK2 DYSFUNCTION

M.J. LaVoie[1], J.D. Nardozzi[1], J. Schapansky[1]
[1]Ann Romney Center for Neurologic Diseases,
Brigham and Women's Hospital Harvard Medical School, Boston, USA

Objectives: Autosomal dominant mutations in the multi-domain kinase LRRK2 are the most common genetic cause of Parkinson's disease (PD). The missense mutations in the LRRK2 protein are believed to impart a gain-of-function at the level of LRRK2 kinase activity, but the functional role of LRRK2 in the cell remains unclear and the impact of disease linked mutations are not known. The goal of our work is to better define the biochemical and functional properties of LRRK2 and understand how pathogenic mutations alter these processes and ultimately how they relate to disease. **Methods**: Using a combination of genetic and pharmacologic tools, we have interrogated the role of LRRK2 in regulating autophagic flux. These include stable shRNA-mediated knockdown of LRRK2 in various cell lines, tissues from mutant LRRK2 knockin mice, and a panel of LRRK2 kinase inhibitors. **Results**: The stimulation of macroautophagy results in the recruitment of endogenous LRRK2 to autophagosome membranes. The resultant kinase activity that follows this LRRK2 activation is important to but not required for the autophagic degradation of insoluble proteins. **Conclusions**: Our data demonstrate that endogenous LRRK2 plays a vital role in the regulation of autophagic flux in a variety of cell types, and that reductions in LRRK2 expression or kinase activity interfere with protein clearance. In addition, when expressed at endogenous levels pathogenic PD-linked mutation in LRRK2 likewise results in dysregulation of autophagy. These data may provide mechanistic insight into the proteinopathy observed in certain LRRK2 animal models and patients carrying mutations in LRRK2.

ADPD5-1929

IDENTIFICATION OF NOVEL FBXO7 INTERACTING PROTEINS

W. Mandemakers[1], R. Masius[1], M. Minneboo[1], M. Grochowska[1], D. Peroni[2], D. Dekkers[3], J. Demmers[3], M. Fasano[2], V. Bonifati[1]
[1]Clinical Genetics, Erasmus MC University Medical Center, Rotterdam, Netherlands
[2]Dept. of Theoretical and Applied Sciences, University of Insubria, Busto Arsizio, Italy
[3]Proteomics Center, Erasmus MC University Medical Center, Rotterdam, Netherlands

Objectives: Parkinson disease-15 (PARK15), or parkinsonian-pyramidal syndrome, is caused by mutations in the FBXO7 gene. Although FBXO7 function is implicated in various cellular processes (i.e. cell cycle regulation and mitophagy), mechanistic insight into FBXO7 signaling pathways and consequences of PARK15 mutations is limited. The goals of our study are identification of novel FBXO7 interacting proteins and investigation of the effect of PARK15 mutations on the detected interactions and related cellular processes.
Methods: TAP-tag and GST-tag wildtype and mutant (R378G) FBXO7 proteins were generated. DNA expression constructs of TAP-tagged FBXO7 proteins were transfected into human neuroblastoma cell lines (SH-SY5Y) and FBXO7 interacting protein were isolated by sequential pull down using FLAG and Streptactin peptide coated beads. GST-tagged proteins were used to pull down FBXO7 protein interactors from brain extracts. Various experimental paradigms were tested (i.e. investigation of cytoplasmic vs. nuclear interaction, phosphorylation dependent interactions, mitophagy dependent interactions). After pull down, eluates were fractionated by PAGE, Coomassie stained and processed for Mass Spec analysis. Candidate interactors were further validated in relevant follow up experiments.
Results: Several FBXO7 protein interaction networks have been identified. Our data confirm previously identified interactions of FBXO7 with proteins from the SCF E3 ubiquitin ligase complex (CUL1, SKP1) and proteasome (PSMF1). In addition, novel FBXO7 interacting proteins involved in various functional pathways (i.e. mitochondrial and nuclear function) have been identified and are currently validated.
Conclusions: Identification of novel FBXO7 protein interactors implicates SCF complex-dependent and -independent roles for FBXO7 function in various subcellular compartments (i.e. nucleus, mitochondria, cytoplasm).

ADPD5-1185

DOPAMINERGIC TOXIN MPTP ACTIVATES ASK1-P38 MAPK DEATH SIGNALING PATHWAY THROUGH TNF-DEPENDENT THIOREDOXIN OXIDATION IN A PARKINSONISM MOUSE MODEL

A. Ray[1], N. Sehgal[1], S. Karunakaran[1], G. Rangarajan[2], V. Ravindranath[3]
[1]Division of Cellular and Molecular Neuroscience, National Brain Research Centre, Gurgaon, India
[2]Department of Mathematics, Indian Institute of Science, Bangalore, India
[3]Centre for Neuroscience, Indian Institute of Science, Bangalore, India

Activation of apoptosis signal-regulating kinase 1 (ASK1) and downstream death signaling MAPK cascade are implicated in selective degeneration of dopaminergic neurons in substantia nigra in PD. ***Objectives:*** Since upstream activator(s) of ASK1 are not delineated, we investigated the same using the MPTP mouse model of Parkinsonism. ***Methods:*** Male C57/BL6 mice were treated with a single dose of MPTP and status of death signaling cascade was assessed over 12 hr in ventral midbrain (VMB) and striatum (ST). We identified the critical hub of this cascade using protein covariation network analysis (PCNA). ***Results:*** MPTP selectively activated ASK1 and its downstream p38 MAPK in a time-dependent manner in VMB alone. This potentially occurs through selective protein thiol oxidation of redox-sensitive thiol disulfide oxidoreductase, thioredoxin (Trx1) resulting in release of its inhibitory association with ASK1. Levels of tumor necrosis factor (TNF), a known activator of ASK1, increased 30 min after MPTP in VMB but not ST. PCNA analysis using protein states as nodes revealed TNF to be an important mediator of ASK1 cascade. Blockade of MPTP-mediated TNF signaling in VMB through intrathecal administration of TNF-neutralizing antibody prevented downstream Trx1 oxidation and ASK1-p38 MAPK activation. ***Conclusions:*** TNF activates ASK1-p38 cascade through protein thiol oxidation. Thus, preventing the increase of TNF levels and thence the downstream signaling through Trx1 oxidation leading to ASK1-p38 MAPK activation may be critical for neuroprotection in PD. Importantly, network analysis, such as PCNA may yield new insights into causes and effects of protein network perturbations in complex disease states.

L-DOPA INDUCES METABOLIC SWITCHES IN A TH POSITIVE NEURONAL CELL MODEL

S. Delcambre[1], J. Meiser[1], K. Hiller[1]

[1]Luxembourg Centre for Systems Biomedicine, University of Luxembourg, Esch-Sur-Alzette, Luxembourg

OBJECTIVES:

The symptoms of PD can be managed for several years by administering L-3,4-dihydroxyphenylalanine (L-DOPA). This drug has been shown to be toxic to dopaminergic neurons *in vitro* and *in vivo.* The focus of our study was to investigate the effects of L-DOPA treatment on the metabolism of a TH positive neuronal cell model.

METHODS:

The fate of various carbon sources was investigated using stable isotope-labeled metabolites such as glucose, glutamine or pyruvate. The LUHMES cells, a human TH positive neuronal cell model, were treated with concentrations of L-DOPA as measured in the plasma of PD patients under L-DOPA treatment.

RESULTS:

The results show clear switches in cellular metabolism of the neurons subjected to L-DOPA treatments. On the one hand, a switch from glucose to glutamine to fuel the tricarboxylic acid (TCA) cycle was observed. On the other hand, the production of lactate was increased and very interestingly, the L-DOPA treatment induced a switch from glucose to extracellular pyruvate-derived carbons for lactate production.

CONCLUSIONS:

Our data suggest that LUHMES cells undergo major perturbations of the central carbon metabolism, including decreased TCA cycle activity and a switch from glucose to glutamine as carbon source for the TCA cycle. This phenomenon has also been observed in cancer cells which rely on glycolysis solely for lactate production. In our case however, L-DOPA does not induce an increase of glycolytic activity for lactate production, but instead, the uptake of pyruvate from the medium was channeled to lactate production.

META-ANALYSIS OF SUBSTANTIA NIGRA TRANSCRIPTOME DATA: SEARCHING FOR NEW BIOMARKERS OF PD

E. Mariani[1], M.C. Pelleri[2], F. Frabetti[2], A. Tarozzi[1], R. Casadei[1]
[1]Department for Life Quality Studies, University of Bologna, Rimini, Italy
[2]Department of Experimental Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy

The understanding of the genetic basis of the PD and the correlation between genotype and phenotype has revolutionized knowledge about the pathogenetic mechanisms of neurodegeneration, opening up exciting new therapeutic and neuroprotective perspectives. Genomic knowledge for PD is still very open and can provide a good start for studies of the molecular mechanisms that underlie the gene expression variations and the epigenetic mechanisms that may contribute to the complex and characteristic phenotype of PD. Here we use the software TRAM (Transcriptome Mapper), to analyse publicly available microarray data of PD patients and controls substantia nigra, to identify chromosomal segments (Map mode) and gene clusters (Cluster mode) which are biologically relevant in the two different conditions. TRAM integrates original methods for parsing, normalizing, mapping and statistically analyzing expression data; in addition, it is able to easily generate maps showing differential expression between two sample groups, relative to two different biological conditions. We performed a systematic meta-analysis of 143 samples from pool A (patients with PD) and 119 samples from pool B (healthy controls), for a total of respectively 4,128,764 data points (gene expression value) and 3,417,633 data points, relative to 37,580 distinct loci for wich A/B ratio value was determinable. Results obtained included 5 significantly over-expressed segments and 90 over/under-expressed clusters. A list of statistically significant over/under-expressed genes has been generated, including coding genes, ncRNAs and uncharacterized transcripts. This study offers a new approach for the regional analysis of gene expression in neurodegenerative diseases.

ADPD5-1715

PURINE METABOLISM GENE DEREGULATION IN PD IS STAGE- AND REGION-DEPENDENT

P. Garcia-Esparcia[1], K. Hernández-Ortega[2], B. Ansoleaga[2], M. Carmona[1], I. Ferrer[1]
[1]Institute of Neuropathology - CIBERNED, Bellvitge Universitary Hospital - Bellvitge University Hospital-Bellvitge Biomedical Research Institute (IDIBELL), Hospitalet de Llobregat, Spain
[2]Institute of Neuropathology, Bellvitge Universitary Hospital - Bellvitge University Hospital-Bellvitge Biomedical Research Institute (IDIBELL), Hospitalet de Llobregat, Spain

Objective: Purines are the core of the DNA, RNA, nucleosides, and nucleotides which participate in a wide variety of crucial metabolic pathways including energy metabolism and cell signalling and form co-factors of several enzymatic reactions. The present study analyses mRNA expression of twenty-two genes involved in purine metabolism, in the *substantia nigra*, putamen and cerebral cortex area 8 in PD at different stages of disease progression. This information permits a better understanding of the primary regulation of purine-related genes and their possible implications in the pathogenesis of Parkinson's disease (PD).
Methods: RT-qPCR and immunohistochemistry were performed in the present study.
Results: Expression of adenylate kinase 2 (*AKA2*), *AK3*, *AK4*, adenine phosphoribosyltransferase (*APRT*), ectonucleoside triphosphate diphosphohydrolase 1 (*ENTPD1*), *ENTPD3*, non-metastatic cells 3, nucleoside-diphosphatese kinase 3 (*NM1*), *NME7*, and purine nucleoside phosphorylase 1 (*PNP1*) mRNA was reduced in the *substantia nigra* at stages 3-6. In contrast, *ADA* mRNA was up-regulated in the frontal cortex area 8 at stages 3-4, as were *AK1*, *AK5*, *NME4*, *NME5*, *NME6*, 5'-nucleotidase (*NT5E*), *PNP1* and prune homolog *Drosophila* (*PRUNE*) at stages 5-6. Gene down-regulation in the *substantia nigra* may be interpreted, in part, as a consequence of dopaminergic cell damage leading to neuronal cell death since *ENTPD3*, *NME1, NME7*, *AK1*, and *PNP1* are expressed in neurons as revealed by immunohistochemistry. Gene up-regulation in the frontal cortex suggests a primary manifestation or a compensation of altered purine metabolism in this region at advanced stages of PD.
Conclusions: Purine metabolism gene deregulation in PD is stage- and region-dependent.

ARE MALE BIOLOGICALLY PREDISPOSED TO PARKINSON'S DISEASE: A PERIPHERAL TRANSCRIPTOMIC STUDY

E. Mutez[1], L. Hopes[1], S. Bleuse[1], P. Semaille[2], T. Comptdaer[2], M.C. Chartier-Harlin[2], A. Destee[1]

[1]Movement Disorders Unit, CHRU de Lille, LILLE, France

[2]Team 6, INSERM UMR837, LILLE, France

Objectives

Parkinson's disease (PD) is characterized by a combination of genetic and environmental factors. PD occurs more often in men than female with a sex ratio from 1.5 to 2. Epidemiologic studies have proposed the male gender as a risk factor of PD. The aim of this study is to determine if men could have a biological predisposition to PD.

Methods

We already proposed that the transcriptome profile in peripheral blood mononuclear cells (PBMC) could reflect the gene expression deregulation occurring in the brain. Transcriptome study was realized from PBMC of 9 male and 9 female sporadic PD patients and 7 male and 10 female controls (Whole Human Genome 44k Agilent microarray). Analyses of differential expression were performed with GeneSpring software. Genes with significant difference of expression (fold change >1.2 and Welch t-test $p< 0.05$) were analyzed using Ingenuity Pathway Analysis software which identified significantly deregulated cellular pathways.

Results

Genes implicated in the estrogen receptor and the androgen signaling pathways were deregulated in both male and female sporadic patients. There were less deregulated genes and pathways in PBMC from the male PD patients compared to male controls than in female PD patients. Deregulations of autophagic and cytoskeleton pathways were observed between male and female PD patients.

Conclusions

This preliminary transcriptomic study suggests that male could present a gene expression profile making them susceptible to PD development. This result needs confirmation in a second and larger set of population.

RETROMER-DEPENDENT NEUROTRANSMITTER RECEPTOR TRAFFICKING TO SYNAPSES IS ALTERED BY THE PARKINSON'S DISEASE VPS35 MUTATION P.D620N

A. Milnerwood[1], L. Munsie[1], P. Seibler[2], D. Beccano-Kelly[1], C. Kadgien[1], I. Tatarnikov[1], J. Khinda[1], M. Volta[1], C. Klein[2], M. Farrer[1]

[1]Centre for Applied Neurogenetics, University of British Columbia, Vancouver, Canada
[2]Neurogenetics, University of Lubeck, Lubeck, Germany

OBJECTIVE: Vacuolar protein sorting 35 (VPS35) is a core component of the retromer complex, crucial to endosomal protein sorting and intracellular trafficking. Recently we linked a VPS35 mutation (p.D620N) to familial parkinsonism. Although retromer function is not very well defined in neurons, we aimed to test the hypothesis that VPS35 has neuron-specific functions, which are perturbed by this mutation.

METHODS: We examined retromer localization and interactions in primary neurons and mouse brain by Western blot and immunocytochemistry. Effects of the mutation were tested by transient over-expression of GFP-fused VPS35 (+/-p.D620N) in primary neurons and by endogenous levels of mutant VPS35 in a novel knock-in mouse model and human patient derived iPS cell dopamine-like neurons.

RESULTS: Endogenous VPS35 localizes to dendritic spines in cortical and striatal neurons and regulates the surface trafficking of synaptic excitatory AMPA-type neurotransmitter receptors (AMPARs). Some retromer functions are unaffected by the p.D620N mutation but the mutation alters VPS35 intracellular trafficking and subcellular localization as well as altering synaptic transmission and AMPAR recycling. We found altered VPS35 binding with known regulatory partners were induced by the p.D620N mutation which may explain partial loss-of function.

CONCLUSIONS: Perturbations to synaptic function induced by the VPS35 p.D620N mutation may produce chronic pathophysiological stress and eventual neurodegeneration in this form of familial parkinsonism

OPTIMIZATION OF DIFFERENTIATION PROTOCOLS FOR HUMAN INDUCED PLURIPOTENT STEM CELL DERIVED DOPAMINERGIC NEURONS

A. Sommer[1], *B. Winner*[1], *I. Prots*[1]
[1]*IZKF, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany*

Objective: PD is the second most common neurodegenerative disease. It is characterized by a slow and progressive degeneration of dopaminergic (DA) neurons in the substantia nigra (SN) pars compacta and of nerve terminals in the striatum, eventually leading to advanced motor symptoms. Generation of DA neurons *in vitro* could offer a great option for biomedical applications including disease modeling, or drug screening.
Methods: Various differentiation protocols were investigated for the differentiation of human induced pluripotent stem cells (hiPSC) into DA neurons. The most promising protocols used two small molecules, LDN and SB, inhibiting SMAD signaling by TGFß and BMP pathways thereby inducing neural fate. Furthermore, small molecules involved in patterning and correct localization of mesencephalic DA neurons were supplemented at different timepoints and in various concentrations. Additionally, we included a sorting step aiming at a pure population of DA neurons. Differentiated neurons were characterized and evaluated by immunocytochemistry and qRT-PCR.
Results: Using dual SMAD inhibition and small molecules for patterning including SHH, FGF8 or CHIR lead to high amounts of DA neurons after at least 30d of differentiation. Sorting steps were challenging to establish since high cell death rates occur.
Conclusion: Differentiation of hiPSC into a high yield of DA neurons is still a challenging process. However, based on our experiments, high amounts of TH-positive neurons could be generated.

[4]University of Tehran, Control and Intelligent Processing Center of Excellence School of Electrical and Computer Engineering University College of Engineering, Tehran, Iran
[5]University of Western Sydney, School of Social Sciences and Psychology and Marcs Institute for Brain and Behaviour, Sydney, Australia

Introduction: A substantial subset of Parkinson's disease (PD) patients suffers from impulse control disorders (ICDs), which are side effects of dopaminergic medication. Dopamine plays a key role in reinforcement learning processes. One class of reinforcement learning models, known as the actor-critic model, suggests that two components are involved in these reinforcement learning processes: a critic, which estimates values of stimuli and calculates prediction errors, and an actor, which estimates values of potential actions.
Objectives: To understand the information processing mechanism underlying impulsive behavior.
Methods: We investigated stimulus and action value learning from reward and punishment in four groups of participants: on-medication PD patients with ICD, on-medication PD patients without ICD, off-medication PD patients without ICD, and healthy controls.
Results: Analysis of responses suggested that participants used an actor-critic learning strategy and computed prediction errors based on stimulus values rather than action values. Quantitative model fits also revealed that an actor-critic model of the basal ganglia with different learning rates for positive and negative prediction errors best matched the choice data. Moreover, whereas ICDs were associated with model parameters related to stimulus valuation (critic), PD was associated with parameters related to action valuation (actor). Specifically, PD patients with ICD exhibited lower learning from negative prediction errors in the critic, resulting in an underestimation of adverse consequences associated with stimuli.
Conclusions: These findings offer a specific neurocomputational account of the nature of compulsive behaviors induced by dopaminergic drugs.

COGNITIVE CORRELATES OF PSYCHOSIS IN PATIENTS WITH PARKINSON'S DISEASE

D. Hewedi[1], A. Moustafa[2], R. Krishnad[3], M. Franke[4]
[1]Department of Psychiatry - Faculty of Medicine - Ain Shams University, Institute of Psychiatry, Cairo, Egypt
[2]University of Western Sydney, cMarcs Institute for Brain and Behaviour, Sydney, Australia
[3]Rutgers University New Jersey USA, Department of Veterans Affairs, New Jersey, USA
[4]Department of Cognitive Linguistic Sciences and Psychological Sciences Brown Univer sity USA, Brown Institute for Brain Science, Brown, USA

Introduction and Objectives. Psychosis and hallucinations occur in 20–30% of patients with
Parkinson's disease (PD). In the current study, we investigate cognitive functions in relation to the occurrence of psychosis in PD patients.
Methods. We tested three groups of subjects – PD with psychosis, PD without psychosis and healthy controls – on working memory, learning and transitive inference tasks, which are known to assess prefrontal, basal ganglia and hippocampal functions.
Results. In the working memory task, results show that patients with and without psychosis were more impaired than the healthy control group. In the transitive inference task, we did not find any difference among the groups in the learning phase performance. Importantly, PD patients with psychosis were more impaired than both PD patients without psychosis and controls at transitive inference. We also found that the severity of psychotic symptoms in PD patients [as measured by the Unified Parkinson Disease Rating Scale Thought Disorder (UPDRS TD) item] is directly associated with the severity of cognitive impairment [as measured by the mini-mental status exam (MMSE)], sleep disturbance [as measured by the Scales for Outcome in Parkinson Disease (SCOPA) sleep scale] and transitive inference (although the latter did not reach significance).
Conclusions. Although hypothetical, our data may suggest that the hippocampus is a neural substrate underlying the occurrence of psychosis, sleep disturbance and cognitive impairment in PD patients.

MOLECULAR CHARACTERIZATION AND ANALYSIS OF THE PORCINE NURR1 GENE

K. Larsen[1], J. Momeni[1], L. Farajzadeh[1], H. Callesen[1], C. Bendixen[1]
[1]Molecular Genetics and Systems Biology, Molecular Biology and Genetics, Århus C, Denmark

Introduction:
NURR1 is a member of the nuclear receptor superfamily and is a regulatory factor of differentiation, migration and maturation of mesencephalic dopaminergic neurons. NURR1 plays a crucial role in nigrostriatal dopmaine neuron development and is therefore believed to be associated with the pathogenesis of neurodegenerative diseases linked to the dopamine system of the midbrain.

Aims:
The aim of this study was to characterize the porcine NURR1 gene.

Results:
Here we report the isolation and characterization of porcine *NURR1* cDNA amplified by reverse transcriptase polymerase chain reaction (RT-PCR). The porcine *NURR1* cDNA encodes a protein of 598 amino acids which shows an extremely high similarity to bovine, human and mouse (99 %) NURR1. NURR1 transcript was detected in various organs and tissues with a differential expression. Also the developmental expression was examined in normally fertilized pigs and in cloned pigs. Two single nucleotide polymorphisms (SNPs) were identified the porcine *NURR1* gene, a missense C/T SNP in exon 3 resulting in an amino acid substitution of a leucine to a phenylalanine residue (L57F) in the porcine NURR1 sequence. Another non-synonymous SNP was identified in exon 3. This C/A SNP leads to an amino acid change from a proline to a histidine residue (P82H). None of the identified SNPs have been observed in human NURR1. The methylation level of the NURR1 gene was determined and displayed significant difference between brain and liver.

Extracellular α-Synuclein has been implicated in interneuronal propagation of disease pathology in Parkinson's Disease. How α-Synuclein is released into the extracellular space is still unclear. Here, we show that α-Synuclein is present in extracellular vesicles in the central nervous system (CNS). We find that sorting of α-Synuclein in extracellular vesicles is regulated by sumoylation and that sumoylation acts as a novel sorting factor for targeting of both, cytosolic and transmembrane proteins, to extracellular vesicles. We provide evidence that the SUMO-dependent sorting utilizes the endosomal sorting complex required for transport (ESCRT) by interaction with phosphoinositols. Ubiquitination of cargo proteins is so far the only known determinant for ESCRT-dependent sorting into the extracellular vesicle pathway. Our study reveals a novel function of SUMO protein modification as the first ubiquitin-independent ESCRT sorting signal, regulating the extracellular vesicle release of α-Synuclein but presumably constituting a mechanism with more general implications for cell biology.

PRION-LIKE SPREADING OF ALPHA-SYNUCLEIN AGGREGATES FROM THE OLFACTORY BULB TO CENTRAL BRAIN REGIONS IN WILD-TYPE MICE.

N.L. Rey[1], K.C. Luk[2], J.Q. Trojanowski[2], V.M.Y. Lee[2], P. Brundin[1]
[1]Center for Neurodegenerative Science, Van Andel Institute, Grand Rapids, USA
[2]Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, USA

In Parkinson's disease (PD), proteic aggregates develop in the brain. Those aggregates are composed of misfolded α-Synuclein (α-syn) arranged into fibrils rich in beta-sheet structures. Based on post-mortem analysis of PD brains, Braak and collaborators suggested that in PD, pathological aggregates develop in a stereotypic pattern, and propagate via neural pathways. Importantly, Braak observed that α-syn aggregates appear first in the olfactory bulb (OB) and the gut, and then spread to interconnected brain regions over several years. Interestingly, olfactory dysfunction accompanies the appearance of pathology in olfactory structures early in the course of PD. Thus, the olfactory system is a relevant model to study early stages of PD, and investigate spreading of α-syn aggregates throughout the brain.

Several recent articles demonstrate that injection of fibrillar α-syn into the striatum, cortex or substantia nigra of wild-type mice induce α-syn aggregation, but the induction of pathology in the OB, and the possible spread of pathology to other brain regions has not been explored yet.

Here, we test the long-term effect of fibrillar α-syn stereotactic injection into the OB of wild-type mice.

We demonstrate that certain species of α-syn recruit endogenous α-syn into pathological aggregates, that then spread sequentially, first to structures directly connected to the OB, and then to structures secondary connected to the OB. Moreover, spreading of pathology is accompanied by progressive and specific behavioral deficits.

Our results support the idea that α-syn spreading from OB to central structures can occur, and could be involved in the progression of PD pathology.

[4]Biotechnology Incubating Center, ToolGen Inc, Seoul, Korea

Deposition of α-synuclein aggregates is a pathological feature of PD. Both pathological and genetic studies suggested lysosomal dysfunction as one of the key features of PD and other neurodegenerative disorders. Recent studies suggested that cell-to-cell transmission of α-synuclein aggregates was the underlying mechanism of the progression of PD. In previous studies, we showed that α-synuclein aggregates can be transferred to neighboring cells through the endolysosomal pathway and broken down in lysosomes. Here, we tested the hypothesis that lysosomal dysfunction promotes cell-to-cell transmission of α-synuclein, thereby leading to the extensive accumulation and secretion of α-synuclein aggregates. Using zinc finger nucleases targeting either *ATP13A2*, a genetic cause of early onset PD, or *CTSD*, a gene encoding lysosomal hydrolase cathepsin D, we generated *ATP13A2-/-* and *CTSD+/-* cell lines. While the depletion of *ATP13A2* did not show alterations in lysosomal degradation, the heterozygous mutation of cathepsin D exhibited the accumulation of autophagic vacuoles and the lysosomal substrates such as p62 and polyubiquitinated proteins. Degradation rate of exogenous dextran was slower only in *CTSD+/-* cells. These results indicate that the lysosomal dysfunction occurs only in *CTSD+/-* cells. Consistent with this, the heterozygous depletion of cathepsin D potentiated the cell-to-cell transmission of α-synuclein, whereas *ATP13A2* deficiency did not increase the transmission of a-synuclein aggregates. These results suggest that the state of lysosomal function is the major determinant of the rate of transcellular transmission of α-synuclein aggregates.

[6]Neural Regeneration Laboratory Biochemistry Microbiology and Immunology, University of Ottawa, Ottawa, Canada

Objectives: Hyposmia occurs early in several neurodegenerative disorders. The nasal cavity's involvement in the pathogenesis of Parkinson disease and Alzheimer's has not yet been studied in part due to difficulty visualizing olfactory and respiratory epithelia.
Methods: After optimizing a formic acid-based method that decalcifies bone and enhances select antigen accessibility, we processed intact mouse heads into 4 micrometer-thin sections for microscopy applications.
Results: Using a standardized protocol for 'holocranomicroscopy', we made 5 observations: 1) Expression of alpha-synuclein and tau in olfactory neurons of the nasal cavity; 2) Correlation between human SNCA allele numbers and alpha-synuclein levels throughout the cranium of PAC1-transgenic mice. There, 4 SNCA alleles induced abnormalities in movements, cognition and odor processing; 3) Formation of thioflavin T-positive amyloid-beta plaques in intracranial portions of the olfactory nerve in mutant human APP-cDNA-transgenic mice; 4) The tracking of infection following inoculation with a respiratory-enteric-orphan virus from the nasal cavity to cranial nerves-1 and -5 and encephalitis; and 5) Improved sensitivity in monitoring intracranial neurogenesis after BrdU administration.
Conclusion: Holocranomicroscopy (Fig.1) allows for the routine visualization of skull and soft tissue components in intact mouse heads including nasal epithelia, cranial nerves and brain. Our protocol permits the experimental study of interactions between human susceptibility alleles and naturally occurring pathogens to explore the etiologies of sporadic Parkinson's ('Braak hypothesis') and late-onset Alzheimer disease.

HEPARAN SULFATE IS INVOLVED IN CELLULAR UPTAKE OF ALPHA-SYNUCLEIN AGGREGATES

E. Ihse[1], J. Esko[2], E. Masliah[1]
[1]Department of Neurosciences, University of California San Diego, San Diego, USA
[2]Department of Cellular and Molecular Medicine, University of California San Diego, San Diego, USA

Objectives: Spreading of the pathology to increasingly larger areas of the brain has been proposed to be caused by a prion-like seeding mechanism in neurodegenerative diseases like Alzheimer´s and Parkinson´s disease. It has been shown that protein aggregates involved in these diseases can transfer from one cell to another, but not much is known about how the secretion or internalization occurs. The objective of the present project was to investigate if heparan sulfate proteoglycans (HSPGs) is involved in cellular internalization of alpha-synuclein aggregates, and if this is true only for aggregates with an amyloid structure or also for oligomeric species.
Methods: Alpha-synuclein in oligomeric or fibrillar conformation was added to the cell media of rat neuroblastoma B103 cells or CHO-cells deficient in HS altogether or in N- or 2-O-sulfation of the HS chains. Cellular uptake was determined by ELISA on cell lysates. Colocalization of HSPGs and alpha-synuclein aggregates was studied through confocal microscopy.
Results: Cellular uptake of fibrillar alpha-synuclein was almost completely abolished by the addition of heparin to the cell media of B103 cells, while internalization of oligomers where not inhibited to the same extent. Both oligomeric and fibrillar alpha-synuclein were seen to colocalize with HS in what seems to be endocytic vesicles. All of the CHO mutants showed strongly inhibited uptake compared to wt cells, but there was no significant difference between the different mutants.
Conclusions: HSPGs are involved in the cellular uptake of alpha-synuclein aggregates and the amyloid fibril structure is probably important for this interaction.

DIFFERENTIAL PATTERN OF NEURONAL LOSS IN THE CHOLINERGIC BASAL FOREBRAIN IN LEWY BODY DISORDERS

A.K.L. Liu[1], R.C.C. Chang[2], R.K.B. Pearce[1], S.M. Gentleman[1]
[1]Division of Brain Sciences, Imperial College London, London, United Kingdom
[2]LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong China

Introduction: The basal forebrain cholinergic system consists of the medial septum/diagonal band nucleus (MS/DBN), nucleus basalis of Meynert (nbM) and nucleus subputaminalis (NSP). These nuclei project to the hippocampus and various cortical regions. A posterior-anterior gradient of cortical cholinergic deficit in Lewy body disorders (LBD) has been reported on imaging studies. However, it is not clear whether this pattern is reflected by the neuronal loss in various basal forebrain cholinergic nuclei.
Objectives: To characterise the pattern of neuronal loss in different subdivisions of the cholinergic basal forebrain in Lewy body disorders.
Methods: Tissue sections containing the basal forebrain from 93 PD, 100 PDD, 14 DLB and 15 age-matched controls were stained using immunohistochemistry with choline acetyltransferase (ChAT) antibodies. ChAT-positive neurons in the MS/DB, NSP and nbM were quantified, blind to the clinical diagnosis.
Results: A significant reduction of ChAT-positive neurons was found in LBD cases, with demented cases showing a greater loss. All subdivisions of the nbM were equally affected in PDD whereas the anterior and posterior nbM have a greater loss in PD. DLB cases have a significantly lower number of ChAT-positive neurons in the MS/DBN. A trend of decrease in ChAT-positive neurons was observed in the NSP among LBD cases.
Conclusions: We have identified a differential pattern of cell loss in various subdivisions of the cholinergic basal forebrain in LBD cases. This could possibly explain the specific cognitive profile presented by LBD patients and support findings from recent imaging studies.

ROLE OF HSPGS IN EXOSOME-ASSOCIATED OLIGOMERIC ALPHA-SYNUCLEIN TRANSMISSION

M. Delenclos[1], T. Trendafilova[1], S. Moussaud[1], A.M. Baine[1], P.J. McLean[1]
[1]Neuroscience, Mayo Clinic, Jacksonville, USA

Objectives: Misfolding and aggregation of alpha-synuclein (αsyn) resulting in cytotoxicity is a hallmark of PD and related synucleinopathies. The recent body of evidence indicates that αsyn can be released from neuronal cells by nonconventional exocytosis involving extracellular vesicles such as exosomes. The transfer of αsyn between cells has been proposed to be an important mechanism of disease propagation in PD. The process by which αsyn is internalized into target cells remains largely unknown; although heparin sulfate proteoglycans (HSPGs) have been proposed to play a role. Here, we tested the hypothesis that HSPGs act as internalizing receptors for exosome-associated oligomeric αsyn.
Methods: Exosomes were purified from conditioned media of stable cells secreting αsyn oligomers. A novel bimolecular protein complementation assay was used to detect exosomes containing αsyn oligomers. Recipient cells were treated with exosomes containing αsyn oligomers and internalization was monitored. The role of HSPGs in exosome-associated αsyn internalization was investigated using both pharmacological and genetic approaches.
Results: We demonstrate that cell-derived exosome-associated αsyn oligomers can be efficiently internalized by recipient cells. Interestingly exosome-free αsyn oligomers isolated from conditioned medium were not internalized but remained bound to the extracellular surface. HSPG manipulation using genetically modified recipient cells (CHO-M1, CHO-745) did not attenuate internalization of exosome-associated αsyn oligomers.
Conclusions: Our data suggest that exosome-associated oligomeric forms of αsyn is preferentially taking up by recipient cells and that this process may be independent of HSPGs. Exosome-associated αsyn appears to be internalized via alternative endocytic pathways that are yet to be elucidated.

ADPD5-1847

IDENTIFICATION OF EXTRACELLULAR VESICLE BIOMARKERS AND CANDIDATE THERAPEUTIC TARGETS IN PD CELLULAR MODELS AND CLINICAL SAMPLES

A. Gharibyan[1], S. Zhu[1], L. Forsgren[1], M. Trupp[1]
[1]Pharmacology and Clinical Neurosciences, Umea University, Umeå, Sweden

Objective: There is increasing evidence that PD is characterized by multi-focal, progressive neurodegeneration that often begins in olfactory and vagal neurons, clinically presenting as a movement disorder only when substantia nigra neurons are severely compromised. Efforts to restore or replace neuronal populations post-presentation are likely to suffer from the existing and progressive load of misfolded and aggregated alpha-synuclein.

Methods: We suggest that the development of disease altering medications must focus upon identification of early markers of disease spread between neurons and characterization of these molecular mechanisms as candidate therapeutic targets. We are investigating the potential of extracellular vesicles (exosomes and ectosomes) to mediate transfer of different alpha-synuclein variants between multiple cell-types and attempting to identify molecular markers of toxic vesicles as candidate therapeutic targets.

Results: We have isolated and characterized extracellular vesicles from neuronal and glial cell lines, patient-derived fibroblast cultures, CSF and plasma, and have analyzed the physical characteristics by atomic force microscopy and electron microscopy. Dye labeled exosomes can be visualized and transferred between distinct cell types. Proteomic analysis of exosomes from patient derived fibroblasts, neuronal and glial cells identifies hundreds of proteins that are being analyzed for alterations in content and quantity following various cellular stresses.

Conclusions: Isolation and characterization of extracellular vesicles from patient biofluids and fibroblast, neuronal and glial cell cultures combined with proteomics and metabolomics analysis of membrane components represents a strong potential to identify candidate therapeutic targets to reduce the progressive spread of protein aggregation diseases.

ASSESSMENT OF THE ROLE OF PARKINSON'S DISEASE ASSOCIATED ATP13A2/PARK9 IN THE IN VIVO INTER-NEURONAL SPREAD OF ALPHA-SYNUCLEIN PATHOLOGY

L. Cottle[1], C.H. Stevens[2], F. Delerue[2], J. van Eersel[2], K.C. Luk[3], L.M. Ittner[2], A.A. Cooper[1]

[1]Neuroscience, Garvan Institute of Medical Research, Sydney, Australia
[2]Dementia Research Unit, University of New South Wales Australia, Sydney, Australia
[3]Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, USA

Objectives: Parkinson's disease (PD) is characterised by Lewy bodies containing aggregated alpha-synuclein. Clinical progression in PD correlates with an increasing number of brain regions displaying alpha-synuclein pathology. Intrastriatial injection of alpha-synuclein proto-fibrils into wild-type (WT) mice results in alpha-synuclein pathology spreading to inter-connected brain regions. Elevated ATP13A2 levels reduce alpha-synuclein toxicity and facilitate the extracellular release of alpha-synuclein *in vitro* while ATP13A2$^{-/-}$ patients have early onset PD. This *in vivo* study assessed the impact of ATP13A2 loss on alpha-synuclein pathology resulting from injected alpha-synuclein proto-fibrils.

Methods: WT and ATP13A2$^{-/-}$ mice were stereotaxically injected into the striatum with recombinant alpha-synuclein proto-fibrils or PBS. At 30 or 90 days post-injection (dpi), brains were fixed, and sections stained and analysed for phosphorylated alpha-synuclein (pS129) pathology.

Results: At 30 dpi, both WT and ATP132$^{-/-}$ mice injected with alpha-synuclein proto-fibrils showed pathology at the injection site (striatum), as well as the amygdala, cortex and thalamus, and at 90 dpi, considerable pathology was also observed in the substantia nigra. Intriguingly, the severity of alpha-synuclein-positive aggregates, particularly in the substantia nigra differed between the genotypes. The PBS injected brains showed no pS129 pathology.

Conclusions: The alpha-synuclein pathology from injected alpha-synuclein fibrils displayed a genotype specific effect with the loss of ATP13A2 modulating the extent and degree of (alpha-synuclein) pathology. This strongly suggests that ATP13A2 influences the inter-neuronal spread of alpha-synuclein toxicity and highlights possible therapeutic approaches to slow or prevent PD progression.

ADPD5-2223

LACK OF RELATIONSHIP BETWEEN NEURONAL INJURY AND NEURON-TO-NEURON ALPHA-SYNUCLEIN PROPAGATION

A. Ulusoy[1], R.E. Musgrove[1], R. Rusconi[1], M. Klinkenberg[1], M. Helwig[1], D.A. Di Monte[1]
[1]Bonn, German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany

Objectives:
Progressive spreading of alpha-synuclein (a-syn) from the lower brainstem to more rostral brain regions is a pathological feature of Parkinson's disease. The aim of this work was to determine if caudo-rostral a-syn propagation in a rat model was dependent upon or enhanced by neuronal injury/degeneration.
Methods:
Overexpression of human a-syn (ha-syn) was induced in the rat medulla oblongata (MO) by injections of AAV vectors carrying ha-syn DNA into the vagus nerve. This overexpression triggered a caudo-rostral protein spreading that was assessed by counting the number of axonal projections immunoreactive for ha-syn in the pons, midbrain and forebrain.
Results:
By varying AAV vector preparations and injection titers, two experimental conditions were obtained. Both conditions resulted in comparable levels of ha-syn overexpression. They differed, however, in regard to neuronal injury that occurred in the MO after treatment with one but not the other experimental paradigm. Spreading occurred regardless of cell injury. Interestingly, the count of ha-syn-containing axons in regions rostral to the MO was significantly higher in the absence than the presence of cell damage and neurodegeneration.
Conclusions:
Passive release from injured neurons is not essential for triggering a-syn transmission, nor does it exacerbate protein spreading. Data are consistent with the possibility that cell-to-cell transfer of a-syn involves active mechanisms within intact neurons and is therefore more pronounced when neuronal integrity is maintained.

03b.Pathophysiology & Disease Mechanisms: prion-like mechanisms

ADPD5-1384
A NOVEL APPROACH TO STUDY ALPHA-SYNUCLEIN UPTAKE AND ITS CONSEQUENCES

J. Gerez[1], *P. Picotti*[1]
[1]*Biology, Swiss Federal Institute of Technology, Zurich, Switzerland*

Objectives: Despite a growing body of evidence indicating that uptake of extracellular alpha-Synuclein (aSyn) can initiate the neurodegenerative cascade and major cardinal features of PD, very little is known about the physio(patho)logical changes associated to this process. Here we present a novel approach to i) study the ability of aSyn to be internalized and ii) characterize the cellular responses triggered by aSyn uptake.
Methodology: neuronal cells were treated with different aSyn species, and i) internalized aSyn was quantified by Selected Reaction Monitoring-mass spectrometry, ii) high-throughput gene and protein expression analysis were conducted and possible associations among differentially expressed genes and proteins were studied using bioinformatics tools.
Observations: We found that aSyn fibrils are efficiently internalized, in a dose and time-dependent manner. On the contrary, we did not observe uptake of monomers or oligomers. Gene expression analysis revealed subtle changes in cells treated with extracellular monomers and oligomers, while a pronounced response was observed in cells treated with aSyn fibrils. Differentially expressed proteins of cells treated with fibrils are functionally related and can be grouped into well-defined clusters according to their involvement in general but also neuron-specific biological processes such as calcium signaling, mitochondrial homeostasis and synaptic transmission, among others.
Conclusions: aSyn fibrils are efficiently internalized by neuronal cells triggering a pronounced and functionally orchestrated cellular response. Future biological follow-ups targeting differentially expressed genes will shed light into the precise contribution of internalized aSyn on the biological processes affected by aSyn uptake.

ADPD5-0729

ZNT3 AND ALPHA SYNUCLEIN IN LEWY BODY DEMENTIA

P. Francis[1], J. Vallortigara[1], A. Alghamdi[1], J. Attems[1], T. Hortobagyi[1], J. O'Brien[1], A. Thomas[1], C. Ballard[1], D. Whitfield[1]

[1]Wolfson Centre for Age-Related Diseases, King's College London, London, United Kingdom

Introduction & methods : The loss of zinc transporter 3 (ZnT3) in mice has been implicated in age-related cognitive decline and pathological aggregation. We investigated the importance of ZnT3 and a postsynaptic marker, PSD95, in people with Parkinson's disease dementia (PDD n=31), dementia with Lewy bodies (DLB n=44), Alzheimer's disease (AD n=16) and controls (n=24), using standardized cognitive assessments during life, semi-quantitative scoring of Abeta, tau and alpha-synuclein at post-mortem semi-quantitative western blotting and immunohistochemistry in three cortical regions. Concentrations of monomeric alpha synuclein were determined by commercially available ELISA. Furthermore, given the emerging relationship between zinc and depression we examined the relationship of ZnT3 and scores for depression.

Results: DLB and PDD were characterized by significant reductions of PSD95 ($p<0.05$) and ZnT3 ($p<0.001$) in prefrontal cortex compared to controls and AD. Strong associations were observed between ZnT3 and PSD95 levels in prefrontal cortex and cognitive impairment ($p=0.001$ and $p=0.002$ respectively). Associations were also seen between ZnT3 levels in cingulate cortex and severity of amyloid-beta ($p=0.003$) and tau pathology ($p=0.011$). Concentrations of monomeric alpha synuclein correlated positively with those of ZnT3 in all three regions (Rs 0.34-0.45, $p<0.01$). Reductions in ZnT3 in BA9 were significantly associated with elevated depression scores in the study cohort (beta=-0.351(SE=0.393) $p=0.0004$).

Conclusions: This study has identified Zn^{2+} modulation as a novel target for the treatment of cognitive impairment and depression in DLB and PDD, and the potential for synaptic proteins to be utilised as biomarkers for the differentiation of DLB and PDD from AD.

03c. Pathophysiology & Disease Mechanisms: synapse pathology

ADPD5-0975

LRRK2 KNOCK-OUT MICE ARE PROTECTED FROM ALPHA-SYNUCLEIN FIBRIL-INDUCED COGNITIVE IMPAIRMENT

A. Milnerwood[1], M. Volta[1], S. Bergeron[1], E. Mitchell[1], L. Munsie[1], D. Beccano-Kelly[1], M. Farrer[1]

[1]Centre for Applied Neurogenetics, Djavad Mowafaghian Centre for Brain Health, Vancouver, Canada

OBJECTIVES: Investigate the effect of alpha-synuclein (aSyn) fibril inoculation on motor and cognitive behavior in mice, with subsequent evaluation of aSyn neuropathology. Assess the involvement of LRRK2 in synuclein pathology using LRRK2 knock-out (KO) mice.

METHODS: aSyn pre-formed fibrils (aSyn-PFFs or PBS control) were unilaterally delivered by stereotactic injection into the dorsolateral striatum of LRRK2 KO mice and their non-transgenic (NT) littermates. Motor ability was evaluated by open field, cylinder and drag tests. Cognition was assessed in a novel object recognition paradigm. Testing was at 30 and 90 days post-injection (dpi). Animals were then transcardially perfused with PBS, brains removed, fixed in NaCl/EtOH and paraffin embedded. Sections (6 um) were stained for pSer129-aSyn to assess inclusion pathology.

RESULTS: Striatal administration of aSyn-PFFs induced cognitive deficits in the absence of motor impairment in NT mice at 30dpi. At this time LRRK2 KO mice were protected from PFF-induced cognitive deficits. Genetic deletion of LRRK2 conferred long-lasting protection, as KO mice retained normal cognitive ability at 90dpi. Pathological aSyn inclusions were not detected at 30dpi, but were observed at 90dpi in aSyn-PFF treated mice.

CONCLUSIONS: We reveal a cognitive deficit that is produced soon after aSyn-PFF injection in NT mice. This manifests in the absence of motor dysfunction and prior to the detection of aSyn neuropathology. Interestingly, genetic deletion of *Lrrk2* protects mice from this cognitive impairment. The data indicate that LRRK2 is required for the immediate pathogenicity of aSyn fibrils and that LRRK2 silencing may confer protection against synucleinopathy

03c. Pathophysiology & Disease Mechanisms: synapse pathology

ADPD5-0980

ENDOGENOUS LEVELS OF G2019S MUTANT LRRK2 ALTER SYNAPTIC TRANSMISSION AND BEHAVIOUR

A. Milnerwood[1], D. Beccano-Kelly[1], M. Volta[1], S. Paschall[1], N. Kuhlmann[1], I. Tatarnikov[1], S. Bergeron[1], E. Mitchell[1], L. Munsie[1], M. Farrer[1]

[1]Centre for Applied Neurogenetics, Djavad Mowafaghian Centre for Brain Health, Vancouver, Canada

Objective: We recently reported that glutamate transmission is elevated in cortical neuron cultures from LRRK2 G2019S knock-in (KI) mice, a finding correlated with alterations to the phosphorylation state of the presynaptic release regulator synapsin1. We sought to test whether results generated *in vitro* are supported by neurophysiological, behavioural and biochemical assays *in vivo*.

Methods: Motor and cognitive function was assessed in KI mice by open field exploration, spontaneous rearing, novel object location / recognition memory paradigms. Electrophysiological recordings in acute brain slices assessed changes in synaptic transmission and plasticity in striatal projection neurons (SPNs). Nigrostriatal dopamine function was probed by voltammetry in brain slices and microdialysis in behaving mice. Neurophysiology and behaviour were probed pharmacologically.

Results: As *in vitro* we found increased glutamatergic transmission in KI SPNs. Mice also exhibited alterations to the dopamine system and behavioural hyperactivity. Relative to littermates, KI mice exhibited differential responses to dopamine receptor pharmacology at both the behavioural and synaptic level.

Conclusions: At physiological expression levels, the LRRK2 G2019S mutation alters neuronal function and produces a consistent glutamatergic synaptic phenotype *in vitro* and *in vivo*. In mice, alterations to the glutamate and dopamine systems are accompanied by behavioural phenotypes. Characterising the manifestation, and natural history, of mutant-induced changes is crucial to understanding the pathophysiology of LRRK2. Accurate animal modeling and insights such as those presented here are required for the design of neuroprotective strategies and may help to provide intervention against this and potentially other forms of PD

03c. Pathophysiology & Disease Mechanisms: synapse pathology

ADPD5-2220

LONG-TERM IN VIVO IMAGING OF DENDRITIC SPINE DYNAMICS IN A MOUSE MODEL OF PARKINSON'S DISEASE

S. Blumenstock[1], *E. Rodrigues*[1], *J. Herms*[1]
[1]*Translational Brain Research,*
German Center for Neurodegenerative Diseases (DZNE) Munich, Munich, Germany

OBJECTIVES:
alpha-Synuclein is considered to be a crucial player in the disease progression of Synucleinopathies like Parkinson's disease (PD) or Lewy body dementia (LBD) and also has been reported in modulating brain plasticity. Alterations in distal neuronal compartments like dendritic spines during the course of neurodegenerative disease progression could hold important implications for the functioning of neural networks. In fact, cognitive decline in PD and LBD is a common symptom and could be attributed to impairments in cortical circuitries and synaptic plasticity.

METHODS:
We investigate how wild-type human alpha -Synuclein overexpression affects the dynamics of dendritic spines in the mouse somatosensory cortex. Imaging of layer V apical dendrites through a chronic cranial window is performed in PDGF-h-a-syn x GFP-M mice and in three different age groups. Using long-term *in vivo* two-photon microscopy, we are able to precisely follow the structural changes of dendritic spines over several weeks.

REULTS:
We find that overexpression of alpha-Synuclein profoundly affects spine dynamics as early as at 3 months of age. Compared to controls, the alpha-Synuclein overexpressing mice show decreased spine density in all analysed age groups. This might not only provide a link to dementia associated with PD and LBD, but also permits to investigate the effects of putative PD drugs *in vivo*.

ADPD5-0551

VPS35 DYSFUNCTION IMPAIRS LYSOSOMAL DEGRADATION OF ALPHA-SYNUCLEIN AND EXACERBATES NEUROTOXICITY IN A DROSOPHILA MODEL OF PD

E. Miura[1], T. Hasegawa[1], M. Konno[1], M. Suzuki[2], N. Sugeno[1], N. Fujikake[2], R. Oshima[1], A. Kikuchi[1], T. Baba[1], Y. Nagai[2], A. Takeda[3], M. Aoki[1]
[1]Department of Neuroscience & Sensory Organs,
Tohoku University Graduate School of Medicine, Sendai, Japan
[2]Department of Degenerative Neurological Diseases,
National Center of Neurology and Psychiatry, Kodaira, Japan
[3]Department of Neurology, National Hospital Organization Sendai-Nishitaga Hospital, Sendai, Japan

Objectives: Recently, a missence mutation of *Vacuolar Protein Sorting 35* (*VPS35*) was identified as the cause of PARK17. VPS35, a core component of the retromer, mediates retrograde transport of cargoes from the endosome to the *trans*-Golgi network. One of the best-characterized cargoes for the retromer is the cation-independent mannose 6-phosphate receptor (CI-MPR), which participates in the delivery of lysosomal hydrolases such as cathepsin D (CTSD). Because CTSD is the lysosomal endopeptidase responsible for alpha-synuculein (aSYN) degradation, the insufficient activation of CTSD by VPS35 malfunction may affect the clearance of aSYN in lysosome.
Methods: The silencing of *VPS35* was performed in HEK293 cells by target-specific siRNA. The expression of retromer components, CTSD and aSYN were evaluated by Western blotting and immunostaining. The effect of VPS35 on aSYN-induced neurotoxicity, *Drosophila* homologue of *VPS35* (*dVPS35*) was silenced using RNAi. VPS35-deficient flies were mated to the transgenic flies expressing human aSYN under pan-neural promoter *elav* or eye-specific promoter *GMR*. Two assays were used to screen for modifiers: eye degeneration and climbing behavior.
Results: *VPS35* RNAi altered distribution of CI-MPR and perturbed the maturation process of CTSD in parallel with the accumulation of aSYN in the lysosomes. Furthermore, *dVPS35* silencing not only induced the accumulation of the detergent-insoluble aSYN species in the brain but also exacerbated both locomotor impairments and eye degeneration in the flies expressing human aSYN.
Conclusions: These findings indicate that retromer may play a role in aSYN degradation by modulating CTSD activity and might thereby contribute to the pathogenesis of PD.

ADPD5-0596

MITOCHONDRIAL QUALITY CONTROL IN NEURONAL CELLS: THE FUNCTIONAL INTERPLAY BETWEEN PGC-1ALPHA AND PARKIN

L. Zheng[1], P. Aebischer[1], B. Schneider[1]
[1]Brain Mind institute, EPFL, Lausanne, Switzerland

As mitochondrial dysfunction plays a key role in the pathology of Parkinson's disease (PD), it is crucial to understand the precise role of factors that control the number and quality of mitochondria in neuronal cells. Parkin is an E3 ligase which actively participates in the mitophagic degradation of dysfunctional mitochondria. PGC-1alpha is a transcription co-activator functioning as the main regulator of mitochondria biogenesis. Here, we are interested in the functional interaction between PGC-1alpha and Parkin in mitochondrial quality control in the context of neuronal cells.

In cortical neuronal cultures, we found that Parkin overexpression further increases the number of mitochondria in cells overexpressing PGC-1alpha. In addition, there is a significant upregulation in the mitochondrial reserve respiratory capacity when PGC-1alpha and Parkin were co-overexpressed. The combined overexpression of both proteins also leads to a rapid recovery of mitochondrial membrane potential following uncoupling stress.

In vivo, we unilaterally overexpressed PGC-1alpha and Parkin in the rat substantia nigra. In conditions of PGC-1alpha overexpression, we found a significant protective effect of Parkin on the dopaminergic function. Although the loss of dopaminergic marker and survival of nigral neurons expressing PGC-1alpha was not significantly rescued by Parkin compared to control, there was a significant difference in the neuron survival between wild-type Parkin and the PD-associated mutants K161N and R42P.

Overall, these results highlight the concerted role of Parkin and PGC-1alpha on mitochondrial function. We propose that this functional interaction may have an important role in the survival and activity of nigral dopaminergic neurons in PD.

03d. Pathophysiology & Disease Mechanisms: autophagy and lysosomes

ADPD5-0655

SUMOYLATION AS A MODIFIER OF AUTOPHAGY IN ALPHA-SYNUCLEIN DISEASE

D.L. Pountney[1], M.B. Wong[1], S. Vijayakumaran[1], A.L. Cook[2], G.D. Mellick[3]
[1]Griffith Health Institute, Griffith University, Gold Coast, Australia
[2]School of Health Sciences, University of Tasmania, Launceston, Australia
[3]ESKITIS Institute, Griffith University, Brisbane, Australia

Objectives. Small ubiquitin-like modifier-1, SUMO-1, conjugates appear in lysosomes in neural cells in response to protein aggregates. We previously identified lysosomal Hsp90 as a major target for SUMOylation in multiple system atrophy (MSA) tissue, mouse and cell culture models. In the unilateral rotenone mouse PD model, aged mice showed higher baseline SUMOylation and a proportionately lower increase in SUMOylated proteins in response to lesion than the younger adult cohort. In the current study, we investigated whether SUMOylation dependent modulation of lysosomes varies in Parkinson's disease human olfactory neurosphere-derived (hONS) cell lines compared to cell lines from unaffected individuals. We also examined the influence of inhibiting SUMOylation on protein aggregate response and autophagy in a neuroblastoma cell model. **Methods.** Immunofluorescence and Western analysis was used to investigate SUMO-1 and alpha-synuclein distribution and expression in PD-derived and control hONS cell lines subjected to proteasome inhibition. Potassium depolarization of SH-SY5Y neuroblastoma cells was used to induce calcium influx and alpha-synuclein aggregates and subjected to anachardic acid, ginkgolic acid and spectinomycin pre-treatment to specifically inhibit SUMOylation. **Results.** We found that neurosphere-derived cell lines from PD cases have a higher baseline level of lysosome SUMOylation than cells from unaffected individuals and show reduced induction in response to proteolytic stress. In the neuroblastoma cell model, we observed reduced frequency of alpha-synuclein aggregates (p, 0.01) and upregulation of LC3-positive macroautophagosomes with SUMOylation inhibitors. **Conclusions.** Lysosomal SUMOylation is raised in PD cell lines and SUMO pathway Inhibitors may promote clearance of alpha-synuclein aggregates by autophagy.

VACUOLAR PROTEIN SORTING 35 (VPS35) INTERACTS WITH LEUCINE-RICH REPEAT KINASE 2 (LRRK2) TO REGULATE AUTOPHAGY

K. Venderova[1], R. Linhart[1], Y.J. Ho[1], D. Kaing[1], D. Sohal[1], E. Hou[1], E. Tsang[1], R. Fedrizzi[1], D. Fong[1], J. Rosales[1]

[1]Physiology and Pharmacology, University of the Pacific, Stockton, USA

Objectives: VPS35 is one of the latest causative genes of Parkinson's disease (PD). The protein is a key component of the retromer complex that prevents lysosomal degradation of specific proteins by their sorting and trafficking back from endosomes either to the plasma membrane, or to the Golgi. This pathway is known to be involved in APP processing and Alzheimer's disease. However, reports on how VPS35 contributes to PD pathogenesis are very limited. Therefore, our goal is to address this fundamental question.

Methods: We take advantage of the power of Drosophila genetics to analyze genetic interactions in vivo. We then assess locomotor activity, lifespan and sensitivity to rotenone in the double or triple transgenic lines. To determine if Vps35 is required for proper function of dopaminergic neurons, we knocked down expression of Vps35, using a Vps35-RNAi line.

Results: Knocking-down Vps35 expression impaired locomotor activity, which suggests that the pathogenic VPS35 mutation may act in a dominant negative fashion. Importantly, overexpression of Vps35 rescued the phenotype of pathogenic mutant LRRK2, including the eye phenotype, locomotor activity and shortened lifespan, highly suggesting that these two genes are part of a common pathway. Finally, we genetically manipulated key components in the cascade that initiates autophagy and determined that LRRK2 and VPS35 are most likely part of the same pathway regulating autophagy.

Conclusions: Our data present in vivo evidence that Vps35 interacts with pathogenic mutant LRRK2 and that these two genes most likely share a common endolysosomal pathway that is involved in regulating autophagic response.

AUTOPHAGY IS INVOLVED IN AGE-RELATED SENSITIVITY TO PARKINSONIAN PATHOGENESIS

Y.P. Yang[1], H.F. Zheng[1], C.J. Mao[1], F. Wang[2], L.F. Hu[2], C.F. Liu[1]
[1]Department of Neurology, The Second Affiliated Hospital of Soochow University, Suzhou, China
[2]Institute of Neuroscience, Soochow University, Suzhou, China

Objective To explore the underlying mechanisms of autophagy in high sensitivity to MPTP-caused neurotoxicity in aged C57BL mice.
Methods 3 and 16 months old male C57BL mice were intraperitoneally injected with MPTP four times a day at 2-h intervals. Pole climbing tests was performed after MPTP exposure. TH-positive neurons and fibers in SNpc and striatum were detected with immunostaining. TEM was used to examine autophagosome. Western blotting was used to examine the protein levels of TH, α-synuclein, LC3-II, P62 and HDAC6 as well.
Results Compared with 3-month-old PD mice, 16-month-old PD mice showed significant shorter pole-climbing time after MPTP treatment. Age-associated changes in 16-month-old PD mice included the reduction in the densities of TH positive cells/fibers in SNc and striatum, lower TH protein expression, and α-synuclein accumulation as well. Under TEM, we observed increased lipofuscin and swollen mitochondria in 16-month-old parkinsonian mice. In 16-month-old mice treated with saline, the protein levels of LC3-II and P62 declined while P62 protein increased with age. Compared with 3-months-old PD mice, 16-months-old PD mice showed lower protein expressions of LC3-II and HDAC6.
Conclusion Ageing aggravated the DA neurons injury caused by MPTP. 16-month-old mice showed a high sensitivity to MPTP neurotoxicity. In 3-month-old mice, autophagy stress mediated by HDAC6 weakened the cytotoxicity of MPTP to a certain degree. While in 16-month-old mice, autophagy decompensation may be responsible for the higher sensitivity to MPTP neurotoxicity in aged mice.
Study Supported by: National Natural Science Foundation of China (No. 81171213 and 81301091).

03e. Pathophysiology & Disease Mechanisms: proteasome and ubiquitin

ADPD5-1779
IMPACT OF IMMUNOPROTEASOMES ON THE PATHOGENESIS OF NEURODEGENERATIVE DISEASES

L. Wagner[1], S. Prokop[1], E. Krueger[2], P.M. Kloetzel[2], F.L. Heppner[1]
[1]Department of Neuropathology, Charite University Medicine Berlin, Berlin, Germany
[2]Institute of Biochemistry, Charite University Medicine Berlin, Berlin, Germany

The ubiquitin-proteasome-system (UPS) plays a central role in clearance of misfolded and oxidant-damaged proteins, which comprise a hallmark of many neurodegenerative diseases. Upon stimulation by interferons (IFN) catalytic subunits of the 20S proteasomes (s-proteasomes) can be replaced by alternative subunits, giving rise to the catalytically active immunoproteasomes (i-proteasomes). Since i-proteasomes play an important role in clearance of oxidant-damaged proteins that preferentially accumulate upon inflammatory stimulation, and neuroinflammation is a common finding in neurodegenerative diseases, we tested the expression of i-proteasomes during disease progression in mouse models of Alzheimer's disease (AD) and Parkinson´s disease (PD) and analyzed the impact of deficient i-proteasome function on disease pathogenesis by genetically ablating the beta5i(LMP7) i-proteasome subunit.
We demonstrate that expression of i-proteasome subunits in the brain increases upon aging, but is significantly accelerated by accumulation of misfolded proteins in AD and PD mice.
Genetic ablation of the LMP7 subunit and therefore i-proteasome activity attenuated the secretion of proinflammatory cytokines by microglia in AD mice but revealed no major impact on cerebral beta-amyloid burden compared to AD mice with functional i-proteasomes. In contrast, PD mice lacking functional i-proteasomes highlight an increase of aggregated alpha-Synuclein accompanied by worsening of associated pathology.
Our studies show that i-proteasomes are upregulated during the course of neurodegenerative diseases and that i-proteasome deficiency has a differential impact on course and associated pathology in models of intracellular and extracellular proteinopathies. These data underscore the importance of considering all aspects of disease associated pathology and highlight i-proteasomes as potential therapeutic targets in neurodegenerative diseases.

HYPERIN ATTENUATES LIPOPOLYSACCHARIDE-INDUCED MICROGLIA ACTIVATION THROUGH INHIBITION OF P38 AND NFκB SIGNALING

N. Wang[1], Y. Wang[2], X. Zhang[2], J. Zhu[2]
[1]Neurology, The First Affiliated Hospital of Fujiang Medical University, Fuzhou, China
[2]Neurology, Wenzhou Medical University, Wenzhou, China

Objectives:Hyperin is an active compound isolated from *Rhododendron brachycarpum* G. Don (Ericaceae). In this study, we aimed to investigate its potentiality in inhibition of neuroinflammation.
Methods:BV2 microglial cells were pretreated with hyperin and stimulated with lipopolysaccharide (LPS).
Results:The results showed that hyperin significantly inhibited LPS-induced production of nitric oxide (NO) and pro-inflammatory cytokines such as TNF-α and IL-1β. Further analysis showed that inducible nitric oxide synthase (iNOS) and mRNA expression of TNF-α and IL-1β were attenuated by hyperin pretreatment. Analyses in signaling pathways demonstrated that hyperin led to suppression of LPS-induced p38 MAPK and p65/NFκB activation, but had little effect on the activation of JNK1/2 and Erk1/2. Interference with specific inhibitors revealed that hyperin attenuated the LPS-induced production of NO, TNF-α and IL-1β via both p38 and NFκB pathways.
Conclusions:Collectively, our data suggest that hyperin may serve as an anti-inflammatory agent and contribute to the suppression of neuroinflammation in disorders such as Parkinson's disease.

ADPD5-2268

ROTENONE ATTENUATES THE TOXICITY AND THE ELEVATION OF REACTIVE OXYGEN SPECIES INDUCED BY PARAQUAT IN SK-N-SH NEURONAL CELL LINE.

C. Ramassamy[1], *M. Lambert*[1], *M. Arseneault*[1]
[1]*INRS–Institut Armand-Frappier, INRS, Laval, Canada*

Parkinson's disease (PD) is a chronic neurodegenerative disorder which affects 1–3% of the elderly population worldwide with the majority of PD cases (90–95%) being sporadic. Recent epidemiological data suggests a link between the exposure to environmental pesticides toxicants such as paraquat and rotenone and an increased risk in developing PD.

The mechanism of paraquat-induced dopaminergic cell damage involves increased production of oxygen-free radicals via a redox cycling mechanism leading to the formation of the superoxide anion in both the cytosol and the mitochondrial matrix. Rotenone is a lipophilic and natural pesticide, able to cross the blood-brain barrier. Rotenone inhibits complex I of the mitochondrial electron transport chain leading to the formation of ROS such as superoxide, subsequently causing reduced glutathione levels and oxidative stress.

Objectives: We have investigated the synergic toxicity of rotenone and paraquat.

Methods: The synergic effect of paraquat and rotenone was studied on SK-N-SH neuronal cell line. For this, SK-N-SH cells were co-treated with paraquat (70 mM) and rotenone (0.1 mM, 10 mM) for 24 hours.

Results: We found that paraquat induced cell death, the elevation of reactive oxygen species (ROS), of glutathione and of mitochondrial superoxide levels. The presence of rotenone at 0.1 mM attenuated the toxicity induced by paraquat, blocked the elevation of ROS and of glutathione induced by paraquat. At this concentration, rotenone did not induce the alteration in ROS steady-state levels.

Conclusion : These results demonstrate that a low dose of rotenone could counteract the toxicity of the pesticide paraquat.

ADPD5-0557

MODULATING AMPK ACTIVITY HAS NEUROPROTECTIVE EFFECTS IN THE IN VITRO AND IN VIVO MODELS OF PARKINSON'S DISEASE

W. Bobela[1], *P. Aebischer*[1], *B. Schneider*[1]
[1]*BMI, EPFL, Lausanne, Switzerland*

1. Objectives

Our objective was to establish how AMPK activity modulation affects the survival of primary cortical neurons and dopaminergic cells in the rat substantia nigra after exposure to rotenone or alpha synuclein over-expression.

2. Methods

We used AAV vectors to over-express three variants of the catalytic alpha2 subunit of the AMPK, wild-type (WT), dominant negative (K45R) and constitutively active (CA) in mouse primary cortical neurons and in the rat *substantia nigra*. Parkinsonian degeneration was induced by either AAV-mediated over-expression of human alpha-synuclein (*in vivo* and *in vitro*) or 2.5nM rotenone (*in vitro*).

3. Results

We discovered that over-expression of WT alpha2 subunit leads to a significant reduction in the AICAR-induced catalytic activity of the AMPK complex in neuronal cells, which predominantly express the alpha1 subunit. This was even more evident for the K45R subunit.

In primary cortical neurons exposed to sub-toxic concentrations of rotenone, basal oxygen consumption is increased in cells expressing the WT and K45R alpha2 subunits. Furthermore, WT alpha2 prevents reduction of mitochondrial load in cells exposed to the toxin.

In vivo, we found that over-expression of the aforementioned forms of AMPK's alpha2 subunit in the rat *substantia nigra* significantly protected dopaminergic neurons against alpha-synuclein-induced neurodegeneration.

4. Conclusions

This study indicates that modulation of AMPK activity may show significant neuroprotective benefits in various models relevant to PD. Our results also strongly support further exploration of the roles of both the alpha1 and alpha2 subunits of AMPK in the context of metabolic perturbations observed during PD progression.

CURCUMIN SHOWS PROTECTIVE EFFECTS AT A MITOCHONDRIAL LEVEL IN A PINK1 SIRNA-MEDIATED CELLULAR MODEL OF PARKINSON'S DISEASE

C. van der Merwe[1], H. van Dyk[2], C. Kinnear[1], F. van der Westhuizen[2], B. Loos[3], S. Bardien[1]

[1]Molecular Biology & Human Genetics, Stellenbosch University, Cape Town, South Africa

[2]Biochemistry, North West University, Potchefstroom, South Africa

[3]Physiological Sciences, Stellenbosch University, Cape Town, South Africa

1. Objectives

Mutations in the *PINK1* gene are responsible for autosomal recessive Parkinson's disease (PD). The project aimed to determine the effect of a *PINK1* knock down (KD) model of PD and the effects of the antioxidant curcumin on mitochondrial function.

2. Methods

A siRNA-mediated KD in a SH-SY5Y neuroblastoma cell line was used for all functional studies. PINK1 KD cells and controls were either i. treated with 25µM paraquat for 24hours or ii. pre-treated with 2µM curcumin for 1hour before the paraquat treatment. Thereafter, cell viability was measured by an MTT assay, and mitochondrial respiration experiments were performed on the Seahorse XF Analyser.

3. Results

The PINK1 KD model showed a significant decrease in cell viability ($p<0.01$, 23.13%), maximal mitochondrial respiration ($p=0.0276$) and ATP production ($p=0.0156$). All cells treated with paraquat alone showed an expected decrease in viability, basal and maximal respiration, ATP production and spare capacity. Curcumin pre-treatment in control cells significantly increased the cell viability ($p<0.001$), the maximal respiration ($p=0.0248$) and the ATP production ($p=0.004$). In PINK1 KD cells, although curcumin did not significantly increase the cell viability or respiration parameters, it did significantly increase the ATP production ($p=0.0253$). These results suggest a protective effect of curcumin against paraquat.

4. Conclusions

PINK1 siRNA-mediated KD in SH-SY5Y cells can be used as a model of PD to study aspects of mitochondrial dysfunction. Furthermore, curcumin should be considered as a possible therapeutic target for PD, as it exhibits protective effects against paraquat at a mitochondrial level.

ADPD5-1501

A STUDY OF MITOCHONDRIAL QUALITY CONTROL IN IPSC-DERIVED HUMAN DOPAMINERGIC NEURONS WITH A PATHOGENIC MUTATION IN OPA1

M. Elschami[1], S. Noack[1], S. Wigfield[2], S.A. Cowley[3], G.K. Tofaris[1]
[1]Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom
[2]Department of Oncology, The Weatherall Institute of Molecular Medicine, Oxford, United Kingdom
[3]Division of Medical Sciences, Sir William Dunn School of Pathology, Oxford, United Kingdom

Objectives:
The viability of dopaminergic neurons is critically dependent on the function of mitochondrial quality control mechanisms, which have been implicated in Parkinson's disease. While many studies have investigated parkin-mediated mitophagy, very little is known about the significance of mitochondrial fusion-fission in human dopaminergic neurons or the neuronal response to defects in this process. To address this question we generated iPSc-derived dopaminergic neurons from patients with haploinsufficiency in the GTPase Opa1, which regulates mitochondrial fusion and cristae morphology.
Methods:
iPSc-derived dopaminergic neurons were differentiated in the presence of neurotrophic factors following dual SMAD inhibition. Neurite length and mitochondrial fragmentation were assessed by fluorescent microscopy. Mitochondrial ultrastructure was imaged by TEM and mitochondrial respiration was assessed by Seahorse. Parkin-mediated mitophagy was analysed by fluorescent microscopy following nucleofection of YFP-tagged parkin.
Results:
We successfully generated iPSc-derived human neurons expressing neuronal (Tuj1, Tau, alpha synuclein) and dopaminergic (TH, GIRK2) markers. Although the percentage of dopaminergic neurons generated was not affected by Opa1 haploinsufficiency, patient neurons displayed reduced neurite length and branching. Initial functional assays indicated that neurons with Opa1 mutation exhibit a reduction in OXPHOS and disorganized cristae morphology. Surprisingly, these defects did not correlate with mitochondrial fragmentation or recruitment of parkin.
Conclusion:
We describe a unique model for the study of mitochondrial dysfunction in human dopaminergic neurons. Detailed understanding of the cellular changes in this model could provide novel fundamental insights into the pathophysiology of Opa1 mutations and the adaptive response of human dopaminergic neurons to mitochondrial damage.

ADPD5-0424

LEVELS OF CSF IL-6 ARE DECREASED AND CORRELATE WITH MMSE AND CSF LEVELS OF ALPHA-SYNUCLEIN IN DLB PATIENTS.

M. Wennström[1], S. Hall[1], O. Hansson[1]
[1]Clinical Sciences Malmö, Lund University, Malmö, Sweden

Objectives: Inflammatory processes have previously shown to influence cognition and dementia progression. An involvement of interleukin (IL)-6 has in particular been suggested, as altered levels of IL-6 in cerebrospinal fluid (CSF) have been found in patients with Alzheimer's disease (AD). Also an association between cognitive decline and levels of IL-6 in CSF have been reported. The current study aimed to investigate whether clinically diagnosed patients with dementia with Lewy bodies (DLB) display altered CSF IL-6 levels in comparison with AD patients and non-demented controls and whether the IL-6 levels are correlated with cognitive status and biomarkers for AD and synucleinopathy.

Methods: Immunoassays measuring levels of IL-6 (Multiplex electrochemiluminiscence, Mesoscale), AD markers P-tau, T-tau and amyloid beta 1-42 (ELISA, Innogenetic) and alpha- synuclein (ELISA, Invitrogen) were used to analyze CSF from AD patients (n=53), DLB patients (n=32) and controls (n=46). Cognitive status was evaluated using the Mini Mental State Examination (MMSE).

Results: Our analysis showed significantly lower levels of IL-6 in CSF from DLB patient compared to CSF from both controls and AD patients. The IL-6 levels were additionally negatively correlated with MMSE in both AD and DLB patients, but not in controls. Also a positive correlation between alpha synuclein levels and IL-6 levels was detected in CSF from DLB patients.

Conclusion: Our findings support previous studies demonstrating a link between inflammatory processes and dementia progression and further strengthen the hypothesis that IL-6 is involved in dementia pathology and cognitive decline.

ADPD5-0450

MICROGLIAL ACTIVATION IN MULTIPLE SYSTEM ATROPHY

A. Kiely[1], Y.T. Asi[1], Z. Ahmed[1], T. Revesz[1], J.L. Holton[1]
[1]Molecular Neuroscience, UCL Institute of Neurology, London, United Kingdom

Objectives:
Multiple system atrophy (MSA) is an adult-onset neurodegenerative disease characterised by aggregation of alpha-synuclein in oligodendrocytes to form glial cytoplasmic inclusions. MSA is classified according to the most severely affected brain regions: striatonigral degeneration (SND), olivopontocerebellar atrophy (OPCA) or as a mixed form. Microglial activation is reported to occur in MSA. Here we determine which microglial activation state, phagocytic M1 or anti-inflammatory M2, dominates in MSA brain and how this relates to severity of pathology.

Methods:
Patient brain donation enabled detailed post-mortem neuropathological examination including immunohistochemical and double label immunofluorescence microscopy in paraffin embedded brain tissue. Double immunofluorescence using a series of M1 (CD68, TSPO and TNF-alpha,) and M2 (Arginase-1, TSPO and YM1) microglial activation markers together with microglial marker Iba-1 was quantified and analysed in severely and mildly affected regions of six control, SND and OPCA MSA brains.

Results:
Microglial activation was observed in all regions examined in both MSA cohorts. Microglia were identified as M1 (positive for CD68 or TNF-alpha and Iba-1 or TSPO) or M2 (positive for Arginase-1 or YM1 and Iba-1 or TSPO). TSPO was determined to be a reliable marker of microglial activation. A trend towards increased M1 activation in MSA compared to M2 was observed by colocalisation of TSPO with CD68 immunoreactivity. This increase was significant in the substantia nigra in SND and OPCA MSA subtypes.

Conclusions:
Neuroinflammation is identified in MSA brain and may contribute to disease pathogenesis. Our results suggest that a specific microglial activation state may dominate in MSA brain.

ADPD5-0658
ALPHA-SYNUCLEIN AS AN EXTRACELLULAR TRIGGER OF NEUROINFLAMMATION IN MULTIPLE SYSTEM ATROPY

D.L. Pountney[1], R. Radford[1], B. Vieira[1], T.C. Dickson[2], G.J. Guillemin[3], R. Chung[3]
[1]Griffith Health Institute, Griffith University, Gold Coast, Australia
[2]Menzies Research Institute Tasmania, University of Tasmania, Hobart, Australia
[3]School of Advanced Medicine, Macquarie University, Sydney, Australia

Objectives. As degenerating neurons release alpha-synuclein it may mediate astrocyte activation or result in intracellular inclusion bodies following endocytosis. Multiple system atrophy (MSA) exhibits widespread astrogliosis together with glial alpha-synuclein cytoplasmic inclusions (GCIs) in mature oligodendrocytes. In the current study, astrocyte activation was analyzed by quantitative morphometry and by using molecular markers. **Methods.** We quantified astrocyte activation by morphometric analysis of MSA cases, and investigated the correlation to distance to nearest GCI as a proxy for extracellular alpha-synuclein. We obtained 'skinned' three-dimensional models of GFAP-positive astrocytes in MSA and control tissue (n = 75) from confocal z-stacks and measured the astrocyte process length and thickness and radial distance to GCI. **Results.** Astrocytes proximal to GCI-containing oligodendrocytes (r < 25 μm) had significantly (p, 0.05) longer and thicker processes characteristic of activation than distal astrocytes (r > 25 μm), with a reciprocal linear correlation (m, 90 μm^2) between mean process length and radial distance to the nearest GCI (R^2, 0.7). In primary cell culture studies, alpha-synuclein addition caused ERK-dependent activation of rat astrocytes and perinuclear alpha-synuclein inclusions in mature (MOSP-positive) rat oligodendrocytes. Activated astrocytes were also observed in close proximity to alpha-synuclein deposits in a unilateral rotenone-lesion mouse model. Moreover, unilateral injection of MSA tissue-derived alpha-synuclein into the mouse medial forebrain bundle resulted in widespread astrocyte and microglial activation in the alpha-synuclein-injected, but not sham-injected hemisphere. **Conclusions.** Taken together, our data suggests that the action of localized extracellular concentrations of alpha-synuclein may underlie both astrocyte and oligodendrocyte MSA pathological features.

ADPD5-0967

LAXATIVES ARE ASSOCIATED WITH LOWER RIGIDITY IN IDIOPATHIC PARKINSONISM

S.M. Dobbs[1], A. Augustin[1], A. Charlett[2], C. Weller[1], D. Taylor[1], I. Bjarnason[3], R.J. Dobbs[1]

[1]Institute of Pharmaceutical Sciences, King's College London, London, United Kingdom
[2]Statistics Unit Centre for Infectious Disease Surveillance and Control, Public Health England, London, United Kingdom
[3]Gastroenterology, King's College Hospital, London, United Kingdom

Aim. To investigate whether improving intestinal-transit might reduce rigidity in idiopathic parkinsonism (IP). Two-thirds of IP-patients are hydrogen-breath-test-positive for small-intestinal-bacterial-overgrowth at presentation. Flexor-rigidity is greater the higher the circulating natural-killer cell count, an effect modulated by CD4+ count. Both counts are higher with breath-test-positivity.

Methods. Relationships of interventions to rigidity were explored using generalised linear mixed models. Surveillance yielded 1461 measures of torque required to extend/flex forearm in 78 IP-patients over 369 person-years. Maintenance osmotic laxative (macrogols) was exhibited in 55 (193 person-years); bulk-forming (ispaghula husk/methylcellulose/sterculia) in 58 (216); enterokinetic agent (prucalopride) in 26 (43); guanylate cylase-C receptor agonist (linaclotide) in 12 (6). Dopaminergic agonists were exhibited in 48 (250), MAO-B inhibitors in 45 (241), levodopa combinations in 31 (149), amantadine in 24 (81), anti-cholinergics (low dose) in 31 (177), propranolol in 11 (39), antidepressant in 13 (20).

Results. There was a significant temporal increase (6 (95% CI 2, 10) % per year, p=0.006) in flexor-rigidity, a consequent increase in the ratio, flexor/extensor, denoting flexed posture (4 (2, 8) % per year, p=0.04). Exhibition of laxatives stemmed the increase in flexor-rigidity. Anti-parkinsonian medication had no additional effect. There was a significant decrease in ratio with propranolol (-19 (-30, -6) %, p=0.006), reflecting an increase in extensor-rigidity (20 (2, 40) %, p=0.03). The ratio increased with antidepressants (28 (12, 46) %, p<0.001), reflecting a tendency to decreased extensor-rigidity (-13 (-24, 0) %, p=0.06).

Conclusions. Laxative may reduce rigidity by reducing inflammation directly or its inhibitory effect on responsiveness to anti-parkinsonian medication.

NEUROINFLAMMATORY MARKERS IN LEWY BODY DEMENTIAS
M.K.P. Lai[1], J.H. Lee[1], Y.L. Chai[1], Y.N. Zhu[1], D. Aarsland[2], C. Ballard[3], P.T. Francis[3], C.P. Chen[1]
[1]Pharmacology, National University of Singapore, Kent Ridge, Singapore
[2]Neurobiology Care Sciences & Society, Karolinska Institute, Stockholm, Sweden
[3]Wolfson Centre for Age-Related Diseases, Kings College London, London, United Kingdom
Introduction: Neuroinflammation is an important feature of Alzheimer's disease (AD). However, little is known about the inflammatory status of Lewy body dementias, including Parkinson disease dementia (PDD) and dementia with Lewy bodies (DLB).
Methods: Levels of beta-amyloid ($Abeta_{1-42}$), phosphorylated tau (pS396 tau) as well as inflammatory cytokines and chemokines in neocortical brain homogenates from aged controls, AD, PDD and DLB cases were measured using ELISA and Luminex assays.
Results: AD and DLB both showed significant $Abeta_{1-42}$ and p396 tau burden, at levels significantly higher than controls. In contrast, only AD showed significantly higher levels of inflammatory markers, while neuroinflammatory markers are unchanged in both PDD and DLB.
Discussion: Both PDD and DLB have a relatively mild neuroinflammatory response compared with AD. The efficacy of anti-inflammatory therapeutic approaches may therefore be more limited in PDD and DLB.

03i. Pathophysiology & Disease Mechanisms: inflammation

[3]pharmacology, Federal University of Ceará, Fortaleza, Brazil
[4]Anatomy, Federal University of Piauí, Picos, Brazil
[5]Faculty of Medicine, Federal University of Ceará, Fortaleza, Brazil

Objetive: Relate the neuroprotective effect with anti-inflammatory activity of *Myracrodruon urundeuva* stantardized extract.**Methods:** Male Wistar rats were submitted to an unilateral striatal injection of 6-OHDA. The groups used: sham-operated (SO), 6-OHDA and 6-OHDA treated with SD (10 and 20 mg/kg, p.o., for 2 weeks). The animals were subjected to apomorphine-induced rotations and rota rod tests; and then euthanized for striatal dissections and dopamine and DOPAC determinations; and immunohistochemical (tyrosine hydroxylase – TH) assay. The anti-inflammatory *in vitro* effect was investigated on human neutrophil degranulation induced by phorbol mirystate acetate (PMA; 0.1 µM); the levels of myeloperoxidase (MPO) were determinated at 620 nm. The cytotoxicity assay of SD (0.1-100 µg/mL) was performed by the MTT test in human neutrophils. The data were analized by ANOVA and Newman-Keuls test or the Student's t test and considered significant at $p<0.05$. **Results:** SD reduced the number of apomorphine-induced circling behavior and number of falls. SD increased TH immunoreactivity and reduced the DA depletion observed in the striatal lesioned side of the 6-OHDA-group. SD also inhibited MPO release by neutrophils, at all concentrations tested, with 67% inhibition at the lowest concentration (0.1 µg/mL), when compared to the control group. Similar results were observed with INDO. The treatment of human neutrophils with SD did not significantly reduce the viability of cells, as determined by the MTT test. **Conclusion:** The present study showed that SD has a neuroprotective effect in the DP model and this may be related, at least in part, to its anti-inflammatory property.

ADPD5-1665

PROFILE OF TIME COURSE OF RIGIDITY FOLLOWING EXHIBITION OF DIFFERENT LAXATIVE CLASSES IN IDIOPATHIC PARKINSONISM

A. Augustin[1], R.J. Dobbs[1], C. Weller[1], A. Charlett[2], I. Bjarnason[3], D. Taylor[1], S. Dobbs[1]
[1]Pharmaceutical Science, King's College London, London, United Kingdom
[2]Centre for Infectious Disease Surveillance and Control, Public Health England, London, United Kingdom
[3]Gastroenterology, King's College Hospital, London, United Kingdom

Aim. To investigate whether stemming of the temporal increase in flexor rigidity [6 (95% CI 2, 10) % per year, p=0.006] by laxatives (AD/PD 2015), in idiopathic parkinsonism (IP), is attributable to particular pharmacological classes.
Methods. The surveillance data (1461 measures of torque required to extend/flex forearm in 78 IP-patients over 369 person-years) was further explored with respect to exhibition of maintenance osmotic and bulk-forming (ispaghula husk/methylcellulose/sterculia) laxatives; an enterokinetic agent (prucalopride); and guanylate cylase-C receptor agonist (linaclotide). Natural logarithms of rigidity values were used as the dependent variable in mixed effects, random coefficient models. Linear splines, pre- and post-intervention, were used to assess temporal trends. All analyses were adjusted for anti-parkinsonian and other relevant medicinal interventions.
Results. Bulk-forming laxatives [exhibited in 58 (216 person-years)] and prucalopride [26 (43)] simply stemmed the increase in flexor-rigidity. Exhibition of macrogols [55 (193)] tended to shift rigidity values downwards (-7 (95% CI (-13, 1) %, p=0.07) as well as stemming the increase. Exhibition of linaclotide [12 (6)] tended to reverse the temporal trend (-42 (-78, 4) % per year, p=0.07).
Conclusions. Laxatives are an integral part of the anti-parkinsonian armamentarium, not only because constipation affects quality of life but also because they appear to ameliorate a cardinal sign. Moreover, osmotic laxatives and linaclotide tended to reversal the upward trend in flexor rigidity, despite anti-parkinsonian medication.

Objetive: evaluate the effect of standardized extract of M. urundeuva in hippocampal changes observed in rats subjected to an experimental model of Parkinson's disease. **Methods:** The standardized extract of *Myracrodruom urundeuva* (SEMU) (20 and 40 mg/kg,p.o), was tested in a experimental model of PD induced by 6-hidoxidopamine (6-OHDA, 12 µg/µl). Male Wistar rats (200 g) were divided in 3 groups (n=8): lesioned group and 6-OHDA treated with SEMU 20 mg/kg and 40 mg/kg (p.o,for 15 days). At the end of the treatments, the brain was dissected for performing cortical histological sections and subsequently, underwent immunohistochemistry for: iNOS and COX-2. For all histological methods, there was a count of marked cells for quantitative analysis. The results were expressed as means ± SEM. One-Way ANOVA and Student Newman Keuls as the *post hoc* test were used and results considered significant at $p<0,05$. **Results:** The number of cells stained for COX-2 and iNOS was significantly lower on SEMU (40mg/kg) treated animals (22,83 ± 1,70; 50,67 ± 3,04; respectively) compared to 6-OHDA group (66,83 ± 1,88; 78 ± 2,88, respectively); Values found in the group SEMU 20 were: 29,67 ± 1,56; 73,17 ± 2,12, respectively ,showing a tendece for a dose dependency.**Conclusion:** SEMU provide decrease in cortical inflammation, responsible in part for non-motor symptoms of PD.

IL-10 MODIFIES DISEASE PROGRESSION AND PATHOLOGY IN A MOUSE MODEL OF ALPHA SYNUCLEINOPATHY

P. Chakrabarty[1], M.T. Brooks[1], V. Hudson[1], Y. Levites[1], N. DiNunno[1], B. Giasson[1], T. Golde[1]

[1]Neuroscience, University of Florida, Gainesville, USA

An invariant feature of the pathological cascade in alpha-synucleinopathies is reactive gliosis and broad activation of the innate immune response in the CNS. Though proinflammatory innate immune activation has been postulated to accelerate alpha-synuclein (aS) pathology in mice, there is a paucity of data exploring the therapeutic potential of dampening immune activation. In primary mixed neuronal cultures treated with exogenous alpha-synuclein fibrils, rAAV mediated expression of IL-10, a master anti-inflammatory cytokine, suppresses proinflammatory chemokine, cytokine and other innate immune factor gene induction (Figure 1). Based on this data that IL-10, an anti-inflammatory cytokine, markedly dampens innate immune activation in vitro, we postulated that IL-10 based therapies may have beneficial outcome in aS mouse models. We have tested the effect of spinal cord targeted delivery of rAAV-IL-10 in the homozygous M83 mice expressing the A53T mutan alpha synuclein. An additional 'seeded' model using the peripheral to central propagation of aS pathology in hemizygous M83 mice were also used (See, Sacino et al, Proc Natl Acad Sci, 2014). Our results, which have been reproduced in at least two cohorts, show that IL-10 expression leads to accelerated disease progression (i.e., paralysis and/or moribund state) in both the homozygous and seeded hemizygus M83 transgenic mice (Figure 2). Biochemical analysis of the spinal cords reveal that IL-10 modulates innate immune activation and also affects the ubiquitination of soluble aS. These intriguing results reveal the unexpected and complex interplay between innate immunity and proteostasis in mouse models of synucleinopathies.

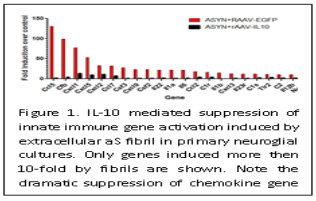

Figure 1. IL-10 mediated suppression of innate immune gene activation induced by extracellular aS fibril in primary neuroglial cultures. Only genes induced more then 10-fold by fibrils are shown. Note the dramatic suppression of chemokine gene

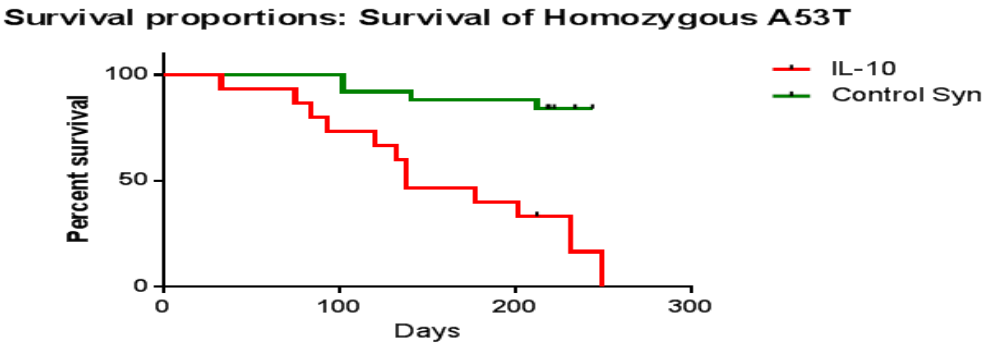

Figure 2: Spinal cord directed expression of rAAV-IL-10 accelerates disease process in homozygous aS M83 mice compared to rAAV-EGFP expressing mice. n=12/group.

LYSOSOMAL CHOLESTEROL ACCUMULATION MIGHT BE BENEFICIAL TO PATIENT SUFFERING FROM PARKINSON'S PATHOLOGY, YET CHOLESTEROL COULD BE A RISK FACTOR TO NORMAL INDIVIDUALS.

S. Nath[1], I. Eriksson[1], A.M.V. Giraldo[1], K. Öllinger[1]
[1]Clinical and experimental medicine, Linköping University, LINKÖPING, Sweden

Objective: Parkinson's disease (PD) is progressive degenerative disease of the central nervous system and till now there is no cure for the disease. According to recent studies, statins, the widely used cholesterol lowering drugs, might be beneficial in PD. However, due to contradictory finding the role of cholesterol in PD is still inconclusive. The true challenge is to understand the cholesterol homeostasis in PD.
Methods and results: We have found that MPP+-induced cell death is accompanied by cholesterol accumulation in pre-apoptotic cells in a lysosomal like pattern in BE(2)-M17 neuroblastoma cells. We hypothesize that increased cholesterol level is an important mechanism to protect membrane integrity in response to early apoptotic stress. To study this we generated a model system in which lysosomal cholesterol was increased using U18666A. We found lysosomal cholesterol to protect the cells from MPP^+ induced cell death by delaying leakage of lysosomal content to the cytosol. However high cholesterol also stimulated formation of α-Syn aggregates, which indicates that cholesterol could be a potential risk factor to induce PD pathology. Treatment with the cholesterol lowering drug lovastatin marginally reduced cholesterol and protected cell by inhibition of ROS production rather than by decreasing cholesterol level.
Conclusions: Our study clearly shows the dual role of cholesterol in PD. Increased understanding of cholesterol equilibrium is necessary to elucidated if statin drugs would be beneficial in PD patients.

ABNORMAL LIPID ALTERATIONS IN LIPID RAFTS RELATED TO PARKINSON'S DISEASE. CORRELATION WITH PROTEIN REARRANGEMENTS

A. Canerina-Amaro[1], N. Fabelo[2], M. Díaz[2], R. Marín[1]
[1]Ciencias Biomédicas, University of La Laguna, SANTA CRUZ DE TENERIFE, Spain
[2]Biología Animal, University of La Laguna, SANTA CRUZ DE TENERIFE, Spain

Our previous work has demonstrated that structural lipids of lipid raft microdomains are altered in cortical areas of PD, even at early preclinical stages. These alterations may be associated with cognitive deterioration during neuropathological progression, as an indicative of the potential correlation with changes in the proteins associated with these microstructures.

Here, using a murine model of PD treated with MPTP as neurotoxic, we have purified lipid rafts from different brain areas, and analyzed their lipid composition. Moreover, we have analyzed by immunoblotting and immunoprecipitation whether lipid changes may correlate with redistribution and interactions within these domains of alpha-synuclein, a main hallmark of this disease known to be integrated in these neuronal domains.

Different brain areas (septum, frontal and posterior cortices and cerebellum) of mice at different ages, 6 and 14 months, were investigated. The potential associations of alpha-synuclein with other raft protein markers related to toxic pathways have also been analyzed.

Our data suggest that, as previously shown for Alzheimer's disease, structural alterations of lipid rafts also affect the behaviour of proteins interacting within these structures, altering their normal behavior and dynamics, and ultimately contributing to neuronal dysfunctions.

ALTERED LIPID LEVELS PROVIDE EVIDENCE FOR MYELIN LIPID DYSFUNCTION IN MULTIPLE SYSTEM ATROPHY

W.S. Kim[1], A.S. Don[2], J.H. Hsiao[1], J.M. Bleasel[1], T.A. Couttas[2], G.M. Halliday[1]
[1]Ageing & Neurodegeneration, Neuroscience Research Australia, Sydney, Australia
[2]Prince of Wales Clinical School, University of New South Wales, Sydney, Australia

Objectives: Multiple system atrophy (MSA) is a rapidly-progressive neurodegenerative disease characterized by parkinsonism, cerebellar ataxia and autonomic failure. A pathological hallmark of MSA is the presence of alpha-synuclein deposits in oligodendrocytes, the myelin-producing support cells of the brain. Although lipid constitutes 78% of myelin and myelin dysregulation is recognized as an important early pathological event in MSA, changes in lipid level/distribution in MSA brain are unknown. In this study we assessed the quantitative changes in myelin lipids in MSA brain.
Methods: We undertook a lipidomic analysis of MSA myelin by liquid chromatography-mass spectrometry. We quantitatively measured three groups of lipids, sphingomyelin, sulfatide and galactosylceramide, which are all important in myelin integrity and function, in affected (under the motor cortex) and unaffected (under the visual cortex) white matter regions in MSA (n=8) and control (n=10) brains.
Results: For all three groups of lipids, most of the species were severely decreased (40–69%) in affected but not unaffected MSA white matter. An analysis of the distribution of lipid species showed no significant shift in fatty acid chain length/content with MSA.
Conclusion: Myelin lipid dysfunction may contribute to MSA pathology.

MOUSE MODEL BASED ON GM1 DEFICIENCY MANIFESTS MOVEMENT AND NON-MOVEMENT SYMPTOMS OF PARKINSON'S DISEASE; ALLEVIATED BY GM1 ANALOG FACILITATING GDNF

R. Ledeen[1], G. Wu[1], P. Hadachek[2], Z. Lu[1], M. Higgins[1], N. Majmundar[1], P. Sharoupim[1], Y. Park[1], A. Yu[1], V. Nguyen[1], J. Forsayeth[2]

[1]Neurology & Neurosciences, Rutgers - New Jersey Medical School, Newark, USA

[2]Neurological Surgery, University of California San Francisco, San Francisco, USA

Objectives: To demonstrate (a) 3 non-movement symptoms in a mouse model of Parkinson's disease (PD) based on ganglioside GM1 deficiency; (b) these symptoms relate to impaired GDNF signaling; (c) alleviation of symptoms with LIGA20, membrane permeable analog of GM1.

Methods: Use of genetically altered heterozygous (HT) mice with one disrupted allele for *B4galnt1*, GM2/GD2 synthase, which reduces GM1 (and other ganglio-series gangliosides) to ~50% of wild type. Immunohistochemistry (IHC) was employed for alpha-synuclein (aSyn), tyrosine hydroxylase (TH), and pRet. T maze determined cognition dysregulation. Constipation was determined by fecal matter content in colon and fecal water content.

Results: (I) Gastrointestinal; constipation was indicated in HT mice and more severely in knockout (KO) mice; also enteric neurons showed aSyn aggregates and depleted pRet. (II) Cardiac sympathetic denervation was indicated by (a) aSyn aggregates in superior cervical ganglion; (b) reduced TH^+ nerve fibers in cardiac tissue. (III) Cognitive impairment was revealed by T maze performance. As with movement impairment and nigral/striatal pathology, these 3 symptoms including restoration of pRet were alleviated by LIGA20.

Conclusions: LIGA20, serving as replacement therapy for deficient GM1, activated deficient GDNF signaling as seen in restored pRet. This study revealed GM1 as associated with the Ret/GFRa1 receptor complex and necessary for formation of this GDNF receptor. IHC of nigral sections from PD patients revealed significant deficiency of GM1 and pRET in TH^+ neurons. Additonal analyses suggested systemic GM1 deficiency as major risk factor in PD. The HT mouse manifests accurate recapitulation of PD.

MECHANISMS OF DOPAMINERGIC NEURODEGENERATION INDUCED BY PD-LINKED MUTATIONS IN VPS35

E. Tsika[1], A. Podhajska[1], L. Glauser[1], D. Moore[2]
[1]Brain Mind Institute, EPFL, Lausanne, Switzerland
[2]Center for Neurodegenerative Science, Van Andel Research Institute, Grand Rapids, USA

Mutations in the *vacuolar protein sorting 35 homolog* (*VPS35, PARK17*) gene were recently identified as a cause of late-onset, autosomal dominant Parkinson's disease (PD). Here, we explore the pathogenic consequences of PD-associated mutations in VPS35 using a number of model systems. The common D620N missense mutation in VPS35 does not compromise its protein stability or vesicular localization, or the vesicular sorting of the retromer cargo, sortilin, SorLA and CI-M6PR, in rodent primary neurons or patient-derived human fibroblasts. Studies in yeast suggest that analogous PD-linked mutations in VPS35 do not act through a loss-of-function mechanism. The overexpression of human VPS35 in primary cultures induces neuronal cell death and increases neuronal vulnerability to PD-relevant cellular stress. Furthermore, D620N VPS35 induces marked dopaminergic neurodegeneration and axonal pathology following viral-mediated gene transfer in a rat model of PD. Studies in mice reveals that genetic deletion of α-synuclein attenuates D620N VPS35-induced dopaminergic neurodegeneration and axonal damage. Additional studies also reveal a functional interaction of VPS35 with the dominant PD gene product, LRRK2. Collectively, these data suggest that dominant mutations in *VPS35* lead to neurodegeneration in PD consistent with a gain-of-function mechanism in a manner that may involve α-synuclein. Our studies support a key role for VPS35 in the development of PD and link together three dominant PD gene products (VPS35, α-synuclein and LRRK2) in a putative common pathogenic pathway.

[3]Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands

Objectives
Parkinson's disease (PD) is characterized by degeneration of midbrain dopamine neurons and caused by a complex interplay of genetic and environmental factors. We aimed to elucidate this interplay and the underlying pathophysiological mechanisms by integrating genetic and functional data from both sporadic and familial PD patients.
Methods
We conducted bioinformatics and systematic literature analyses of the 429 top-ranked genes from 12 published genome-wide association studies (GWAS) of PD (involving 13,534 cases and 47,148 controls). Of these, 249 genes encode proteins that interact in a molecular landscape. Other studies - such as expression studies in postmortem brain tissue of PD patients and functional studies in (genetic) cell and animal models of PD - provided corroborating evidence for these PD GWAS gene-encoded proteins and for additional PD-related proteins (including those encoded by genes associated with familial forms of PD) to be included in the molecular landscape.
Results
The uptake, processing and signaling of lipoproteins, their metabolites and derivatives plays a key role in the generated molecular PD landscape. These lipids and lipid-signaling molecules regulate mitochondrial and lysosomal function, as well as the immune response, and are important modulators of cellular stress and apoptosis.
Conclusions
The biological signaling cascades and processes within the molecular PD landscape integrate classical (i.e., familial PD gene-derived) functional themes with PD GWAS and expression data, functional data from cell and animal models, and lifestyle-related environmental risk factors. As such, the PD landscape provides unique clues for the development of novel PD treatment strategies.

PARKINSON'S DISEASE: LOST IN TRANSLATION

V. Dawson[1], I. Martin[1], S. Karuppagounder[1], J.W. Kim[1], H. Jia[1], S.M. Eacker[1], T.M. Dawson[1]
[1]Institute for Cell Engineering, Johns Hopkins University School of Medicine, Baltimore, USA

Proteins conduct the actions and functions of a cell. Protein synthesis is dynamic and tightly controlled in order to respond to the needs of the cell. Cells direct and regulate protein synthesis in response to hormones, nutrient availability and following episodes of intracellular stress by changing which proteins are translated. Alterations in the regulation of mRNA translation and protein synthesis can have serious effects on the function and health of a cell. Disease causing mutations in eukaryotic translation initiation factor 4 gamma-1 (EIF4G1) and LRRK2 when expressed in mice lead to age dependent dopaminergic neurodegeneration. Additionally, disease-causing mutations in EIF4G1 and LRRK2 result in altered mRNA translation and protein expression. Understanding the changes in mRNA translation and protein expression may provide clues to disease pathways that result in Parkinson's disease, a common age-related progressive neurodegenerative disorder with an unknown etiology.

[2]Molecular Mechanisms of Biological Adaptation,
Engelhardt Institute of Molecular Biology, Moscow, Russia
[3]Biochemical Genetics of Animals, Institute of Molecular Genetics, Moscow, Russia

Objectives: Neurodegenerative disorders (NDs) affect both elderly (Alzheimer's, AD; Parkinson's, PD; Huntington's HD, diseases) and newborns (spinal muscular atrophy, SMA). Three main diagnostic symptoms of AD, PD, HD are memory defects, motor impairments, amyloid inclusions. A deregulation of specific microRNAs (miRs) has been shown to be concomitant to a certain disorder. Since one miR can change expression of hundreds of target genes, NDs can be considered as an RNA disorder. Surprisingly, studies in nematodes and Drosophila, rather than in mammals, allows the elucidation of specific miRs as biomarkers of NDs. Among these are let-7/miR-184 for PD, target genes are Parkin and PINK. miR-34 is believed to be a biomarker of AD, the main gene targets being TAU, CREB, HSP70. Poorly studied miR-9 has been indicated as a biomarker of HD and SMA. **Methods:** Isolated in our lab temperature-sensitive mutant a*gn*^{ts3} of the *agnostic* locus harboring *dlimk1* manifests the triad of NDs diagnostic symptoms mimicking PD with Dementia and Leavy Bodies at normal temperature. Therefore, microRNAs libraries from a*gn*^{ts3} and three wild type strains were obtained and compared. **Results:** a*gn*^{ts3} manifests a suppressed content of let-7/miR-184 and increased content of miR-34. A novel binding site for miR-34 is created due to an S-element (Tc1/mariner family) insertion near to *dlimk1* 3'-UTR. **Conclusions:** Heat shock acts as a trigger between pathologic and normal states and can completely abolish the triad of NDs diagnostic symptoms via miRs regulation of actin remodeling.

DOWN-REGULATION OF P21-ACTIVATED SERINE/THREONINE KINASE1 IS INVOLVED IN LOSS OF MESCENPHALIC DOPAMINE NEURONS.

J. Oh[1], W. Kim[1], H.K. Kim[1]
[1]Medicine and Microbiology College of Medicine, Chungbuk National University, Cheongju, Korea

Objectives: Although the roles of p21-activated serine/threonine kinase 1 (PAK1) have been reported in Alzheimer's disease (AD), details in Parkinson's disease (PD) are restrictive. Thus, we tried to determine a role of PAK1 in PD.
Methods: We took advantage of SH-SY5Y cells, cultured dopamine (DA) neurons, 6-OHDA–induced hemiparkinsonian model rat, lentiviral expression system, along with a variety of molecular and cellular biological tools.
Results: Expression of a dominant-negative form of PAK1 (PAK1-DN) decreased the viability and increased cell death by oxidative stresses. PAK1-DN reduced the protein level of Bcl-2, an anti-apoptotic protein, through an ubiquitin/proteasome-dependent mechanism. Although the down-regulation of Bcl-2 induced by PAK1-DN was rescued by extracellular signal-regulated kinase 2 (ERK2), a phosphomimetic form (S70E) of Bcl-2 by PAK1 was also resistant with PAK1-DN expression, indicating that the Bcl-2 level might be regulated by both PAK1-ERK signaling and PAK1. Oxidative stress by 6-OHDA treatment decreased the phosphorylation of PAK1. Conversely, expression of an active form of PAK1 (PAK1-CA) could rescue behavioral defects and loss of DA neurons in hemiparkinsonian rat model.
Conclusions: Our data suggest that the down-regulation of PAK1 activity could involved in the loss of mesencephalic DA neurons, suggesting a new molecular mechanism in pathogenesis of PD.

H-3 RECEPTOR ANTAGONIST AND JNK-3 INHIBITOR: A NEW THERAPEUTIC APPROACH TO TREAT PARKINSON'S DISEASE.

N. Ambhore[1], K. Elango[1], M.N. Satish Kumar[1], M. Shubhashri[2], K. Ramsatyanarayana Raju[1], M. Shashank[1]
[1]Pharmacology, JSS College of Pharmacy, Ooty, India
[2]Pharmaceutical Analysia, JSS College of Pharmacy, Ooty, India

Background: Parkinson disease is a progressive loss of neuromelanin containing dopaminergic neurons from the substantia nigra *pars compacta*. Reports suggest that the highest density of H_3-receptors is found in basal ganglia and H_3-antagonists can increase the turnover of dopamine in basal ganglia. c-Jun N-terminal kinase (JNK) pathway plays an important role in stress mediated neurotoxicity, inflammation; while blockade of JNK by specific inhibitors may prevent or effectively slow-down the progression of PD. **Objective:** The study is aimed to evaluate the effectiveness of conessine as H3 antagonist and 1,9-pyrazolanthrone as JNK-3 inhibitor. **Methods:** By using Maestro 9.3 version of Schrodinger suite, binding affinity of Conessine is evaluated with histamine H-1 [PBD ID: 3RZE], H-2 [PBD ID: 1JQD] and H-3 receptors. The structure of H-3 receptor is not available in Protein Data Bank and was prepared by homology model using Maestro 9.3 version of Schrodinger suite. The receptors of human c-jun-n-terminal kinase JNK1 [PDB ID: 1UKH], JNK2 [PDB ID: 3E7O] and JNK3 [PDB ID: 2EXC] are taken from the Protein Data Bank and further modified for Glide docking calculations. **Results:** It reveals conessine shows better G score of -3.96 with H3 receptor and 1,9-pyrazolanthrone selective inhibiter of JNK-3. Conessine demonstrated functional antagonism of H3receptor in an in-vivo pharmacological model. The enzyme inhibitory assay in SH-SY5Y human neuroblastoma cell line shows that 1,9-pyrazolanthrone inhibits JNK-1, 2 with good affinity towards JNK-3 (IC_{50}- 0.05 µM). **Conclusion:** This study supports targeting H-3 receptor and JNK-3 is an important strategy in treatment of neurodegenerative disorders.

CEREBROSPINAL FLUID ANGIOGENIC BIOMARKERS IN PARKINSONS DISEASE

S. Janelidze[1], D. Lindqvist[2], S. Hall[2], Y. Surova[2], D. van Westen[2], O. Hansson[1]
[1]Department of Clinical Sciences Malmö, Lund University, Lund, Sweden
[2]Department of Clinical Sciences Lund, Lund University, Lund, Sweden

Background: Existing evidence suggests that Parkinson´s disease (PD) is accompanied by angiogenesis in the affected brain areas. However, studies on well-characterized clinical cohorts are needed in order to establish the role of angiogenesis in PD pathology.

Methods and materials: We analyzed cerebrospinal fluid (CSF) levels of several angiogenic factors in 38 healthy controls and 100 patients with PD, including 18 PD dementia (PDD) patients, from the prospective Swedish BioFinder study. VEGF, PlGF, sVEGFR-1, sVEGFR-2, Ang2, and IL-8 were quantified using ultra-sensitive electrochemiluminescence immunoassays. In addition, we assessed white matter lesions and microbleeds with magnetic resonance imaging (MRI) and blood brain barrier (BBB) integrity using CSF/serum albumin ratio. Angiogenic factors were also measured in additional cohort of healthy controls (n=64) and PD patients with and without dementia (n=87).

Results: We found high CSF levels of VEGF, PLGF, sVEGFR-2, and lower levels of Ang2 in non-demented PD patient group and in PDD group compared to controls after controlling for the confounding effects of age and gender. Angiogenesis markers, including VEGF and PlGF, were associated with gait difficulties and poor memory in PD. We also found robust associations of angiogenic markers with BBB dysfunction, white matter lesions (WMLs) and microbleeds in PD patients. Moreover, VEGF and PlGF positively correlated with neurodegeneration and glial activation markers, NFL and MCP-1. The main findings were confirmed in the validation cohort.

Discussion/conclusion: The results presented here provide new evidence implicating angiogenesis in PD and uncover potential drug targets for future therapies.

DISSECTING THE ROLE OF DJ-1 IN ADULT NEUROGENESIS BY MODULATION OF ENDOGENOUS NEURAL STEM CELLS WITH LENTIVIRAL VECTORS

L. Osório[1], J. Pascual-Brazo[1], V. Reumers[1], Z. Debyser[2], C. Van den Haute[1], R. Gijsbers[2], V. Baekelandt[1]

[1]Department of Neurosciences Laboratory for Neurobiology and Gene Therapy, KU Leuven, Leuven, Belgium

[2]Department of Pharmaceutical and Pharmacological Sciences Laboratory for Molecular Virology and Gene Therapy, KU Leuven, Leuven, Belgium

Objectives: The endogenous neural stem cell (eNSC) pool in the adult brain provides an attractive cell source for neuroregeneration. We demonstrated labeling of the eNSC in the subventricular zone (SVZ) of adult mouse brain by stereotactic injection of lentiviral vectors (LV). In the present study we employ this technology to investigate the role of DJ-1. DJ-1 protects neurons against oxidative stress and cell death and loss-of-function mutations in DJ-1 lead to autosomal recessive early-onset PD.

Methods: We generated HIV-based LV expressing an eGFP reporter and a short-hairpin RNA against DJ1 (LV-shDJ1) or a mismatch control (LV-shDJ1MM). In a first step, we transduced primary neurosphere cultures derived from adult eNSC isolated from the SVZ. Next, LV-shDJ1 and LV-shDJ1MM were injected in the SVZ of 2 months old mice. eGFP allowed to follow the fate, morphology and number of newly generated neurons.

Results: Knockdown of DJ-1 resulted in reduced proliferation, size and renewal capacity of the neurospheres. Moreover, DJ-1 deficient neural progenitors showed elevated ROS levels and impaired mitochondrial homeostasis. In vivo, we observed reduced proliferation of the eNSC in the SVZ and a decrease in the number of newborn neurons in the OB.

Conclusion: Our data suggests that DJ-1 plays a relevant role in the adult neurogenesis pathway by protecting neural progenitors from high levels of reactive oxygen species (ROS). To dissect the role of DJ-1 in a cell-specific manner, we now employ Cre conditional LV in nestin-Cre transgenic mice, which switches on the knockdown solely in nestin-positive eNSC.

EXTENSIVE UPTAKE OF ALPHA-SYNUCLEIN OLIGOMERS IN PRIMARY ASTROCYTES – A CENTRAL PATHOLOGICAL MECHANISM IN PD?

V. Lindström[1], G. Gustafsson[1], J. Sigvardson[2], A. Kasrayan[2], L. Lannfelt[1], M. Ingelsson[1], J. Bergström[1], A. Erlandsson[1]

[1]Molecular Geriatrics, Public Health and Caring Sciences, Uppsala, Sweden

[2]PD, BioArctic Neuroscience AB, Stockholm, Sweden

Objectives: In order to clarify the role of glial cells, other than microglia, in Parkinson's disease and dementia with Lewy bodies, we have studied uptake, degradation and toxic effects of oligomeric alpha-synuclein in a co-culture system of neurons, astrocytes and oligodendrocytes.

Methods: Primary neurons, astrocytes and oligodendrocytes, derived from E14 wild-type mouse cortices, were exposed to 500 nM (Cy3- or pHrodo-labeled) recombinant HNE-induced alpha-synuclein oligomers for 24 h. The cells were then thoroughly washed and the uptake and degradation of alpha-synuclein was studied at different time points, 0-12 days after exposure, by immunostainings, confocal microscopy, time-lapse microscopy, electron microscopy, Western blot and ELISA.

Results: Alpha-synuclein oligomers were taken up by all three cell types, but most readily by astrocytes, which accumulated large amounts of oligomers intracellularly. Cy3-labeled alpha-synuclein oligomers engulfed by astrocytes were shown to co-localize with the lysosomal marker Lamp-1, indicating that alpha-synuclein are degraded by lysosomes. Supporting this, alpha-synuclein oligomers labelled with pHrodo, an indicator dye which only fluoresces in the acidic environment of active lysosomes, were visualized 24 hours after exposure. Moreover, Western blot and ELISA of cell lysates showed that degradation of alpha-synuclein occurs 2-4 days after exposure. Interestingly, electron microscopy revealed that the oligomers caused mitochondrial damage, but without being lethal to the glial cells.

Conclusion: The intracellular processing of oligomeric alpha-synuclein by astrocytes emphasizes an important and possibly protective role of astrocytes in the presence of toxic alpha-synuclein oligomers.

INVOLVEMENT OF THE TRANSCRIPTION FACTOR NFAT IN PD

J.A. Freitas[1], C. Braga[2], D. Foguel[1], B.K. Robbs[3]
[1]Medical Biochemistry Leopoldo de Meis, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil
[2]Medical Biochemistry Leopoldo de Meis, Federal University of Rio de Janeiro - Xerem, Rio de Janeiro, Brazil
[3]Faculty of Odontology of Nova Friburgo, Federal Fluminense University, Rio de Janeiro, Brazil

Parkinson's Disease (PD) is the second leading cause of dementia worldwide and the mechanism that underlie the neurodegeneration are unknown. Alpha-synuclein (α-syn) is described as the culprit in PD. Apoptosis and inflammation are known to be key events in neurodegeneration of PD, which can be triggered upon an increase in intracellular Ca^{+2} caused by α-syn. Although, the Nuclear Factor of Activated T-Cells (NFAT) is activated by Ca^{+2} influx, its contribution to PD is poorly understood. NFAT proteins directly regulate the gene expression involved in the control of apoptosis and in the inflammatory process. Therefore, the main goal of the present project is to evaluate the involvement of NFAT in the neurodegenerative process induced by aggregates of α-synuclein. Our results have shown that only oligomers of α-synuclein were able to mediate increase in cell death in primary cultures of dopaminergic neurons from embryonic mice (E15) or N2A cells differentiated into dopaminergic cells and this effect was partially reversed when these cultures were pretreated with cyclosporine or VIVIT, two inhibitors of NFAT In addition we examined the involvement of monomers, oligomers and fibers in the synaptic events. We found that only oligomers and fibers showed to be capable of causing a decrease in Synapsin I, a protein involved in pre-synaptic events and this effect was likewise reversed when these cultures were pretreated with a NFAT inhibitor. In conclusion, these results suggest that the NFAT may have a role in the process of cell death and synaptic loss mediated by α-synuclein aggregates.

MULTIVARIATE ANALYSES OF AMYLOID-BETA OLIGOMER POPULATIONS INDICATE A CONNECTION BETWEEN PORE FORMATION AND CYTOTOXICITY

M. Mayer[1], P. Prangkio[1], D. Sept[1], J. Yang[2]
[1]Biomedical Engineering, University of Michigan, Ann Arbor, USA
[2]Chemistry, University of California, San Diego, USA

This work established well-controlled aggregation conditions of amyloid-beta 1–40 or amyloid-beta 1–42 peptides over a 20-day period and characterized these preparations with regard to their beta-sheet content, degree of fibril formation, relative abundance of various oligomer sizes, and propensity to induce membrane pore formation and cytotoxicity. Using this multivariate data set, a systematic and inherently unbiased partial least squares (PLS) approach showed that for both peptides the abundance of oligomers in the tetramer to 13-mer range contributed positively to both pore formation and cytotoxicity, while monomers, dimers, trimers, and the largest oligomers (>210 kDa) were negatively correlated to both phenomena. Multivariate PLS analysis is ideally suited to handle complex data sets and interdependent variables such as relative oligomer concentrations, making it possible to elucidate structure function relationships in complex mixtures. This approach, therefore, introduces an enabling tool to the field of amyloid research, in which it is often difficult to interpret the activity of individual species within a complex mixture of bioactive species.

THE SLEEP MODULATING PEPTIDE OREXIN-B IS PROTECTIVE FOR VULNERABLE MIDBRAIN DOPAMINE NEURONS

P.P. Michel[1], S. Guerreiro[1], C. Florence[1], E. Rousseau[1], S. Hamadat[1], E.C. Hirsch[1]
[1]Institut du Cerveau et de la Moelle Epinière, CNRS UMR 7225 - Inserm U 1127 - UPMC-P6 UMR S 1127, Paris, France

Objectives: Orexin-A and orexin-B (also known as hypocretin-1 and -2) are small hypothalamic neuropeptides involved in the control of sleep, wakefulness and energy homeostasis (Tsujino and Sakurai, Front Behav Neurosci, 2013). The loss of orexin containing neurons in Parkinson disease (PD) is therefore likely to explain some of the sleep disturbances associated to this disorder (Fronczek et al, Brain, 2007; Thannickal et al, Brain, 2007). Here, we tested the possibility that dysfunction of the orexin system in PD may also have an impact on neurodegenerative events affecting brainstem dopamine (DA) neurons.

Methods: To this aim, we used a model system of rat midbrain cultures in which DA neurons degenerate spontaneously and progressively as they mature (Toulorge et al, Faseb J, 2011).

Results: We found that orexin-B provides partial but robust protection to spontaneously dying DA neurons whereas orexin-A has only marginal effects. Rescued neurons accumulated DA efficiently by active transport suggesting that they were also functional. The effect of orexin-B was comparable in intensity to that provided by GDNF but independent of it. It was instead attributable to activation of G protein-coupled orexin receptors and to downstream signaling events requiring intracellular calcium mobilization. In addition to its own protective action for DA neurons, orexin-B had also the potential to reveal that of the alkaloid nicotine via a mechanism involving α7 nicotinic acetylcholine receptors.

Conclusions: Altogether, our data suggest that a relationship may exist in PD between degenerative events affecting hypothalamic orexin neurons and brainstem DA neurons.

S-NITROSYLATION OF PARKIN AS A NOVEL REGULATOR OF EXTRACELLULAR ALPHA-SYNUCLEIN-EVOKED DOPAMINERGIC CELL DEATH.

A.M. Lenkiewicz[1], A. Wilkaniec[1], K. Friedland[2], A. Adamczyk[1]
[1]Department of Cellular Signaling, Mossakowski Medical Research Centre, Warsaw, Poland
[2]Department of Chemistry and Pharmacy, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

Objectives:
Parkin encodes an E3 ubiquitin ligase, and disruption in parkin-mediated protein ubiquitination may contribute to accumulation of damaged protein and cell death. It was suggested, that parkin is inactivated in sporadic form of Parkinson's disease (PD) via S-nitrosylation or oxidative and dopaminergic stress, leading to the accumulation of defective proteins. However, the role of alpha-synuclein (ASN), the key protein component in Lewy bodies, in parkin modulation is unknown. Therefore, the aim of this study was to investigate the effect of extracellular ASN on parkin post-translational modifications and dopaminergic cell death.
Methods:
The experiments were performed using spectrophotometrical, spectrofluorometrical, immunochemical methods and real-time PCR analysis.
Results:
Our results indicated, that ASN is liberated from the cells into extracellular space and that this extracellularly acting protein leads to dopaminergic PC12 cells death. We first demonstrated that extracellular ASN leads to free radicals generation, increased cytoplasmic calcium concentration and decreased intracellular ATP level. Furthermore, stress response genes activation was observed. Finally, we showed substantial increase of parkin S-nitrosylation in ASN treated cells.
Conclusions:
Taken together, our data indicate that ASN affects parkin function through its S-nitrosylation. We suggest, that ASN-induced cellular stress could contribute to parkin deregulation and in consequence to accumulation of defective proteins and propagation of neurodegeneration. These findings may thus provide a molecular link between ASN liberation, oligomerization and parkin dysfunction in sporadic PD.

MITOCHONDRIAL COMPLEX I INHIBITION INDUCES IRON ACCUMULATION AND CELL DEATH THROUGH THE ACTIVATION OF IRON REGULATORY PROTEIN 1

N.P. Mena[1], P. Aguirre[1], P.J. Urrutia[1], V. Tapia[1], A. Esparza[1], M. Nunez[1]
[1]Biology, Universidad de Chile, Santiago, Chile

Unpaired mitochondrial function, oxidative stress and iron accumulation are common features of several neurodegenerative disorders, between them AD and PD. It was recently reported that inhibition of mitochondrial complex I results in decreased iron-sulfur cluster (ISC) synthesis and activation of Iron Regulatory Protein 1 (IRP1), a key regulator of cellular iron homeostasis. These findings established a causal relationship between decreased mitochondrial activity and iron homeostasis, a finding particularly relevant for the understanding of neuropathological events where mitochondrial dysfunction and iron accumulation are pathognomonic signs. Objectives. To evaluate the functionality of IRP1 activation and its role in the death of SHSY5Y dopaminergic neuroblastoma cells subjected to complex I inhibition.
Methods. Complex I was inhibited with rotenone. IRP1 activity was evaluated by EMSA. The oxidative tone was evaluated fluorescent maleimides. Iron homeostasis proteins were evaluated by Western blot. shRNA was used to silence IRP1 expression.
Results. Activation of IRP1 by complex I inhibition associated with increased levels of Transferrin Receptor 1 (TfR1) and Divalent Metal Transporter 1 (DMT1), and decreased levels of Ferroportin 1 (FPN1), together with increased iron accumulation, oxidative stress and cell death. Silencing of IRP1 largely abolished the rotenone-induced changes in DMT1, TfR1, FPN1 and iron accumulation, and protected cells from cell death induced by complex I inhibition.
Conclusions. These results support the notion that IRP1 activation, secondary to inhibition of mitochondrial ISC synthesis, may underline the events leading to iron accumulation observed in PD. Financed by grants FONDECYT 1130068 and CONICYT-PIA ACT1114.

LASER ABLATION INDUCTIVELY COUPLED PLASMA MASS SPECTROMETRY TO MEASURE ZINC, COPPER, AND MANGANESE IN THE HUMAN PARKINSON'S DISEASE SUBVENTRICULAR ZONE

B. Gardner[1], S. Cameron[2], R.L.M. Faull[1], M.A. Curtis[1]
[1]Centre for Brain Research and Anatomy with Radiology, University of Auckland, Auckland, New Zealand
[2]Waikato Mass Spectrometry Facility, University of Waikato, Hamilton, New Zealand

1. Objectives. In Parkinson's disease (PD) there are changes in essential biometal concentrations in affected brain regions. Specifically, zinc and iron are increased in the PD substantia nigra, while copper is decreased compared to controls. In addition, occupational manganese exposure has been linked to PD, and manganese neurotoxicity shows similar symptoms to PD. However, detecting metals in the human brain has long been a challenge on the basis of spatial resolution and accuracy of measurement.
2. Methods. Laser ablation inductively coupled plasma mass spectrometry (LA-ICP-MS) was used to quantify copper, zinc, and manganese concentrations in the subventricular zone (SVZ), a region on the lateral wall of the lateral ventricle that is home to a population of neural progenitor cells, in age-matched PD (n = 5) and control (n = 5) brains. LA-ICP-MS allows quantitative measures of metal species to be acquired at a detailed anatomical level.
3. Results. There were no apparent changes in copper in the PD SVZ compared to the control SVZ; however, there was a significant increase in zinc in the PD vs. control SVZ ($p < 0.01$), and an even greater increase in manganese in the same region in PD compared to controls ($p < 0.001$). No significant changes were seen in the neighbouring caudate nucleus.
4. Conclusions. In this study, biometals that have been implicated in the pathology of PD are increased in the PD SVZ. The implications of increased concentrations of these metals in the SVZ will be discussed.

IRON CHELATION PROTECTS SYMPATHETIC NERVE CELLS AGAINST OXIDATIVE STRESS INDUCED BY DOPAMINE AND 6-HYDROXYDOPAMINE

P. Haskova[1], H. Jansova[1], T. Simunek[1]
[1]Department of Biochemical Sciences,
Faculty of Pharmacy Charles University in Prague, Hradec Kralove, Czech Republic

The oxidative stress-induced loss of dopamine(DA)-secreting neurons in the substantia nigra is one of hypotheses of Parkinson's disease (PD) pathophysiology. These neurons are particularly prone to oxidative stress due to DA. It belongs to the catecholamines that are able to undergo spontaneous oxidation giving rise to reactive intermediates (aminochromes) and reactive oxygen species (ROS). No less important is the local impairment in iron ions balance, when free or loosely bound iron ions can aggravate the ROS-mediated toxic injury.

PC12 rat pheochromocytoma cell line differentiated with nerve growth factor into sympathetic neurons was used in our studies. We examined relationship of DA and 6-hydroxydopamine (6-OHDA) to free iron ions in pathobiochemistry of PD and the possibility of neuroprotection by iron chelation. Our cellular experiments assessed the ability of DA, 6-OHDA and their oxidised forms to induce injury to PC12 cells (LDH assay) and production of ROS inside PC12 cells (dichlorofluorescein assay), as well as, the ability of strong cell-permeable iron chelator salicylaldehyde isonicotioyl hydrazone (SIH) and boronic ester prochelator BSIH to suppress their harmful effects. Both SIH and BSIH were able to dose-dependently and significantly protect differentiated PC12 cells from the toxicities of DA, 6-OHDA and their oxidation products, suggesting that catecholamines can significantly contribute to oxidative injury of neurons in PD, which can be prevented by iron chelation.

This study was co-financed by the European Social Fund and the state budget of the Czech Republic. Project no. CZ.1.07/2.3.00/30.0061.

German Research Center for Environmental Health GmbH, Neuherberg, Germany

Introduction and objectives: Manganese (Mn) is essential for living organisms, playing an important role in nervous system function, bone mineralization, protein and energy metabolism, metabolic regulation and cellular protection. Nevertheless, chronic and/or acute exposure for this metal, mainly during early life stages can lead to neurotoxicity, but the mechanism for these events is still unclear. We hypothesize that exposure to Mn species induces differential neurotoxicogenomic alterations. Thus, the aim of the present study was to compare the toxicity of several and representing common aquatic chemical species of manganese, and to understand the mechanism of Mn-induced neurodisorders. **Methods**: The toxic effects of the manganese (Mn(II)-Chloride, Mn(II)-Citrate and Mn(III)-Citrate) in embryos of *Danio rerio* was verified by chemical speciation, chemical fractioning, neurobehavioral and toxicogenomic approaches (DNA microarray and RT-PCR). The embryos of zebrafish were exposed during different development stage from 2 hours post fertilizations –hpf to 122 hpf, for 48 h, 72 h and 120 h. **Results**: We found a stage-specific increase of lethality, being more significant for embryos exposed for Mn(II)-Citrate, specially > 48 hpf. Additionally, we verified that the zebrafish embryos exposed for manganese (48-120 hpf) showed significant Mn bioaccumulation, behavioral (locomotor and cognitive) impairment and finally disruption of genes associated with protein metabolism pathway. These genes (*bcat2, cenpj, dpp4, eif2s1, ell2, erbb2ip, mmp2, myl6, sgce, slc14a2 and tcea3*) are potentially associated with dementia (Parkinsonism and Alzheimer´s) too. **Conclusion:** These toxicogenomics findings suggest that early-life exposure for manganese may contribute to late-life neurodegeneration.

EXCLUSION OF ALPHA-SYNUCLEIN AGGREGATES FROM CALBINDIN-D28K CELLS IN THE UNILATERAL ROTENONE-LESIONED MOUSE MODEL OF PD

D.L. Pountney[1], A.N. Rcom-H'cheo-Gauthier[1], J. Weetman[1], S. Sharry[1], A.C.B. Meedeniya[1]

[1]Griffith Health Institute, Griffith University, Gold Coast, Australia

Objectives. Neurodegeneration in Parkinson's disease is associated with formation of neuronal inclusion bodies composed mainly of aggregated alpha-synuclein protein. Expression of the Ca(II)-buffering protein, Calbindin-D28K (CB), correlates with neuronal survival in PD and elevated intracellular free Ca(II) can trigger alpha-synuclein aggregation and inclusion body formation in model systems pointing to the influence of Ca(II) regulation in neurodegeneration. In the current study, the relationship between CB expression and alpha-synuclein aggregation was examined in a unilateral mouse PD model, whereby lesion of the medial forebrain bundle of C57 black mice (WT, neurturin-/-, Aged WT) with the mitochondrial inhibitor, rotenone, was performed to trigger neurodegeneration and alpha-synuclein inclusions. **Results.** Immunofluorescence of brain tissue sections revealed more frequent CB-positive cells within the lesioned hemisphere than within the control hemisphere. Large alpha-synuclein aggregates (>1µm) were 4-fold more frequent in the lesioned hemisphere compared to the non-lesioned hemisphere (p, 0.01). NTN-/- mice showed a greater frequency of CB-positive cells than WT mice, especially in the lesioned hemisphere. Alpha-synuclein inclusions were almost completely absent in CB-positive cells. Western analysis showed total CB expression was 20% higher (p, 0.05) in treated compared to control hemisphere in the aged animals and 25 % higher in aged compared to young mice in the lesioned hemisphere (p, 0.05), but not significantly different between young and aged in the unlesioned hemisphere. **Conclusions.** The findings show alpha-synuclein aggregation is excluded from CB-positive neurons and that the increased sensitivity of aged animals to lesion is not related to differential CB expression.

CALCIUM TRIGGERS NUCLEATION OF ALPHA-SYNUCLEIN ON SYNAPTIC VESICLES AND THUS INCREASES THE VULNERABILITY OF DOPAMINERGIC NEURONES IN PARKINSON'S DISEASE

G.S. Kaminski Schierle[1], C.H. Michel[1], D. Pinotsi[1], E.J. Rees[1], C.F. Kaminski[1]
[1]Chemical Engineering and Biotechnology, University of Cambridge, Cambridge, United Kingdom

Objectives: It has been reported that alpha-synuclein (AS)-phospholipid interactions can enhance the formation of AS fibrils. However, AS-lipid interactions lead to the formation of an extended α-helix and thus the question remains as to how AS undergoes the structural conversion from an α-helical structure to a β-sheet-rich fibril.
Methods: We apply super-resolution microscopy on dopaminergic neurones to image AS aggregation on synaptic vesicles (see Fig.). Having performed NMR and other biophysical and biochemical measurements in combination with small unilamellar vesicles (SUV) that resemble synaptic vesicles we propose a model of AS function/dysfunction at the presynaptic terminal.
Results: We show that Ca^{2+} can enhance endogenous AS aggregation on synaptic vesicles in a PD related model system which can be prevented by treating the cells with the Ca^{2+} channel inhibitor isradipine (see Fig.). We give evidence that Ca^{2+} can influence AS-phospholipid interactions and thus provide a link through which a conversion from an α-helical to a β-sheet-rich state may become feasible. However, preventing aggregation does not prevent neuronal death and thus we show that other factors such as mitochondrial stress and free radical production are more causative of cell death.
Conclusions: Controlling Ca^{2+} homeostasis by isradipine treatment and providing patients suffering from PD with anti-oxidants may result in a better neuroprotective strategy than preventing AS fibril formation.

Fig. DA induced AS aggregation is Ca2+ dependent and initiated on synaptic vesicles.

DO L-TYPE CALCIUM CHANNEL CAV1.3 AND ITS SPLICE VARIANT PLAY A ROLE IN SELECTIVE DEGENERATION OF DOPAMINERGIC NEURONS SEEN IN PD?

A. Verma[1], P. Michel[2], A. Prigent[2], E. Hirsch[2], V. Ravindranath[1]
[1]Centre for Neuroscience, Indian Institute of Science, Bangalore, India
[2]Experimental therapeutics of Parkinson disease,
Inserm U 1127 CNRS UMR 7225 Sorbonne Universités UPMC Univ Paris 06 UMR S 11 27 Institut du Cerveau et de la Moelle épinière ICM F-75013 Paris France, Paris, France

Objectives - Dopaminergic neurons of substantia nigra pars compacta (SNpc) show selective vulnerability to neurodegeneration in PD. Influx of calcium during pacemaking in SNpc through L-type calcium channel Cav1.3 has been proposed to lead to neurodegeneration through increased intracellular calcium. Cav1.3-42A, an alternatively spliced short variant of Cav1.3-42 opens during pacemaking leading to increased calcium entry and has been implicated in PD pathogenesis. Our study examines expression of Cav1.3 in SNpc in mouse and human autopsy samples from controls and PD patients.

Methods – Brain regions from C57BL/6J mice and human samples from patients with PD confirmed at autopsy and matched controls (brain bank, ICM, Paris) were used in the study. qRT-PCR, in situ hybridization and immuno-histochemistry were used for quantitation and localization.

Results – In mouse SNpc and VTA Cav1.3-42A was expressed in greater amounts compared to cortex and co-localized with tyrosine hydroxylase (TH) positive neurons. However, in human autopsy brains, the expression levels of Cav1.3-42 and 42A were similar across brain regions. Further, no significant difference was observed in expression levels of Cav1.3-42 and 42A between controls and PD patients across midbrain regions even upon normalization with dopamine active transporter (DAT) to account for loss of TH positive neurons.

Conclusions – Our results indicate that there is no difference in the expression of Cav1.3 42 or 42A between midbrain and cortex and across midbrain regions from PD brains, making it unlikely for Cav1.3 to confer selective vulnerability to SNpc in PD.

ADPD5-2163

STRONG CAUSAL RELATIONSHIP BETWEEN THE STORE-OPERATED CALCIUM ENTRY (SOCE), INTRACELLULAR CALCIUM STORES AND ER STRESS (UPR) IN DOPAMINERGIC NEURONS.

A. Yen[1], C. Oslowski[1], V. Bolotina[1]
[1]Medicine, Boston University School of Medicine, Boston, USA

Store-operated Ca^{2+} entry (SOCE) is essential for the refilling of intracellular Ca^{2+} stores, but its relation to endoplasmic reticulum (ER) stress, and its role in degeneration of dopaminergic (DA) neurons is poorly understood. In this study, human DA neuronal SH-SY5Y cell line was used to test the role of SOCE in the depletion of Ca^{2+} stores, ER stress, unfolded protein response (UPR), and cell viability, which may determine whether DA neurons will live or die. We found that the main components of SOCE (Orai1, STIM1 and PLA2g6) are present and fully functional in DA neurons, and thapsigargin (TG)-induced depletion of ER stores results in Orai1/STIM1 co-localization and activation of SOCE. Inhibition of SOCE causes depletion of Ca^{2+} in ER and significant ER stress (UPR). Dose-dependence of TG effects revealed that ER Ca^{2+} depletion precedes ER stress and loss of cell viability. More than 85% of Ca^{2+} need to be lost from ER to initiate UPR (CHOP expression), and lead to cell death. TG-induced depletion of the stores (rather than activation of SOCE) is the cause of UPR, and it can be rescued by molecular up-regulation of SOCE (Orai1 overexpression). Thus, there is a strong causal relationship between Orai1-mediated SOCE, ER Ca^{2+} stores, ER stress/UPR and cell viability in the model DA neurons. Our results suggest that Orai1 and SOCE-dependent refilling of Ca^{2+} in the ER is essential for the prevention of ER stress, and impairment of SOCE may be a trigger for DA neuronal death.

1st Dept. of Psychiatry Eginition Hospital, ATHENS, Greece

Recent studies have suggested that pathologically relevant species of alpha-synuclein (AS) can be propagated between neurons in a prion-like manner. Due to this evidence, extracellular AS is considered the most promising target to hinder disease progression in PD. We have previously shown that AS is readily released in human and mouse brain parenchyma, even though the physiological role of the secreted AS has not been yet elucidated. Given the importance of extracellular AS levels, we aimed to investigate the mechanism of AS secretion *in vivo*. In mouse striatum, we have found that AS is exclusively localized to the glutamatergic terminals. However, absence of AS from the lumen of brain-isolated synaptic vesicles suggested that they are unlikely to mediate its release. To dissect the mechanism of AS release, we have used reverse microdialysis to locally administer reagents that target specific cellular pathways. Using this approach, we have shown that AS secretion is a calcium-regulated process that also dependents on the activation of SUR1-sensitive K_{ATP} channels. SUR1 is distributed in the cytoplasm of GABAergic neurons from where the K_{ATP} channel regulates GABA release. Using a combination of specific agonists and antagonists, we were able to show that, in the striatum, GABA release via the SUR1-KATP channels on the GABAergic neurons could regulate AS secretion from glutamatergic terminals. Importantly, this mechanism is mediated by the activation of the presynaptic $GABA_B$ receptors on the glutamatergic terminals. We believe that understanding the mechanism of AS secretion will help us identify new therapeutic targets for PD.

[3]Department of Psychiatry and Behavioral Sciences, Stanford University, Palo alto, USA

Striatal cholinergic interneurons (CINs) are considered as key players in basal ganglia-related functions and pathologies. Their contribution to motor dysfunction in Parkinson's disease (PD), although supported by the symptomatic relief provided by anticholinergic drugs, remains elusive. Here, we used an optogenetic approach to address the implication of CINs in the normal and pathological functioning of the basal ganglia network. Using a behavioral approach, we demonstrated that CINs inhibition alleviates haloperidol-induced catalepsy and motor asymmetry in the unilateral 6-hydroxydopamine-induced lesion model. As possible cellular substrates for this antiparkinsonian effect, in vivo electrophysiological recordings reveal that CINs inhibition normalizes the burst activity in the main basal ganglia output structure, the substantia nigra pars reticulata, and strengthens cortical information transfer through the direct striatonigral pathway. Slice electrophysiological recordings demonstrate that, in PD state, CINs become hyperexcitable and their photoinhibition potentiates cortical synaptic transmission onto striatal medium spiny neurons. CINs inhibition in non-lesioned mice had no impact on the behavioral and physiological parameters examined, suggesting that the role of these interneurons in motor function is highly dependent on dopamine tone. Our findings, without excluding indirect pathway contributions to PD, point to the CINs modulation of cortical information processing through the direct pathway as a critical component involved in the control of basal ganglia outflow and motor dysfunction in PD state. We are currently investigating whether thalamic inputs, which provide another major source of excitatory drive to the striatum, are also modulated by CINs modulation in control and PD states.

DOPAMINE SYNTHESIS BY NON-DOPAMINERGIC NEURONS IN THE STRIATUM OF PARKINSONIAN MICE

A. Kim[1], E. Kozina[1], M. Ugrumov[1]
[1]Laboratory of Neural and Neuroendocrine Regulations,
Koltzov Institute of Developmental Biology Russian Academy of Sciences, Moscow, Russia

Objectives were to determine whether: (i) striata of parkinsonian and control mice contain neurons expressing the tyrosine hydroxylase (TH) gene and possessing TH only or aromatic L-amino acid decarboxylase (AADC) only, (ii) presumptive monoenzymatic TH-neurons and AADC-neurons synthesize dopamine (DA) due to L-DOPA transfer from the former to the latter.
The study was performed in C57BL/6 mice at the presymptomatic and early symptomatic stages of parkinsonism induced by 2-fold and 4-fold s.c. injections of MPTP, respectively, at the individual dose of 12 mg/kg. Striatal neurons were immunostained for TH and AADC, TH mRNA was measured with PCR RT. Our hypothesis about DA synthesis in the monoenzymatic neurons was tested by incubating slices with L-leucine which inhibits L-DOPA membrane transporter.
Results:
1. The axons containing both enzymes, TH only or AADC only, were observed in striata of MPTP-treated and control mice in the proportion (i) 55:22:23 in the control, (ii) 34:44:22 at the presymptomatic stage, (iii) 29:47:24 at the symptomatic stage showing an increase of the fraction of TH axons in parkinsonian mice.
2. Total DA amount in slices and incubation medium dropped under L-leucine administration proving DA synthesis by monoenzymatic axons.
3. TH gene expression was observed in the striatum at the symptomatic stage though no TH-immunostainig was observed in cell bodies.
Thus, DA is synthesized in the striatum of intact and parkinsonian mice by bienzymatic and monoenzymatic axons.

EARLY DYSFUNCTIONS PRECEDING NEURODEGENERATION IN ALPHA-SYNUCLEINOPATHY

E. De Leonibus[1], N.C. Giordano[1], A. Iemolo[2]
[1]Telethon Institute of Genetics and Medicine, Telethon Foundation, Naples, Italy
[2]Institute of Genetics and Biophysics (IGB), National Research Council, Naples, Italy

Objective: Adenoviral vector (AAV) mediated overexpression of human wild-type alpha-synuclein (alpha-syn) in the substantia nigra (SN) of normal animals has been shown to lead to a time-dependent DA neuronal loss and motor symptoms in rats, mimicking the progression of Parkinson's disease (PD) neuropathological cascade. Mild cognitive impairment is knwon to precede motor symptoms and dementia in PD, and therefore is considered as an early clinical marker of the pathology. In this study we explored the mechanisms through which alpha-syn accumulation leads to the development of dementia in PD.

Methods: AAV-mediated overexpression of human wild-type alpha-syn was induced in different brain regions in adult naive mice, and compared with AVV-GFP injected control. Animals were subjected to behavioral tasks at different time points after the injection, and the brain processed to detect neurodegeneration.

Results: We identified selective memory impairments, which were specifically related to the neuronal dysfunctions of the targeted regions. The cognitive defects observed, however, were not associated to neurodegeneration.

Conclusions: These findings provide *in vivo* evidence showing that cognitive impairment precedes alpha-syn overexpression-mediated neurodegeneration. They suggest the interesting hypothesis that alpha-syn overexpression might be the cause not only of dementia and motor symptoms occurring in the end-stage stage of PD, but also of cognitive impairment occurring in the very early stage of the disease. Supported by a grant from the Fondazione con il Sud (2011-PDR-13).

ADPD5-1959

THE EFFECTS OF CLINICAL MOTOR VARIABLES AND MEDICATION DOSAGE ON WORKING MEMORY IN PARKINSON'S DISEASE

D. Hewedi[1], A. Moustafa[2], P. Bell[3]
[1]Department of Psychiatry - Faculty of Medicine - Ain Shams University, Institute of Psychiatry, Cairo, Egypt
[2]University of Western Sydney, Marcs Institute for Brain and Behaviour, Sydney, Australia
[3]University of Western Sydney, School of Social Sciences and Psychology, Sydney, Australia

Objectives: We investigate the relationship between disease duration, dopaminergic medication dosage, and motor disability (UPDRS score) with WM in PD.
Methods: We recruited three groups: unmedicated, medicated PD patients, and healthy controls. All subjects were tested on three WM tasks: short-delay WM, long-delay WM, and the n-back task. Further, PD encompasses a spectrum that can be classified either into akinesia/rigidity or resting tremor as the predominant motor presentation of the disease. In addition to studying medication effects, we tested WM performance in tremor-dominant and akinesia-dominant patients. We further correlated WM performance with disease duration and medication dosage.
Results: No difference between medicated and unmedicated patients in the short-delay WM task, but medicated patients outperformed in the long-delay WM and n-back tasks. Interestingly, we also found that akinesia-dominant patients were more impaired than tremor-dominant patients at various WM measures, which is in agreement with prior studies of the relationship between akinesia symptom and basal ganglia dysfunction. Moreover, the results show that disease duration inversely correlates with more demanding WM tasks (long-delay WM and n-back tasks), but medication dosage positively correlates with demanding WM performance.
Conclusions: Our results show that WM impairment in PD patients depend on cognitive domain (simple vs. demanding WM task), subtype of PD patients (tremor- vs. akinesia-dominant), as well as disease duration and medication dosage. Our results have implications for the interrelationship between motor and cognitive processes in PD, and for understanding the role of cognitive training in treating motor symptoms in PD.

THE P300 AND DUAL TASK STUDIES REFLECT DEFICITS IN THE ALLOCATION OF ATTENTIONAL RESOURCES IN PATIENTS WITH PARKINSON'S DISEASE

M. Yamada[1], J. Murata[2], T. Tabira[3], A. Satoh[4], M. Tsujihata[4]
[1]Rehabilitation, Nagasaki Kita Hospital, Nagasaki, Japan
[2]School of health sciences, Nagasaki University, Nagasaki, Japan
[3]School of health sciences, Nishikyushu University, Kanzaki, Japan
[4]Neurology, Nagasaki Kita Hospital, Nagasaki, Japan

Objectives: The aim of this study is to investigate the attentional deficits of PD patients by measuring the P300 using the dual task platform, and considered the effects of performing dual tasks on their daily activities.
Methods: Eighteen PD patients without dementia, and twenty age-matched healthy controls were included in this study. The cognitive functions of all subjects were assessed using the MMSE, HDS-R, TMT part-A, and FAB. Daily experiences reflecting attention were interviewed. Auditory and visual odd-ball tasks were used for the ERP recordings. All subjects executed three single tasks and a dual task. The behavioral indicators included the response time (RT) for auditory tasks and percentage of correct answers for each task.
Results: The duration of time required for TMT performance was significantly prolonged in the PD patients as compared with that of the control subjects. PD patients showed more prolonged latencies and larger amplitudes of the P300 in all tasks, a delayed RT for the auditory task, a high error rate in performing all tasks, and more difficulties in performing dual tasks in daily activities compared with the control subjects.
Conclusions: Prolonged latencies of the P300 reflect slow cognitive processing. PD patients needed larger attentional resources to execute the tasks, and their capacity for attentional resources was smaller than that of the control subjects. As a result, the PD patients showed the performance errors and difficulties in performing daily activities. These results indicate that deficits in the allocation of attentional resources are present in the PD patients.

TWO AUTOPSY CASES OF DLB PRESENTING PROLONGED REFRACTORY DELIRIUM IN CLINICAL COURSE

S. Iritani[1], H. Fujishiro[1], H. Sekiguchi[1], C. Habuchi[1], K. Oshima[2], K. Niizato[2]
[1]Dept. of Psychiatry, Nagoya University Graduate School of Medicine, Nagoya, Japan
[2]Dept. of Psychiatry, Tokyo Metropolitan Matsuzwa Hospital, Tokyo, Japan

(Background) In the diagnosis criteria of DLB, the fluctuating cognition with pronounced variations in attention and alertness has been listed as one of core features. Sever conscious level down would be shifted to delirium state. In this study, we discussed about the etiology of consciousness level clinico-neuropathologically from two autopsy cases of DLB presenting the prolonged delirium. **(Method)** Investigate for two autopsy cases of DLB. (Case 1) Ninety one years old female. At age of 89y.o., she admitted the internal medicine due to dysfunction of hart. Until then, she has been healthy mentally and physically. Since first admitted day, she showed delirium state with psychomotor excitement. After three months treatment, her physical condition had recovered, but the delirium was observed intermissive. The delirium symptoms was gradually worsen and died at 90 y.o. due to pneumonia. (Case 2) Seventy four years old male. At age of 71 y.o., he was pointed out the impairment of memory and sometimes presented the visual hallucination. Gradually, the sever fluctuation of consciousness level was constantly observed and died at 74 y.o. due to pneumonia. (**Result)** Neuropathological diagnosis as follows: (Case1) 1) Lewy body disease, 2) Argyrophilic grain disases, (Case2) 1) Lewy body disease, 2) tauopathy. In common, neuropathological findings were observed in brainstem including dorsal nucleus of vagus or locus coeruleus.**(Conclusion)** Patients presenting the prolonged delirium in the clinical settings may be included DLB, especially may be having the pathology in the brain stem that concerning the level of consciousness.

ADPD5-0646

THE REGULATION OF ASIC1A ON DOPAMINE RELEASE AND ITS IMPLICATION IN THE PATHOGENESIS OF PARKINSON'S DISEASE

S. Liu[1], F. Wang[2], L.F. Hu[2], C.F. Liu[1]
[1]Department of Neurology,
The Second Affiliated Hospital &Institute of Neuroscience of Soochow University, Suzhou, China
[2]Institute of Neuroscience, Soochow University, Suzhou, China

Objective: To study the distribution of acid-sensing ion channel 1a (ASIC1a) in dopaminergic neurons and its role in regulating dopamine release, and to explore its pathogenic role in Parkinsons disease development.
Materials and Methods: Immunofluorescence and Confocal(CLSM) were used to observe the distribution of ASICs in MES 23.5 cells; whole cell patch clamp technique was used to test the electronic properties of ASIC1a current; High Performance Liquid Chromatography (HPLC) was used to determine DA level; and Western blot was performed to study the expression of ASIC1a, pCaMKII proteins.
Results: ASIC1a co-localized to TH-postive in MES23.5 cell. Inhibitors of ASICs Amiloride and PcTx1 blocked the acid-induced current in a dose-dependent manner; the current density of ASICs increased after MPP+ (100uM) incubation for 1h, this was attenuated by PcTx1 (10nM, $P<0.05$). Compared to control group (PH7.4), extracellular application with pH6.0 solution induced a significant increase of DA release ($P<0.05$), which was diminished by PcTx1 pretreatment; simultaneously, PcTx1 blocked the DA release caused by MPP+ (100uM). Moreover, the intracellular calcium level increased after MPP+ application, and this was blocked by PcTx1. Pretreatment of KN-93 could reverse the ASICs current increase induced by MPP+; In addition, we observed the level of ASIC1 and pCaMKII proteins increased after MPP+ treatment for 24h ($P<0.05$).
Conclusion: Functional ASIC1a expresses on dopaminergic cells, and intracellular DA may be exhausted by MPP+ due to over activation of ASIC1a through Ca2+-CaMKII pathway. ASIC1 channel may represent as a target for regulating DA release and thereby protection against DA neuron losses.

FACTORS UNDERLYING PROBABILISTIC AND DETERMINISTIC STIMULUS-RESPONSE LEARNING PERFORMANCE IN MEDICATED AND UNMEDICATED PATIENTS WITH PARKINSON'S DISEASE

D. Hewedi[1], A. Moustafa[2], R. Krishna[3]
[1]Department of Psychiatry - Faculty of Medicine - Ain Shams University, Institute of Psychiatry, Cairo, Egypt
[2]University of Western Sydney, Marcs Institute for Brain and Behavior, Sydney, Australia
[3]Rutgers University, Department of Psychology, New Jersey, USA

Objective: Prior studies have not tested individual differences or effects of medication dosage on stimulus-response learning in patients with Parkinson's disease (PD). In the current study, we investigated the effects of motor variables (including tremor, akinesia, and disease duration) as well as dopaminergic medication dosage on learning in unmedicated PD patients, medicated PD patients, and healthy controls. Method: We tested all subjects on probabilistic and deterministic learning tasks, and also collected awareness measures data using postexperimental questionnaires. Importantly, we tested learning performance in tremor-dominant and akinesia-dominant PD patients, and further correlated learning performance with disease duration and medication dosage. Results: Results show that akinesia-dominant patients were more impaired than tremor-dominant patients at probabilistic rewardbut not punishment-based learning, which is in agreement with prior studies of the relationship between akinesia and basal ganglia dysfunction. We also found no difference between medicated and unmedicated PD patients in reward- or punishment-based deterministic learning, but medicated patients were better than unmedicated patients at reward-based probabilistic learning. Our results show that awareness measures explain differences among probabilistic and deterministic learning performance. Moreover, we found that disease duration and motor severity are inversely correlated, and medication dosage is positively correlated, with reward-based probabilistic learning. Conclusion: Our results suggest that stimulus-response learning performance in patients with PD depends on the type of learning (probabilistic vs. deterministic), medication status (on vs. off medication, dopaminergic medication dosage), disease duration as well as motor severity and subtype in PD patients (tremor- vs. akinesia-dominant).

[2]Pharmacology, Boston University School of Medicine, Boston, USA

The origins of age-dependent Parkinson's disease (PD) remain enigmatic despite recent success in identification of some genetic triggers (PARKs) and several major hallmarks of this incurable neurodegenerative disease. In search for the new keys to this complex process, we focused on a poorly understood PARK14 (*Pla2g6* gene), and discovered a previously unknown sequence of pathological events that can lead to age-dependent PD. Here we present the results of integrated genetic, molecular, biochemical, imaging, live cells and live animals studies. We demonstrate that a human PD-associated mutations, or truncation of the N terminus of PARK14 (PLA2g6) results in impairment of the store-operated Ca^{2+} entry and sustained depletion of intracellular Ca^{2+} stores, which we found to be a novel trigger for autophagic dysfunction, progressive loss of dopaminergic (DA) neurons in substantia nigra pars compacta (SNc), and age-dependent L-DOPA-sensitive PD-like motor dysfunction in a new PLA2g6 $ex2^{KO}$ mouse model. Discovery of a novel Ca^{2+} signaling pathway leading to DA neuronal death, and creation of a mouse model that mimics human age-dependent PD, opens unique opportunities for unveiling new mechanistic details of this multifaceted process.

[2]Department of Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden

[3]Department of Neurodegeneration,

Hertie Institute for Clinical Brain Research and German Center for Neurodegenerative Di seases, Tübingen, Germany

Background: Large soluble alpha-synuclein oligomers (protofibrils) have been shown to have pronounced neurotoxic properties. Such species are therefore attractive therapeutic targets for disease modification in Parkinson's disease and dementia with Lewy bodies, where alpha-synuclein deposition is believed to be a central pathogenic hallmark. Several mechanisms for disease modification using immunotherapy have been suggested.

Objectives: To investigate whether treatment with a protofibril-selective antibody can prolong survival in h[A30P]alphaSYN tg mice and to evaluate possible mechanisms of action of a protofibril-selective antibody using *in vitro* assays.

Methods: Starting at 12 months of age, h[A30P]alphaSYN tg mice were administered bi-weekly i.p. injections (10 mg/kg) of the protofibril-selective antibody mAb47. The occurrence of motor symptoms and survival was recorded during the study until termination of animals for ethical reasons.

The ability of mAb47 to mediate protofibrillar uptake in microglia was investigated using BV-2 cells. In addition, the ability to block cell-to-cell spreading of alpha-synuclein protofibrils was studied in H4 neuroglioma cells in the presence of mAb47.

Results: The survival of mAb47-treated h[A30P]alphaSYN tg mice was significantly prolonged compared to placebo treated animals. Uptake of alpha-synuclein protofibrils in BV-2 microglia cells was increased in the presence of mAb47 and uptake was abrogated when blocking Fc-gamma receptors. Also, the cell-to-cell spreading of alpha-synuclein protofibrils was reduced after mAb47 treatment.

Conclusions: Treatment with the alpha-synuclein protofibril-selective antibody mAb47 prevented motor related death and increased overall survival of h[A30P]alphaSYN tg mice. Also, mAb47 enhanced uptake in a microglial cell line and decreased cell-to-cell spreading of alpha-synuclein protofibrils.

[3]Department of Neurodegeneration and Restorative Research, University Medical Center Göttingen, Göttingen, Germany

Objectives

Immunotherapy targeting aggregated alpha-synuclein has emerged as a potential therapeutic strategy against Parkinson's disease and other alpha-synucleinopathies. We have developed alpha-synuclein oligomer/protofibril selective antibodies and demonstrated that they can lower levels of toxic alpha-synuclein in human cell lines and, upon intraperitoneal administration, in spinal cord of transgenic mice. However, it is not known whether they exert their effects intra- or extracellularly. Here, we have further evaluated treatment related mechanisms with emphasis on whether the antibodies are internalised by cultured cells.

Methods

Wild type or alpha-synuclein-BiFC overexpressing H4 human neuroglioma cells were treated with a set of monoclonal oligomer/protofibril selective alpha-synuclein antibodies, linear epitope monoclonal alpha-synuclein antibodies or with an irrelevant isotype control. Cells were incubated with antibody for up to 24h in regular growth media at 37°C. Presence of treatment antibody was analysed with immunofluorescence. Antibody levels in conditioned media were measured by sandwich ELISA.

Results

The alpha-synuclein oligomer/protofibril selective antibody mAb47 showed the highest degree of intracellular presence, which reached its maximum after four hours of incubation. The other antibodies displayed different degrees of uptake. Induction of oligomers with the BiFC system led to an increased uptake of alpha-synuclein antibodies, partly overlapping with the localisation of the oligomers. Along with the cellular uptake the extracellular antibody levels decreased continuously, as measured by ELISA.

Conclusions

The oligomer/protofibril selective alpha-synuclein antibody mAb47 was readily internalised by cells in culture, especially if oligomer formation was induced. Ongoing studies will elucidate by which mechanisms the antibodies are internalised by the cells.

ADPD5-2219

ACTIVE IMMUNIZATION AGAINST ALPHA-SYNUCLEIN AMELIORATES DEGENERATIVE PATHOLOGY AND PREVENTS DEMYELINATION IN A MSA MODEL

M. Mandler[1], E. Valera[2], E. Rockenstein[2], M. Mante[2], H. Weninger[1], C. Patrick[2], A. Adame[2], S. Schmidhuber[1], R. Santic[1], A. Schneeberger[3], W. Schmidt[1], F. Mattner[1], E. Masliah[4]

[1]Neurodegeneration Department, AFFiRiS AG, Vienna, Austria

[2]Departments of Neurosciences, UCSD, San Diego, USA

[3]Clinical Department, AFFiRiS AG, Vienna, Austria

[4]Departments of Neurosciences and Pathology, UCSD, San Diego, USA

Objective: MSA is a neurodegenerative disease characterized by parkinsonism, ataxia and dysautonomia. Histopathologically, hallmarks of MSA include abnormal α-syn accumulation within oligodendroglia, leading to neuroinflammation, demyelination and neuronal death. To date, no disease-modifying treatment modalities for α-synucleinopathies, including PD and MSA, are known. Recent studies suggest that immunotherapy increases α-syn clearance and might constitute a viable synucleinopathy therapy. The main objective of this study was to evaluate effects of active vaccination using novel AFFITOPE®-vaccines on reducing MSA-like pathology in the MBP-α-syn transgenic mouse model.

Methods: AFFiRiS has developed novel active immunogens (AFFITOPE®-vaccines) for treating synucleinopathies by targeting α-syn. AFFITOPEs® are short immunogenic peptides that don't carry the native α-syn-epitope but rather a sequence mimicking the original α-syn-epitope. AFFITOPE®-peptides, when conjugated to KLH and adjuvanted with aluminum, induce long-term, sustained, α-syn-specific antibody responses suitable for synucleinopathy treatment. We have previously shown that active AFFITOPE®-vaccination technology was effectively reducing behavioral deficits, α-syn accumulation and inflammation in two synucleinopathy-models.

Results: We used AFFITOPE®-vaccines for immunizing MBP-α-syn mice, a MSA model expressing α-syn in oligodendrocytes. AFFITOPE®-vaccination resulted in production of specific anti-α-syn antibodies that crossed into the central nervous system and recognized α-syn aggregates within glial cells. AFFITOPE®-vaccination resulted in decreased accumulation of α-syn, reduced demyelination in neocortex, striatum and corpus callosum, and reduced neurodegeneration. Clearance of α-syn involved activation of microglia and reduced spreading of α-syn to astroglia.

Conclusions: Results on AFFITOPE®-vaccination in different synucleinopathy-models indicate a potential disease-modifying effect, which is currently tested within a Phase I study in MSA-patients.

04d. Therapeutic Targets & Mechanisms for Treatment: alpha-synuclein

ADPD5-0440
PROLYL OLIGOPEPTIDASE MODULATES ALPHA-SYNUCLEIN OLIGOMERIZATION VIA DIRECT PROTEIN-PROTEIN INTERACTION

Y. Xu[1], S. Mari H.[2], M. Timo T.[2], H. Henri J.[1]
[1]Neuroscience Center, University of Helsinki, Helsinki, Finland
[2]Division of Pharmacology and Toxicology Faculty of Pharmacy, University of Helsinki, Helsinki, Finland

Objectives
Prolyl oligopeptidase (PREP) modulates alpha-synuclein aggregation *in vitro* and *in vivo*. Small-molecule PREP inhibitor KYP-2047 reduces alpha-synuclein aggregation in two A30P alpha-synuclein transgenic mouse strains. The aim of this study was to explore the mechanistic basis of PREP-based modulation of alpha-synuclein oligomerization.

Methods
We combined a live-cell alpha-synuclein dimerization assay, based on protein-fragment complementation assay (PCA), with a novel cell-free method, microscale thermophoresis (MST), to explore the effects of PREP on alpha-synuclein. PCA detects protein-protein interaction based on the reconstitution of reporter protein (Gaussia luciferease) fragments fused to proteins of interest (alpha-synuclein or PREP). MST is a novel cell-free technology analyzes interactions of biomolecules based on their movement in a microscopic temperature gradient.

Results
Our results demonstrate that PREP binds directly to alpha-synuclein and enhances its dimerization. Pharmacological inhibition of PREP reduces its self-oligomerization resulting in enhanced interaction of PREP and alpha-synuclein, and reduced alpha-synuclein dimerization.

Conclusions
These results suggest that via its self-oligomerization and direct interaction with alpha-synuclein, PREP acts as a seeding point for alpha-synuclein aggregation. Our results also provide a mechanism of action for KYP-2047, a PREP inhibitor previously shown to reduce alpha-synuclein aggregation *in vivo*. Taken together, our results support PREP inhibition as a potential new therapy for synucleinopathies. The novel combination of a live-cell method and a cell-free method complement each other, and provides a powerful platform for studying pathophysiologically relevant protein-protein interactions.

04d. Therapeutic Targets & Mechanisms for Treatment: alpha-synuclein

ADPD5-0682

ADIPONECTIN, THE ANTI-DIABETIC ADIPOKINE, HAS A THERAPEUTIC EFFECT IN MODELS OF ALPHA-SYNUCLEINOPATHIES.

K. Sekiyama[1], M. Waragai[1], Y. Takamatsu[1], M. Hashimoto[1]
[1]Department of Sensory and Motor Systems,
Tokyo Metropolitan Institute of Medical Science, Tokyo, Japan

Objectives
The main objective of this study was to determine whether adiponectin (APN), a adipokine with anti-diabetic and anti-atherosclerosis properties, may protect against a-synucleinopathies, such as PD and dementia with Lewy bodies (DLB).
Methods
Biochemical and histological studies were carried out for various experimental systems, including autopsy brains of Parkinson's disease (PD) and dementia with Lewy bodies (DLB), cellular and transgenic-mouse models of α-synucleinopathies.
Results
First, the immunoreactivities of APN were detected in Lewy bodies derived from PD and DLB, suggesting the involvement of APN in the pathogenesis of α-synucleinopathies. Second, APN was protective in vitro; aggregation of α-synuclein (αS) in B103 neuroblastoma cells expressing αS, was significantly ameliorated by treatment with recombinant APN. In addition, APN was protective against various neurotoxicities (i.e. ER stress, mitochondrial toxicity and proteasome inhibition). Furthermore, phosphorylation levels of Akt and other molecules situated in insulin receptor signaling pathway were stimulated by APN in these cells. Finally, various neuropathological features in αS transgenic mice, including αS aggregation and movement disorder, were significantly ameliorated by nasal treatment of the mice with APN.
Conclusions
Our results suggest that APN may act as anti-neuropathogenic in the pathogenesis of α-synucleinopathies and that APN signaling pathway might be a therapeutic target of α-synucleinopathies.

[3]Neurosciences, University California at san Diego, San Diego, USA
[4]Laboratory of Molecular and Chemical Biology of Neurodegeneration, Brain Mind Institute EPFL, Lausanne, Switzerland
[5]HHMI Department of Biology, Stanford University, Stanford, USA
[6]Genetics, Stanford University, Stanford, USA

Parkinson's disease (PD) is the second most common neurodegenerative disorder and its prevalence is expected increase as our population ages. Recently, two distinct VPS35 mutations have been described in familial PD, the P316S mutation (Prol316Ser) and the missense mutation D620N (Asp 620 Asn). The VPS35 gene encodes for a subunit of the retromer system. Furthermore, VPS35 plays an important role in sorting proteins of the retrograde trafficking cargo in early endosomes to the trans-Golgi network. Defects in retrograde trafficking and endosomal dysfunction have been described in PD and related synucleophaties. In order to understand the role of the VPS35 protein in PD we investigated the effects of VPS35 modulations on α-synuclein uptake, accumulation and clearance in neurons, neuronal cell line and in α-synuclein transgenic mice. Our results suggest that manipulating VPS35 expression levels may induce abnormalities in retrograde transport and endosomal function causing accumulation in the neurons. Moreover, our results suggest that VPS35 influences α-synuclein degradation pathway and may affect aggregation. Together our results suggest an important role for VPS35 in the uptake, transport and degradation of α-synuclein and thus may represent a target for therapeutic strategies in PD. Moreover our studies reveal unexpected genetic and functional interactions between two genes associated to PD, VPS35 and EIF4G1, and we described a functionally connection of the genes to α-synuclein pathobiology in yeast, warms and mouse.

DEVELOPMENT OF NOVEL SMALL MOLECULES AS DRUG CANDIDATES FOR PD

A. Davranche[1], S. Papin[1], P. Benderitter[1], J. Molette[1], E. Gabellieri[1], A. Hamel[1], S. Nampally[1], H. Kroth[1], W. Froestl[1], D. Lowe[1], P. Paganetti[1], A. Pfeifer[1], A. Muhs[1]
[1]CH-1015, AC Immune SA, Lausanne, Switzerland

Objective: design of novel disease modifying therapeutics for PD
Background: For PD and several other synucleinopathies, a pathological hallmark is the presence of alpha-synuclein (aSyn) deposits. Several studies suggest that synucleinopathies as well as other protein aggregation diseases share key molecular features, including aggregate toxicity. Previous studies from our group demonstrated that oligomeric toxicity is strongly influenced by the capacity of oligomers to grow, indicating that the aggregation process *per se* is a major contributor to the toxicity.
Methods: We set out to discover small molecule entities (SME) targeting both pathological aSyn oligomer formation, growth and toxicity. The Morphomer platform developed by AC Immune enables the generation of compounds targeting and modifying the beta-sheet conformation of aggregation-prone proteins and rendering them harmless.
Results: We generated interesting drug candidates with appropriate biophysical CNS properties that reduced the cytotoxicity of aSyn aggregates by a decrease of their beta-sheet content. We then confirmed that our lead compound was able to bind human Lewy bodies (LB) and assessed its affinity for aSyn. Our biological rationale was validated *in vivo* in two transgenic mice models (PDGF-aSyn (D-Line) and Thy1-aSyn (TNWT61)) with our lead, which was able to significantly reduce *in vivo* the formation of aSyn pathological structures in a dose dependant manner accompanied by improvement of neuronal marker (tyrosine hydroxylase) in the substantia nigra and rescuing of body weight loss linked to the disease model.
Conclusion: These findings will guide the design of novel disease modifying therapeutics for PD and other synucleopathies.

PASSIVE IMMUNOTHERAPY AGAINST ALPHA-SYNUCLEIN REDUCES TRANS-SYNAPTIC ALPHA-SYNUCLEIN PROPAGATION AND AXONAL DEGENERATION IN A COMBINED VIRAL VECTOR AND TRANSGENIC MODEL OF SYNUCLEINOPATHY

D. Games[1], W. Zago[1], E. Valera[2], E. Rockenstein[2], M. Mante[2], B. Spencer[2], A. Adame[2], C. Patrick[2], P. Seubert[1], R. Barbour[1], D. Schenk[1], E. Masliah[3]
[1]R&D, Prothena Biosciences, South San Francisco, USA
[2]Department of Neurosciences, University of California - San Diego, San Diego, USA
[3]Departments of Neurosciences and Pathology, University of California - San Diego, San Diego, USA

Background
Parkinson's Disease (PD) and Dementia with Lewy bodies (DLB) are characterized by progressive accumulation of alpha-synuclein (alpha-syn) in neurons. Recent studies have proposed that neuron-to-neuron transmission of alpha-syn plays a role in the pathogenesis of PD/DLB. Therefore, we explored the effect of passive immunization against alpha-syn in a new mouse model of trans-synaptic propagation.
Methods
For these experiments, non-transgenic (non-tg), alpha-syn knock-out and human alpha-syn tg (line 61) mice received unilateral intra-cerebral injections with a lentiviral (LV)-alpha-syn vector construct followed by systemic administration of control IgG or the monoclonal antibody 1H7 for 3 months. Cerebral alpha-syn accumulation and axonopathy was assessed by immunohistochemistry and effects on behavior by Morris water maze.
Results
Unilateral LV-alpha-syn injection resulted in axonal propagation of alpha-syn in the contra-lateral site with subsequent behavioral deficits and axonal degeneration. Passive immunization with 1H7 antibody reduced the trans-synaptic propagation, impairment in water maze behavior and axonal degeneration.
Conclusion
Together this study supports the notion that an antibody against alpha-syn is capable of reducing propagation of alpha-syn, thus ameliorating PD-like pathology and improving the associated deficits in a new alpha-syn transmission model. This work was funded by NIH grant AG18840 and Prothena Biosciences.

04d. Therapeutic Targets & Mechanisms for Treatment: alpha-synuclein

REPURPOSING DRUGS FOR ANTI-ALPHA SYNUCLEIN AGGREGATION

M.E. Herva[1], J. Fan[2], M. Goedert[2], M.G. Spillantini[1]
[1]Clinical Neurosciences, University of Cambridge, Cambridge, United Kingdom
[2]Neurobiology division, MRC Laboratory of Molecular Biology, Cambridge, United Kingdom

Objectives:
PD is a brain disorder characterized by the presence of alpha-synuclein (a -syn) aggregates forming intraneuronal inclusions known as Lewy bodies and Lewy neurites. Symptomatic treatments are available, but there are no disease-modifying therapies. Therefore, we aim to find compounds that inhibit the aggregation of a-syn and might halt the progression of PD.
Methods:
Recently, we published the a-syn protein misfolding cyclic amplification (PMCA), an *in vitro* system to produce a-syn fibrils in a fast, efficient and reproducible manner. We demonstrated that known anti-amyloid compounds inhibited the formation of a-syn aggregation by PMCA. We are now using the a-syn PMCA to screen previously used drug libraries to identify inhibitors of a-syn aggregation. Moreover, we are using cell assays to test the effects of the candidate drugs in culture.
Results:
Using a-syn PMCA as a high-throughput assay, we have screened hundreds of compounds and have found some that inhibit the aggregation of a-syn.
Conclusion:
Our results indicate that by using a non-biased assay such as the a-syn PMCA to screen for compounds with anti-a-syn aggregation properties, we might be able to find disease-modifying agents.

04d. Therapeutic Targets & Mechanisms for Treatment: alpha-synuclein

IDENTIFICATION OF NOVEL ALPHA-SYNUCLEIN BINDING SMALL MOLECULES BY STRUCTURE-BASED VIRTUAL SCREENING

R. Kiss[1], F. Aigbirhio[2], G. Tóth[1]
[1]Institute of Organic Chemistry, MTA-TTK, Budapest, Hungary
[2]Wolfson Brain Imaging Center Department of Clinical Neurosciences, University of Cambridge, Cambridge, United Kingdom

1. Objectives: The aggregation of alpha-synuclein (alphaSyn) is linked to the onset and pathology of Parkinson's disease (PD). In a recent 3D structure of an 18 residue-long fragment of alphaSyn, the alphaSyn fragment monomer is stabilized into a beta-hairpin structure by beta-wrap proteins (Mirecka et. al., 2014, Angew.Chem.Int.Ed.Engl., 53, 4227). This fragment of alphaSyn covers a critical, fibril-forming part of alphaSyn and also contains multiple disease-related mutations. The availability of this experimental structure prompted us to apply structure-based virtual screening for the identification of novel alphaSyn ligands.

2. Methods: OpenEye programs were used to define small molecule binding sites in the alphaSyn structure (PDB ID: 4BXL), and to perform high throughput structure-based docking calculations. A small molecule CNS-like fragment library was prepared in Mcule. Stereoisomers, major tautomers and protomers were generated by ChemAxon. Calculations were run at the Hungarian supercomputing centre (NIIF Institute).

3. Results: Two possible small molecule binding sites were identified in close proximity of residues Tyr39 and His50. The generated CNS-like fragment small molecule library contained 22,521 fragments. From the docking calculations highest-ranked compounds with a favorable interaction profile were analyzed and 68 compounds were selected for experimental testing.

4. Conclusions: We have identified potential binders of alphaSyn *in silico* using structure-based virtual screening. These *in silico* hits can be potentially PET imaging agent candidates as well as hit candidates as alphaSyn aggregation inhibitors for PD therapeutics.

This work was supported by the Hungarian Brain Research Program -KTIA_NAP_13-2014-0009.

As a powerful platform for understanding of disease mechanism and consequent evaluation of disease-modifying therapies aimed at both familial and sporadic PD patients, we have recently generated ventral mesencefalic DA neurons (vmDAn) from idiopathic (ID) PD-iPSC lines, familial LRRK2-PD iPSC lines and control hiPS cell lines. With the aim to characterize PD-dependent neuronal alterations, we first differentiated control and PD-specific iPSC toward midbrain dopaminergic neurons following the protocol recently implemented in our laboratory that relies on lentiviral-mediated forced expression of the ventral midbrain determinant LMX1A, together with DA neuron patterning factors. All iPSC lines tested generate vmDAn, with the characteristics of A9 ventral midbrain DA neurons as revealed by expression of G protein-activated inward rectifier potassium channel 2 (GIRK2) and FOXA2. We then co-cultured neural progenitor cells -derived iPS over a monolayer of mouse embryo cortical astrocytes, which supported viable cultures of vmDA neurons for up to 75 days. Under these conditions, Ctrl-iPSC gave rise to vmDAn that were morphologically homogeneous and showed the expected features of mature vmDAn, including complex dendritic arborizations. However, DAn differentiated from ID-PD or LRRK2-PD iPSC developed over long-time culture a range of altered morphologies that were not evident at shorter time-points. When we measured the number of vmDAn and the length of neuritis, we found that both the number and length of neurites of Ctrl-iPSC-derived DAn were significantly higher than those of DAn differentiated from ID-PD or LRRK2 iPSC.
We have also observed an abnormal α-synuclein accumulation, and alterations in the autophagy machinery. We are now analyzing whether DAn degeneration in PD is truly a cell-autonomous phenomenon, or whether it is influenced by an altered cross-talk between DAn and glial cells, by exploring combinations of DAn and astrocytes differentiated from PD patient-specific and control iPSC. The generation of genuinely human experimental models of PD provides a platform that will disclose new opportunities not only for basic research but also for drug discovery and cell therapy in PD.

[3]Department of Molecular and Life Sciences, Hanyang University, Ansanshi, Korea
[4]Department of Neurology, Wonkwang Unic. Sanbon Clinic, Gunposhi, Korea

1. Objectives: Leucine-rich repeat kinase 2 (LRRK2) has been identified as a causative gene for Parkinson's disease (PD). LRRK2 contains a kinase and a GTPase domain, both of which provide critical intracellular signal-transduction functions. We showed previously that Rab5b, a small GTPase protein that regulates the motility and fusion of early endosomes, interacts with LRRK2 and co-regulates synaptic vesicle endocytosis. We investigated meaning of this interaction.

2. Methods: Using Rab5b recombinant proteins, we applied *in vitro* kinase assays with mass spectrophotometry analysis. GTPase, neurite outgrowth and EGFR degradation assays were used to test physiological meaning of Rab5 phosphorylation by LRRK2, using nonphosphorylatable or phosphomimetic mutant Rab5 recombinant proteins.

3. Results: We show here that LRRK2 phosphorylates Rab5b at its Thr6 residue. Phosphorylation of Rab5b by LRRK2 on the threonine residue was confirmed by Western analysis using animals or cells stably expressing LRRK2 G2019S. The phosphomimetic mutant T6D recombinant protein exhibited reduced GTP binding and increased GTPase activity compared to that of the wild type Rab5b protein, suggesting that LRRK2-mediated phosphorylation of Rab5b makes the Rab5b signal weaker than that of the unphosphorylated form. Neurite outgrowth analysis and epidermal growth factor receptor (EGFR) degradation assays showed that Rab5b T6D exhibited phenotypes that were expected to be observed in the inactive Rab5b, including longer neurite length, and less degradation of EGFR.

4. Conclusion: These results suggest that LRRK2 kinase phosphorylates Rab5b and its kinase activity functions as a Rab5b GTPase activating protein and thus, negatively regulates Rab5b signaling.

ADPD5-0668

INHIBITION OF C-ABELSON TYROSINE KINASE (C-ABL) AS A POSSIBLE STRATEGY FOR TREATMENT OF PD: STUDY IN MPTP-INDUCED MICE MODEL

J. Kasahara[1], Y. Yamamura[1], A. Tanabe[1], R. Morigaki[2], R. Kaji[3], S. Goto[2]
[1]Department of Neurobiology and Therapeutics, The University of Tokushima, Tokushima, Japan
[2]Department of Motor Neuroscience and Neurotherapeutics, The University of Tokushima, Tokushima, Japan
[3]Department of Clinical Neuroscience, The University of Tokushima, Tokushima, Japan

Objective: c-Abelson tyrosine kinase (c-Abl) is known to phosphorylate Cdk5 at Tyr15 (Tyr15-Cdk5) and thereby facilitates the Cdk5 activity. We found that Cdk5 with Tyr15 phosphorylation (Cdk5-pTyr15) is enriched in the mouse striatum, where dopaminergic stimulation inhibited phosphorylation of Tyr15-Cdk5 by acting through the D2 class dopamine receptors. To see if c-Abl is involved in the pathophysiology of Parkinson's disease (PD) and inhibition of this kinase would be a possible strategy for PD treatment, we examined the effect of c-Abl inhibitors in 1-methyl-4-phenyl-1,2,4,6-tetrahydropyridine (MPTP) mouse model of PD in this study.
Methods: Male C57Bl/6 mice were subjected of MPTP treatment to establish PD model. Inhibitors of c-Abl, imatinib or nilotinib, were administered by intraperitoneal injection with 25 mg/kg. After behavioral examinations assessing motor dysfunction, biochemical and immunohistochemical examinations were performed.
Results: Administration of c-Abl inhibitors normalized motor dysfunction induced by MPTP in mice. Both of the inhibitors reduced the MPTP-induced phosphorylation of Cdk5 protein at Tyr15 (Cdk5-pTyr15), together with its substrate DARPP32 phosphorylated at Thr75. Most of these effects were as same as those of L-dopa (15 mg/kg), showing the c-Abl inhibitors possess equivalent potential compare to other PD therapeutics. Our results suggested use of c-Abl inhibitors is a possible strategy for future PD treatment.

ADPD5-2053

NEUROPROTECTIVE EFFECTS OF DELAYED START ADMINISTRATION OF THE CLASS III HDAC INHIBITOR NICOTINAMIDE IN THE LACTACYSTIN MODEL OF PARKINSON'S.

D. Dexter[1], *I. Harrison*[1]
[1]*Division of Brain Sciences, Imperial College London, London, United Kingdom*

Objective(s): Determine whether the class III pan-HDAC inhibitor nicotinamide is neuroprotective in the lactacystin model of Parkinson's using a delayed start treatment model.

Background: Epigenetic changes, both DNA methylation and histone modification, occur in the Parkinson's brain. It has been hypothesised that histone hypoacetylation through overactivity of histone deacetylases (HDAC's) leads to chromatin condensation and repression of gene expression leading to neuronal death. Hence, HDAC inhibitors (HDACI's) have been proposed as neuroprotective agents. Nicotinamide, a naturally occurring substance well tolerated by humans, a pan HDAC class III (Sirtuins) inhibitor and has been demonstrated to protect against MPTP toxicity when given as a pre-treatment which does not mirror the potential clinical setting.

Methods: 250mg/kg or 500mg/kg nicotinamide was administered i.p. for 28 days starting 7 days after the induction of a lactacystin lesion to the substantia nigra (SNc). Forepaw-use asymmetry, amphetamine induced rotations, MRI brain scans was assessed at baseline and weekly during the study. At the end of the study SNc dopaminergic neuronal counts were performed by tyrosine hydroxylase immunohistochemistry/stereological counting. RT-PCR was utilised to assess gene expression.

Results: Despite nicotinamide reversing the lactacystin induced histone hypoacetylation and stimulating gene expression of glial derived neurotrophic factor (GDNF) and the anti-apoptotic factor Bcl2, nicotinamide failed to induce any neuroprotective effects when assessed by MRI, behaviour or via SNc dopaminergic neuronal counts.

Conclusions: Unlike the pan-class I/IIa HDACI valproate the pan-class III HDACI nicotinamide is not neuroprotective in the lactacystin model of Parkinson's, suggesting pan-inhibition of Sirtuins is not neuroprotective.

ADPD5-1282

THE ANTI-INFLAMMATORY ACTIONS OF NORADRENERGIC AGENTS AS A TARGET TO PREVENT NEURODEGENERATION IN PARKINSON'S DISEASE

J. Yssel[1], T. Connor[1], A. Harkin[2]
[1]Neuroimmunology Research Group Dept. of Physiology School of Medicine, Trinity College Dublin, Dublin, Ireland
[2]Neuropsychopharmacology Research Group School of Pharmacy and Pharmaceutical Sciences, Trinity College Dublin, Dublin, Ireland

Neuroinflammation is recognised as a key player in the progression of Parkinson's disease (PD) and interest is increasing in inflammatory models of PD including lipopolysaccharide (LPS)-induced degeneration of dopaminergic neurons in the substantia nigra (SN). In recent years there has been an additional focus on the degeneration of noradrenergic neurons. Degeneration within the locus coeruleus, the main noradrenergic cell body region within the midbrain, is evident in PD, and a loss of noradrenaline (NA) appears to exacerbate both the demise of DA neurons and the motor symptoms of PD. NA is potentially involved in an array of compensatory, anti-inflammatory and possibly neuroprotective mechanisms in PD. Moreover as a number of drugs that can increase noradrenergic function are already in clinical use for various conditions, the potential for targeting NA for treating the symptoms of PD is high. In the current investigation we have observed that a combination of treatment with the noradrenaline reuptake inhibitor atomoxetine and the alpha$_2$-adrenoceptor (AR) antagonist idazoxan, a combination which serves to enhance the extrasynaptic availability of noradrenline, exerts anti-inflammatory effects in the LPS model of PD. Functional deficits in motor function were partially rescued following treatment. Furthermore there was a complete restoration of nigral DA levels and reduced striatal DA depletion. In addition, IBA-1 immunohistochemical staining of microglia in the SN displayed a greater percentage of ramified processes in rodents treated with atomoxetine/idazoxan, compared with saline treated animals which displayed an amoeboid morphology, indicating the anti-inflammatory actions of NA leading or contributing ultimately to neuroprotection.

DIFFERENTIAL OCCUPANCY OF RAT BRAIN 5-HT2A AND 5-HT2C RECEPTORS BY PIMAVANSERIN: RELEVANCE TO EFFICACY IN RAT MODELS OF ANTIPSYCHOTIC-LIKE ACTIVITY

M. Mugnaini[1], B. Otterstätter[1], K. Drescher[2], A.L. Relo[3], G.C. Terstappen[1], V. Lakics[1]
[1]Biology, AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany
[2]CNS Late Discovery, AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany
[3]Pharmacology, AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany

Pimavanserin is an inverse agonist of 5-hydroxytryptamine (5-HT) 2A receptors (5-HT_{2A}Rs), currently being investigated for Parkinson's disease-related psychosis (Hacksell et al., *Neurochem.Res.* **39**:2008, 2014). Its efficacy in animal models of antipsychotic-like activity can only partially be explained in terms of 5-HT_{2A}Rs inhibition. Since pimavanserin is also a 5-HT_{2C}R inverse agonist (Vanover et al., *JPET* **317**:910, 2006), in the present study its occupancies of 5-HT_{2A} and 5-HT_{2C} receptors were compared in parallel, at doses commonly used to reveal its antipsychotic properties. Adult, male, Wistar Han rats were treated with increasing doses of pimavanserin (0.1, 0.3, 1, 3 and 10 mg/kg, ip) and euthanized after 30 min. 5-HT_{2A}Rs and 5-HT_{2C}Rs occupancy was determined by means of *ex vivo* [^{3}H]MDL100907 and 5-HT_{2C}-selective [^{3}H]mesulergine autoradiography, respectively.

Pimavanserin dose-dependently occupied 5-HT_{2A}Rs, with a dose resulting in 50% of maximal occupancy (OD_{50}) at 0.11±0.01 mg/kg, corresponding to a pimavanserin concentration of 0.53±0.28 ng/ml in plasma and 16.8±1.1 ng/g in the brain. For 5-HT_{2C}Rs, the occupancy was significantly lower, as revealed by an OD_{50} of 1.59±0.32 mg/kg, while its concentration in plasma and in the brain was 24.0±5.8 ng/ml and 276±55 ng/g, respectively.

In conclusion, we describe here the differential occupancy of pimavanserin at 5-HT_{2A}Rs and 5-HT_{2C}Rs for the first time. Our occupancy data correlate well with the respective affinities of the compound (5-HT_{2A}R>5-HT_{2C}R). The significant 5-HT_{2C}Rs occupancy by pimavanserin (at doses commonly used to reveal its antipsychotic properties) will be considered in the context of the pharmacokinetic/pharmacodynamic relationship in our own behavioral data and existing literature.

04k. Therapeutic Targets & Mechanisms for Treatment: nicotinic & other ionotropic receptors

ADPD5-1622

MODULATION OF SYNAPTIC GLUN2A-CONTAINING NMDA RECEPTORS IN L-DOPA INDUCED DYSKINESIA

F. Gardoni[1], J. Stanic[1], M. Mellone[1], E. Zianni[1], M. DiLuca[1]
[1]Department of Pharmacological and Biomolecular Sci, University of Milano, Milan, Italy

Objectives: In PD, an aberrant subunit composition of striatal NMDA receptors (NMDARs) play a key role in the regulation of the abnormal motor behavior observed in L-DOPA induced dyskinesia (LID). Research focused on identification of compounds able to reduce NMDAR activity. However, so far, clinical trials provided conflicting results. Accordingly, the identification of novel approaches to rescue the alterations of the glutamatergic synapses underlying LID has become an urgent need in the field.
Methods: We have evaluated a new approach to reduce synaptic GluN2A-containing NMDARs in L-DOPA treated dyskinetic animals. In particular, we have analysed the role of GluN2A binding with Rabphilin-3A (Rph3A), a novel GluN2A interacting protein, involved in NMDAR stabilization at synaptic membranes. Rph3A/GluN2A interaction and Rph3A synaptic levels have been analysed in L-DOPA-treated animals. A cell-permeable peptide corresponding to the GluN2A domain involved in the interaction with Rph3A (TAT2A40) has been administered in vivo to reduce the formation of Rph3A/GluN2A complex.
Results: L-DOPA treated dyskinetic animals are characterized by an increase level of Rph3A in the excitatory postsynaptic membranes and by an augmented formation of GluN2A/Rph3A complex, leading to an aberrant synaptic localization of GluN2A-containing NMDARs. The concomitant treatment with L-DOPA and TAT2A40 ameliorates significantly the dyskinetic behaviour in L-DOPA treated rats. In particular, a single injection with the TAT2A40 peptide induces a long-lasting (3 days) reduction of LIDs.
Conclusions: Modulation of GluN2A/Rph3A complex could represent an innovative strategy to reduce GluN2A-containing NMDARs in L-DOPA-treated dyskinetic animals and, consequently, the onset of LIDs.

ADPD5-2054

NEUROPROTECTIVE AND BEHAVIOURAL EFFECTS OF MGLUR8 AGONIST DCPG IN THE LACTACYSTIN AND LPS MODELS OF PARKINSON'S DISEASE:

D. Dexter[1], *C. Williams*[1]
[1]*Division of Brain Sciences, Imperial College London, London, United Kingdom*

Objective: Ascertain the neuroprotective/behavioural effects of targeting metabotropic glutamate receptor subtype 8 (mGluR8) in the lactacystin and LPS rat model of Parkinson's utilising the agonist (*S*)-3,4-dicarboxyphenylglycine (DCPG).
Background: Excess glutamatergic signalling in the basal ganglia and neuroinflammation are features of neurodegenerative process in Parkinson's. Evidence suggests that pharmacological activation of the mGluR4 subtype can provide significant neuroprotection and reduce behavioural deficits in traditional toxin rodent models of Parkinson's by reducing neuronal excitability. However, it is not known whether targeting mGluR8 can trigger similar effects.
Methods: Rats were unilaterally lesioned with the proteasome inhibitor lactacystin or Lipopolysaccharides (LPS) in the substantia nigra (SNc).DCPG was administered systemically for 14 days starting 4 days after lactacystein lesioning and for 7 days starting the next day after LPS lesioning. Forelimb-use asymmetry tests and amphetamine-induced rotations were used to assess behavioural deficits, whilst immunohistochemistry and stereological quantification of SNc dopaminergic neurons and microglia was performed.
Results: DCPG treatment was associated with a small neuroprotective effect on the loss of dopaminergic neurons in both the lactactacystin (~10% neuroprotection) and LPS (~24% neuroprotection. This was associated with a small attenuation in forelimb-use asymmetry but not in amphetamine-induced rotations in both models. DCPG treatment was also associated with a modest but not significant reduction in SNc microglial activation in both models.
Conclusion: Although the mGluR8 agonist DCPG did induce neuroprotection in both animal models the degree of neuroprotection was too small to support the concept that targeting mGluR8 receptors are a worthwhile neuroprotective target for treating Parkinson's.

PARKINSON'S DISEASE: THERAPEUTIC TARGETING OF TOLL-LIKE RECEPTORS

L. Soraci[1], S. Cartella[1], P. De Domenico[1], M.E. Gambuzza[2], V. Sofo[1], F.M. Salmeri[1]
[1]Environmental protection School of Medicine, University of Messina, Messina, Italy
[2]Territorial Office of Messina, Ministry of Health, Messina, Italy

Microglia play opposing roles in Parkinson's disease (PD) pathogenesis: in early stage they exert neuroprotection mediated through alpha-synuclein (Sa) phagocytosis, while as the disease progresses, they fail in Sa clearance and induce neuroinflammation and neurodegeneration. Innate immunity plays important role both in Sa-clearance and inflammation Sa-mediated. Toll-like receptors (TLRs) promote Sa clearance in the early stage, while during the disease they result chronically activated by accumulated Sa and induce a pro-inflammatory cascade leading to neurodegenerative changes. This current knowledge could allow to select specific TLR immunomodulators, to treat PD, mainly blocking neuroinflammatory cascade.
Specific small TLR antagonists, perhaps able to cross the blood brain barrier could also inhibit TLRs expressed by microglia, then exerting their anti-inflammatory effects directly on CNS. In addition, some of these TLR modulators exhibit high affinity, have the potential to be given to patients as an inhaled drug, a skin patch or a pill. Recently, small interfering RNA-selective compounds have become more straightforward because of the significant progress made in predictive modeling for new therapeutic approaches.
Modulation of TLR expression with small molecules acting as TLR antagonists might represent an alternative approach in PD therapy, especially in the late state, in order to decrease the inflammatory response, slowing the progression of the desease. Moreover, these TLR-targeting drugs have fewer side effects and lower or no toxicity compared to drugs with non specific anti-inflammatory effect commonly used in PD treatment.

[2]Department of Pharmacology Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Sao Paulo, Brazil
[3]Department of Morphology Physiology and Pathology, University of Sao Paulo Dental School of Ribeirao Preto, Sao Paulo, Brazil

Objectives: Our previous work showed that the antibacterial drug doxycycline (DOX) confers neuroprotection in a mouse model of Parkinson disease by inhibiting glial cell activation (Lazzarini et al, Glia, 2013). In the present work, we aimed to get further insights into the molecular mechanisms behind the anti-inflammatory effect of DOX.
Methods: To do that we used a model system of microglial cells in which the inflammatory process is triggered by low concentrations of the bacterial lipopolysaccharide (LPS).
Results: Our data show that DOX significantly inhibits the response of microglial cells to LPS treatment. In particular, we demonstrate that DOX diminishes the synthesis of two key pro-inflammatory cytokines, TNF-alpha and IL-1 beta. DOX treatment also leads to a reduction in the levels of reactive oxygen species and nitric oxide. The effects of DOX are associated to decreased phosphorylation levels of p38 and NF-kB p65, two master regulators of inflammation.
Conclusions: These results suggest that DOX besides its well-known antibacterial activity can also operate as an anti-inflammatory drug that may be useful for treating neurodegenerative diseases such as Parkinson disease.

ADPD5-1485

PRETREATMENT WITH PHOSPHODIESTERASE INHIBITOR (IBUDILAST) PREVENTS THE NEUROINFLAMMATION AND AMELIORATES MOTOR DISTURBANCE IN THE MPTP MODEL OF PD

M. Zaremba[1], J. Schwenkgrub[1], I. Joniec – Maciejak[1], A. Cudna[2], I. Kurkowska – Jastrzebska[2]

[1]Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Warsaw, Poland

[2]2nd Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland

Objective: To estimate a possible preventive effect of Ibudilast (IBD), a non-selective (3, 4, 10, 11) phosphodiesterase inhibitor in the MPTP model of Parkinson's disease.

Methods: 3 months-old male C57Bl/10Tar mice were treated IBD b.i.d. for 9 days with subcutaneous injections [0, 20, 30, 40 or 50 mg/kg], beginning 2 days prior to MPTP (60 mg/kg) intoxication. Locomotor activity was examined by the RotaRod performance test. Expression of mRNA cytokines (TNFα, IL-6, IL-1β) and neurotrophic factor (GDNF) in the striatum were examined by the Real Time RT-PCR method. Micro- and astroglia activation markers (Iba-1 and GFAP, respectively) were estimated by Western blot analysis. Tyrosine hydroxylase (TH) expression and dopamine (DA) metabolism were evaluated by Western blot analysis and high-performance liquid chromatography, respectively.

Results: Compared to control, IBD in the dose of 40 mg/kg significantly improved motor abilities in MPTP mice. In addition, IBD attenuated astroglial reactivity and decreased release of all investigated pro-inflammatory cytokines in the striatum in a dose-dependent manner. IBD (40 mg/kg) also promoted production of GDNF. However, IBD administration did not change DA metabolism and striatal TH expression and had no impact on microglial activity in MPTP-treated mice.

Conclusions: IBD may have preventive effects mostly as a glial cell attenuator and promoter of neurotrophic factor. However, long-term observation will be needed to confirm its potential role in the restoration of neuronal function and promotion of dopaminergic cell survival.

ADPD5-0273

THE EFFICACY AND SAFETY OF COENZYME Q10 IN PREVENTING THE PROGRESSION OF EARLY PD: A META-ANALYSIS

R. De Roxas[1], *R. Jamora*[1]

[1]*Department of Neurosciences, University of the Philippines-Philippine General Hospital, Manila, Philippines*

Objectives: The objective of this study is to assess and summarize the available evidence on the efficacy and safety of Coenzyme Q10 administration in the prevention of the progression of early Parkinson's Disease.

Methodology: A Literature search in several databases was conducted for relevant randomized controlled trials on the use of Coenzyme Q10 in Parkinson's Disease. Three randomized controlled trials met the inclusion criteria. The efficacy of Coenzyme Q10 were measured using the total and the component scores of the Unified Parkinson Disease Rating Scale on follow-up. On the other hand, safety were measured using the withdrawal rate and the associated adverse reactions during the therapy of CoQ10. The Review Manager Software was utilized for the meta-analysis.

Results: Compared to Placebo, treatment of CoQ10 did not show any significant difference in the mean scores of the UPDRS mental and ADL scores. Interestingly, the UPDRS motor score showed a significant difference between Coenzyme Q10 and placebo, but no significant difference when a subgroup analysis between high-dose (-4.03 [-15.07-7.01], p-value= 0.47, I^2=67%, P for heterogeneity=0.08) and low-dose Coenzyme Q10 (0.53 [-0.89-1.94], p-value= 0.47, I^2=34%, P for heterogeneity=0.22) was done. Overall, there was no significant difference in the total UPDRS score (0.68 [-0.61-1.97], p-value= 0.30, I^2=0%, P for heterogeneity=0.70). The most common side effects of the use of Coenzyme Q10 are anxiety, back pain, headache, sore throat, nausea, dizziness and constipation.

Conclusions: Coenzyme Q10 did not show enough evidence to prove its efficacy in early PD, however, its safety can be secured.

NEUROPROTECTIVE ACTIVITIES OF NEPALESE AND NATIVE AMERICAN TRADITIONAL MEDICINE

A. de Rus Jacquet[1], R. Subedi[2], S.K. Ghimire[2], J.C. Rochet[1]
[1]Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, USA
[2]Central Department of Botany, Tribhuvan University, Kathmandu, Nepal

Parkinson's disease (PD) affects more than five million people worldwide, but there are no treatments to stop or slow the neurodegenerative process. With 80% of the world population using medicinal plants as a primary source of healthcare, the development of plant-based therapies would critically impact the lives of these patients. The objective of our research is to identify plant-based therapies that would be readily available to these populations but could also be developed into more modern drugs. Nepalese healers and local people as well as members of Native American tribes (Blackfeet and Lumbee) were interviewed to document their use of medicinal plants to treat symptoms related to PD. The neuroprotective activity of a selection of botanical extracts was assessed in cell culture models relevant to PD. Extracts with the greatest neuroprotective activity were further characterized in terms of mechanisms of action including activation of the Nrf2 antioxidant pathway in primary cortical astrocytes and primary midbrain cultures and rescue of mitochondrial function. Among the 50+ plants documented in our ethnopharmacological studies, we identified six promising candidates characterized by distinct chemical compositions. These botanical extracts alleviate dopaminergic neuron death and neurite loss elicited by rotenone and/or paraquat, two PD-related toxins. Furthermore, the extracts activate critical neuroprotective pathways such as the Nrf2 antioxidant response. Further mechanistic studies will provide a deeper understanding of the neuroprotective activities of these extracts and suggest strategies for designing herbal remedies to slow or stop PD progression.

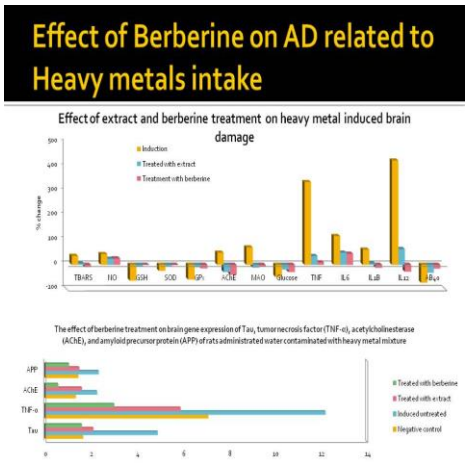
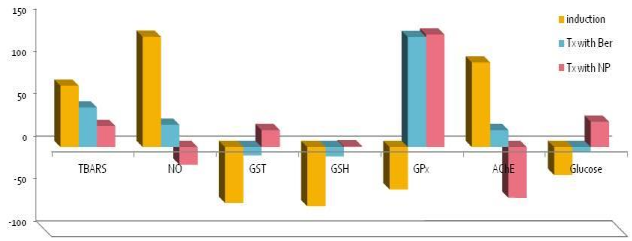
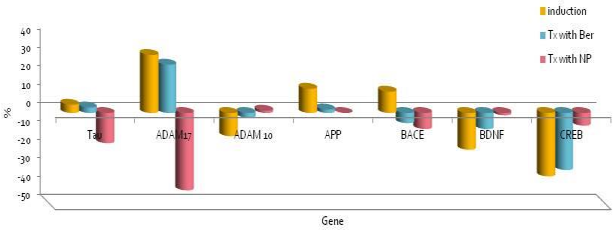
Major characteristics of Alzheimer's disease (AD) aresynaptic loss, cholinergic dysfunction, and abnormal protein depositions in thebrain in form of toxic non-soluble amyloids and hyperphosphorylated tau. Ourmain focus in the present study is to assess the therapeutic effect ofberberise vulgaris extract, berberine and berberine nanoparticle againstAD-like disease by tracking its effect on the oxidative stress-inflammatorypathway and MAPK pathway as well as AD hall markers. AD induced in rats by oraladministration of 5 ml of contaminant water for 3 months or insulin resistancefor one month. Then the treatment with tested compounds was carried out foranother one month. Firstly, we examined the berberine effect *in silico* and we found that berberine was potent anti-acetylcholine and inhibited bothTNF-alpha-converting enzyme and COX-2. Our biochemical and molecular parametersshowed that tested compounds inhibited the AChE and down-regulated itsexpression that could be returned its ability to act as potent antioxidants inbrain tissue. Matching with *-in silico* study, berberine normalized theproduction of TNF- alpha. IL12, IL 6 and IL 1β and ADAM 10 and ADAM 17. Finally,Berberine activated the production of APP-40 that acts as antioxidants forbrain tissue and inhibited the production of APP-42 fragment that responsiblefor Beta-amyloid plaques formation. Altogether, our data confirmed the use ofberberine as well as berberine nanoparticles, as drug candidate for AD likedisease treatment as berberine can lower Amyloid beta via multiple mechanisms



Effect of Berberine nanoparticles on AD treatment



Effect of berberine or Ber-NP on relative gene expression in AD-like disease induced in animal



Neurotransmitter control	• Inhibits AChE
Neurotrophic factor	• Increases BDNF
Antioxidants	• Reduces ROS • Increases antioxidants
Anti-inflammatory	• Inhibits the production of TNF, ADAM, IL 1B, iNOS and COX
Metabolic enhancer	•Increases ATP, NADP
Neuron Plasticity	• increases CREB

NEURO-PEPTIDE TREATMENT WITH CEREBROLYSIN ENHANCES THE SURVIVAL OF GRAFTED NEURAL STEM CELL IN THE THY1-ALPHA SYNUCLEIN TRANSGENIC MODEL OF PD

E. Rockenstein[1], P. Desplats[1], M. Mante[1], J. Florio[1], S. Anderson[1], D. Meier[2], S. Winter[2], H. Brandstatter[2], A. Adame[1], H. Moessler[2], E. Masliah[1]

Stem cell grafting has been investigated as a neuro-restorative therapy in Parkinson's Disease (PD) and other a-synucleinopathies but graft cell survival is hampered in a toxic neural environment where a-synuclein can propagate and trigger toxicity. Supplying neurotrophic factors to grafts has been proposed to augment survival. We investigated Cerebrolysin (CBL), a peptidergic mixture with neurotrophic-like properties, as an adjunct to stem cell therapy in the mThy1-a-synuclein tg model of PD.
Fetal mouse cortex-derived neural stem cells (NSC) were tagged with GFP and BrdU and injected into the striatum of non-tg and a-synuclein tg mice. Simultaneously, mice received saline or CBL (i.p.) until sacrifice.
Groups were assessed at 1 and 3 months post-grafting, Vehicle-treated a-synuclein tg mice displayed decreased NSC survival compared to vehicle-treated non-tg mice. Less than 5% of grafted NSCs in vehicle-treated a-synuclein tg mice were BrdU or GFP-positive. CBL enhanced NSC survival in both groups above baseline. Most surviving NSCs remained as neuroblasts and were DCX and PCNA-positive. Grafted NSCs in CBL-treated animals displayed lower caspase-3 activation and TUNEL-positive cells as compared to vehicle-treated a-synuclein tg mice. No tumor growth was detected. Levels of a-synuclein were similar in vehicle- and CBL-treated tg mice. Transfer of a-synuclein from host to graft cells was similar between vehicle- and CBL-treated groups.
CBL increases NSC survival in the a-synuclein environment. The mechanism may involve neurotrophic effects, as CBL did not affect total a-synuclein levels. This indicates that CBL can support graft cell survival and may support their therapeutic efficacy.

[3]Laboratorio di Immunologia e dei Trapianti/Cell Factory/Oncoematologia Pediatrica, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy

Mesenchymal stem cells (MSCs) have been proposed as a potential therapeutic tool for Parkinson's disease (PD). Systemic administration of MSCs has been tested in patients with degenerative parkinsonism. These studies reported slightly positive results, but left open questions regarding the actual capacity of MSCs to reach the brain and exert neuroprotective effects.

Objectives We infused autologous MSCs into the internal carotid of rats bearing a 6-hydroxydopamine-induced lesion of the nigrostriatal tract. The aim was to evaluate: 1) rat (r)MSC homing in the brain with or without transient blood-brain barrier (BBB) permeabilization, 2) symptomatic and neuroprotective efficacy of rMSC infusion.

Methods rMSCs were infused 14 days after 6-hydroxydopamine injection. Hyperosmolar solution of mannitol was used to transiently permeabilize the BBB. Behavioral impairment was assessed by stepping test and response to apomorphine. Seven and twenty-eight days after cell infusion, animals were sacrificed and the lesion in the striatum and substantia nigra was evaluated.

Results A noteworthy percentage of cells was found only within the brains of animals pre-treated with mannitol. Infused rMSCs showed a scattered localization. Cell infusion did not reduce the 6-hydroxydopamine-induced neurodegeneration or the motor impairment at the stepping test, but induced progressive normalization of the pathological (rotational) response to apomorphine.

Conclusions BBB permeabilization is required to grant passage of rMSCs into the brain. MSCs infusion does not modify the progression of PD-like neuronal damage, while it may affect behavioral responses associated with dopaminergic stimulation. These aspects should be further investigated before considering any translation into the clinical setting.

COMBINING NEURONAL-PRIMED MESENCHYMAL STEM CELL AND GENE THERAPY IN HEMI-PARKINSONIAN RHESUS MONKEYS

Y. Zhou[1], L.I. Hongjun[1], X.I.E. Yuping[1], W.U. Jinyuan[1], S.U.N. Maosheng[1], Y.A.N. Shanshan[1]

[1]Department of Molecular Biology, Institute of Medical BiologyCAMS, Kunming, China

Objectives The treatment situation of PD is grim. Therefore, a treatment method which is safe but also fundamentally to restore the function of the nigrostriatal system and can greatly ease the treatment of their symptoms is in urgent needed.**Methods** We investigated a novel in vitro neuronal differentiation strategy with the use of LIM homeobox transcription factor 1, alpha (LMX1A) and Neurturin (NTN). Neuronal-primed ASCs and MSCs derived from rhesus monkey (rASCs), USCs derived from human were implanted into the striatum and substantia nigra of methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP)-lesioned hemi-parkinsonian rhesus monkeys. Monkeys were monitored with the use of behavioral tests and health measures until the fourth month after implantation.**Results** The differentiated cells derived from ASCs, MSCs and USCs transcribed and expressed a variety of dopaminergic neuron-specific genes. Compared with MSCs and ASCs, USCs are more easily differentiated into neuron like cells. The Neuronal-primed adult stem cells were transplanted into the brains of PD monkeys may play a therapeutic role to ameliorate the symptoms of PD. Single-photon emission computed tomography analysis and postmortem analysis revealed that the grafting of adult stem cells combined with rAd-NTN-TH had neuroprotective effects compared with rAd-NTN-TH or stem cells alone. **Conclusions** These findings may lead to cellular sources for autologous transplantation of Parkinson disease. Combined transplantation of gene vectors such as adenovirus with therapeutic genes and induced mesenchymal stem cells expressing inducible gene may be a better therapy candidate for the treatment of Parkinson’s disease.

[3]Neurosciences, University of California San Diego, San Diego, USA

Objectives: Stem cell transplantation for Parkinson's disease (PD) has primarily focused on dopamine replacement strategies. While this approach can improve PD-related motor deficits in both models and patients, it has achieved little to no impact on the cognitive aspects of the disease. Here, we explore the potential of neural stem cell (NSC) transplantation in an α-synuclein transgenic model of PD dementia (PDD) and dementia with Lewy bodies (DLB).

Methods: To examine the potential of NSC transplantation on α-synuclein induced cognitive and motor dysfunction, NSCs were transplanted into the striatum of 12-month old α-synuclein transgenic mice. To further investigate the role of neurotrophic support in NSC-mediated benefits, a line of $BDNF^{shNRA}$-NSCs was also developed and examined. One month following transplantation, performance in multiple motor and cognitive domains was assessed and pathology examined.

Results: Our findings reveal that transplantation of predominantly gliogenic NSCs into aged α-synuclein transgenic mice dramatically improves both cognitive and motor function. In addition, NSC-derived BDNF is critical for this process and changes in dopaminergic, glutamatergic, and neurogenic function differentially contribute to motor and cognitive recovery.

Conclusions: Considered together, our data show that striatal NSC transplants can dramatically improve both motor and cognitive function in a transgenic model of PDD/DLB by elevating levels of BDNF and enhancing dopaminergic, glutamatergic, and neurogenic systems. These studies demonstrate that transplantation of gliogenic NSCs could offer a promising new approach to treat both the motor and understudied yet devastating cognitive symptoms of synucleinopathies.

HUMAN ADIPOSE-DERIVED STEM CELLS: POTENTIAL IN TREATMENT OF PD

H.J. Kim[1], H.S. Choi[1], Y.H. Suh[1]
[1]Research Division, Korea Brain Research Institute, Daegu, Korea

Treatment of PD using stem cells has focused by many researchers for a long time, but the ideal therapeutic strategy is not developed yet. And the consistency and high reliability of the experimental results verified by the animal models have been considered greatly important factors for the stability of human adipose-derived stem cells (hASCs), a kind of mesenchymal stem cells (MSCs) isolated from adipose tissue.
The aim of this study is to investigate preventive and therapeutic potential of hASCs for PD and is to identify the factors related to this therapeutic effect. Using the PD toxin models induced by 6-hydroxydopamine (6-OHDA), we demonstrate that the behavioral performances were significantly improved at 3 weeks after the intravenous injection of hASCs. Also, dopaminergic neurons were rescued and the increased structure-modified mitochondria in PD mice model were decreased by injection of hASCs. Furthermore, inhibited mitochondrial complex1 activity by 6-OHDA was restored in the brain of hASCs injected PD mice model. Taken together, our findings suggest that intravenous injection of hASCs may have a therapeutic potential for PD by recovering of mitochondrial dysfunctions.

ADPD5-1507

TRANSPLANTATION OF HUMAN NEURAL STEM CELLS IN IMMUNODEFICIENT ALPHA-SYNUCLEIN TRANSGENIC MICE: EXAMINING THE ROLE OF NEUROTROPHIC SIGNALING IN COGNITVE RECOVERY

M. Blurton-Jones[1], N. Sashkin Goldberg[1], B. Shelley[2], C.N. Svendsen[2]
[1]Neurobiology and Behavior, University of California Irvine, Irvine, USA
[2]Biomedical Sciences, Regenerative Medicine Institute Cedars Sinai, Los Angeles, USA

Objectives: We recently found that transplantation of syngeneic murine neural stem cells can dramatically improve cognitive and motor deficits in an α-synuclein transgenic (ASO) model of PD dementia (PDD) and dementia with Lewy bodies (DLB) via a neurotrophic mechanism. To examine xenotransplantation of clinically relevant human neural stem cells (hNSCs), we have now generated and examined a immunodeficient ASO mouse line.
Methods: ASO mice were backcrossed onto a Rag2/IL2rg double knockout background to generate a xenotransplantation-compatible PDD/DLB model that lacks B-cells, T-cells and NK-cells. The resulting mice develop similar α-synuclein pathology and behavioral deficits as the parental ASO strain, yet allow robust engraftment of human NSCs (hNSCs). Either WT-hNSCs or glial derived neurotrophic factor (GDNF)-secreting-hNSCs were then transplanted into the striatum of 6-month old Rag-ASO mice, and performance on multiple motor/cognitive tasks was assessed one month later.
Results: We find that transplanted hNSCs engraft well and begin to differentiate in Rag-WT and Rag-ASO mice. Both WT-hNSCs and GDNF-NSCs rescue motor function with similar magnitude in Rag-ASO mice. Fascinatingly, while both cells types also improve cognitive performance, transplantation with GDNF-NSCs provides substantially greater improvements than WT-hNSCs.
Conclusions: Our findings indicate that hNSC-derived neurotrophic support promotes behavioral recovery in a novel xenotransplantation-compatible transgenic model of PDD/DLB. Our data also suggest that enhancement of hNSC neurotrophin secretion may be critical for improving α-synuclein-related cognitive deficits. Together, these studies aim to enhance our understanding of the potential impact of hNSCs on PDD/DLB related cognitive dysfunction and further elucidate the therapeutic potential of NSC transplantation.

IN VITRO KINETIC STUDIES FOR NEW DRUG TESTING IN AMYLOIDOGENIC DISORDERS

R. Crespo Rodríguez[1], F. Rocha[1], A.M. Damas[2], P. Martins[3]
[1]LEPABE Chemical Engineer, FEUP University of Porto, Porto, Portugal
[2]Molecular Structure, IBMC, Porto, Portugal
[3]LEPABE Chemical Engineer, FEUP/ICBAS, Porto, Portugal

With increasing evidence of protein aggregation as an early sign in neurodegenerative and prionopathies pathogenesis, the expectation of a common therapy has become a primary goal for drugs development. The aim of this work is to establish a consistent *in vitro* protocol for testing the effect of new potential drugs through kinetic studies.
Using alpha-synuclein as model protein, the aggregation process is followed by classic biophysical methods such as Thioflavin-T binding fluorescence and turbidity measurements. The kinetics obtained are described according to the recently proposed crystallization-like model [1] , quantitatively characterizing the weight of nucleation and growth steps.
True inhibition happens when the kinetics of amyloid fibrillization are retarded by decreasing rates of fibril formation and elongation. Apparent inhibition may however result from, e.g., the alteration of thermodynamic properties such as the solubility of the amyloidogenic protein. Apparent inhibitors markedly influence protein aggregation kinetics measured in vitro, yet they are likely to lead to disappointing results when tested in vivo. This is because cells and tissues media are in general much more buffered against small variations in composition than the solutions prepared in lab [2].

04s. Therapeutic Targets & Mechanisms for Treatment: misfolding and chaperones

ADPD5-0327

EFFECTS OF MOLECULAR CHAPERONES IN FIBROBLASTS FROM PATIENTS WITH SPORADIC AND GLUCOCEREBROSIDASE-RELATED PD

G. Ambrosi[1], C. Ghezzi[1], F. Blandini[1]
[1]Center for Research in Neurodegenerative Diseases, C.Mondino National Neurological Institute, Pavia, Italy

Objectives: Parkinson's disease (PD) pathogenesis is associated with a combination of genes and environmental stressors. In particular, heterozygous mutations in GBA gene, encoding for lysosomal enzyme glucocerebrosidase (GCase), are responsible for misfolding and loss of function of the protein and have been associated with higher risk of developing PD, indicating that impaired lysosomal clearance is critical in disease pathogenesis. The aim of this study is highlighting changes affecting proteins linked to proteostasis and GCase folding, especially saposin c, in fibroblasts derived from patients with sporadic and GBA-related parkinsonism, at baseline and after administration of molecular chaperone Ambroxol.
Methods: fibroblast primary cultures were established from skin biopsies obtained from sporadic (n=5) or GBA-related (n=5) PD patients and age/gender-matched healthy controls (n=7). Fibroblasts were treated with Ambroxol according to McNeill et al (Brain, 2014). Protein levels and distribution of GCase, saposin c and saposin c precursor (PSAP) were assessed by immunochemical analysis. Activity of GCase and cathepsin D, responsible for PSAP cleavage, were measured using the fluorogenic substrate 4-Methylumbelliferyl-β-D-glucuronide-hydrate and a commercial kit, respectively.
Results: protein levels for GCase, PSAP and saposin c are unchanged among groups at baseline and increase with Ambroxol. Basal GCase activity is reduced in fibroblasts from GBA-related patients. Ambroxol administration enhances both GCase and cathepsin D activity.
Conclusions: studying the effects of Ambroxol in patient-derived fibroblasts, which share the same genetic complexity of the neurons, might improve our understanding of molecular chaperone-induced responses in sporadic and GBA-related PD and identify novel therapeutic targets for disease-modifying treatments.

NOVEL GENE THERAPY TO TARGET THE PROTEOSTASIS NETWORK IN PARKINSON DISEASE

R. Vidal[1], C. Verges[1], M. Gonzalez[1], C. Hetz[1]
[1]Research and Development, Neurounion Biomedical Foundation, Santiago, Chile

Parkinson´s disease (PD) is the second most common neurological disorder. PD is characterized by the lost of the dopaminergic neurons of the *substantia nigra*, leading to a gradual decrease in the levels of the neurotransmitter dopamine and progressive alterations in the control of voluntary movements. Recent evidence implicates adaptive responses to endoplasmic reticulum (ER) stress in this disease, mediated by the unfolded protein response (UPR) pathway. Here we investigated a novel combination of UPR transcription factors to selectively modulate the homeostasis state of dopaminergic neuron without altering apoptosis programs.

We generated 6 different fusion proteins between of UPR components XBP1s and ATF6f. We evaluated the levels of expression and subcellular localization of these proteins. The transcriptional activity and specificity were evaluated by luciferase assay and real time PCR.

We observed a nuclear localization of all fusion proteins and different of expression levels. The transcriptional activity was different between these variants and we identified a version of ATF6f-XBP1s that induces a strong UPR transcriptional activity. This novel transcription factor is capable of increasing the levels expression of particular cluster genes that were describe as target of heterodimer between ATF6f and XBP1s.

Our results describe a novel molecule that effective tunes selective UPR of a particular cluster gene associate to ATF6f/XBP1s heterodimer activity.

Supported by FONDEF-D11I1007, PAI-7912010006, FONDECYT-1140549, Millennium Institute P09-015-F, The Michael J. Fox Foundation for Parkinson Research, and Ring Initiative ACT1109.

ADPD5-0904

NOVEL NON-VIRAL VECTORS TARGETING THE CENTRAL NERVOUS SYSTEM MEDIATE RNA INTERFERENCE-KNOCKDOWN OF ALPHA-SYNUCLEIN IN A PD MODEL

S. Menon[1], K. Al-Mansoori[1], H. Javed[1], M. Al-Wandi[1], M. Ardah[1], S. Varghese[1], N. Majbour[1], O. El-Agnaf[2]

[1]Department of Biochemistry, College of Medicine and Health Sciences UAEU, Al-Ain, United Arab Emirates

[2]College of Science Engineering and Technology, HBKU, Doha, Qatar

Objective: To develop novel non-viral vectors for the systemic delivery of siRNA into the central nervous system (CNS)

Methods: The efficacy of our novel vectors in siRNA delivery into neurons was first tested *in vitro* using flow cytometry, immunofluorescence analysis and western blotting on cultured neuroblastoma cells. Brain specific delivery of *SNCA* siRNA and gene knockdown *in vivo* was confirmed by ELISA and Western blot analyses of mice brain lysates as well as by behavioral tests and immunohistochemistry analysis in a Parkinson's disease mouse model.

Results: We developed two novel non-viral vectors named C2-9r and RI-C2-9r that can efficiently deliver siRNA into neurons. Delivery of siRNA against alpha-synuclein gene *(SNCA)* using these vectors enabled 60% knockdown of alpha-synuclein expression in neuronal M17 cells, which resulted in a significant resistance to MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) mediated cytotoxicity ($P<0.001$). Our vectors confer superior stability to systemically delivered siRNA *in vivo*, and thereby mediate enhanced alpha-synuclein protein knockdown by 60%-90% within different brain regions. Further, we provide compelling evidence for the *in vivo* therapeutic application of our vectors to silence *SNCA* in the CNS of a Parkinson's disease mouse model and confer protection against dopaminergic neurodegeneration.

Conclusion: We have successfully designed novel vectors that provide an effective and clinically relevant tool for non-viral gene therapy of brain diseases.

[2]Translational Science & Molecular Medicine Cell & Molecular Biology Program, Michigan State University, Grand Rapids, USA
[3]Pharmaceutical Sciences and College of Pharmacy at Rosalind Franklin University, Michigan State University, Grand Rapids, USA

Objective. We have demonstrated that levodopa-induced dyskinesia (LID) in parkinsonian rats is associated with aberrant 're-wiring' of corticostriatal input to the striatum. Further, using microarray gene analysis we have identified that one particular synaptic plasticity gene, Nr4a2 (aka: Nurr1), normally not expressed in striatum shows a >30-fold induction in the striatum of levodopa treated parkinsonian rats that developed LID but not in those that remained dyskinesia-free.
Methods. Toward understanding potential clinical utility of this novel striatal target, we are examining the ability of rAAV-Nurr1-shRNA in our rat model of LID to provide antidyskinetic efficacy against moderate and high dose levodopa. The impact of striatal Nurr1 silencing on motor function and corticostriatal remodeling associated with LID are also being monitored.
Results. To induce LID, we first employed a sub-chronic escalating levodopa dosing paradigm and either viral vector mediated overexpression or silencing (shRNA) of Nurr1 in the DA-depleted, dorsolateral striatum. Nurr1 overexpression reduced the threshold for, and increased the LID severity score for equivalent levodopa administrations. Conversely, silencing of striatal Nurr1 by shRNA attenuated peak dose LID. Additional studies examining the impact of striatal Nurr1 silencing on chronic, long-term levodopa administration are ongoing.
Conclusions. Silencing striatal Nurr1 may present an experimental therapeutic that is not palliative but addresses an underlying cause of LID. We propose that Nurr1, acting as a transcription factor is a nexus of divergent signaling that underlie changes in ultrastructure and subsequent physiologic output. (Supported by Udall Center grant P50NS058830 and the St. Mary's Foundation)

REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION FOR ON-FREEZERS WITH ADVANCED PD. A LONG-TERM FOLLOW UP

H. Shehata[1], N. Shalaby[1], M. Tamawy[1], E. Hassan[1], S. Gaafary[1]
[1]Neurology, Cairo University, Cairo, Egypt

BACKGROUND AND OBJECTIVES: Freezing of gait is experienced in about 30% of PD patients within 5 years, and nearly in 60% after 10 years. Treatment of “off” time FOG is relatively straight forward, but “on-freezing” is a difficult to treat scenario. Objectives. Evaluation of the efficacy and safety of rTMS in management of “on-freezing” in patients with advanced PD

METHODS. This study was performed in two phases, first phase was a randomized, double-blind, placebo-control, which included 22 Egyptian patients received 12 rTMS sessions over 4 weeks (either real or sham) over the leg area of motor cortex contralaterally to the more affected side in addition to rehabilitation program involving specific gait training techniques. In the second open label long term phase, we enrolled 20 patients (all are included in phase I) who received over a 6 months period 3 cycles of rTMS, (12 sessions each) which were performed every other month. Primary efficacy variables are FOG Q (SF), motor section and total score of UPDRS, 2ry outcomes are gait variables (Cadence, number of falls, stride length, stride time and turn time), and on-time.

RESULTS: improving of FOG Q, with significant decrease in number of falls and widened stride length ($P<0.001$) were detected with rTMS. The total score of UPDRS and other gait variables were not changed. No serious adverse events were recorded.

CONCLUSIONS: These results indicate that rTMS has a positive long term effects in on-freezers with advanced PD with subsequent decrease of number of falls.

EXERCISE-INDUCED NEUROPLASTICITY IN THE MPTP MOUSE MODEL OF PARKINSON'S DISEASE

C.J.H.M. Klemann[1], G. Poelmans[2], G.J.M. Martens[1], J.E. Visser[3]
[1]Molecular Animal Physiology, Radboud University, Nijmegen, Netherlands
[2]Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands
[3]Neurology, Radboud University Medical Center, Nijmegen, Netherlands

Objectives

Parkinson's disease (PD) is characterized by degeneration of dopamine (DA) neurons in the substantia nigra, resulting in hypokinetic rigidity. Physical exercise has been shown to improve motor function in PD patients and DA-related neuronal signaling in rats. In this study, we aimed to determine which underlying molecular processes are involved in exercise-induced adaptive neuroplasticity and motor function improvement.

Methods

Mice were treated with 1-methyl-4-phenyl-1,2,3,6-tetrahydropyrimidine (MPTP) that destroys DA nigrostriatal neurons, providing a model of reduced striatal DA innervation similar to human PD. To capture the behavioral effects and the underlying specific molecular pathways involved in exercise-induced neuroplasticity, the behavioral outcome (i.e. motor performance) in MPTP-treated and control mice following forced treadmill running was correlated with genome-wide mRNA expression analyses of multiple brain areas.

Results

Forced treadmill running improved motor performance in MPTP-treated but not in MPTP-untreated control mice. Preliminary analysis of the mRNA expression data showed that both running and MPTP particularly affected 'mitochondrial (dys)function' and 'oxidative phosphorylation' related processes.

Conclusions

Based on these preliminary data, forced running appears to improve motor function in MPTP-treated mice. Both MPTP treatment and forced exercise affect mRNA expression patterns related to 'mitochondrial (dys)function' and 'oxidative phosphorylation', processes that have also been implicated in human PD pathogenesis. Hence, these data may lead to the development of new treatments for PD, involving physical exercise and/or neuroplasticity.

[2]Institute of Experimental Neuroregeneration, Paracelsus Medical University, Salzburg, Austria

[3]Department of Neurosciences, University of California San Diego, La Jolla, USA

[4]Institute of Molecular Regenerative Medicine, Paracelsus Medical University, La Jolla, USA

Leukotrienes, inflammatory mediators of inflammation, are well-studied in the field of asthma. In the brain, elevated leukotriene levels are reported in acute as well as chronic lesions (eg Alzheimer´s disease), and increasing concentrations of the leukotriene-producing enzyme 5-LOX have been demonstrated in the aged brain and in Parkinson´s disease (PD). Here, elevated leukotriene signaling might be involved in neuroinflammatory processes and in the development of dementia in PD (PDD).

With respect to aging, we recently demonstrated that a 6-week oral treatment of young and aged rats with the leukotriene receptor inhibitor montelukast resulted in reduced neuroinflammation, enhanced neurogenesis, and remarkably, in a restoration of cognitive functions in aged rats. Now, we examined if montelukast has beneficial effects on cognition in a PDD animal model. We used 6 month-old PDGF-ß α-Syn transgenic mice, which show microgliosis, deficitis in neurogenesis, and cognitive impairments. Mice were treated orally with montelukast or vehicle daily for 6 weeks, and several behavioural tests were performed. First, we analyzed CNS pharmacology and showed that, after oral administration, montelukast entered the brain of the treated animals. In respect to cognition, the 6-week treatment with montelukast lead to significant improvement in learning and memory in the Morris Water maze in PDD mice. Ongoing histological analyses of the hippocampus will validate if the beneficial effects of montelukast on cognition in PDD mice are accompanied by increased hippocampal neurogenesis and/or decreased neuroinflammation. Based on the current behavioural data, we suggest montelukast as a promising drug to ameliorate dementia in PDD.

MODULATION OF CYCLIC AMP AS A NEW THERAPEUTIC STRATEGY FOR PARKINSON DISEASE TREATMENT

A. Martinez[1], C. Gil[1], A. Perez-Castillo[2], J.A. Morales-Garcia[2]
[1]CIB, CSIC, Madrid, Spain
[2]IIB, CSIC, Madrid, Spain

1. Objectives . Parkinson disease (PD) is the second most prevalent neurodegenerative disease and no effective treatment is available to date. In our search for new innovative drugs, we have found that PDE7 inhibitors are good drug candidates for this disease [1]. We want now to check if the enhancement of intracellular levels of cAMP could stimulate neurogenesis events on PD animal models.
2. Methods. Hemiparkinsonian rats orally treatment with S14, a small heterocyclic molecule that inhibits PDE7. Phenototypic and biochemical analysis determining neurotrophic factors modulation and neurogenesis induction.
3. Results. After a S14 dose-response curve looking for phenotypic scores, we have observed a great neuroprotection of dopaminergic neurons in the *substantia nigra pars compacta*, accompanied by higher levels of neurotrophic factors and a consistent increase of the neurogenesis with in this brain area.
4. Conclusions. Modulation of cAMP is a good therapeutic strategy to the future treatment of Parkinson disease. PDE7 inhibitors, and specifically our drug candidate S14, merit to be developed till clinical trials to assess its therapeutic potential in Parkinson disease patients.

SUBTHALAMIC NUCLEUS STIMULATION VERSUS PREOPERATIVE MEDICAL THERAPY FOR PATIENTS WITH PD: A SYSTEMATIC REVIEW

X. Wenbiao[1], C. Ling[1], L. Yanmei[1], J. Lulu[1], Z. Yifan[1], Y. Jing[1], P. Zhong[1]
[1]Department of Neurology, The First Affiliated Hospital Sun Yat-sen University, Ganzhou, China

Objectives: Subthalamic nucleus stimulation is one of the most promising therapies for PD. This study aimed to compare the efficacy of bilateral subthalamic nucleus stimulation versus preoperative medication in the treatment of Parkinson's disease by making a comprehensive review and meta-analysis of published literature.
Methods: A systematic literature search up to December of 2013 was performed in PubMed, Ovid and Chinese Biomedical Retrieval System. The clinical outcomes were assessed using unified Parkinson's disease rating scale.
Results: A total of 27 studies comprised of 861 patients with one year follow-up were identified for systematic review. After one year of stimulation, activities of daily living and motor scores were improved by 46 and 54% in the off-medication state, respectively, compared with preoperative off-medication scores. Average reduction in levodopa equivalent dose intake following surgery was 48%, with dyskinesia and fluctuation reduced by 64 and 50%, respectively. Meta-analysis showed that bilateral subthalamic nucleus stimulation was as well as preoperative medication in improving tremor, rigidity, postural stability and total motor scores, but was less effective than preoperative medication on bradykinesia, gait and activities of daily living scores. Combined therapy (stimulation plus medication) achieved better improvement than preoperative medication. Severe surgical side effect was intracranial hemorrhage in 4.0% of patients. Common stimulation-induced adverse effects were weight gain (21.1%), hypophonia (16.8%), depression (9.3%) and eyelid apraxia (6.2%).
Conclusions: Bilateral subthalamic nucleus stimulation is an efficacious therapy as an adjunct to medication. Carefully selection of Parkinson's disease patients may reduce the incidence of adverse events.

STRIATAL GLUTAMATE AND GABA AFTER HIGH FREQUENCY SUBTHALAMIC STIMULATION IN PARKINSONIAN RAT

C. Cho[1]
[1]*Neurosurgery, St. Vincent's hospital Catholic University of Korea, Suwon, Korea*

Background: High frequency stimulation of the subthalamic nucleus is recognized as an effective treatment of advanced Parkinson's disease. However, the neurochemical basis of its effects remains unknown. The aim of this study is to investigate the effects of high frequency stimulation of the subthalamic nucleus in intact and 6-hydroxydopamine-lesioned hemiparkinsonian rat model on changes of principal neurotransmitters, glutamate, and gamma-aminobutyric acid in the striatum.
Methods: The authors examined extracellular glutamate and gamma-aminobutyric acid change in the striatum on sham group, 6-hydroxydopamine-lesioned group, and 6-hydroxydopamine-lesioned plus deep brain stimulation group using microdialysis methods. High-pressure liquid chromatography was used to quantify glutamate and gamma-aminobutyric acid.
Results: The results show that high frequency stimulation induces a significant increase of extracellular glutamate and gamma-aminobutyric acid in the striatum of 6-hydroxydopamine-lesioned plus deep brain stimulation group compared with sham and 6-hydroxydopamine-lesioned group.
Conclusions: The clinical results of high frequency stimulation of the subthalamic nucleus are not restricted to the direct subthalamic nucleus targets but involve widespread adaptive changes within the basal ganglia.

CAN DEEP BARIN SITMULATION PRESERVE WORKING ABILITES IN PARKINSON'S DISEASE?

G. Deli[1], N. Kovacs[1], I. Balás[2], S. Komoly[1], T. Dóczi[2], J. Janszky[1], Z.S. Aschermann[1], F. Nagy[3], A. Makkos[1], E. Bosnyák[1]
[1]Department of Neurology, University of Pecs, Pécs, Hungary
[2]Department of Neurosurgery, University of Pecs, Pécs, Hungary
[3]Department of Neurology, Kaposi Mór Country Hospital, Kaposvár, Hungary

Objective: There is a debate on the potential advantageous effects of bilateral subthalamic deep brain stimulation (DBS) in the treatment of Parkinson's disease with early fluctuations. Our investigation aimed to evaluate if DBS therapy was able to preserve the working capabilities.
Methods: We reviewed the data of 40 young (<60 yearsold) PD patients who underwent DBS implantation at University of Pécs and had an at least 2 years followup. Patients were categorized into two groups based on their working capabilities at time of surgery: 'Active job' group (n=20) and 'No job' group (n=20). Baseline characteristics were comparable. Severity of motor symptoms (UPDRS3), quality of life (EQ5D) and presence of active job were evaluated preoperatively and 2 years postoperatively.
Results: Although similar (approximately 50%) improvement was achieved in the severity of motor and major nonmotor symptoms in both groups, the postoperative quality of life was significantly better in the 'Active job' group (0.687 vs. 0.587, medians, $p<0.05$). Majority (80%) of 'Active job' group members were able to preserve their job 2 years after the operation. However, only a minimal portion (5%) of the 'No job' group members was
able to return to the world of active employees ($p<0,01$).
Conclusion: Although our study has several limitations, our results fits well with the conclusions of EarlyStim study. In patients with active job the appropriately 'early' usage of DBS might help preserve working abilities in a twoyear timeframe and gain higher improvement in quality of life.

ADPD5-1049

INTRATHECAL BACLOFEN INJECTION RELIEVES DYSTONIC CAMPTOCORMIA IN PARKINSON'S DISEASE.

T. Ichikawa[1], Y. Hashimoto[1], M. Hizume[1], Y. Fumimura[1]
[1]Neurology, Saitama prefectural Rehabilitation Center, Ageo-City, Japan

Objectives: Axial symptoms in Parkinson's disease (PD) are more difficult to treat. Especially, camptocormia is one of the most resistant symptoms to various therapies, for example botulinum toxin therapy or deep brain stimulation (DBS). Xylocain injection to lateral oblique abdominal muscle is reported to be effective to camptocormia in case the bent point is upper thoracics. In this study we tried intrathecal baclofen injection to find the efficacy on camptocormia in PD.

Methods: 7 patients (3 male and 4 female) with camptocormia, who had no cause other than PD, were included. Mean disease period was 11.7year and its SD was 4.69. Intrathecal baclofen injection was performed by by lumbar puncture. Injections were consisted three steps, first 50, second 75, and three 100microgram. Each patients was infected two steps or three steps. Postural change was evaluated photographically before and 3-4 hours after injection.

Results: In 6 of 7 patients, camptocormia was improved after baclofen injection. 2 patients started to show improvement at first step (50microgram), 3 other patients started to improve at second step, and 1 patient showed improvement only at 3rd step (100microgram). One patients denied third step after two steps whose were not effective to camptcormia.

Conclusion: From the results of this study, intrathecal baclofen injection has potentiality to treat camptocormia in patients with PD.

THERAPEUTIC EFFECT OF PEPTIDE AMPHIPHILE NANOFIBERS IN A RAT MODEL OF PARKINSON'S DISEASE

C. Sevinc[1], M. Sever[2], M. Turkyilmaz[1], A. Cakir[3], B. Ocalan[3], A.B. Tekinay[2], M.O. Guler[2], M. Cansev[1]

[1]Department of Pharmacology, Uludag University Faculty Of Medicine, BURSA, Turkey
[2]National Nanotechnology Center (UNAM), Bilkent University, ANKARA, Turkey
[3]Physiology, Uludag University Faculty Of Medicine, BURSA, Turkey

Objectives: Parkinson's Disease (PD) is characterized by progressive degeneration of dopaminergic nigrostriatal neurons and reduction in striatal dopamine levels. Peptide nanofibers are new generation biomaterials that have been shown to induce neurite outgrowth in vitro and to stimulate axonal growth and reduce apoptosis in spinal cord injury in vivo. In this study, we tested the effect of a synthetic peptide amphiphile (PA) nanofiber system that can mimic the activities of laminin (LN) and heparan sulfate proteoglycans (GAG) in a rat model of PD.

Methods: Adult male Sprague-Dawley rats (250-300 g) received two intrastriatal injections of 6-hydroxydopamine (6-OHDA; 8 ug) or L-ascorbic acid (LAA; 0.3%) and one week later randomized into three groups with equal number of rotations for 30 min after intraperitoneal d-amphetamine (5 mg/kg) injection as follows: 6-OHDA+PA; 6-OHDA+Sucrose; and LAA+PA. Nanofibers were administered in two consecutive fragments as PA-LN and PA-GAG by microinjections to the 6-OHDA lesion sites. Rotational behavior test was repeated 6 weeks later followed by sacrificing rats and obtaining striata for further neurochemical and immunohistochemical studies.

Results: Our results revealed for the first time that the PA-LN and PA-GAG combine and form a peptide gel in vivo. In addition, Parkinsonian rats receiving site-specific injections of PA nanofibers showed significantly (by 18%; $p<0,05$) reduced number of rotations 6 weeks after treatment.

Conclusion: These data suggest that PA nanofibers may have therapeutic potential in PD.

ADPD5-1820

RESULTS FROM A PHASE I STUDY TO ASSESS THE TOLERABILITY, SAFETY AND IMMUNOLOGICAL AND CLINICAL ACTIVITY OF AFFITOPE® PD01A IN PATIENTS WITH EARLY PARKINSON'S DISEASE

D. Volc[1], S. Hendrix[2], C. Thun-Hohenstein[1], A. Kutzelnigg[3], M. Facheris[4], D. Kuldip[4], M. Mandler[5], F. Mattner[5], W. Schmidt[5], A. Schneeberger[5]
[1]NA, Confraternitaet Privatklinik, Vienna, Austria
[2]Statistics, Pentara Corporation, Salt Lake City, USA
[3]Department of Psychiatry, Medical University of Vienna, Vienna, Austria
[4]NA, MJFF, New York, USA
[5]Clinical Development, AFFiRiS AG, Vienna, Austria

Objectives: This 12- month study was designed to assess safety and tolerability of AFFITOPE® PD01A, the first alpha-synuclein (aSyn)-targeting vaccine candidate tested clinically, in early Parkinson's disease. This single-center, parallel group, patient blinded Phase I study also assessed immune and clinical response.
Methods: 32 patients were enrolled: 24 randomly assigned to 15 µg or 75 µg PD01A, and 8 untreated patients served as a control group. Active patients received 4 subcutaneous injections at weeks 0, 4, 8 and 12 with final assessments at week 52. Primary objective was to test the safety and tolerability of two doses of PD01A. Secondary endpoints encompassed the vaccine-specific immune response as well as clinical parameters (UPDRS Ia, II, III, PDQ-39, PD-NMS, IGE). Each patient was evaluated regularly over 12-months.
Results: All 32 patients completed the study. All 24 patients in the active groups received four vaccinations as planned. Both doses tested were found to be safe and well tolerated. The most frequent adverse events were local reactions to vaccine administration, which all were self-limited. The active groups performed similarly to each other and showed significant effects against the control group on multiple immunological and efficacy outcomes. 62.5% of treated patients demonstrated increased levels of aSyn-specific antibodies, and these immune responders showed statistically significant treatment effects over non-responders for several efficacy outcomes.
Conclusions: This is the first clinical trial assessing an aSyn-targeting agent. PD01A was found to be safe and well-tolerated at both doses tested. Results are consistent with a disease-modifying effect of PD01A.

CORRECTION OF NON-MOTOR FLUCTUATIONS IN PATIENTS WITH PD

K. Taryanyk[1], N. Lytvynenko[1]

[1]Neurological, Ukrainian Medical Dental Academy, Poltava, Ukraine

1. Objectives: To evaluate the effect of dopamine receptor agonists and amantadine on vegetative, sensory, mental non-motor fluctuations at Parkinson's disease.

2. **Methods :** 20 patients, different sex, middle ages - 58,4 ± 6,01 years, akinetic - rigid form of the disease. Duration of PD - 6,8 ± 1,5 years, all patients received standard therapy with L-Dopha 4 times a day (daily dose of 250 - 375mg).

Middle estimation degree of weight at PD on the Hoehn and Yahr scale was 3,5±0,2. Used UPDRS (I, II, III A and B parts), Mini-Mental State Examination (MMSE), BDI. Patients were divided into groups: 1). was treated with amantadine sulfate 500 ml intravenous infusion for 5 days, 2). got treatment of the pramipaxole| prolonged action (Mirapex® ER) 1,5 mg/per day, 3). received amantadine sulfate orally 200 mg per day. Clinical and neuropsychological testing was performed at baseline, after 5 days and one month after treatment.

3. **Results:** the study of non-motor symptoms (UPDRS I, II parts) showed a significant decrease in scores at patients of all three groups, but the effect was more rapid at using intravenous form (from 25,2 ± 2,1 to 20,3 ± 2,4).

The therapy showed a significant improvement in cognitive function, reduction of depressive disorders.

Conclusions: amantadine sulphate and non-motor manifestations of pramipexole reduce fluctuations at Parkinson's disease. More rapid effect in sensory and autonomic fluctuations was at amantadine sulfate, in mental at pramipexole.

DIETARY INTERVENTIONS WITH STRONG PREVENTIVE AND THERAPEUTIC EFFECTS ON BOTH MOTOR AND NON-MOTOR SYMPTOMS IN A MOUSE MODEL OF PARKINSON'S DISEASE

P. Perez Pardo[1], E.M. De Jong[1], L.M. Broersen[2], A. Attali[2], N. van Wijk[2], J. Garssen[1], B. Olivier[1], A.D. Kraneveld[1]

[1]Pharmaceutical Sciences, Utrecht University, Utrecht, Netherlands

[2]Medical Nutrition, Nutricia Research, Utrecht, Netherlands

Introduction. Administration of dietary precursors and cofactors for membrane synthesis may enhance synapse formation relevant for neurodegenerative disorders. Indeed, preventive treatment with the precursors UMP/DHA reduced rotational behavior in the 6-OHDA Parkinson's Disease (PD) model. Here we examined the efficacy of dietary interventions in the rotenone model of PD, inducing both motor and non-motor symptoms, including gastrointestinal dysfunction. In addition, we tested the effects of an extended nutritional formula based on the same precursors.

Method. Male C57BL/6J received a unilateral rotenone injection in the striatum (5.4 ug). Dietary interventions started either 1 week before (preventive) or 3 weeks after surgery (therapeutic), when PD-like symptoms had developed. Readout parameters included behavioral tasks as the rotarod, novel object discrimination, grip strength, and inverted screen test, as well as histological examination of brain and gut.

Results. Our results show that the preventive UMP/DHA treatment improved rotenone-induced disturbances in rotarod performance and intestinal transit. Similar effects were found in the therapeutic setting, indicating that the diets did not interfere with rotenone toxicity. The therapeutic treatment also alleviated rotenone-induced deficits in novel object discrimination, grip strength, and inverted screen test. Our extended nutritional intervention was more effective than the diet providing UMP/DHA only.

Conclusion. This is the first study demonstrating a therapeutic effect of specific dietary interventions in a mouse model of PD. The improved efficacy of the extended nutritional intervention suggests synergies within our specific multi-nutrient approach.

ADPD5-2119

CAPSAICIN PRE-TREATMENT CONFERS NEUROPROTECTION IN A MODEL OF PARKINSON'S DISEASE

G.M. Fong[1], D. Johnstone[2], S. Antao[1], J. Stone[2], P.K. Witting[2]
[1]Pathology, The University of Sydney, Sydney, Australia
[2]Physiology, The University of Sydney, Sydney, Australia

Introduction: Parkinson's disease (PD) is characterised by progressive loss of motor function and dopaminergic neuron (DN) density. The neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) is neurotoxic to DN in the mouse *substantia nigra* yielding PD-like symptoms. Red peppers contain capsaicin that can protect neurons in an *in vitro* model of acute oxidative insult (Fong and Witting *unpublished*). We ***aim*** to test whether capsaicin prevents neuronal loss and brain function in a mouse model of PD.
Methods: Male C57BL/6 mice were given vehicle (DMSO) or capsaicin (1 mg/kg) 6 h prior to saline or MPTP (25 mg/kg/day) treatment over 2 consecutive days. Gait was assessed on a subset of mice six days after the onset of treatment. Serum and various organs were harvested for biochemical and histological (DN counting using stereological post tyrosine-hydroxylase staining) analyses.
Results: Serum GGT and creatinine were below detection while serum urea decreased slightly in MPTP-treated animals although this did not reach significance. Cerebral levels of IL-6, TNF-α and p-mTOR (anti-apoptotic mediator) were also unchanged. Total DN counts decreased slightly in the MPTP-treated animals while in capsaicin-treated mice DN were not different to controls. Notably, capsaicin restored rear paw brake timing indicating an improved gait.
Discussion: Neither MPTP nor capsaicin caused detectable liver or kidney damage. The dose of MPTP employed only induced a marginal decline in DN density, yet this was sufficient to affect gait as measured by front/rear paw brake time. Pre-treatment with capsaicin significantly improved gait but had no meaningful impact on DN density.

ADPD5-2328

Combination of acamprosate and baclofen as a promising therapeutic approach for Parkinson's disease

R. Hajj[1], A. Milet[1], D. Toulorge[1], Cholet. N.[1], J. Laffaire[1], J. Foucquier[1], S. Robelet[2], R. Mitry[2], M. Guedj[1], S. Nabirotchkin[1], I. Chumakov[1], D. Cohen[1]
[1]Pharnext, 11 rue des Peupliers, 92130 Issy-Les-Moulineaux, France
[2]Syncrosome, 163 avenue de Luminy, 13288 Marseille, France

Objectives: Parkinson's disease (PD) is a progressive neurodegenerative disorder characterised by the loss of dopaminergic nigrostriatal neurons but which involves the loss of additional neurotransmitter pathways in brain and the autonomic nervous system. Mono- or polytherapeutic symptomatic interventions in PD patients have declining efficacy long-term and no influence on disease progression. The systematic analysis of available genetic and functional data as well as the substantial overlap between Alzheimer's disease (AD) and PD features led us to repurpose and explore the effectiveness of a combination therapy (ABC) with two drugs – acamprosate and baclofen – that was already effective in AD animal models, for the treatment of PD. Results: We showed in vitro that ABC strongly and synergistically protected neuronal cells from oxidative stress in the oxygen and glucose deprivation model, as well as dopaminergic neurons from cell death in the 6-hydroxydopamine (6-OHDA) rat model. Furthermore, we showed that ABC normalised altered motor symptoms in vivo in 6-OHDA-treated rats, acting by protecting dopaminergic cell bodies and their striatal terminals. Interestingly, ABC also restored a normal behaviour pattern in lesioned rats in a symptomatic fashion. Conclusion: Our results demonstrate the potential value of combining repurposed drugs as a promising new strategy to treat this debilitating disease.

EFFECTS OF DOPAMINERGIC MEDICATION ON COGNITIVE FUNCTION IN DRUG-NAIVE DE NOVO PATIENTS WITH PD

H. Murakami[1], Y. Owan[1], Y. Mori[1], A. Futamura[1], Y. Saito[1], S. Yano[1], S. Ishigaki[1], H. Kato[1], M. Kezuka[1], M. Kawamura[1]

[1]Department of Neurology, Showa University School of Medicine, Tokyo, Japan

Objectives: There is a correlation between cognitive and motor functions in Parkinson's disease (PD). However, the effects of dopaminergic medication on cognitive function in PD patients are uncertain, especially in drug-naive *de novo* PD patients. We examined the cognitive effect of dopaminergic medication in drug-naive PD patients. **Methods**: Dopaminergic drugs (levodopa, dopamine agonist, selegiline) were introduced to 16 drug-naive PD patients and increased to an optimal dose for motor symptoms. Patients were tested prior to and after 4-7 months of drug initiation. Motor function was assessed using the Unified Parkinson's Disease Rating Scale (UPDRS; total score and subscores of tremor, rigidity, bradykinesia, gait and postural instability). Cognitive function was assessed using the Japanese version of Montreal Cognitive Assessment (MoCA-J: total score and subscores of delayed recall, attention, visuospatial function, executive function, language and orientation). Score changes from baseline for both motor and cognitive assessment were compared. **Results**: Dopaminergic drugs ameliorated the UPDRS total score in all participants. MoCA total score improved in 12 patients, but 4 patients had deteriorated by one point. Amelioration in gait score showed a significant negative correlation with that of attention. Amelioration in bradykinesia score also showed a negative correlation with visuospatial function. However, there was a significant positive correlation in amelioration score between gait and language. **Conclusions**: Dopaminergic treatment can relieve cognitive function in drug-naive PD patients. However, the dopaminergic effects on cognitive and motor functions are domain specific.

ADPD5-1985

EFFICACY OF COMBINATION THERAPY WITH LEVODOPA AND SERTRALINE ON PARKINSONIAN RATS

H. Kavandi[1], J. Mahmoudi[2], S. Reyhani-Rad[2]
[1]neurology department,
School of Medicine Tabriz University of Medical Sciences Alzahra hospital, Tabriz, Iran
[2]neurology department, Tabriz University of Medical Sciences Alzahra hospital, Tabriz, Iran

Objective: Parkinson's disease is a neurodegenerative condition. In this disease nigro striatal dopaminergic pathway and some other neurotransmitter systems (i.e. serotonergic system) are involved. Long-term administration of Levodopa in parkinsonian patients leads to development of some motor disorders such as L-dopa induced dyskinesia and off-phenomena. Hence employment of strategy for effective treatment of this disease is of interest.
In this investigation we attempted to evaluate the effect of sertraline, as a selective serotonin reuptake inhibitor, on anti-cataleptic effect of L-dopa in 6-hydroxydopamine (6-OHDA) lesioned rats.
Methods: Catalepsy was induced by unilateral infusion of 6-OHDA (8µg/2µl/rat) into the substantia nigra, compact part (SNc). Male wistar rats weighting 180-200g were used in the present study. These rats received intraperitoneally (i.p.) L-Dopa (15mg/kg) twice daily for 20 consecutive days, and anti-cataleptic effect of L-dopa was evaluated by bar-test on days 5, 10, 15 and 20. On the day 21, these rats co-injected with three different doses of sertraline (0.5, 1and 2mg/kg, i.p.) and L-dopa (15mg/kg, ip).
Results: L-dopa exerts anti-cataleptic effect only until day 15, and its effect was vanished on the day 20. Sertraline (1 and 2 mg/kg i.p.) markedly attenuated the cataleptic behavior ($P<0.001$). Furthermore, the effect of sertraline (2 mg/kg, i.p.) on anti-cataleptic effect of L-dopa (15mg/kg, ip) was antagonised by NAN-190 (0.5 mg/kg, i.p.) as a 5-HT_{1A} receptor antagonist.
Conclusion: Sertraline improves the anti-cataleptic effect of L-dopa in the 6-OHDA-lesioned rats and probably this effect mediated through activation of $5HT_{1A}$ receptors.

EFFECTS OF ISTRADEFYLLINE ON NON-MOTOR SYMPTOMS AND QUALITY OF LIFE IN PARKINSON'S DISEASE PATIENTS

N. Kawashima[1], A. Kumon[1], A. Tsuneta[1], A. Sato[1], K. Miyashita[1], S. Nakamura[2], E. Horiuchi[2], T. Yokoyama[2], K. Hasegawa[2]
[1]Neurology, Kawashima Neurology Clinic, Fujisawa Kanagawa, Japan
[2]Neurology, Sagamihara National Hospital, Sagamihara Kanagawa, Japan

Objective: To clarify the effect of istradefylline for non-motor symptoms (NMS) and quality of life (QoL) in Parkinson's disease (PD) patients. **Background**: Istradefylline decreases daily OFF time and improves the UPDRS Part III in PD patients, but the efficacy for NMS and QoL in patients with PD has not been investigated enough. **Methods**: We investigated out-patients with PD at Hoehn-Yahr (HY) stage 2-3, who had over 1 hour of OFF time / day and were taking above 300 mg of levodopa/decarboxylase inhibitor / day. The subjects received istradefylline 20 or 40 mg / day for 12 weeks. We estimated the Self-Rating Depression Scale (SDS), the Apathy Scale (AS), the Sagamihara-Keio Apathy Scale (SKAS), the Parkinson's Disease Sleep Scale-2 (PDSS-2), the Non-Motor Symptom Scale for Parkinson's Disease Study 2 (NMSS-2), the Parkinson's Disease Questionnaire (PDQ-39) and UPDRS, before, 8 and 12 weeks after the intervention. **Results**: 24 subjects (10 males, mean age 71.5 years, disease duration 9.5 years, HY 2.2, MMSE 28.3, FAB 14.5) were included. The summary index of PDQ-39 improved from the baseline (26.3) by 4.3 (p = 0.006) and the mobility, stigma and social support domains became significantly better. The UPDRS total and the UPDRS Part III improved from the baseline (28.0 and 13.0) by 5.7 (p = 0.002) and 3.7 (p = 0.000) significantly. The SDS, AS, SKAS, PDSS-2 and NMSS-2 scores did not change remarkably. **Conclusion**: Istradefylline improved QoL and motor symptoms in PD patients, but its efficacy for NMS was not proven.

A CASE OF PARKINSON'S DISEASE THAT GABAPENTIN IMPROVED BOTH VISUAL HALLUCINATIONS AND PAIN

K. Abe[1], Y. Chiba[1], O. Katsuse[1], Y. Hirayasu[1]
[1]Psychiatry, Yokohama City University School of Medicine, Yokohama city, Japan

OBJECTIVES: Parkinson's disease (PD) is the most common neurodegenerative disease. Visual hallucinations (VH) and pain are common non-motor symptoms. Although dopaminergic dysfunction has traditionally been considered as one of the causes of these symptoms, the detail mechanisms have not been understood well. General treatments for VH, decrease of dopamine agonists and use of antipsychotic medication, often lead to exacerbation of motor symptoms and excessive sedation. Gabapentin, an anti-epilepsy drug, effects glutamic acid neuron system and gamma-amino butyric acid neuron system. Gabapentin also has an analgesic effect. We report our experience that gabapentin improved both VH and pain in a patient with PD.
METHODS: A case report.
RESULTS: The case is an 81 year-old Japanese male, who was diagnosed with PD at the age of 67. His Hoehn and Yahr staging scale was IV. He suffered from pain caused by hallucinations of insects invading his body. In spite of the general treatments, VH and pain persisted. Moreover, exacerbation of motor symptoms and excessive sedation hindered a further attempt. Gabapentin was administered to ease his pain. After that, not only pain but also VH disappeared without any adverse effects. He has been managed without recurrence of VH and pain for 10 months until now.
CONCLUSIONS: To our knowledge, this is the first report suggesting positive effects of gabapentin for VH and pain. VH and pain in PD might be associated with non-dopaminergic pathways. Further experience and study are needed.

LEVODOPA PHARMACOKINETICS DURING ORAL INTAKE IN ONE PATIENT WITH PARKINSON'S DISEASE

M. Nord[1], P. Zsigmond[2], A. Kullman[3], N. Dizdar[1]
[1]Clinical and experimental medicine and neurology, Linkoping University, Linkoping, Sweden
[2]Clinical and experimental medicine and neurosurgery, Linkoping University, Linkoping, Sweden
[3]Clinical and experimental medicine, Linkoping University, Linkoping, Sweden

Objective: One patient was accidentally given oral levodopa during a study aiming for better understanding of the basal ganglia and of the mechanisms of deep brain stimulation of the subthalamic nucleus (STN DBS) with and without levodopa treatment in patients with Parkinson's disease (PD). The results from the accidental oral levodopa intake are presented. *Methods*: Five patients with advanced PD were included in the study. During planned STN DBS surgery three microdialysis catheters were implanted in the right putamen and in the right and left globus pallidus interna. During three study days microdialysis was performed continuously and STN DBS was performed according to a specific protocol. On the third day levodopa was given intravenously. After DBS surgery but before STN DBS was started one of the patients was accidentally given levodopa/benserazide and entacapone tablets at several occasions. *Results*: The levodopa levels increased promptly in CNS after each levodopa intake. Immediately the levodopa seemed to be metabolized to dopamine since these levels correlated well with the levodopa concentrations. *Conclusion:* The results indicate that PD patients still have capacity to metabolize levodopa to dopamine despite advanced disease with on-off symptoms and probably also pronounced nigral degeneration.

ROTIGOTINE TRANSDERMAL PATCH IS EFFECTIVE AND SAFE IN PD WITH DEMENTIA.

K. Ohta[1], Y. Kujuro[1], T. Osada[1]
[1]Department of Neurology, Tachikawa Hospital, Tokyo, Japan

Objective
Safety of dopamine agonist (DA) in demented patients has not been elucidated yet, because the previous RCTs excluded such patients. We aimed to assess the influences on daytime sleepiness and other adverse effects (AEs) of transdermal patch of rotigotine in patients with PD with dementia (PDD).
Methods
This was an open-label study. We enrolled PDD patients (MMSE score <26 points) with unsatisfactory control of motor symptoms. Treatment with transdermal patch of rotigotine was titrated to optimal dose (4-8 mg/24 hour) over 2-4 weeks. The primary outcome was the Epworth Sleepiness Scale (ESS) for evaluation of daytime sleepiness. The secondary outcomes included Hoehn &Yahr (H&Y) stage, time spent with dyskinesia by MDS-UPDRS Part IV, Clinical Global Impression of Change (CGIC) of motor symptoms, AEs of nausea/vomiting, syncope, hallucination, and skin reactions requiring treatment, and compliance.
Results
The subjects were 6 PDD patients (age 77±6 years, H&Y stage 3±1, mean±SD). ESS did not change significantly after the treatment (12.2±5.4 before treatment (n=6), 10.7±2.3 with rotigotine 4 mg/24 hour (n=6), and 16.0±8.7 with rotigotine 8 mg/24 hour (n=3)). CGIC improved after the treatment. Other secondary outcomes did not worsen after the treatment.
Conclusions
Twenty four-hour transdermal delivery of rotigotine at doses up to 8 mg/24 hours does not worsen the daytime sleepiness and other AEs in PDD patients. This is achieved together with satisfactory improvement in motor symptoms, demonstrating that this new modality of non-ergot DA is well tolerated and beneficial in PDD patients.

CONTROLLABLE SYNTHESIS AND CHARACTERIZATION OF LEVODOPA-LOADED POLY(LACTIC-CO-GLYCOLIC ACID) NANOPARTICLES FOR PARKINSON'S DISEASE TREATMENT

S. Moztarzadeh[1], R. Fuzhan[1], M. Fathollah[1], M. Mozafari[2]
[1]Faculty of Biomedical Engineering (Center of Excellence), Amirkabir University of Technology, Tehran, Iran
[2]Department of Nanotechnology and Advanced Materials, Materials and Energy Research Center (MERC), Tehran, Iran

Abstract:

1. Objectives

Although several progressive treatments have been developed, many effective drugs have failed in clinical examinations due to the penetration ability across the blood-brain barrier. As an attractive strategy, local and controlled delivery of levodopa using biodegradable polymeric nanoparticles has attracted more attention in Parkinson's disease treatment. In this study, in order to obtain desired surface morphology and particle size of poly(lactide-co-glycolide) (PLGA) nanoparticles, and high emulsifying effects, vitamin E TPGS and different amounts of chitosan have been used.

2. Methods

The particle size, surface morphology and phase composition correlated with different percentages of chitosan and different pH were characterized. In addition, the *in vitro* cytotoxicity of the samples using PC12 cell line was investigated. In the next step, six groups of mice received intravenous tail-vein administration of levodopa-loaded poly(lactic-co-glycolic acid) nanoparticles to monitor the *in vivo* blood-brain barrier transport behavior.

3. Results

According to the results, with the increase of chitosan ratio, more effective *in vitro* therapeutic effects could be observed, which achieved high cell viability. In addition, the levodopa-loaded poly(lactic-co-glycolic acid) nanoparticles showed high efficacy while the same doses of levodopa provided no significant effect in the *in vivo* models.

4. Conclusions

The proposed drug delivery system represents a promising agent for potential chronic administration in the Parkinson's disease therapy. This demonstrates the great prospect of chitosan as ligand in the brain targeting that could be effectively optimized for a better functionality.

WILLINGNESS TO PAY FOR A NEW DRUG DELIVERY IN PARKINSON PATIENTS

J. lökk[1], U. persson[2], S. olofsson[2]
[1]NVS, Karolinska Institute, Stockholm, Sweden
[2]health economics, IHE, Lund, Sweden

Objective:The Swedish reimbursemant system operates a system where prices are set based on the expected value to the consumer.This value can be measured using willingness to pay(WTP).
Aim:To assess PD patients´ WTP for newly developed microtablets of levodopa in combination with a drug-delivering device(M/E) compared to standard treatment with levodopa combined with the COMT-inhibitor entacapone (L/e).
Method: 2000 randomly included PD patients had a postal questionnaire covering demographics, disease-specific issues, views on medication and WTP in diffrerent hypothetical scenarios. The first scenario was M/E with no change in effects or side effect; the second scenario was M/E with same effect and less side effects;and the third scenario was M/E with improved effects with less side effects. These scenarios were coupled to different costs to choose from.
Results: 999(50%) patients responded, mean age 71 years, mean PD duration of 9 years. 50% of all patients preferred M/E before L/e in scenario one with increasing preference to scenario three. The average monthly WTP among all respondents in scenario one was SEK 230, and SEK 226 in L/e, both with an almost longitudinal doubling up to scenario three. Duration of PD-related sypmtoms, high education, and high medication intake implied a higher WTP in all scenarios in contrast to age, sex, and extra doses of levodopa
Conclusion: WTP for M/E increased gradually with high medication intake and education as well as with expected increased reduction of PD symptoms.

NPT088, A GAIM-IMMUNOGLOBULIN FUSION, REDUCES ALPHA-SYNUCLEIN DEPOSITS AND INCREASES TYROSINE HYDROXYLASE IN ALPHA-SYNUCLEIN OVEREXPRESSING TRANSGENIC MICE

K.S. Gannon[1], E. Masliah[2], E. Rockenstein[2], J. Carroll[1], J.M. Levenson[1], V. Cullen[1], S. Schroeter[1], R. Fisher[1]

[1]Preclinical Research & Development, NeuroPhage Pharmaceuticals, Cambridge, USA

[2]Dept of Neurosciences, UCSD, San Diego, USA

Objectives. NeuroPhage Pharmaceuticals is developing novel therapeutics for the treatment of neurodegenerative diseases, including Parkinson's and Alzheimer's disease. NPT088 is a clinical candidate with potential disease-modifying activity that disrupts and clears a variety of amyloid aggregates in the brain. In addition to targeting Abeta and tau aggregates, NPT088 disrupts alpha-synuclein fibrils in biochemical, cell-based and animal studies. The current study investigated the effects of chronic systemic administration of NPT088 on neuropathological endpoints in transgenic mice overexpressing human alpha-synuclein.

Methods. mThy-1-h-alpha-synuclein transgenic mice (~3 months old at start of dosing) received weekly intraperitoneal injections of NPT088 (2 or 20 mg/kg) or PBS for 13 weeks. Age-matched wildtype mice received PBS injections. Effects on proteinase K (PK) resistant alpha-synuclein and tyrosine hydroxylase immunoreactivity were assessed in various brain regions, including frontal cortex, striatum and hippocampus. NTP088 effects on alpha synuclein were also assessed using western blot analyses.

Results. NPT008, at both doses (2 & 20 mg/kg), significantly improved neuropathology in alpha-synuclein transgenic mice following chronic systemic treatment. NPT088 significantly reduced PK resistant alpha-synuclein in striatum, frontal cortex and hippocampus. A significant reduction in PK resistant alpha-synuclein (LB509) was also shown by western blot. In addition, NPT088-treated mice had significantly greater levels of tyrosine hydroxylase immunoreactivity than PBS-treated mice, similar to levels of wildtype mice.

Conclusions. Chronic NPT088 treatment of alpha-synuclein mice produced significant reductions of alpha-synuclein with greater levels of tyrosine hydroxylase compared to PBS treatment. NPT088 was well-tolerated and produced no adverse effects. IND filing is planned for 3Q2015. MJFF-funded research.

TOPOGRAPHY OF CORTICAL THINNING ASSOCIATED WITH WHITE MATTER HYPERINTENSITIES IN PARKINSON'S DISEASE

P.H. Lee[1], *J. Ham*[1], *Y.H. Sohn*[1]
[1]*Department of Neurology, Yonsei University College of Medicine, Seoul, Korea*

Background: Although white matter hyperintensities (WMHs) are associated with cognitive impairments in Parkinson's disease (PD), the relationships between WMHs and cortical atrophy in regard to cognitive impairments are unknown. Here, we investigated the topography of cortical thinning related to deep (DWMHs) and periventricular WMHs (PWMHs) and their differential impacts on cognitive performance in PD.
Methods: We enrolled 242 patients with non-demented PD and evaluated WMH scores using a semi-quantitative visual rating system. The patients were divided into low-, moderate-, and high-grade groups based on WMH severity for total WMHs (TWMHs), DWMHs, and PWMHs, and cortical thickness was measured using a surface-based method according to the WMH severity. Additionally, the correlations between WMH-associated cortical thinning and neuropsychological performance were analyzed.
Results: The detailed neuropsychological test demonstrated that PD patients with high-grade WMHs showed poorer performance on frontal lobe-based cognitive tasks compared with those with low-grade DWMHs. The areas of cortical thinning were more extensive in patients with DWMHs, involving the entire frontal areas and restricted temporoparietal areas, whereas in patients with PWMHs, cortical thinning was localized in the small frontal areas. A multiple regression analysis of the relationships between WMH-associated cortical thickness and cognition revealed that DWMH-associated frontal thickness had an independent effect on frontal lobe-based cognition, while frontal thickness related to PWMHs did not have a significant correlation with cognitive tasks.
Conclusions: These data suggest that in patients with PD, DWMHs are closely coupled with decreased cortical thickness in the frontal areas and may lead to declines in executive function.

ADPD5-0652

EFFECT OF OLFACTORY IMPAIRMENT AND WHITE MATTER HYPERINTENSITIES ON COGNITION IN NON-DEMENTED PARKINSON'S DISEASE

P. Lee[1], *J. Ham*[1], *Y. Sohn*[1]
[1]*Department of Neurology, Yonsei University College of Medicine, Seoul, Korea*

Background: Although white matter hyperintensities (WMH) and olfactory dysfunction are independently associated with the cognitive impairments in Parkinson's disease (PD), the effects of simultaneous presence of these abnormalities remain unknown. Thus, we investigated the different effects of deep WMH and periventricular WMH on olfactory and cognitive performance and evaluated the additive effects of the concurrent presence of WMH and olfactory dysfunction on cognitive performance in PD.
Methods: We enrolled 171 patients with non-demented PD whose WMH scores were assessed using a semi-quantitative visual rating system. The olfactory and cognitive performance was assessed using the Cross-Cultural Smell Identification (CCSI) test and the Seoul Neuropsychological Screening Battery. Additionally, the additive effects of concurrent WMH and olfactory dysfunction on cognitive performance were investigated using binary logistic regression.
Results: The deep WMH exhibited a significant negative correlation with the CCSI score (p=0.026) but the total WMH and periventricular WMH did not. A multiple regression analysis revealed that the total WMH (β=-0.109, p=0.011) and deep WMH (β=-0.153, p=0.020) severities had significant negative correlations with semantic fluency. A logistic regression analysis revealed that the simultaneous presence of severe olfactory dysfunction and deep WMH was associated with a greater risk for the semantic fluency impairments (odds ratio=15.909, p= 0.0005) compared to patients with mild deep WMH or high CCSI scores.
Conclusions: These data indicate that deep WMH was closely coupled with olfactory impairments and cognitive decline in PD. Moreover, the concurrent presence of high-grade deep WMH and severe olfactory impairments has a greater influence on semantic fluency.

[3]Department of Psychiatry, Stavanger University Hospital, Stavanger, Norway
[4]Institute of Psychiatry, King's College London, London, United Kingdom
[5]Department of Physics, Bilkent University, Ankara, Turkey
Objectives: To assess whether mild cognitive impairment (MCI) is associated with disruption in large-scale structural networks in newly diagnosed, drug-naïve patients with Parkinson's disease (PD).
Methods: Graph theoretical analyses were applied to 3T MRI data from 123 PD patients and 56 controls from the Parkinson's Progression Markers Initiative (PPMI). Thirty-three patients were classified as having MCI using the Movement Disorders Society Task Force criteria, while the remaining ninety patients were classified as cognitively normal. Global measures (clustering coefficient, characteristic path length, global efficiency, small-worldness) and regional measures (local clustering coefficient, local efficiency, hubs) were assessed in the structural networks that were constructed based on cortical thickness and subcortical volume data in each group.
Results: Patients with MCI showed a marked reduction in the average correlation strength between cortical and subcortical regions compared to controls. These patients had larger characteristic path length and reduced global efficiency in addition to a lower local efficiency in frontal and parietal regions compared to cognitively normal patients and controls. A reorganization of the highly connected regions in the network was observed in patients with and without cognitive deficits.
Conclusions: This study shows the earliest stages of cognitive decline in PD are associated with a disruption of the large-scale coordination of the brain network and with a decrease of the efficiency of parallel information processing. These changes are likely to herald further cognitive decline and provide support to the view of PD as a disconnection syndrome capable of spreading along the connections of the cerebral network.

DIFFUSION MRI ALTERATIONS IN PRODROMAL DEMENTIA WITH LEWY BODIES

A. Bouchon[1], V. Noblet[1], B. Cretin[2], B. Jung[2], N. Philippi[2], C. Heitz[2], P. Loureiro de Sousa[3], J.P. Armspach[3], F. Heitz[1], F. Blanc[2]

[1]Modèle Images et Vision, Icube, Illkirch, France

[2]University Hospital of Strasbourg, Neuropsychology Unit, Strasbourg, France

[3]Imagerie Multimodale Intégrative en Santé, Icube, Strasbourg, France

Introduction: Diffusion Tensor Imaging (DTI) is an imaging modality which allows to visualize *in vivo* the bundles structures. We investigate the early diffusion MRI alterations in prodromal stage of dementia with Lewy bodies (DLB) using a newly proposed tensor-based method, in comparison to the standard SPM scalar-based approach.

Methods: Twelve controls were compared to 22 patients affected by DLB in prodromal stage. Voxelwise analyses were carried out on 1) scalar measures (FA and MD) using SPM and 2) a novel tensor-based method [1], that we recently proposed and which extends the general linear model to tensor images, taking into account the whole tensor information. We also compared hallucinated DLB *vs* no hallucinated DLB.

Results: The results show diffusion alterations in DLB as compared to healthy controls in insular cortex, anterior cingulate cortex and occipital lobe. Hallucinations seem to be more specifically related to modifications in anterior cingulate cortex, occipital lobe and temporal lobe. The tensor-based method appears to be more sensitive to detect the involved regions.

Conclusion: This study highlights the early diffusion alterations in the prodromal stage of DLB, that are mainly located in the grey matter and in the insular cortex, which seems to be an important region for this pathology, as proven in others studies. We also demonstrate the interest of specifically designed tensor-based methods to detect subtle diffusion alterations.

ADPD5-2277

HOT CROSS BUN SIGN IN A PATIENT WITH PARKINSONISM AND CEREBELLAR ATAXIA

S. Cagirici[1], A. Bajrami[1], E. Demir[1], B. Aslan[1], N. Sozer Topcular[1], D. Bozkurt[1], V. Yayla[1]
[1]Neurology, Bakirkoy Dr Sadi Konuk Training and Research Hospital, ISTANBUL, Turkey

Objectives:

The "Hot cross bun" sign is a cruciform hyperintensity in the pons, especially on transverse T2-MR images of the brain. We discussed the differential diagnosis of the "hot cross bun" sign in a patient presenting with cerebellar ataxia, parkinsonian symptoms and cranial MR showing hot cross bun sign and cerebellar atrophy.

Case:

A 49-year-old male presented with 8 year history of gait disturbance, drop attacks and urinary incontinence. Three years ago he was diagnosed as Parkinson's disease and his symptoms gradually worsen, responding poorly to dopaminergic treatment. Medical history included diabetes mellitus and polyneuropathy. The patient was being treated with levodopa/carbidopa/entacapone 150 mg (5x1) on admission. Neurological examination revealed hypophonic and heavily slurred speech, slow saccades, hyperreflexia and right extensor plantar response. Bradymimia, severe bradykinesia, rigidity, postural instability and Romberg sign were also noted. The patient could not stand up without assistance. MRI revealed prominent serebellar atrophy and 'hot cross bun" sign in the pons on T2/FLAIR sequences (Figure 1, 2).

Discussion:

The hot cross bun sign reflects degeneration of transverse pontocerebellar fibers, regardless of the underlying pathogenic process. Although it has been reported to be specific for multiple system atrophy, it is also present in other neurodegenerative diseases including spinocerebellar ataxia, cerebrotendinous xanthomatosis, HIV-associated progressive multifocal leucoencephalopathy, leptomeningeal carcinomatosis, variant Creutzfeldt-Jakob or vascular diseases. Findings of cranial images in correlation with careful clinical examination narrows this differential diagnoses. Our patient has been diagnosed probable multiple system atrophy mostly depending on exclusion of other diseases.

ADPD5-2294
REFINING STRUCTURAL BRAIN CONNECTIVITY FOR ALZHEIMER'S DISEASE AND PARKINSON'S DISEASE CLASSIFICATION
G. Prasad[1], L. Mackey[2], A. Mezher[1], P. Thompson[1]
[1]Institute for Neuroimaging and Informatics, University of Southern California, Los Angeles, USA
[2]Statistics, Stanford University, Stanford, USA
Objectives: We adaptively refine the partition of the brain for connectivity-based classification of Alzheimer's disease (AD) and Parkinson's disease (PD).
Methods: Structural and diffusion MRI at 3T was analyzed for (1) 47 AD patients and 51 age- and sex-matched controls from ADNI (73.8±7.5Y; 48F), and (2) 62 PD patients and 62 age- and sex-matched controls from PPMI (60.8±9.8Y; 45F). We computed anatomic connectivity among 68 cortical regions from the Desikan-Killiany atlas using tractography to compute the number of fibers between regions. Each individual's 68x68 connectivity matrix was normalized by fiber count and optimized by merging regions using a novel algorithm. "Evolving Partitions to Improve Connectomics"(EPIC).
Results: The baseline classification accuracy for AD vs. controls based on 68x68 connectivity matrices was 62.75%; EPIC-based matrices of size 18x18 yielded no significant change in accuracy. For PD vs. control classification, the initial accuracy was 73.38% and the 20x20 EPIC-derived architecture did not boost classification performance (see Figure). Significance was assessed by a corrected repeated k-fold cross-validation t-test.
Conclusions: In both AD and PD, the EPIC algorithm combines most of the cortical regions into a single connectivity component to remove redundant predictors. In PD, this composite region influenced classification accuracy the most; in AD the anterior cingulate influenced performance the most.

[2]Neuroradiology, San Raffaele Hospital, Milan, Italy
[3]Brain Connectivity Center, C. Mondino National Neurological Institute, Pavia, Italy
[4]Center for Research in Neurodegenerative Diseases, C. Mondino National Neurological Institute, Pavia, Italy
[5]Parkinson's Disease and Movement Disorders Center, C. Mondino National Neurological Institute, Pavia, Italy

Background

The neuromelanin-rich substantia nigra (SN) can be identified by T1 hyperintensity after magnetization transfer (MT) pulse (Ogisu 2013). In this pilot study, we implemented two volumetric sequences, PD and T1-MT, to measure respectively the whole SN and the neuromelanin-rich SN in Parkinson's disease.

Methods

17 patients with Parkinson's disease (8M,9F, 54.7±8.5yrs) and 14 normal controls (6M,8F, 50.8±14.1yrs) were studied by 3T MRI (Siemens Skyra). Whole brain T1 MPRAGE and two axial volumetric slabs, PD and T1-MT, perpendicular to the fourth ventricle floor, were acquired.
After multiplying the mean midbrain signal for a standard normalization factor, an individual signal threshold was obtained, and applied to segment the SN in every subject in both sequences. SN volumes were compared between patients and controls by two tailed t-test. In patients, SN volumes were correlated with the total UPDRS score (average 38.0±12.2) in off phases.

Results

While proton-density volumetry did not differentiate SN of patients (L 397.1mm^3±109,6, R 339.2+87,4) from controls (L 365.4±76.7, R 341.4±69.0), T1-MT volumetry significantly (p±45, R 138.3±52.9) from controls (L 239.2±42.8, R 221.5±55.8). Moreover, in this limited sample of patients there was a trend for correlation between decreased volume of neuromelanin-rich left SN and UPDRS-III score (Pearson -0.5, p=0.053).

Discussion

3T MRI with PD and T1-MT can identify substantia nigra and its neuromelanin-rich pars. Using a volumetric acquisition and a semiautomatic segmentation, the neuromelanin-rich pars differentiates patients from controls with statistical significance, higher than previously reported (Ogisu 2013).

REGIONS OF CEREBRAL HYPOPERFUSION RELATED TO ORTHOSTATIC HYPOTENSION ARE STRONGLY ASSOCIATED WITH DOMAIN-SPECIFIC COGNITIVE IMPAIRMENT IN LEWY BODY DISORDERS

A.D. Robertson[1], M.A. Messner[2], D.E. Crane[1], Z. Shirzadi[1], K.V. Sherborn[2], G. Kleiner-Fisman[3], J. Lee[4], S.E. Black[5], B.J. MacIntosh[1], M. Masellis[5]

[3]Department of Neurology, Baycrest Centre for Geriatric Care, Toronto, Canada
[4]Elder Care Program, North York General Hospital, Toronto, Canada
[5]Department of Medicine (Neurology),
Sunnybrook Health Sciences Centre University of Toronto, Toronto, Canada

Orthostatic hypotension (OH) is the most common dysautonomia associated with Lewy Body Disorders (LBD). The contribution of OH to cognitive impairment in LBD, however, remains uncertain. **Objective:** To examine the interrelationships of cerebral blood flow (CBF), cognitive function, and OH. **Methods:** Fifteen LBD patients (76.3±6.9 years, 4 women) underwent 3T MRI to quantify CBF using arterial spin labeling. CBF estimates were also performed on matched adults with small vessel disease (SVD) to establish group differences. OH was quantified as the change in systolic blood pressure (delta-SBP) between supine and standing postures. Cognitive function was assessed by the Montreal Cognitive Assessment (MoCA), Rey-Osterrieth Complex Figure Test, Digit Symbol Substitution Test and Wisconsin Card Sorting Task. **Results:** Compared to SVD, LBD exhibited lower grey matter CBF (46±12 vs. 59±21 mL/100g/min, p=0.047), but similar global cognitive status (MoCA: 19.1±4.8 vs. 22.8±7.0, p=0.104). Within LBD, a voxel-wise relationship between delta-SBP and CBF identified four regions of interest. In the right lingual gyrus and bilateral precuneus, as well as the left frontal and precentral gyri, a greater SBP drop was associated with lower CBF ($p<0.001$ [uncorrected], $k_E \geq 8$ voxels). Lower CBF within the identified regions was associated with poorer cognitive performance (false discovery rate, $q \leq 0.05$), as follows: lingual (visuospatial, attention); precuneus (visuospatial, executive function); frontal (visuospatial, executive function); and precentral (visuospatial, attention, executive function). **Conclusions:** Domain-specific cognitive impairment was strongly related to regionally-specific cerebral hypoperfusion. These findings provide new insight into the relevance of OH on cognitive function in LBD and the salient brain regions involved.

06b. Imaging & Biomarkers: functional MRI

ADPD5-1232
DOES DORSAL STRIATUM MEDIATE STIMULUS-RESPONSE LEARNING OR DECISION-MAKING?

P. MacDonald[1], N. Hiebert[2], A. Owen[3], K. Seergobin[1]
[1]Clinical Neurological Sciences, Western University, London, Canada
[2]Physiology and Pharmacology, Western University, London, Canada
[3]Psychology, Western University, London, Canada

We tested the prevalent contention that dorsal striatum (DS) mediates later-stage stimulus-response learning when responses become automatic or habitual. Using functional magnetic resonance imaging, we examined striatal brain activity during later-stage stimulus-response learning, once performance accuracy was greater than 90%. Seven males and seven females (mean age 22) learned to associate abstract images with left or right button-presses during an initial study phase. These pairings were reinforced by feedback in Session 1 and practiced without feedback in Session 2. Session 3 measured whether stimulus-response associations had achieved habit status. DS activity correlated with stimulus-response events only during Blocks 1-3 of Session 1 when response times and accuracy suggested a level of deliberation in responding. No significant DS activity occurred for Blocks 4-12 or in Session 2 when responses times and accuracy had reached plateau, though stimulus-response associations had not reached automaticity in Session 3.

We conclude that DS underlies decision-making that continues to require deliberation and not stimulus-response learning or habit formation. DS activation ceased to occur in late stages of Session 1 and in Session 2, when responding was fast and highly accurate but *before* relations became automatic based on performance in Session 3. In Parkinson's disease, DS is significantly dopamine depleted. Increasingly, DS is shown to mediate cognitive functions. Elucidating DS-mediated cognition improves our understanding of cognitive dysfunction in Parkinson's disease. These results clarify the cognitive profile in Parkinson's disease and guide dopaminergic therapy. Indeed, learning seems spared but decision-making is impaired, reviewing cognitive studies in PD.

06b. Imaging & Biomarkers: functional MRI

ADPD5-1256

DORSAL STRIATUM MEDIATES COGNITIVE FLEXIBILITY, NOT COGNITIVE EFFORT: AN EVENT-RELATED FMRI STUDY IN HEALTHY YOUNG ADULTS

P.A. MacDonald[1], B. Robertson[2], N.M. Hiebert[2], A.M. Owen[3], K.N. Seergobin[1]
[1]Clinical Neurological Sciences, Western University, London, Canada
[2]Physiology and Pharmacology, Western University, London, Canada
[3]Psychology, Western University, London, Canada

Whether dorsal striatum (DS) mediates cognitive flexibility or cognitive effort is unclear due to a pervasive confound. Neuropsychological tasks with greater cognitive flexibility demands require increased cognitive effort. We manipulated cognitive flexibility and effort separately to specify the role of DS in decision making.

Sixteen healthy young adults completed a number Stroop task, measuring functional magnetic resonance imaging data. Participants selected the physically larger number of a pair. Smaller physical size differences between a number pair increase cognitive effort for the discrimination but not demand for flexibly shifting attention or responding. We also investigated the effect of conflict between the physical and numerical dimensions of targets *(e.g.,* **2** in larger print, compared to 6 in smaller print). Selections in this incongruent case are more cognitively effortful but they also require flexibly shifting attention to physical size, suppressing conflicting responses related to numerical magnitude. Both increased cognitive flexibility and effort yield slowed and more error-prone responses. The aim was to determine whether DS differentially mediates cognitive flexibility and cognitive effort, however.

As expected, behavioural interference effects occurred for both increased cognitive flexibility and cognitive effort. Despite similar magnitude interference, DS only mediated the interference arising due to increased cognitive flexibility requirements in the incongruent case. DS was not preferentially activated for smaller relative to larger physical size differences between number pairs.

DS underlies cognitive flexibility specifically, not merely cognitive effort.

Specifying DS-mediated functions increases understanding of cognitive dysfunction in PD and clarifies the impact of dopaminergic therapy on cognition in Parkinson's disease.

[3]Laboratory of Movement Analysis,
Scientific Institute and University Hospital San Raffaele, Milan, Italy

[4]Department of Neuroradiology, Scientific Institute and University Hospital San Raffaele, Milan, Italy

Objective. To assess brain functional and structural changes following action observation therapy (AOT) in PD patients with freezing of gait (PD-FoG).

Methods. 23 PD-FoG patients underwent a 4-week (W4) rehabilitation training. Subjects were randomized into 2 groups: in AOT-group, therapy consisted of AO combined with practicing the observed actions; control-group performed the same training combined with landscape-videos observation. At baseline (T0) and W4, patients underwent: clinical/motor functional evaluations, 3D-T1-weighted and functional MRI. At T0, 15 controls performed the same MRI protocol. FMRI tasks consisted of: foot simple-movement; observation of videos showing a man with FoG; motor-imagery in the same circumstances as observation task. Clinical/motor assessments were repeated at week8 (W8).

Results. At W4, both groups showed reduced FoG severity and walking-speed improvement, with AOT-group showing additional UPDRSIII, balance, and quality of life improvements. At W4, AOT and the control-group showed increased grey matter (GM) volume of bilateral parietal regions and primary motor cortex, respectively. FMRI showed that AOT was associated with increased recruitment of primary sensorimotor/premotor cortices, mirror neuron system (MNS) and caudate nucleus bilaterally during simple-motor and motor-imagery tasks. At W4, control-group showed reduced recruitment of primary sensorimotor areas and parietal regions during all tasks. Only in AOT, functional brain changes were associated with clinical improvements at W4 and predicted clinical evolution at W8.

Conclusions. AOT has a positive additional effect on walking ability recovery of PD-FoG patients. In PD, AOT promotes brain structural/functional plasticity of both the primary sensorimotor and MNS.

CEREBRAL PERFUSION IN PRODROMAL AND NON-PRODROMAL DEMENTIA WITH LEWY BODIES: AN ARTERIAL SPIN LABELING STUDY.

D. Roquet[1], B. Cretin[1], N. Philippi[1], X. de Petigny[2], B. Jung[1], C. Demuynck[2], C. Martin-Hunyadi[2], J.P. Armspach[1], F. Blanc[1]

[1]Integrative and multimodal imaging in health, Icube, Strasbourg, France

[2]Geriatry, Hôpitaux Universitaires de Strasbourg, Strasbourg, France

Objectives

In the scope of dementia with Lewy bodies (DLB), brain functional analyzes aim to explain how the brain activities adapt to the neural degeneration. Still, functional disturbances at the early stage of the pathology are poorly understood. Since they may impact the diagnosis and medical care, we investigate how much cerebral perfusion, as a possible biomarker, is early affected and reflects cognitive decline.

Methods

Twenty-eight prodromal (mild cognitive impairment) patients with DLB, 10 DLB patients with dementia, and 12 healthy controls received a multimodal magnetic resonance imaging including a 6 minutes resting-state pulsed arterial-spin labeling sequence. Spatially normalized cerebral blood flow maps were corrected for age and global mean value then analyzed using voxel-wise ANOVA.

Results

We showed that prodromal patients did not significantly differ from healthy controls, although we observed a tendency to a diffuse increased perfusion ($p<0.001$, uncorrected). Non-prodromal patients differed from healthy controls by a hypo-perfusion in the left insula ($p<0.05$, FWE-corrected). Non-prodromal patients also showed less perfusion than prodromal patients in the middle frontal gyrus, post-central gyrus and superior temporal sulcus ($p<0.05$, FWE-corrected).

Conclusions

Cerebral perfusion distinguishes prodromal from patients with dementia. The tendency of a higher perfusion in prodromal patients might reveal a compensatory phenomenon in these slightly affected patients. Patients with dementia showed a decreased perfusion in other brain parts than the areas usually reported as altered in Alzheimer disease. Therefore, cerebral perfusion imaging might be suitable for clinical and scientific investigations.

[5]Neuroscience Research Center, Chang Gung Memorial Hospital, Taoyuan County, Taiwan
[6]Molecular Imaging Center, Chang Gung Memorial Hospital, Taoyuan County, Taiwan

Objectives: The diagnosis of Parkinson's disease (PD) and Parkinson plus syndrome (PP), including multiple system atrophy (MSA), progressive supranuclear palsy (PSP), and corticobasal syndrome (CBS), is based on clinical symptoms. To develop an objective tool to distinguish PD from PP is critical. We have proved that positron emission tomography (PET) imaging with ^{18}F-FP-(+)-DTBZ, a novel radiotracer targeting vesicular monoamine transporter 2 (VMAT2), may sever as a potential marker in investigating the monoaminergic integrity in PD. Our previous studies also suggested that the regional K1 obtained by early-phase ^{18}F-FP-(+)-DTBZ PET imaging is highly correlated with regional cerebral blood flow.
The objective of this study is to evaluate the capability of ^{18}F-FP-(+)-DTBZ PET imaging in the differential diagnosis of PD and PP by the early-phase (brain perfusion) and delayed-phase (monoaminergic integrity) imaging.
Methods: We enrolled 22 patients with MSA-parkinsonism type (MSA-P), 39 PSP patients, 16 CBS patients, 75 PD patients and 20 age-matched healthy subjects (HC). The regional standardized uptake volume ratio (SUVR) was calculated with occipital as reference from MRI-based spatially normalized ^{18}F-FP-(+)-DTBZ.
Results: In all subjects, PSP patients had the lowest VMAT2 availability in bilateral caudate, anterior putamen and substantia nigra (SN). The delayed-phase SUVRs of the striatum and SN had no difference between PD and MSA-P group. Nevertheless, the early-phase SUVRs of ^{18}F-FP-(+)-DTBZ in contralateral caudate and putamen in MSA-P patients were significantly lower than those of the PD group.
Conclusion: The dual imaging of ^{18}F-FP-(+)-DTBZ PET could provide more information and power to distinguish PD from PP.

QUANTITATIVE EVALUATION OF THE SEVERITY OF PD BY [11C]CFT PET IMAGING AND SPM ANALYSIS

X. Wenbiao[1], C. Ling[1], L. Yanmei[1], J. Lulu[1], Y. Jing[1], S. Xinchong[2]
[1]Department of Neurology, The First Affiliated Hospital Sun Yat-sen University, Ganzhou, China
[2]PET-CT Center, The First Affiliated Hospital Sun Yat-sen University, Ganzhou, China

Objective To investigate the clinical value of [^{11}C]CFT PET in the diagnosis and assessing the severity of PD.
Methods Thirty-eight patients with PD at various Hoehn & Yahr (H&Y) stages were included and underwent a [^{11}C]CFT PET scan. The correlation between [^{11}C]CFT uptake and Unified Parkinson's Disease Rating Scale part III (UPDRS III) of PD patients was evaluated by calculating Pearson's regression coefficient. Statistical Parametric Mapping (SPM) analysis was performed to compare the difference of dopamine transporer (DAT) distribution between early and advanced PD patients.
Results There was a significant reduction of [^{11}C]CFT uptake in the bilateral striatum of PD patients. There was a significant negative correlation between clinical scores of UPDRS III, rigidity, bradykinesia, posture, gait and [^{11}C]CFT uptake in the striatum. The SPM analysis of early PD (H&Y 1-2) patients, compared with the normal controls, revealed a significant and asymmetric decrease of [^{11}C]CFT uptake in the striatum, predominantly in the putamen and caudate nucleus contralateral to the onset limb, and the posterior area of ipsilateral putamen. There was a significant symmetric decrease of [^{11}C]CFT uptake in both putamen and caudate nucleus in advanced PD (H&Y 3-5) patients, compared with normal controls. Compared with early PD patients, the reduction of DAT was more severe in bilateral caudate nucleus and the ipsilateral putamen in the advanced PD patients.
Conclusions [^{11}C]CFT PET can serve as a suitable biomarker to represent the severity of PD in early and advanced stages.

ADPD5-0854

CONSTRUCTION AND EVALUATION OF A NEW TEMPLATE-BASED SPATIAL NORMALIZATION FOR 18F-FP-(+)-DTBZ (AV-133) IMAGING

Y.H. Lin[1], I.J. Chen[1], C.J. Hsieh[1], K.J. Lin[2], Y.H. Weng[3], I.T. Hsiao[1], S.P. Wey[4]
[1]Department of Medical Imaging and Radiological Sciences, Chang Gung University, Taoyuan, Taiwan
[2]Department of Nuclear Medicine and Molecular Imaging Center, Chang Gung Memorial Hospital, Taoyuan, Taiwan
[3]Department of Neurology, Chang Gung Memorial Hospital, Taoyuan, Taiwan
[4]IRR Department of Medical Imaging and Radiological Sciences, Chang Gung University, Taoyuan, Taiwan

Objectives
18F-FP-(+)-DTBZ (AV-133) is a PET VAMT2 radiotracer for studying dopaminergic nerve-terminal integrity. The summed AV133 images acquired from the early time frames can provide estimate for relative perfusion information. The aim is to construct and evalute a new tempate from the early time frame images for 18F-DTBZ quantitation.
Methods
Seventy-three subjects were divided into two cohorts: 18F-FP-(+)-DTBZ images from the first cohort (6 HC and 25 PD) for constructing templates, and from the second cohort (11 HC and 31 PD) for validation. Four templates were constructed including normal (HC_{tmp}), PD patients (PD_{tmp}), all subjects (MIX_{tmp}), and perfusion ($pAV\text{-}133_{tmp}$). Each subject's MRI images were first coregistered to PET images. Then, the MRI images were normalized to MNI template (MNI_{tmp}), and resulted parameters were applied to coregistered PET images to obtain the spatially normalized PET images. The four templates were constructed from the spatially normalized PET images. The performance of the four PET templates were evaluated in terms of template-based quantitation. Occipital was selected as a reference to compute standardized uptake value ratios (SUVR) within target VOIs, including caudate, anterior and posterior putamen. The percentage difference of SUVR within each target between the four PET templates and MNI_{tmp} .
Results
The pAV133 template generated the minimal and stable SUVR %difference among all PET templates as compared to MNI_{tmp}.
Conclusions
The pAV-133 template of AV-133 imaging shows better performance in stable and accurate quantitation, therefore is potential for clinical applications.

[5]Pathology, Brain Research Institute University of Niigata, Niigata, Japan
[6]Neuroathology, Institute for Medical Science of Aging Aichi Medical University, Nagakute, Japan
[7]Neurology, Nakano General Hospital, Tokyo, Japan

Objective: The aim of this study is to quantify the degree of cardiac sympathetic denervation in pathologically-veirfied Lewy body disease (LBD) and to examine the relationship between the degree of cardiac sympathetic denervation and cardiac MIBG uptake.

Methods: Twenty-three subjects with pathologically-verified LBD (17 men and six women, mean age at death: 77.5±6.9 years) who were performed MIBG cardiac scintigraphy in life, were enrolled in this study. One subject with multiple system atrophy and one Alzheimer's disease were served as controls. The sections of the left ventricular anterior wall from the specimens were immunostained with anti-thyrosine hydroxylase (TH) and anti-neurofilament (NF) antibodies. We quantified the immunoreactive areas of the residual cardiac nerve axons and examined the relationship between the degree of cardiac nerve axons and H/M ratios on MIBG cardiac scintigraphy.

Results: 1) Cardiac MIBG uptake in the early and delayed phases were reduced in 90.9% and 95.7% of the subjects with LBD, respectively. 2) The area of TH-immunoreactive axons was correlated with the degree of cardiac MIBG uptake both in early (correlation coefficient (r) =0.57, $p<0.01$) and delayed ($r=0.54$, $p<0.01$) phases. The area of NF-immunoreactive axons was correlated with the degree of cardiac MIBG uptake both in early ($r=0.65$, $p<0.01$) and delayed ($r=0.58$, $p<0.01$) phases.

Conclusions: This study confirms that MIBG cardiac scintigraphy is a useful imaging tool to make a clinical diagnosis of LBD and can assess the degree of cardiac sympathetic denervation.

PARKINSON'S DISEASE IS DISTINGUISHABLE FROM OTHER RELATED NEURODEGENERATIVE DISORDERS ON 123-I-MIBG MYOCARDIAL SCINTIGRAPHY

R. Nakata[1], T. Yuasa[1], Y. Nakao[1], K. Ichinose[1], I. Tomita[1], H. Satoh[1], A. Satoh[1], M. Ochi[2], M. Seto[1], M. Tsujihata[1]
[1]Neurology, Nagasaki Kita Hospital, Nagasaki, Japan
[2]Radiology, Nagasaki Kita Hospital, Nagasaki, Japan

Objectives: The aim of this study was to investigate the diagnostic significance of 123-I-metaiodobenzylguanidine(MIBG) in differentiating PD from other related neurodegenerative diseases.
Methods: In total 718 patients were recruited based on their medical records, including 530 patients in the PD group(88 patients with DLB, 58 patients with Hoehn & Yahr(H&Y) stage 1(PD1), 106 patients with stage 2(PD2), 230 patients with stage 3(PD3), and 48 patients with stage 4(PD4)), 42 patients with Alzheimer's disease(AD), 19 patients with corticobasal syndrome(CBS), 33 patients with multiple system atrophy(MSA), 41 patients with progressive supranuclear palsy(PSP), 24 patients with normal pressure hydrocephalus(NPH), 18 patients with essential tremor(ET), and 13 patients with vascular parkinsonism and dementia(VP). SPECT images were obtained at 30 minutes(early image) and four hours (delayed image) after injection, and the H/M ratio, and washout rate were evaluated.
Results: The H/M ratios for the early and delayed images were compared for each disease using a one-way ANOVA(Tukey's test) . The H/M ratios of PD group was significantly lower than those in other diseases. The upper confidence limit of 99% was 2.17 on the early images, and 2.03 on the delayed images. A two-way ANOVA(Bonferroni test) showed a significantly lower delayed H/M ratio than early H/M ratio in the PD group, but not in the other groups. In the PD group, the H/M ratio decreased in the order of PD1, PD2, PD3, DLB and PD4.
Conclusions: The present findings indicate that MIBG scintigraphy can be used to clearly differentiate PD patients from those with other related disorders.

ADPD5-0553

TIMING OF ABNORMALITIES ON CARDIAC 123I-MIBG SCINTIGRAMS IN PATIENTS WITH DEMENTIA WITH LEWY BODIES

M. Seto[1], R. Nakata[1], T. Yuasa[1], Y. Nakao[1], K. Ichinose[1], I. Tomita[1], H. Satoh[1], A. Satoh[1], M. Ochi[2], M. Tsujihata[1], S. Seto[3]
[1]Neurology, Nagasaki Kita Hospital, Nagasaki, Japan
[2]Radiology, Nagasaki Kita Hospital, Nagasaki, Japan
[3]Cardiology, Inoue Hospital, Nagasaki, Japan

Objectives: Dementia with Lewy bodies(DLB) is characterized clinically by dementia, fluctuating consciousness, parkinsonism and hallucinations. This study was undertaken to investigate the relationship between abnormal MIBG scintigram findings and parkinsonism.Methods: Eighty-eight DLB patients, 56-90 years of age, with a MMSE score of 21.3±5.5, who underwent MIBG scintigraphy were enrolled. The subjects were divided into two groups, 65 patients with parkinsonism(DLB-P), and 23 patients without parkinsonism(DLB-N). SPECT images were obtained at 30 minutes(early image) and four hours (delayed image) after injection, and the H/M ratio, and washout rate were evaluated. Results: The duration of disease until the MIBG examination was not significantly different between the DLB-P and DLB-N groups. The H/M ratios on the early and delayed images, and washout rate in the DLB-P and DLB-N groups were as follows: 1.72±0.30, 1.62±0.62 (NS), 1.45±0.33, 1.30±0.21($P<0.05$), and 47.7±7.0, 50.3±4.6($P<0.05$), respectively. The frequency of visual hallucinations, non-visual hallucinations, delusions, and REM sleep behavior disorder (RBD) was not significantly different between the groups.Discussions and Conclusions: The decreased H/M ratios on delayed images and increased washout rates in the DLD-P group suggest that the presence of parkinsonism may be related to a decreased H/M ratio. However, the fact that 23 patients with DLB(26%) showed a decreased H/M ratio prior to the appearance of parkinsonism indicates that the other factors must be considered. Further investigation is therefore necessary to clarify this issue.

ADPD5-1017

IOFLUEPANE (123I) UPTAKE AND COGNITIVE DECLINE IN PATIENTS WITH PD.

M. Takagi[1], T. Kimura[1], A. Unaki[1], T. Takami[1], H. Okayasu[1]
[1]Neurology, St. Luke's international hospital, Tokyo, Japan

Background: PD are known to affect not only motor function but also cognitive ability. On the other hand, there is no useful measurement of cognitive decline other than neuropsychological examinations. Recent studies showed that iofluepane (^{123}I) injection is diagnostically effective in patients with movement disorders and dementia, and that striatal dopamine transporter binding of iofluepane (^{123}I) provides an accurate and highly sensitive measure of dopamine degeneration. However, it is uncertain whether information on dopamine transporter has role in describing cognitive decline in Parkinson's disease.
Objective: To elucidate the relationship of cognitive function and dopamine degeneration.
Method: A series of 9 patient with Parkinson's disease were included. Disease duration, age, and the maximum value of modified Hoehn and Yahr staging score (H-Y score) were obtained to know disease progression and disease burden. To measure cognitive performance, Mini-Mental State examination (MMSE) and Addenbrook's cognitive examination-revised (ACE-R) were performed. Brain MRI were performed to exclude cerebral vascular diseases or other causes of Parkinsonism. In addition, we analysed striate binding ratio (SBR), which is obtained from iofluepane (^{123}I)-SPECT, and correlation coefficient were calculated.
Result: SBR showed strong positive correlation to ACE-R ($r=0.77$, $p<0.05$) and MMSE ($r=0.73$, $P<0.05$). We also found strong negative correlation to disease duration ($r=-0.80$ $p<0.05$) but there were no correlation to H-Y score.
Conclusion: Iofluepane (^{123}I)-SPECT is possibly useful to know the disease progression and SBR will help to confirm the possible decline of cognitive performance in patients with Parkinson's disease.

06m. Imaging & Biomarkers: SPECT imaging

ADPD5-1020

[(123)I]FP-CIT SPECT AND [(123)I]MIBG SCINTIGRAPHY BETWEEN LEWY BODY DISEASE AND OTHER NEURODEGENERATIVE DISORDERS

M. Yoshita[1], Y. Odake[1], M. Hosokawa[2], H. Sakamoto[2]
[1]Neurology, National Hokuriku Hospital, Nanto, Japan
[2]Psychiatry, National Hokuriku Hospital, Nanto, Japan

Objectives: To compare myocardial scintigraphy imaging using ^{123}I-metaiodobenzylguanidine (MBG) scintugraphy and striatal dopaminergic imaging using N-(3-fluoropropyl)-2β-carbomethoxy-3β-(4-^{123}I-iodophenyl)nortropane (FP-CIT) single photon emission computed tomography (SPECT) in patients with Lewy body disease (LBD).
Methods: Twenty patients (Parkinson disease (PD);n=5, Dementia with Lewy bodies (DLB); n=5, idiopathic REM sleep behaviour disorder (RBD);n=4, Alzheimer disease (AD);n=3, Progressive supranuclear palsy (PSP);n=3) were prospectively investigated. All patients performed both methods for differential diagnosis between LBD and other neurodegenerative disorders.
Results: There was no significant difference between these two methods in patients with LBD. The overall sensitivity, specificity, accuracy, positive and negative predictive values in LBD were 90%, 92%, 90%, 90%, 90%, respectively for ^{123}I-MIBG scintigraphy. For ^{123}I-FP-CIT SPECT, the overall sensitivity, specificity, accuracy, positive and negative predictive values in LBD were 90%, 58%, 72%, 70%, 78%, respectively.
Conclusions: LBD usually present both myocardial and striatal dopaminergic impairments. ^{123}I-MIBG scintigraphy method provides a very high diagnostic accuracy for differentiating between LBD and other neurodegenerative disorders, which is clearly superior to the accuracy of ^{123}I-FP-CIT SPECT. The combination of ^{123}I-MIBG scintigraphy and ^{123}I-FP-CIT SPECT imaging may lead to a improvement in distinguishing LBD from other neurodegenerative disease.

ADPD5-1139

INITIAL NEGATIVE DAT SPECT IN DEMENTIA WITH LEWY BODIES: A DLB SUBTYPE?

J. van der Zande[1], J. Booij[2], P.G.H.M. Raijmakers[3], A.W. Lemstra[1]
[1]Neurology, VU University, Amsterdam, Netherlands
[2]Nuclear Medicine, Academic Medical Center, Amsterdam, Netherlands
[3]Nuclear Medicine, VU University, Amsterdam, Netherlands

Objective

Low striatal dopamine transporter (DAT) binding uptake on SPECT imaging is a suggestive feature in diagnostic criteria for dementia with Lewy bodies (DLB). Little is known about patients meeting criteria for probable DLB with normal DAT-scans (clin+DAT-).There has been no record of follow-up scans in these patients. This study aims to describe these patients and compare them to DLB patients with positive DAT-scans (clin+DAT+).

Methods

Sixty-seven DLB-patients with DAT-scans ([^{123}I]FP-CIT SPECT) available were selected from the Amsterdam Dementia Cohort. Stable diagnoses were confirmed based on clinical follow-up. Clin+DAT- patients were checked for follow-up imaging. DAT-scans were evaluated independently by two nuclear medicine physicians. Clin+DAT- patients were matched for age and disease duration 1:2 with clin+DAT+ patients. Cross-sectional data on cognition, extrapyramidal signs, hallucinations, fluctuations, orthostatic hypotension and REM-sleep behavior disorder (RBD) were compared.

Results

Seven DAT-scans were reported negative (10.4%). 43% Of clin+DAT- patients presented with extrapyramidal signs (vs 64% of clin+DAT+ patients), 57% with orthostasis (vs 36%), 86% with hallucinations (vs 42%), 57% with fluctuations (vs 50%) and 100% with (suspected) RBD (vs 42%). MMSE scores were comparable. In five clin+DAT- patients, a second DAT-scan was performed. All follow-up scans were abnormal, consistent with DLB diagnosis.

Discussion

This study is first to describe a subset of DLB patients with initial negative DAT-scans, which turned positive during disease progression. We hypothesize that clin+DAT- cases could represent a subtype of DLB with possibly a different severity or spread of alpha-synuclein pathology. Recognizing this phenotype may be important for clinical management.

METABOLIC ALTERATIONS IN THE RIGHT HIPPOCAMPUS DETECTED IN VIVO BY 1H MR SPECTROSCOPY IN THE MPTP MODEL OF PD

M. Zaremba[1], J. Orzel[2], M. Fiedorowicz[2], M. Swiatkiewicz[2], P. Grieb[2]
[1]Department of Experimental and Clinical Pharmacology Centre for Preclinical Research and Technology (CePT), Medical University of Warsaw, Warsaw, Poland
[2]Department of Experimental Pharmacology, Mossakowski Medical Research Centre, Warsaw, Poland

Objective: To determine the effects of MPTP-induced nigrostriatal neurodegeneration on the biochemical profile in the hippocampi (Hpc) in mice.
Methods: One year old male C57Bl/10Tar mice were injected *i.p.* with MPTP (40 mg/kg) or equivalent vehicle volume. One week later brains of the control and MPTP-injected mice (n=10/group) were scanned with Bruker BioSpec 70/30 Avance III system equipped with 7T magnet. Structural MR images were acquired with T2-weighted TurboRARE sequence. Spectroscopic recordings were then carried out in two volumes of interest (1.6 x 1.8 x 2.7 mm^3 each) comprising left and right Hpc. Metabolite concentrations were estimated with LC model and expressed as ratios to total creatine concentration.
Results: Compared to controls, MPTP mice displayed significantly lower glutamate (Glu) and combined glutamate+glutamine (Glx) resonance signals and slightly lower glycerophosphocholine + phosphocholine (GPC+PCh) signals in the right Hpc. However, no significant differences were observed in the left Hpc.
Conclusions: Reduced Glu and GPC+PCh in the right Hpc may signify deficits in neuronal metabolism and/or firing rate and possible neuronal shrinkage toward the right hippocampus.

ADPD5-0418

COMPLEMENTARY ROLE OF 99MTC-TRODAT-1 SPECT AND FDG-PET CT: REDEFINING THE MANAGEMENT OF PATIENTS WITH PARKINSON'S DISEASE AND OTHER MOVEMENT DISORDERS.

R. Verma[1], R. Ranjan[2], P. Pankaj[1], E. Belho[1], A. Jain[1]
[1]Nuclear Medicine and PET CT, Sir Ganga Ram Hospital, Delhi, India
[2]Neurology, Sir Ganga Ram Hospital, Delhi, India

Objectives: To investigate the potential usefulness of 99mTc-TRODAT-1 SPECT and FDG PET CT imaging in the evaluation of subjects with suspected or diagnosed parkinson's disease and other movement disorders with the following objectives:

· Documenting the complementary role of 99mTc-TRODAT-1 and FDG PET CT imaging in various neurodegenerative movement disorders
· Early diagnosis of parkinson's disease
· Pre clinical diagnosis of parkinson's disease in high risk groups
· Differentiation of mono symptomatic tremor of parkinson's disease from other causes
· Differential diagnosis of different parkinson plus syndromes

Methods: 200 patients with movement disorders and 50 age matched healthy volunteers were evaluated. 99mTc-TRODAT-1 was prepared from a lyophilized kit and SPECT imaging performed using a double-head camera. Uptake in the striatum and its sub regions was calculated and compared with that of healthy volunteers. 150 patients were evaluated by FDG PET CT on a separate day by GE Discovery STE PET CT system.

Results: Reduced striatal uptake of 99mTc-TRODAT-1 was found in idiopathic parkinson's disease subjects with a significant rostro-caudal gradient. Significant reduction of 99mTc-TRODAT-1 was found in atypical parkinson's disease and other parkinson plus syndromes. FDG PET CT images showed variable striatal FDG uptake in subjects suspected or diagnosed as idiopathic Parkinson's disease. However, different patterns of cortical/sub cortical hypo metabolism was noted in parkinson plus syndromes.

Conclusion: 99mTc-TRODAT-1, in conjunction with FDG PET CT, may serve as a useful imaging agent for the early detection of parkinson's disease and differentiation of different parkinson plus syndromes.

CORPUS CALLOSUM DAMAGE AND MOTOR FUNCTION IN PD

S. Galantucci[1], F. Agosta[1], I. Stankovic[2], I. Petrovic[2], T. Stojkovic[2], G. Comi[3], V. Kostic[2], M. Filippi[1]

[1]Neuroimaging Research Unit, Scientific Institute and University Hospital San Raffaele, Milan, Italy

[2]Clinic of Neurology, University of Belgrade, Belgrade, Serbia

[3]Department of Neurology, Scientific Institute and University Hospital San Raffaele, Milan, Italy

Objective: To investigate corpus callosum (CC) damage and its relationship with motor impairment in PD.

Methods: We enrolled 173 PD (98 with Hoehn and Yahr score [HY]=1-1.5, 37 with HY=2-2.5, 29 with HY=3-3.5, 9 with HY=4-5) and 39 healthy controls (HC). Diffusion tensor (DT) MRI tractography was performed to obtain the CC and its main three partitions: CC-genu, CC-body, and CC-splenium. Fractional anisotropy (FA) and mean diffusivity (MD) were measured. Age-adjusted group comparisons were assessed. Pearson's correlations were used to explore the relationship between CC DT MRI metrics and UPDRS III score.

Results: All PD showed decreased FA and increased MD of the whole CC and its partitions. Such a damage was more marked with increasing PD severity, being only mild in PD with HY=1-1.5 (prevalent in CC-body) and severe (similar in all CC partitions) at the later stages of the disease. UPDRS III score correlated significantly ($p<0.001$) with FA of CC, CC-genu, CC-body, and CC-splenium and MD of CC, CC-body, and CC-splenium.

Conclusions: PD is associated with damage to the CC that increases with disease worsening. In PD patients, the best predictor of CC deterioration of motor functions is the involvement of the CC-body, which includes the transcallosal motor tracts. Assessing CC alterations may improve the understanding of the pathogenetic mechanisms associated with motor impairment in PD.

WHITE MATTER MICROSTRUCTURAL DAMAGE AND COGNITIVE IMPAIRMENT IN PARKINSON'S DISEASE

S. Galantucci[1], F. Agosta[1], F. Caso[1], I. Stankovic[2], I. Petrovic[2], T. Stojkovic[2], G. Comi[3], V.S. Kostic[4], M. Filippi[1]

[1]Neuroimaging Research Unit, Scientific Institute and University Hospital San Raffaele, Milan, Italy

[2]Clinic of Neurology Faculty of Medicine, University of Belgrade, Belgrade, Serbia

[3]Department of Neurology, Scientific Institute and University Hospital San Raffaele, Milan, Italy

[4]Clinic of Neurology Faculty of Medicine, University of Belgrade, Milan, Serbia

Objectives: To investigate white matter (WM) damage and its relationship with cognitive impairment in Parkinson's disease (PD).

Methods: We enrolled 168 PD patients (105 without cognitive impairment [PD-ncog]; 48 with MCI [PD-MCI] and 15 with dementia [PD-DEM]), and 41 healthy controls (HC). PD and controls underwent a clinical and neuropsychological evaluation. Tract-based spatial statistics were used to perform a voxel-wise analysis of fractional anisotropy (FA) and mean diffusivity (MD), adjusted for subject's age. PD were compared with controls and between each other.

Results: All PD showed decreased FA and increased MD in the splenium of corpus callosum (CC), right frontal WM and internal capsule. In PD-MCI, WM damage spreads to anterior regions of CC, bilateral frontal, anterior temporal and parietal WM. WM damage increased in severity in PD-DEM, involving frontal and parietal WM . PD-DEM *vs* PD-ncog showed alterations in the body of CC There were no differences in DT MRI metrics in PD-DEM *vs* PD-MCI.

Conclusions: WM damage appears to be limited to the splenium of CC and to part of the right frontal WM in PD-ncog. WM damage in PD becomes more severe with worsening of cognitive performance. WM damage spreads in the anterior regions in PD-MCI, showing the maximum severity in PD-DEM patients. Assessing WM alterations may improve the understanding of the mechanisms associated cognitive impairment in PD

[3]Laboratory of Movement Analysis,
Scientific Institute and University Hospital San Raffaele, Milan, Italy

[4]Department of Neuroradiology CERMAC,
Scientific Institute and University Hospital San Raffaele, Milan, Italy

Objective. To assess brain functional and structural alterations in Parkinson's disease patients with freezing of gait (PD-FoG).

Methods. T1-weighted, diffusion tensor (DT) MRI and resting state (RS) fMRI were obtained from 22 PD-FoG patients and 36 controls. Grey (GM) and white matter (WM) damage were assessed with SPM8 and FSL. RS fMRI data were analyzed using a model free approach investigating sensorimotor and cognitive networks. MRI differences between patients and controls, and the relationships between MRI and clinical/cognitive variables were assessed.

Results. Compared with controls, patients showed WM damage in the corpus callosum and cingulum, WM underneath frontal, parietal and occipital cortices and corticospinal tracts, bilaterally. GM volume loss was not detected in patients relative to controls. RS fMRI analysis showed that PD-FoG is associated with a decreased functional connectivity relative to controls: in the bilateral superior frontal gyrus and precuneus within the default mode network; in the bilateral insula, right cingulum, left thalamus and putamen within the ventral-attentional network; and in the left inferior occipital gyrus within the visual-associative network. More severe motor disability and lower cognitive scores were associated with greater WM damage and reduced functional connectivity.

Conclusions. PD-FoG patients showed a widespread pattern of WM damage and altered functional connectivity involving mainly the frontal and parietal regions. MRI alterations were related with patient clinical and cognitive profiles, supporting the theory of FoG as the result of poor integration between motor programming, visuo-spatial and attentional abilities.

ADPD5-0635
DELTA BAND EEG ACTIVITY IS INCREASED IN INCIDENT PD DEMENTIA
J. Caviness[1], J. Hentz[2], C. Belden[3], H. Shill[4], M. Sabbagh[4], J. Powell[3], E. Driver-Dunckley[1], C. Adler[1]

[2]Biostatistics, Mayo Clinic, Scottsdale, USA
[3]Neuropsychology, Banner-Sun Health Research Institute, Sun City, USA
[4]Neurology, Banner-Sun Health Research Institute, Sun City, USA
Objectives: We previously showed that in PD, low EEG background rhythm predicts future decline in cognition. Our objectives: 1) determine if spectral EEG measures changed with incident PD dementia, and 2) compare the degree of change among the spectral EEG measures.
Methods: 71 PD subjects participated as part of Arizona Study of Aging and Neurodegenerative Disorders which utilizes annual neuropsychological and biennial EEG evaluation. We excluded subjects with dementia at baseline and EEG examinations with deep brain stimulation and barbiturate or benzodiazepine use. Initial and follow-up EEG (mean 3.9 years apart) were analyzed for EEG measures of background rhythm frequency (BRF) and relative power (percentage) in delta (2.5-4 hz), theta (4-8 hz), alpha (8-13 hz), and beta (13-30 hz) bands. Neuropsychological evaluation was used to determine PD dementia by movement disorder society criteria. Change from baseline among subjects with incident dementia was compared to that of subjects without incident dementia by using the two-sample *t* test.
Results: Delta increased by a mean of 6.9 % (SD 8.3) among the 13 subjects who developed dementia, versus only 1.4 % (SD 4.6) among the 58 subjects who did not develop dementia (P=.002). The change in BRF, theta, alpha, and beta did not differ between the same groups.
Conclusions: Delta bandpower showed a significant specific increase among spectral EEG measures in those subjects that developed dementia among spectral EEG measures. In addition to being used as a potential biomarker, the pathophysiological significance of EEG delta activity in PD should be studied.

ELECTRO-PHYSIOLOGICAL DIFFERENTIAL DIAGNOSTIC MARKER FOR AD AND DLB

K. Johnsen[1], G. Johannesson[1], M. Johannsson[1], N. Blin[1], A. Emilsdottir[1], T. Gudmundsson[2], J. Snaedal[2], B. Einarsson[2]
[1]Research and Development, MentisCura, Reykjavík, Iceland
[2]Geriatrics, Landspitali University Hospital, Reykjavík, Iceland

Objective
Demonstrate the applicability and properties of an electro-physiological based biomarker for differential diagnosis of AD and DLB.
Methods
In a database, EEGs from 209 healthy (NRM), 22 individuals with DLB, 26 individuals with PDD, and 560 clinical subjects of other types than PDD and DLB, have been entered. Applying statistical pattern recognition (SPR) to a large set of EEG features classifiers contrasting clinical cohorts in a pairwise manner are developed. For each classifier, the SPR finds an optimal combination of the EEG features which separate the two groups under consideration. The accuracy, sensitivity, and specificity of each classifier are estimated using 10–fold cross validation.
Results
The receiver operating characteristic (ROC) curves for the “NRM vs clinical“ classifier system have the following qualities: area under curve (AUC) is 0.91(0.04), specificity (SPE) is 0.85(0.06), sensitivity (SEN) is 0.85(0.04), and the accuracy (ACC) is 0.85(0.05). The standard deviation is given in parentheses. For the “PDD/DLB vs other clinical types“ classifier system the results are: AUC=0.92(0.01), SPE=0.84(0.05), SEN=0.88(0.03), and ACC=0.86(0.02). Applying the same methodology to the DLB and PDD groups showed no separation.
Conclusion
We have introduced an EEG based biomarker for PDD and DLB combined into one group that shows good sensitivity and specificity and it is argued that this method can be a good addition to available methods. EEG is a standard method that is inexpensive and readily available and is therefore attractive for use in various settings.

ADPD5-1532
INVESTIGATIONS INTO SYNTACTIC PROCESSING AND ITS RELATIONSHIP TO GENERAL COGNITION IN PD
M. Ueno[1], L. Kemmer[2], C. Barkley[3], M. Kutas[1], S. Suwazono[4], V. Filoteo[5], I. Litvan[6]

[3]Linguistics, University of California San Diego, La Jolla, USA
[4]Neurology, National Hospital Organization Okinawa National Hospital, Ginowan, Japan
[5]Psychiatry, University of California San Diego, La Jolla, USA
[6]Neurosciences, University of California San Diego, La Jolla, USA
1. Objective:
Recent work has demonstrated language deficits in PD. Friederici et al. (2003), for example, reported reduced P600 amplitudes -- an event related brain potential (ERP) component related to syntax -- to word category violations in speech in PD, and concluded that basal ganglia circuitry is crucial for late/integrative syntactic processes. We assess the generality of this conclusion by examining the processing of morphosyntactic violations during reading in combination with performance on an extensive neuropsychological battery.
2. Methods:
We recorded the EEG while individuals with PD (Mean MoCA=26.2) and age-matched controls read sentences containing morphosyntactic violations (and grammatical controls). We correlated P600 effect (violations minus controls) amplitudes and latencies with various neuropsychological measures.
3. Results:
Statistically indistinguishable P600 effects were observed in both groups. P600 parameters for both groups were significantly correlated with Executive Function/Working Memory (EF/WM) scores: higher scores were associated with earlier and larger P600 effects (PD, r=.8~.9; controls, r=.6~.7).
4. Conclusions:
We found no evidence for P600 effect amplitude reductions in individuals with PD with severity equal or greater to those in previous reports. Preliminary analyses suggest that in PD syntactic P600 amplitude and latency are better predicted by scores on tests of EF/WM than grammaticality judgment accuracy. This suggests that the link between the basal ganglia and syntactic processing is more complicated than presumed to date.

EEG FINDINGS IN DEMENTIA WITH LEWY BODIES, ALZHEIMER'S DISEASE AND DEMENTIA ASSOCIATED WITH PD.

A. Vergallo[1], F. Baldacci[1], F.S. Giorgi[1], R. Ceravolo[1], L. Kiferle[1], P. Borelli[2], U. Bonuccelli[1]

[1]clinical and experimental medicine neurology unit, university of pisa, Pisa, Italy

[2]neurology unit, versilia hospital, Viareggio Lucca, Italy

Objectives

We tried to elucidate the diagnostic value of conventional electroencephalogram (EEG) in the clinical overlap between dementia with Lewy bodies (DLB), dementia associated with PD and Alzheimer's disease (AD).

We used Grand Total EEG score (GTEs), a simple EEG scoring method.

Methods

20 patients with mild AD, 26 with DLB and 26 with PDD were studied with EEG. GTEs was calculated for every patient. The three groups were compared in terms of GTEs, age, neuropsychological assessmens, disease onset and duration, drug exposure, etc..

Results

We found a clear-cut difference in the GTEs between DLB and PDD. There was a difference in median GTE score of DLB, PDD and AD subjects.

Frontal intermittent rhythmic delta activity (FIRDA), was similar in DLB and PDD, but was absent in AD patients.

Conclusions

DLB and PDD showed marked electroencephalographic differences in term of GTEs. GTEs and FIRDA were significatively different between patients with DLB and PDD compared to AD, according to previous reports.

From a strictly clinical point of view, EEG with the GTEs may help to orientate clinicians towards the correct diagnosis and management of these dementia disorders.

SLEEP ALTERATIONS AS A BIOMARKER OF PARKINSON DISEASE.

A. Rachalski[1], D. Caudal[2], A. Bogstedt[1], A. Björklund[3], P. Svenningsson[2], E. Åberg[1]
[1]AstraZeneca Personalized Healthcare and Biomarkers, Translational Science Centre, Solna, Sweden
[2]Clinical Neuroscience, Laboratory of Translational Neuropharmacology, Solna, Sweden
[3]Department of Experimental Medical Sciences, Wallenberg Neuroscience Center, Lund, Sweden

Background: Disturbed sleep is a frequent complain of patients with Parkinson Disease (PD; 1) but the relationship and underlying mechanisms remain unclear. The aim of our study is to understand how PD can impact sleep and to select the best sleep parameter as a biomarker for PD.
Methodology: Rats were injected bilaterally with AAV- α-Synuclein in Substantia Nigra and compared to AAV-GFP control animals (2). Both groups were implanted with electroencephalographic (EEG) and electromyographic (EMG) electrodes. Sleep architecture and spectral profile of the vigilance states were analyzed over 24h.
Results: Five weeks after injection, the AAV- α-Synuclein rats presented a fragmented sleep pattern compared to the AAV-GFP littermates with disruption of the spectral profiles. Moreover, these animals have an important increase of muscle tone during their sleep.
Conclusion: Together, our results demonstrate that AAV- α-Synuclein rats have similar alteration of their sleep pattern as PD patients and confirm the model as translationally relevant for PD. This model will then be used to characterize the development of sleep disturbances as an early marker of disease in correlation with α-Synuclein accumulation. In addition, our data highlight the importance of sleep alteration in PD and validate the potential of EEG/sleep characteristics to provide a valuable animal-clinical interface in PD.

ADPD5-1503

REDUCTIONS IN BRAIN PHOSPHOCREATINE LEVELS ARE SIMILAR IN PD AND METHAMPHETAMINE DEPENDENCE

Y. Sung[1], D. Yurgelun-Todd[1], X. Shi[1], P. Renshaw[1]
[1]Department of Psychiatry, Univerity of Utah, Salt Lake City, USA

Objectives: Accumulation of α-synuclein plays a critical role in early-onset PD. Overexpression of α-synuclein is toxic to neurons and depletes striatal dopamine, causing oxidative stress as well as mitochondrial damage (Kirik, 2002). Interestingly, methamphetamine, a potent psychostimulant, also produces significant overexpression and conformational changes of α-synuclein (Tavassoly, 2012). Further, converging evidence implicates a similar pattern of mitochondrial dysfunction associated with PD and methamphetamine toxicity. Thus, this study measured *in vivo* high energy phosphorus metabolites in methamphetamine users to compare profiles of oxidative phosphorylation between methamphetamine toxicity and PD.

Methods: Phosphorus-31 magnetic resonance spectroscopy (^{31}P-MRS) data were acquired in 56 methamphetamine-dependent subjects (age=33±7) and 23 healthy comparison subjects (age=31±7). Chemical shift imaging was completed on a 3-Tesla scanner. Bilateral basal ganglia spectroscopic data were quantified using AMARES.

Results: In the basal ganglia, methamphetamine users had significantly decreased (-6.2%, p=0.001) phosphocreatine (PCr, an indicator of high energy phosphate buffer stores) levels compared to healthy controls. This finding was similar to prior reports of PD studies, in which reduced PCr levels in early and advanced PD were consistently noted.

Conclusions: These preliminary data are consistent with oxidative damage that has been reported in both PD and methamphetamine addiction. Interestingly, a recent large-scale epidemiologic study reported that the risk of Parkinson's disease is significantly higher in methamphetamine users (Callaghan, 2012), further supporting our findings. Due to the oxidative stress observed in PD and MA toxicity, neuroprotective agents may have benefits through a common pathophysiology. Further evaluation of novel interventions for maintaining high energy phosphate is warranted.

ADPD5-1758
INCREASED THALAMIC GABA LEVELS CORRELATE WITH PD SEVERITY
U. Dydak[1], S. Dharmadhikari[1], S. Snyder[1], S.E. Zauber[2]
[1]School of Health Sciences, Purdue University, West Lafayette, USA
[2]Department of Neurology, Indiana University School of Medicine, Indianapolis, USA
Objectives: The loss of dopamine producing cells in PD leads to alterations in basal ganglia pathway firing patterns. We used Magnetic Resonance Spectroscopy (MRS) to determine if basal ganglia gamma-aminobutyric acid (GABA) levels are altered and related to disease severity in unmedicated patients.
Methods: Subjects were divided into two groups: PD patients (mild-to-moderate PD, n=18, age: 62.67±8.27 y) and controls (n=15, age: 59.67±8.62 y). Three PD subjects were medication-naïve while the rest withheld medication for at least 12 hours before testing. Disease severity was measured using the Unified Parkinson's Disease Rating Scale (MDS UPDRS-III). All subjects underwent MRS on a 3-T Siemens Trio MR scanner. J-edited GABA MRS data was acquired from 25 mm x30 mm x25 mm volumes of interest placed in the right thalamus and right striatum. GABA levels were quantified and expressed as ratios to creatine (Cr).
Results: GABA/Cr was significantly higher (p=0.018) in the thalamus of the PD group (0.31±06) compared to the control group (0.26±05). No significant group differences were seen in striatal GABA levels. A significant positive correlation was found between thalamus GABA/Cr and UPDRS-III scores (p=0.029, Spearman's rho =0.375).
Conclusion: The increased inhibitory output from the internal pallidal segment in the indirect pathway is responsible for hypokinetic symptoms in PD and this is reflected as higher GABA values detected in the thalamus by MRS. The correlation of thalamic GABA measured by MRS with UPDRS scores indicates that GABA MRS holds potential to be a non-invasive biomarker for assessing PD severity.

ADPD5-0235
CLINICAL CORRELATES OF RAPID EYE MOVEMENT SLEEP WITHOUT ATONIA IN PARKINSON'S DISEASE
Y. Shen[1], K.P. Xiong[1], J. Li[1], C.J. Mao[1], J. Chen[1], P.C. He[1], J.Y. Huang[1], Y.P. Dai[1], W.F. Luo[1], C.F. Liu[1]
[1]Department of Neurology, The Second Affiliated Hospital of Soochow University, Suzhou, China
Objective: Rapid eye movement (REM) sleep behavior disorder (RBD) is characterized by REM sleep without atonia (RWA) and is associated with Parkinson's disease (PD) progression.
Methods: We quantified tonic and phasic RWA by performing polysomnography (PSG) in 198 PD patients and correlated the findings with their clinical characteristics.
Results: All PD patients were categorized into quartiles of tonic and phasic RWA. Although none of the differences were significant, we found that patients with higher RWA tended to be older, had longer PD disease durations, were more likely to have RBD, had higher Hoehn & Yahr (H&Y) stages, took higher doses of parkinsonian medications, had poorer cognition, experienced worse quality of life, and had more severe sleep disturbances. After adjusting for age, sex, and PD duration, patients in the highest quartile of RWA were more likely to be severe PD patients (H&Y scale ≥3.0) compared to those in the lowest quartile.
Conclusions: These findings provide evidence that RWA was associated with PD severity, especially with regard to tonic muscle activity.

06r. Imaging & Biomarkers: other

ADPD5-0953

CEREBROSPINAL FLUID LEVELS OF YKL-40 PROTEIN IN DEMENTIA WITH LEWY BODIES.

E. Morenas-Rodríguez[1], D. Alcolea[1], M. Carmona-Iragui[1], I. Sala[1], M. Suárez-Calvet[1], M.B. Sánchez-Saudinós[1], R. Blesa[1], J. Clarimón[1], J. Fortea[1], A. Lleó[1]
[1]Neurology, Institut de Recerca Biomèdica - Hospital de Sant Pau, Barcelona, Spain

Objectives: to investigate the cerebrospinal fluid levels of YKL-40, an inflammatory biomarker, in Dementia with Lewy bodies (DLB) and prodromal DLB (prod-DLB), and its relationship with Alzheimer´s disease (AD) biomarkers in this group of patients.
Methods: We defined prod-DLB as mild cognitive impairment (MCI) with at least one suggestive feature of underlying synucleinopathy (Parkinsonism/REM-sleep behaviour disorder/visual hallucinations). We measured Ab42, total-tau, p-tau, and YKL-40 in CSF from 145 participants with amnestic MCI (aMCI, n=43), AD (n=57), DLB (n=15), prod-DLB (n=6) and cognitively normal controls (n=24). Biomarkers were compared between groups defined by clinical diagnosis or CSF-profile (tau/Ab42 ratio above or below 0.52)
Results: CSF YKL-40 was higher in prod-DLB patients compared to DLB (299.06 vs. 230.79, p=0.008). The prod-DLB group showed higher YKL-40 than controls (299.07 vs. 208.25, p=0.001) and a trend towards higher levels compared to aMCI (299.07 vs. 256.13, p=0.079). No difference was detected in YKL-40 between DLB patients and controls (p=0.20), although there was a trend towards lower levels in DLB compared to AD (230.79 vs. 258.36, p=0.079). Within the composite group DLB/prod-DLB, there were no differences in YKL-40 levels according to CSF-profile (tau/Ab42 ratio above or below 0.52, p=0.247). YKL-40 levels correlated with total-tau and p-tau in all groups.
Conclusion: YKL-40 is increased in CSF in prodromal DLB, suggesting that inflammation is an early process in the disease. This feature is also observed in AD and aMCI. The YKL-40 levels do not seem to be affected by the AD underlying co-pathology in the DLB/prod-DLB group.

PHOSPHOLIPID BINDING FOR ANALYSIS OF ERYTHROCYTE ALPHA-SYNUCLEIN AND DIAGNOSIS OF PARKINSON'S DISEASE

R. Sharon[1], S. Abd-Elhadi[1], A. Honig[2], D. Simhi-Haham[1], M. Schechter[1], E. Linetsky[2], T. Ben-Hur[2]

[1]Biochemistry and Molecular Biology, Hebrew University Faculty of Medicine, Jerusalem, Israel

[2]Neurology, Hadassah Medical Center, Jerusalem, Israel

A quantitative phospholipid-ELISA assay was developed to investigate the pathophysiology of alpha-Synuclein (a-Syn) expressed in red blood cells (RBC). The assay is based on the biochemical property of a-Syn to specifically bind acidic phospholipids for its capture from samples. We though to study whether RBC-expressed a-Syn, detected by its ability to bind phospholipids, may differ between patients with PD and healthy controls. Twenty one individuals with PD and fifteen healthy controls, with similar demographic features, were recruited to this study. Total and proteinase K-resistant a-Syn levels were determined in samples of packed red blood cells (PRBCs) by the phospholipid-ELISA assay.

The results indicated a significantly lower ratio of total-to-proteinase K-resistant a-Syn levels in PD patients than in the healthy control group. However, there was considerable overlap between the two groups. Of note, the higher levels of proteinase-K-resistant a-Syn detected in RBC from PD patients may support an involvement of systemic mechanisms in the pathophysiology of PD.

We concluded that the biochemical property of a-Syn that enables it to bind phospholipids and the occurrence of proteinase K-resistant a-Syn in PRBCs, provide promising tools for the diagnosis of PD.

ADPD5-1074

CHARACTERISATION OF COGNITIVE DECLINE OVER 5 YEARS IN AN INCIDENT PARKINSON'S DISEASE COHORT: RESULTS FROM THE CAMPAIGN STUDY

C.J. McAllister[1], C.H. Williams-Gray[2], S.L. Mason[2], T. Foltynie[3], R.A. Abbott[1], P.J. Nathan[1], R.A. Barker[2]

[1]Cambridge Cognition, Cambridge Cognition, Cambridge, United Kingdom

[2]John van Geest Centre for Brain Repair, University of Cambridge, Cambridge, United Kingdom

[3]Institute of Neurology, University College London, London, United Kingdom

Objectives

Parkinson's disease (PD) is associated with cognitive deficits in memory, attention and executive function. However, little is known about the pattern of decline over time, which is important for selecting appropriate test outcomes for disease and symptom modifying treatment trials.

Methods

In this population-based cohort of incident PD patients, detailed neuropsychological assessments were performed at baseline, 3.5 years and 5 years from diagnosis. Participants were assessed with pentagon copying, phonemic and semantic verbal fluency and three CANTAB® tasks measuring memory (Spatial Recognition Memory (SRM), Pattern Recognition Memory (PRM)), and executive function (One Touch Stockings of Cambridge (OTS)). Participants also completed the MMSE®.

Results

MMSE® scores declined over five years (baseline, N=142; effect size =-0.93) as did pentagon and semantic fluency scores (effect sizes= -0.13 and -0.19 respectively). In the more cognitively-able participants who completed all tasks over all visits ('completers', n=71) there was minimal decline in MMSE® scores (effect size= -0.1) but significant decline in CANTAB® SRM (effect size= -0.38) and OTS (effect size= -0.33). Semantic fluency scores declined for completers (effect size= -0.16), although there was significant improvement in PRM.

Conclusions

A decline in SRM and OTS was detected in the more cognitively-able subgroup, suggesting that this group show impairments that are frontal-specific. These data suggest that although MMSE® is sensitive to decline in cognition in PD, it does not detect decline in more-able, non-demented patients. Findings are discussed in relation to depression, treatment and QoL outcomes.

ADPD5-1104

PRELIMINARY DEMONSTRATION OF THE BIOMARKER POTENTIAL OF METAL ACCUMULATION MEASURED WITH QUANTITATIVE SUSCEPTIBILITY MAPPING (QSM) IN PARKINSON'S DISEASE

J. Acosta-Cabronero[1], A. Cardenas-Blanco[1], G. von Hartrott[2], I. Galazky[2], P.J. Nestor[1]
[1]Brain Plasticity and Neurodegeneration Group,
German Center for Neurodegenerative diseases (DZNE), Magdeburg, Germany
[2]Department of Neurology, Otto-von-Guericke University, Magdeburg, Germany

OBJECTIVE

Determine the PD landscape of metal overload with QSM—a new MRI contrast—in relation to white matter (WM) alterations probed with DTI and grey matter loss with structural MRI, with investigation of its biomarker value.

METHODS

Eight PD patients—age = 63(9)—and thirty-four matched controls were recruited. All MRI measurements were performed in a Siemens Verio 3T scanner. T2 images were inspected to exclude vascular pathology. Structural MPRAGE scans were used for FreeSurfer-v5.3 cortical thickness analysis, SPM12b-based voxel-based morphometry and FSLv5.0-FIRST deep grey matter nuclei volumetry. Parametric DTI maps—obtained from an optimised diffusion-imaging scheme—were introduced in TBSS for a group-level evaluation of WM integrity. QSM—sensitive to metal overload (predominantly that from tissue iron), deoxygenated-blood products and calcifications—was calculated and analysed with *state-of-the-art* methods (Acosta-Cabronero et al. 2013).

RESULTS

Magnetic susceptibility was profoundly increased in PD in the globus pallidus (almost complete group separation, see plot). Strong abnormalities were also observed in the substantia nigra and red nucleus while the insular and motor cortices were also affected at $P_{FWE}<0.05$. Only statistically weak DTI (meso-striatal) and structural abnormalities (motor cortex) were found.

CONCLUSIONS

Metal deposition measured with QSM shows strong potential as an imaging biomarker for the diagnosis of PD unlike more established MRI measures which only show weak group-level changes.

[3]MIRECC and Department of Psychiatry and Behavioral Sciences, VA-Puget Sound Health Care System/University of Washington, Seattle, USA
[4]MIRECC, VA-Puget Sound Health Care System, Seattle, USA
[5]MIRECC and Psychiatry and Behavioral Sciences, VA-Puget Sound Health Care System/University of Washington, Seattle, USA
[6]GRECC and Neurology, VA-Puget Sound Health Care System/University of Washington, Seattle, USA
[7]Pathology, University of Washington, Seattle, USA
[8]Genomics Institute, Cleveland Clinic, Cleveland, USA

Objectives: Development of biomarkers for early PD continues to be an important area of research, with the eventual goal of identifying patients for early therapeutic intervention. Previous studies have suggested that certain catecholamines in the cerebrospinal fluid (CSF) might serve as biomarkers for PD. To further examine the potential use of CSF catecholamine levels as a biomarker for PD we studied both early untreated and treated PD patients.
Methods: CSF was obtained from normal controls and PD patients participating in several studies of aging and PD. Catecholamines and metabolites were purified from CSF using the alumina extraction method, separated by HPLC, and measured using electrochemical detection.
Results: Three groups of patients were studied: controls (N=40, mean age 63 years); never treated PD (N=20, mean age 63 years); treated PD (N=49, mean age 68 years). Treated PD patients had significantly higher DOPA, dopamine, norepinephrine, and DOPAC levels and untreated PD patients had significantly lower DOPAC levels (table).

	Controls	**PD no Treatment**	**PD Treated**
DA (pg/ml)	11.2 (17.3)	8.6 (5.5)	58.9 (76.3)*#
DOPA	689.8 (164.4)	600.1 (185.5)	1,173,311 ($3.1x10^6$)*#
DOPAC	465.6 (162.5)	346.8 (163.7)*	2290.8 (3300.8)*#
NE	121.3 (55.2)	123.2 (59.2)	179.9 (107.0)*#
DHPG	2165.9 (635.4)	2140 (815.9)	2525.1 (1134.3)

Mean(SD), $p<0.05$ (versus control*, between PD groups#)
Conclusions: It would appear that CSF catecholamines are not a useful biomarker in actively treated PD patients, however it is possible that CSF DOPAC may have a role as a biomarker for early PD detection.

06r. Imaging & Biomarkers: other

ADPD5-1379
COLONIC ALPHA-SYNUCLEIN: A POTENTIAL DIAGNOSTIC BIOMARKER IN PARKINSON'S DISEASE
L. Parkkinen[1], C. Ruffmann[1], M. Hu[1], K. Talbot[1], O. Ansorge[1]
[1]Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom
Objectives: Alpha-synuclein deposition has been identified in colonic biopsies taken from Parkinson's disease (PD) patients, occasionally years prior to the development of motor symptoms. However, these findings are from very few cases and we want to validate detection of alpha-synuclein pathology in the gastrointestinal (GI) tract as a pre-symptomatic diagnostic marker of PD.
Methods: Oxford Parkinson's Disease Centre (OPDC) cohort is a prospective, longitudinal study comprising patients with early idiopathic PD (n=1200), healthy controls (n=300) and participants at risk of Parkinson's (n=300). To date, 135 participants have given written consent to use their previous GI tract biopsies, making this potentially the largest study of its kind. We have retrieved and stained 51 colonic biopsies (36 PD, 15 controls) so far with an optimized neuronal marker, calretinin and alpha-synuclein antibodies for both its normal (LB509) and phosphorylated (WAKO) forms.
Results: Calretinin showed optimal decoration of mucosal nerve fibers and submucosal ganglionic cells in all samples superior to any other neuronal markers tested. All of our 36 PD patients showed staining for both forms of alpha-synuclein. However, the samples were fairly superficial, sparsely revealing the submucosal plexus and the detected alpha-synuclein staining was variable and frequently diffuse with no clear co-localization with calretinin. We also detected alpha-synuclein accumulation in plasma and vascular endothelial cells. Moreover, some controls also showed alpha-synuclein staining.
Conclusions: Issues of specificity and sensitivity remain to be solved. We plan to address these issues by applying alternative techniques to immunohistochemistry that could better detect the disease-specific neuronal alpha-synuclein accumulation.

THE NINDS PD BIOMARKERS PROGRAM
M. Sutherland[1], K.K. David[2], C. St. Hillaire-Clarke[2], S. Baker[3], J. Linde[3], M. Mc Auliffe[3], B. Landin[3], D. Grolling[3], W.A. Koroshetz[2], D. Babcock[2], B.A. Sieber[2], K.A. Gwinn[2]
[1]NIH, National Institute of Neurological Disorders and Stroke, Bethesda Maryland, USA
[2]NIH, National Institute of Neurological Disorders and Stroke, Bethesda Maryland, USA
[3]NIH, Center for Information Technology, Bethesda Maryland, USA
Objectives: PD affects at least one-half million patients across the United States. Currently available pharmacological and surgical treatments provide some symptomatic relief, but do not impact progression. The National Institute of Neurological Disorders and Stroke (NINDS) Parkinson's Disease Biomarkers Program (PDBP) was established to advance discovery of biomarkers that will improve the efficiency and outcome of Phase II clinical trials for PD and advance therapeutic development.
Methods: The PDBP is a longitudinal program gathering clinical data and biospecimens in subjects who span the disease spectrum, as well as from control subjects. Ten projects are supported under the PDBP; six are clinical. PDBP has enrolled >1000 well-characterized participants. Each clinical site follows a standardized protocol for subject visits and biospecimen collection.
Results: There are >250 cerebrospinal fluid samples and collectively more than 3800 RNA, DNA, plasma and serum samples available for analysis. These biospecimens and associated quality control data are available through the NINDS Repository catalog in the PDBP data management resource (DMR) at no cost, after a straightforward application and review process with a fast turn-around.
Conclusion: The PDBP is a resource with a collection of detailed clinical data and extensive associated biospecimens on subjects with PD and controls. Researchers gain access to the PDBP DMR data by requesting an account. They can subsequently request biospecimens through a straightforward process. More information about requesting an account, ordering biospecimens and more generally, the NINDS PDBP, can be found on the PDBP website (https://pdbp.ninds.nih.gov).

UNILATERAL AND BILATERAL SUBTHALAMIC NUCLEUS STIMULATION (STN DBS) EFFECTS ON SACCADIC EYE MOVEMENTS

P. Walecki[1], E.J. Gorzelanczyk[2], J. Feit[2], M. Kunc[3]
[1]Department of Bioinformatics and Telemedicine,
Jagiellonian University Medical College, Krakow, Poland
[2]Department of Theoretical Basis of Bio-Medical Sciences and Medical Informatics,
Collegium Medicum of Nicolaus Copernicus University in Torun, Bydgoszcz, Poland
[3]Airedale NHS Trust Steeton, University of Leeds, Leeds, United Kingdom

Objective: The goal of this study was to assess changes of saccadic eye movements in unilateral and bilateral subthalamic nucleus stimulation (DBS STN) in PD (ICD-10; G20).
Material and Methods: Patient was qualified for surgery (ICD-10; 02.931, 00.36, 86.95): implantation of stimulating electrodes (model 3387 Medtronic) to the STN on the left side and after three months on the right side. Before and after treatment, the patient was examined using a Saccadometer (Ober Consulting Poland, Advanced Clinical Instrumentation Cambridge UK), allowing the measurement of eye position with the time resolution of 1 msec .
Results: Before surgery the patient showed an asymmetry of the saccades, depending on the direction of movement of the eyes. After the surgery saccadic parameters have changed. The latency of left saccades was reduced. The duration of left saccades was increased and right has not changed. The amplitude of left saccades was reduced. The peak velocity of left saccades was reduced.
Conclusions: The results show that left DBS-STN significantly impacts on the saccadic refixations, in particular its asymmetry depending on the direction of eye movement. This study shows that the STN plays an important role in the control of eyeball movement. Its function is probably related to the determination of contralateral range of motion (amplitude) and velocity, as well as the ipsolateral latency.

ADPD5-2177

IDENTIFICATION OF POST-TRANSLATIONALLY MODIFIED ALPHA-SYNUCLEIN PROTEIN IN BIOFLUIDS OF PARKINSON'S DISEASE PATIENTS USING A TARGETED AND QUANTITATIVE MASS SPECTROMETRY APPROACH.

C. Vocat[1], A. Schmid[2], B. Fauvet[1], B. Mollenhauer[3], H. Lashuel[1]
[1]Brain Mind Institue, Ecole polytechnique fédérale de Lausanne, Lausanne, Switzerland
[2]Proteomics Core Facility, Ecole polytechnique fédérale de Lausanne, Lausanne, Switzerland
[3]Neurology, Paracelsus-Elena-Klinik, Kassel, Germany

Parkinson's disease (PD) is a movement disorder characterized by the progressive loss of dopaminergic neurons and the presence of intracellular protein inclusions (Lewy Bodies) found in the brain of affected patients. Protein aggregation and post-translational modifications (PTMs), such as the site specific phosphorylation of alpha-Synuclein protein have been reported to be strongly linked to PD pathogenesis. Therefore, pathologically modified alpha-Synuclein species represent a primary target for the diagnosis and treatment of PD. We aimed at conducting a comprehensive study, using targeted and quantitative mass spectrometry approaches, to identify and map the pattern of alpha-Synuclein PTMs in plasma and red blood cells from PD patients compared to healthy control subjects. More specifically, we focused on the pattern of PTMs in the blood in order to identify if these modifications correlate with alpha-Synuclein PTM's observed in the brain and cerebrospinal fluid (CSF) during disease progression. The use of full-length, heavy isotope-labelled (^{15}N) alpha-Synuclein protein and peptide standards with site-specific modifications, combined with selected reaction monitoring (SRM) have enabled us to specifically identify single or multiple site-specific modifications of alpha-Synuclein. We have developed a multiplexed SRM assay which allows us to monitor several PTMs during a single analytical run. The identification of a specific isoform or PTMs pattern that correlate with PD or DLB could provide novel insights into the mechanism of the disease development, contribute to the identification of novel therapeutic targets and most importantly, could provide a diagnostic marker to detect and monitor the progression of PD and related synucleinopathies.

DOES COGNITIVE DECLINE IN PD STARTS BEFORE DIAGNOSIS? A POPULATION-BASED STUDY.

A. Foubert-Samier[1], M. Le-Goff[2], C. Helmer[2], H. Jacqmin-Gadda[3], J.F. Dartigues[1], F. Tison[4]

[1]Equipe vieillissement, CHU Bordeaux and INSERM U897, BORDEAUX, France
[2]Equipe vieillissement, INSERM U897, BORDEAUX, France
[3]Equipe biostatistique, INSERM U897, BORDEAUX, France
[4]IMN, CHU Bordeaux and CNRS UMR 5293, BORDEAUX, France

Objective: New concepts propose that PD starts decades before motor signs (pre-motor PD) with non-motor symptoms such as REM sleep behaviour disorder, hyposmia, constipation etc. It is accepted that 20-30% of newly diagnosed PD subjects have some cognitive decline but it isnot known if it starts before diagnosis. Thanks to the very long-term follow-up study of the population based PAQUID study (Perez et al. Alzheimers Dement. 2012 ;8:463-9), we challenged the occurrence of cognitive symptoms over a 14-year period before the diagnosis of PD.

Methods: This is a case-control study nested in the PAQUID cohort. Of the 3,777 initial subjects of the cohort, 43 have developed a PD during the 14 years of follow-up. These cases were matched to 86 elderly control subjects. The evolution of scores on cognitive, functional, and depression scales was described throughout the 14-year follow-up using a semiparametric extension of the mixed-effects linear model.

Results: We have not found significant cognitive decline or emergence of depressive symptoms in future PD subjects before clinical diagnosis compared with controls. Only psychomotor speed was found to significantly 4 years before PD diagnosis. Also, there was no difference in the impact on daily activities, except in using public transportation two years before diagnosis of PD.

Interpretation: This study shows that slower psychomotor speed occurs 4 years before motor diagnosis while other cognitive functions seemed preserved until diagnosis. We could not confirm pre-motor depression in PD. Limits of our study are that of the test used and subjects numbers.

ADPD5-2126

NON-MOTOR SYMPTOM BURDEN IN PARKINSON'S DISEASE: A LONGITUDINAL STUDY

K.M. Prakash[1], N.V. Nadkarni[2], W.K. Lye[2], L.M. Chew[1], E.K. Tan[1], P. Manharlal[1]
[1]Department of Neurology, National Neuroscience Institute (SGH campus), Singapore, Singapore
[2]Centre for Quantitative Medicine, Duke-NUS Graduate Medical School, Singapore, Singapore

Background: Non-motor symptoms (NMS) are common among patients with Parkinson's disease however little is known about their progression in terms of severity or burden.
Objective: This study was aimed to establish the progression of NMS burden and factors affecting it.
Methods: Parkinson's disease patients were prospectively enrolled and followed-up for up to 18 months. Non-motor symptoms scale (NMSS) was used to evaluate the burden of non-motor symptoms.
Results: There was a significant reduction of total NMS burden (from 25.0 to 17.0, p-value <0.001)) over the follow-up period. Similarly all NMS domains except domains 2 (sleep/fatigue) and 3 (mood/cognition) showed significant reduction of scores. In the univariate analysis, Hoehn & Yahr staging, disease duration, Schwab & England Activities of Daily Living score and UPDRS motor scores were individually predictive of change in total NMS burden. However, in multivariable analysis only the latter two were significantly predictive of change in the total NMS burden.
Conclusion: There was a significant reduction of total NMS burden over the study period. The severity of motor and activity of daily living impairment were the best predictors of NMS change.

GENOME WIDE GENE-VITAMIN D INTERACTION ANALYSIS SUGGESTS POTENTIAL ROLE OF MELANOMA RELATED GENES IN PARKINSON DISEASE

L. Wang[1], L. Maldonado[2], J. Ritchie[3], M. Evatt[4], J.L. Haines[5], M. Pericak-Vance[1], G.W. Beecahm[1], E.R. Martin[1], J.M. Vance[1], W.K. Scott[1]
[1]Human Genetics HIHG, University of Miami Miller School of Medicine, Miami, USA
[2]HIHG, University of Miami Miller School of Medicine, Miami, USA
[3]Pathology, Emory University School of Medicine, Atlanta, USA
[4]Neurology, Emory University School of Medicine, Atlanta, USA
[5]Epidemiology and Biostatistics, Case Western Reserve University, Cleveland, USA

Objectives: Vitamin D (vit D) deficiency has been associated with increased Parkinson disease (PD) risk. We sought to identify novel genes contributing to PD via a genome-wide interaction analysis with vit D deficiency.
Methods: We imputed up to 7.2 million single nucleotide polymorphisms (SNPs) in 477 PD cases and 430 controls from a previous genome-wide association study. Vit D metabolites were measured using mass spectrometry. Joint tests of gene-environment interaction were conducted by comparing a full model containing SNP dosage, vit D deficiency (plasma 25(OH)D <20 ng/ml), an interaction term, and covariates (age, sex and sampling season) to a restricted model with only vit D deficiency and covariates.
Results: Vit D deficiency was associated with PD (Odds Ratio (OR)=2.7, P<0.0001). The strongest evidence for interaction was found at rs7312710 in *FBRSL1* (P=2x10^{-6}). The effect of rs7312710 on PD depended on vit D status: the minor allele is associated with increased risk in vit D deficient individuals (OR=2.3, P=0.0004) and with decreased risk in vit D non-deficient individuals (OR=0.7, P=0.0036). The second strongest interaction was found in *C10orf11* with a similar pattern. Both genes are implicated in melanin production and risk of melanoma.
Conclusion: Our study demonstrates vit D-gene interactions and suggests that PD and melanoma share biological pathways (i.e. melanin production) that when perturbed modify risk to both diseases. This is supported by 1) our previous pathway analysis implicating melanogenesis pathway in PD pathogenesis; 2) increased incidence of melanoma in PD patients; 3) substantia nigra is enriched with melanin-positive neurons.

ADPD5-1680

ASSESSING PLASMA LEVELS OF HEAVY METALS IN PATIENTS OF PD

S.J. Kang[1], W.J. Seong[1], K.W. Oh[1], H.T. Kim[1]
[1]Neurology, Hanyang University Medical Center, Seoul, Korea

Background : PD is a progressive neurodegenerative disorder. Oxidative stress contributes to the cascade, leading to dopamine cell degeneration in PD. Metals play a key role in the intracellular oxidative balance. However their implication in the degeneration process remains unknown.
Objective : To assess Aluminum, Cadmium, Copper, Lead, Manganese, Mercury and Zinc concentrations in serum of a group of PD patients in order to determinate, in comparison with age-matched controls, whether alteration in their levels could be involved in PD.
Method : A serum level of 7 trace elements (Al, Cd, Cu, Lead, Mn, Mercury and Zinc) was investigated in 192 patients with PD and 90 matched controls (non-neurodegenerative disease). We compared these parameters in PD patients with controls, and we also compared the variations within the PD group according to age, illness duration, stage of the disease and levodopa intake.
Results : Patients with PD had significantly lower Zn levels compared to controls. Other heavy metal levels in PD patients did not differ significantly from those of controls. Levodopa therapy, age, stage, and illness duration did not significantly influence the measured parameters.
Conclusions : These results suggest that low plasma level of Zn could be a marker of PD or at least, a risk factor for the development of this disease.

07f. Epidemiology, Risk Factors, Genetics & Epigenetics: inflammation

ADPD5-0352

NIGRAL NEURODEGENERATION RESULTED FROM AXONAL DAMAGE AND INFLAMMATION AFTER DIFFUSE BRAIN INJURY

M. Liu[1], A. Bachstetter[1], B. Xing[1], J. Lifshitz[2], W. Cass[1], G. Bing[1]
[1]Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, USA
[2]Barrow Neurological Institute at Phoenix Children's Hospital, University of Arizona, Phoenix, USA

Objectives: Many epidemiological studies have demonstrated traumatic brain injury (TBI) as a risk factor for developing sporadic Parkinson's disease (PD). In this study, we elucidated that TBI-induced axonal injury and inflammation in the medial forebrain bundle (MFB) and inflammation in the nigrostriatal system may contribute to dopaminergic neurodegeneration in the substantia nigra.
Methods: midline fluid percussion injury (mFPI) rodent model, ELISA, immunohistochemistry, HPLC, locomotor behavioral test
Results: In response to mFPI, a significant increase of cytokines and chemokine (IL-1β, IL-6, TNFα and CXCL1) was detected in the striatum and substantia nigra at 1-6 hours post-injury. Meanwhile, impaired axonal transport via antibodies targeting amyloid precursor protein (APP) was found in the MFB, which connects the substantia nigra and striatum, at 24 hours post-injury. Additionally, we found long-lasting increases of both Iba1 and OX-6 stained activated microglia in the MFP, striatum and substantia nigra at 1, 7, and 28 days post-injury. Importantly, dopaminergic neurons identified with both TH immunostaining and retrograde tracer Fluoro-Gold labeling were significantly decreased in the substantia nigra at 28 days post-injury.
Conclusions: Current studies suggested that a single moderate diffuse brain injury resulted in dopaminergic axonal damage in the MFB and inflammatory responses in the nigrostriatal system, potentially leading to dopaminergic neurodegeneration in the nigra, which may associate with the risk of developing late-onset PD.

07i. Epidemiology, Risk Factors, Genetics & Epigenetics: genetic associations & susceptibility genes

ADPD5-1261

CHARACTERIZATION OF GENETIC VARIABILITY IN THE PARK10 LOCUS

K. Nuytemans[1], G.W. Beecham[1], W.K. Scott[1], E.R. Martin[1], L. Wang[1], J.M. Vance[1]
[1]John P. Hussman Institute for Human Genomics,
University of Miami Miller School of Medicine, Miami, USA

Objective: A recent genome wide association study (GWAS) using autopsy-confirmed cases and controls (Beecham et al, Neurology 2014, in press) replicated the previously identified PARK10 locus and reduced its size from 10.6 Megabases to ~100 kilobases (kb), a risk association which has not been seen in GWAS studies using only clinically-diagnosed patients. As part of an ongoing next generation sequencing project in Parkinson Disease (PD), we examined the PARK10 region in a dataset of cases and controls with only a clinical diagnosis, to characterize the region.
Methods: Genomic sequencing was done on a 160 kb region spanning PARK10 in 333 PD cases and 167 controls. Variants were characterized using SeattleSeq, GWAVA, CADD and RegulomeDB for functionality, and analyzed for association.
Results: 77 variants with potential effect on functionality were identified. One (rs11206279; eQTL) showed a trend for association with PD, but was not replicated in the original autopsy-confirmed dataset. However, a small region of Hardy-Weinberg disequilibrium (HWD) was seen near the most associated marker in the PARK10 locus. This region contains multiple known transcription factor binding sites and previously reported copy number variants. Importantly, this HWD was observed in cases, but not in controls.
Conclusion: No obvious functional sequence variant changes potentially contributing to PD were seen in this clinically-diagnosed-only dataset, though the additional heterogeneity compared to the autopsy-confirmed data could be problematic. However, the experiments suggest that initial follow-up experiments using the autopsy-confirmed PD and control dataset should be focused on the identified area of HW disequilibrium.

IDENTIFICATION OF PROGNOSTIC BIOMARKERS FOR PERSONALISED MEDICINE IN PD

J. Grødem[1], J. Chung[1], K.A. Lunde[1], J. Lange[1], C. Sletten[2], T. Hughes[3], G. Alves[1], O.B. Tysnes[4], J.P. Larsen[1], M. Doitsidou[1]

[1]The Norwegian Centre for Movement Disorders, Stavanger University Hospital, Stavanger, Norway

[2]Centre for Organelle Research, University of Stavanger, Stavanger, Norway

[3]Department of Medical Genetics, Oslo University Hospital, Oslo, Norway

[4]Department of Neurology, Haukeland University Hospital, Bergen, Norway

Long-term studies demonstrate that the progression of PD varies greatly from one patient to another. This makes it impossible for clinicians to accurately predict the course of the disease in each individual, and to properly evaluate treatment efficacy or clinical trials. Thus, there is a great need for prognostic biomarkers to establish personalized medicine in PD.

In this project we have worked with The Norwegian ParkWest study, one of the world's longest running longitudinal studies of PD, to search for prognostic biomarkers of cognitive decline in PD. Our aim was to look for differences in DNA that distinguish between individuals who developed dementia relatively quickly after PD diagnosis and individuals who remained cognitively normal. We have taken both a targeted approach, analyzing known candidate biomarkers, and an unbiased approach, using partial exome sequencing of 1045 genes and a two-step extreme trait design.

We identified genetic variants in phenotypic extremes and prioritized them using Ingenuity Variant Analysis software. Variants with predicted effects on protein structure and function and association with cognitive decline were subsequently genotyped in the entire Norwegian ParkWest cohort. These and the known candidate variants were analyzed for association with both disease risk and the time of onset of dementia in PD. This work is an important step in the development of early prognostic biomarkers of disease heterogeneity. We will discuss how genetic variability impacts heterogeneity of disease progression in our cohort and the potential to identify new therapeutic targets to prevent or delay disease progression.

07i. Epidemiology, Risk Factors, Genetics & Epigenetics: genetic associations & susceptibility genes

BOOSTING POWER TO DETECT PARKINSON'S DISEASE GENETIC RISK VARIANTS BY CONDITIONING ON GENETIC DETERMINANTS OF BRAIN STRUCTURE

D. Hibar[1], N. Jahanshad[1], M. Nalls[2], N. Pankratz[3], A. Singleton[2], T. Foroud[4], P. Thompson[1]

[1]Neurology, University of Southern California, Marina del Rey, USA
[2]Laboratory of Neurogenetics, National Institute on Aging, Bethesda, USA
[3]Department of Laboratory Medicine and Pathology, University of Minnesota, Minneapolis, USA
[4]Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, USA

Objectives. As the basal ganglia are implicated in Parkinson's disease (PD), we tested for genetic overlap between PD risk variants and common variants associated with putamen volume. Given evidence of pleiotropy, we show how to boost power to detect PD risk variants by conditioning on ENIGMA's brain volume GWAS findings.
Methods. We used continuous inflation analysis (CIA) to examine genetic overlap (pleiotropy) between a published genome-wide association study (GWAS) of Parkinson's disease (Nalls et al., 2014) and our recent GWAS of putamen volume (Hibar et al., 2015). Next, we performed a pleiotropy-informed conditional false discovery rate (FDR) analysis conditioning on the putamen GWAS results to search for novel Parkinson's disease risk variants (FDR q-value < 0.05).
Results. We found significant evidence of overlap in the genetic determinants of Parkinson's disease and putamen volume using CIA (Figure 1). With pleiotropy-informed conditional FDR, we found 16 significant, previously undetected, Parkinson's disease risk variants (implicating genes like ITGA2B, DLG2, and KTN1).
Conclusions. Shared genetic factors influence brain structure and Parkinson's disease risk. We can leverage this overlap by incorporating recently-discovered information about gene variants that influence brain structure to boost power to detect gene variants that affect risk of developing Parkinson's disease. Several genetic variants discovered in this analysis represent novel biological targets for further investigation.
Figure 1. Continuous inflation analysis (CIA) plot of PD enrichment conditioned on putamen volume GWAS. Points outside of 5th and 95th percentile (blue dotted lines) are considered to be significantly enriched.

AN ASIAN-SPECIFIC ALDH2 SINGLE NUCLEOTIDE POLYMORPHISM AND PARKINSON'S DISEASE

C.H. Tan[1], R.L. Yu[2], Y.C. Lu[3], R.M. Wu[3]
[1]Wolfson Centre for Age-Related Diseases, King's College London, London, United Kingdom
[2]Institue of Behavioral Medicine, National Cheng Kung University, Tainan, Taiwan
[3]Department of Neurology National Taiwan University Hospital, National Taiwan University, Taipei, Taiwan

Objective: To determine whether an Asian-specific ALDH2 single nucleotide polymorphism rs671(A) can increase the risk of development of Parkinson's disease (PD).
Methods: An association analysis of rs671(A) in a large cohort of Taiwanese patients with PD (n = 627) and age matched controls (n = 480) with TaqMan genotyping was performed.
Results: The genotype distribution of rs671(A) in PD patients and control subjects was consistent with Hardy-Weinberg equilibrium. Compared with the GG genotype, the frequency of the genotypes that render ALDH2 inactive (AA and AG genotypes) was not significantly different between the patient and control groups. The adjusted odd ratios (ORs) for the genotypes with lower ALDH2 activity (AA and AG genotypes) were not statistically significant (OR = 1.0450, 95% CI = 0.8231-1.3268, p = 0.7176).
Conclusion: Our results show that the single nucleotide polymorphism rs671(A) alone is not associated with the development of PD.

07i. Epidemiology, Risk Factors, Genetics & Epigenetics: genetic associations & susceptibility genes

ADPD5-2265

LEFT-SIDE DEBUT OF PARKINSONISM SYMPTOMS AS A SPECIFIC CLINICAL FEATURES OF MUTATION IN GLUCOCEREBROSIDASE GENE.

O. Gankina[1], E. Vasenina[1], O. Levin[1]
[1]neurology, Russian medical academy of postgraduate education, Moscow, Russia

Introduction. Glucocerebrosidase (GBA) gene mutation represent a genetic risk factors for the development of Parkinson's disease (PD), but feature of parkinsonism symptoms according with mutation remain poorly understood.
Aim. The aim of the study was to detect specific clinical features in patients with PD carrying GBA gene mutation.
Materials and methods: 12 patients with PD carrying GBA gene mutation and 20 PD patients without this mutation were observed. In all patients a complex assessment of the cognitive status (MoCA), movement disturbances (UPDRS III scale) were applied.
Results. There were no differences in cognitive status according MoCA scale in groups carrying and without mutation (24.72±3.2 and 24,85 ±3.2 accordingly). In group with GBA mutation was detected only moderate cognitive impairment and no cases of dementia, in spite of the fact that duration of illness in some cases was high (9,6±4,6 years). No differences were found in movement disturbances in both group (46,1±19,6 vs 44,4±18,3 accordingly), but PD patients carrying GBA gene mutation more often had left-side debut of parkinsonism symptoms (83,3% vs 55% in group without GBA mutation) ($p<0,05$).
Conclusion. We decided only left-side debut of parkinsonism symptoms as specific clinical features in patients with PD carrying GBA gene mutation, but not cognitive impairments and movement disturbances at all.

[2]Service of Neurology, Hospital Virgen de las Nieves, Granada, Spain

[3]Service of Neurology, Hospital Clínico San Cecilio, Granada, Spain

[4]Department of Psychiatry University of Granada, Institute of Neurosciences, Granada, Spain

[5]Department of Health Sciences University of Jaen, Institute of Neurosciences, Jaen, Spain

1.- Objectives

Increasing evidence supports an extensive and complex genetic contribution to Parkinson's disease (PD) etiology. Our aim was to evaluate the association between certain genetic variants and the risk to develop Parkinson's disease (PD) in a cohort of Andalusian population.

2.- Methods

We performed a case-control association study by genotyping 64 single nucleotide polymorphisms (SNPs) in 117 patients diagnosed with PD and 408 controls from southern Spain. The SNPs included were selected from PD traditionally related genes (SNCA, LRRK2, PARK2, DJ-1, VPS37) besides those proceeding from genome wide association studies (GWAS) as MAPT, GBA, HLA-DOA, STK39, ACMSD and GAK. Genotyping was carried out using Taqman assays in an OpenArray Real-Time PCR platform. Data analysis includes logistic regression adjusted by multiple testing.

3.- Results

Significant differences were observed in the allele frequencies between PD patients and controls after multiple testing adjustment for the following SNPs. HLA rs206769 ($p= 1.187x\ 10^{-10}$; OR= 0.2135), SNCA rs2736990 (p= 0.009268; OR= 1.75), SNCA rs356204 (p= 0.022; OR= 1.673), SNCA rs356219 (p= 0.03002; OR= 1.752), LRRK2 rs34637584 ($p= 0.001774; 5.87x\ 10^{9}$), LRRK2 rs28903073 (p= 0.0181; OR= 11.09). No significant differences were found in allele distribution between cases and controls for the rest of the SNPs analyzed.

4.-Conclusions

Our findings suggest that SNPs SNCA rs2736990, SNCA rs356204, SNCA rs356219 and LRRK2 rs34637584, LRRK2 rs28903073 likely contribute to PD susceptibility in Andalusian population whereas HLA rs206769 might be protective against neurodegeneration.

ADPD5-0932

GENOME-WIDE INTERACTION STUDY IDENTIFIES MAPK10 AS A GENETIC MODIFIER FOR THE PROTECTIVE EFFECT OF COFFEE AGAINST PD

H. Payami[1], E.M. Hill-Burns[1], W.T. Wissemann[1], R.J. Donahue[1], C.P. Zabetian[2], S.A. Factor[3]
[1]Division of Genetics, Wadsworth, Albany, USA
[2]VA Puget Sound Health Care System and Department of Neurology, University of Washington, Seattle, USA
[3]Department of Neurology, Emory University School of Medicine, Atlanta, USA

OBJECTIVE: Clinical trials for neuroprotective treatment of PD have all failed, many due to low efficacy. Drug-efficacy varies among individuals due to genetic difference in drug response. When efficacy is averaged over all genotypes, the effect becomes diluted. Our goal is to find genetic markers to enable pre-selection of subjects for clinical trials. Here, the aim was to identify genes that influence efficacy of caffeine. Caffeine is inversely associated with risk of developing PD, and clinical trials have suggested caffeine and adenosine A_{2A} agonists may benefit some patients. **METHODS:** We used the NeuroGenetics Research Consortium dataset (1450 cases and 930 controls with genetic and exposure data) in a genome-wide gene-environment study. We tested interaction between seven-million genetic-variants and caffeine-intake on the risk of PD. **RESULTS:** Significant interaction was detected with variants in the *MAPK10* gene on chromosome 4 (P=4E-8) indicating association of coffee with PD varied significantly by *MAPK10* genotype. Considering *MAPK10* and previously-identified *GRIN2A* together separated the individuals into three distinct genotypic groups: high-responders showed 87% risk reduction with coffee (OR=0.13, P=2E-5), moderate-responders had 52% risk reduction (OR-0.48, P=4E-6); and one-half of the study population were non-responders (OR=1.0, P=0.76). **CONCLUSIONS:** Results suggest genotyping two variants, at a cost of $1 per subject, may distinguish responders from non-responders, which if confirmed, will enable pharmacogenomic trials for prevention and treatment. This study provides the first genetic link between PD and *MAPK10 (JNK3),* a brain-specific stress-induced gene whose activation is required for neuronal apoptosis.

ADPD5-1411

IDENTIFICATION OF LOW-FREQUENCY GENETIC VARIANTS WITH LARGE EFFECTS ON AGE-AT-ONSET OF PARKINSON'S DISEASE

OBJECTIVES: Parkinson's disease (PD) is a common neurodegenerative disorder with variable age-at-onset. If age-at-onset can be delayed by a few years, a significant number of cases may never occur, and among those who develop PD, fewer will experience physical disability, dementia and psychosis which affect 75%-90% of individuals as disease progresses. **METHODS:** To identify genetic modifiers of age-at-onset, we performed a GWAS using 1,985 PD cases from NGRC followed by replication in 3,986 PD cases from eight datasets. Unlike GWAS for risk, there is no consensus on most suitable method for analysis of age-at-onset. After assessing six different methods, we chose Cox proportional-hazards-model for GWAS. We used 1,986 NGRC controls to rule out association with age, and the moving average frequency plots to confirm association is with age-at-onset and not risk. **RESULTS:** We identified and replicated two regions that showed association with age-at-onset in familial PD (P_{NGRC}<3E-8, 3E-4≤$P_{Replication}$<0.05), but not in non-familial PD (P_{NGRC}≥0.79, $P_{Replication}$≥0.15). The signals mapped to *LHFPL2* on chromosome 5q14.1 and *TPM1* on chromosome 15q22.2. The alleles had low frequencies (MAF_{LHFPL2}=0.016; MAF_{TPM1}=0.012) and were associated with 6-15 years earlier onset (*LHFPL2*: NGRC=12.3 years, Replication=6.37 years; *TPM1:* NGRC=15.3 years, Replication=6.0 years). **CONCLUSIONS:** In summary, we uncovered evidence for the existence of uncommon variants with large effects on age-at-onset of PD. The candidate loci identified, *TPM1* (which regulates muscle-contraction) and *LHFPL2* (highly-expressed in brain tumors), are both biologically plausible considering that PD is a movement disorder and it shares genetically-controlled pathways with cancer.

PARKINSON DISEASE VARIANT DATABASE (PDVD) WITH MULTIPLE EVIDENCE LEVELS TO RANK THE SIGNIFICANCE OF SEQUENCE VARIANTS

K. Nuytemans[1], L. Wang[1], G.W. Beecham[1], C. Van Broeckhoven[2], J. Vance[1]
[1]John P. Hussman Institute for Human Genomics,
University of Miami Miller School of Medicine, Miami, USA
[2]Department of Molecular Genetics, University of Antwerp, Antwerp, Belgium

Objective: Next generation sequencing (NGS) has significantly increased the rate of rare sequence variants (SV) reported in PD patients. But interpretation of the functional significance of SV can be difficult. Current databases do not address this question and/or do not accommodate NGS data. The PDVD is designed to address these needs.
Methods: SV included will come from the literature and existing NGS databases. SV are ranked in each of three evidence levels: 1) "Genetic evidence" (e.g. population frequency, family segregation) and 2) "functional evidence" extracted from literature and data repositories and 3) in-silico analyses for all variants to determine potential functional effect of the variants ("in-silico evidence") (e.g. PolyPhen2 for nonsynonymous, RegulomeDB and GWAVA for non-coding variants).
Results: Each variant is placed in one of six categories, based on the strength of evidence from the three evidence-levels, and this data will be available through a website. Summary data for each dataset and/or for each SV will be linked to the NGS laboratory or publication, to facilitate collaborative efforts.
Conclusions: The PDVD will allow users to quickly evaluate variants and initiate collaborations. The summary data format avoids individual identifiers to allow rapid availability of NGS data to the PD research community. The database meets recommendations by NINDS PD2014. Funded by the US Department of Defense.

Table 1. Rankings for SV

	Category 1	Category 2	Category 3
Genetic support	Highest	High	High
In-silico support	High	High or Intermediate	High or Intermediate
Functional support	Any	High	Intermediate or Low
	Category 4	**Category 5**	**Category 6**
Genetic support	Intermediate	Low	Low
In-silico support	Any	High	Intermediate or Low
Functional support	Any	Intermediate or Low	Low

EXOME SEQUENCING AND 2ND SNP-GWAS OF PD

T. Toda[1], W. Satake[1], N. Hattori[2], M. Murata[3]
[1]Neurology/Mol Brain Science, Kobe University Graduate School of Medicine, Kobe, Japan
[2]Neurology, Juntendo University, Tokyo, Japan
[3]Neurology, NCNP, Tokyo, Japan

PD is a complex disorder caused by multiple genetic variants. We reported a genomewide association study (GWAS) in a total of 2,011 cases and 18,381 controls from the Japanese, which detected 4 PD-risk loci; PARK16, BST1, α-synuclein, and LRRK2 (Satake et al, Nat Genet 2009).

To search for further PD-risks in exonic areas, we performed exome sequencing of 755 PD patients using Sureselect and HiSeq2500. Moreover, in parallel, to identify further common variant PD-risks, we performed Japanese 2nd SNP-GWAS, which expanded our previous one.

Average depth of our data is x 126, and 94.4 % of whole exon sequence was covered by 10 x or more reads. At first, using exome sequencing data of 625 PD cases and 259 controls, we tested association between PD and exonic SNVs within the 4 PD-loci reported by SNP-GWAS. Genetic variants with strong PD-risk did not exist within these 4 PD-loci, indicating that these 4 PD-loci will contribute to this disease as common SNP variants. Further, in 2nd GWAS using 1,948 cases and 28,990 controls, we identified a novel susceptibility locus with P <5 x 10-8. Expression level of a gene within the locus was reduced when the risk SNP exists. In a fly model, knockout of the gene worsened motor function.

We will test association between whole exonic SNVs and PD to identify novel PD-genes harboring rare-variant risks. Our GWAS and in-vivo model data showed that this gene is a novel PD-risk.

[2]Bonn-Aachen International Center for IT, University of Bonn, Bonn, Germany

[3]Department of Neurodegeneration, Hertie Institute for Clinical Brain Research, Tübingen, Germany

[4]Institute of Neurogenetics, University of Lübeck, Lübeck, Germany

1. Objectives

Mounting evidence suggests a prominent role for alpha Synuclein (*SNCA)* expression in the aetiology of Parkinson's disease (PD). In addition to the dominant point mutations in the *SNCA* gene, increasing gene dosages of *SNCA* induce familiar PD, and polymorphisms in regulatory elements of *SNCA* (REP1) increase the risk of sporadic PD. *SNCA* gene expression is controlled at multiple levels including DNA methylation. We performed a thorough analysis of *SNCA* intron 1 methylation in DNA from peripheral blood of 975 individuals.

2. Methods

DNA methylation of *SNCA* intron 1 was analysed using bisulfite specific PCR and pyrosequencing. Lymphocytes were treated with l-DOPA *in vitro* and analyzed for DNA methylation and *SNCA* expression.

3. Results

We detected significant hypomethylation in PD and the difference was more obvious in female individuals. Methylation of *SNCA* in blood decreases with age in healthy individuals. A genetic polymorphism in the investigated sequence stretch (rs3756063) was correlated with methylation and increased the specificity of the observed differences. Male PD patients, who had been exposed to higher doses of l-DOPA, displayed higher levels of *SNCA* methylation, while female PD patients on l-DOPA showed a much weaker effect. These trends prompted us to mimick the presumed effect of l-DOPA *in vitro*. Overall methylation of *SNCA* increased with l-DOPA treatment and decreased *SNCA* mRNA levels.

4. Conclusions

Our data put epigenetic mechanisms on the map of mechanisms determining the individuals' suscebtibility toward PD and point to several hitherto unappreciated phenomena.

DNA METHYLATION AS AN EPIGENETIC BIOMARKER FOR ALZHEIMER'S AND PD

E. Driver-Dunckley[1], B. Meechoovet[2], R. Caselli[3], C. Adler[3], T. Beach[4], T. Dunckley[2]
[1]Neurology, Mayo Clinic, Scottsdale, USA
[2]Neurogenomics, TGen, Phoenix, USA
[3]Neurology, Mayo, Scottsdale, USA
[4]Neuropathology, Banner SunHealth Research Institute, Sun City, USA

Objective: Biomarkers that aid in earlier diagnoses of Alzheimer's (AD) or Parkinson's disease (PD) could facilitate earlier diagnosis and treatment of these diseases. Here we characterize the global methylation profiles from patients with post-mortem neuropathologic confirmation of either AD or PD and confirm specific methylation changes in a prospective cohorts of patients.
Methods: Genome-wide methylation profiles were obtained on blood samples from 19 neurologically normal controls, 20 AD and 19 non-demented PD patients using the Illumina Infinium 450K Methylation BeadChip. Consented subjects gave blood samples and subsequently followed through end of life. Neuropathology analyses confirmed the respective clinical diagnoses. A second validation cohort of 15 controls, 10 AD, and 15 PD patients was prospectively recruited based purely on clinical criteria.
Results: We obtained robust data on over 480,000 CpG methylation sites in the form of beta values, which represent the ratio of methylated CpG to the sum of methylated plus nonmethylated CpG at a given site. Thus, these values range from 0 (unmethylated) to 1 (fully methylated). Significant methylation differences in the discovery cohort of neuropathological-confirmed cases and controls were then confirmed in the second prospectively recruited cohort.
Conclusions: Methylation profiles in the blood of individuals with AD or PD and healthy controls show distinct differences. Further validation efforts on larger sample sets, and characterization of methylation status in patients at varying stages of disease, will help to establish whether methylation status at specific loci could be leveraged as a biomarker to track disease progression or aid in disease diagnosis.

ADPD5-0218
CLINICAL COURSE OF MIGRAINE IN PARKINSON PATIENTS
M. Lotfinia[1]
[1]*Neuroscience, Shefa Neuroscience Research Center, Tehran, Iran*
Migraine is a public health problem of great impact on both the patient and society. The overall migraine prevalence in western countries is 6–8% in men and 15–25% in women. The dopamine theory of migraine pathogenesis, first proposed by F. Sicuteri in 1977. It has been shown that the most migraine symptoms can be induced by dopaminergic stimulation. Moreover, there is dopamine receptor hypersensitivity in migraineurs, as demonstrated by the induction of yawning, nausea, vomiting, hypotension, and other symptoms of a migraine attack by dopaminergic agonists at doses that do not affect nonmigraineurs. We decided to investigate the course of migraine in Parkinson's disease. To study the role of the dopaminergic system in the pathogenesis of migraine, the course of migraine is evaluated after the onset of PD in 25 migraineurs. Our result shows that the migraine attacks became shorter and milder after the onset of PD. Approximately 60% of PD patients reported an improvement in or remission of migraine after PD onset. These findings suggest that PD might somehow shorten the clinical course of migraine, and call for a larger survey.

WHITE MATTER LESIONS ARE CORRELATED TO OLFACTORY DYSFUNCTION IN DE NOVO PD

C. Toyoda[1], T. Umehara[2], H. Oka[2]
[1]Neurology, Jikei University School of Medicine, Tokyo, Japan
[2]Neurology, Daisan Hospital Jikei University School of Medicine, Tokyo, Japan

Objectives
It is well known that white matter lesions (WMLs) are often found in patients with Parkinson's disease (PD). We assessed the relationships between WMLs and several clinical features including olfactory dysfunction in patients with de novo PD.
Methods
We enrolled 36 patients with de novo PD (14 men and 22 women, 74.4 ± 7.7 years, disease duration 1.8 ± 1.6 years); and examined them using the Unified Parkinson's Disease Rating Scale (UPDRS), mini-mental state examination (MMSE), frontal assessment battery (FAB), and Odor Stick Identification Test for the Japanese (OSIT-J). Based on the fluid attenuated inversion recovery (FLAIR) MR image of the brain, we graded deep and subcortical white matter hyperintensity (DSWMH) from 0 to 4. Furthermore, we compared the clinical symptoms between the following 3 groups: grade 0+1: 10 patients, grade 2: 10 patients, grade 3+4: 16 patients. Using DSWMH (grade 0+1 vs. grade 2+3+4) as the objective variable, we conducted logistic regression analysis for the clinical parameters.
Results
Grade 0+1 patients had significantly lower age and higher MMSE, FAB, and OSIT-J than the other patients ($p < 0.01$). Disease duration and UPDRS part III score did not differ between the 3 groups. Logistic regression analysis showed that the OSIT-J had the strongest correlation with DSWMH ($p < 0.05$).
Conclusions
Age, cognitive function, and olfactory function were correlated with WMLs in de novo PD. Specifically, olfactory dysfunction was highly correlated to WMLs. It may suggest that pathogenesis of olfactory dysfunction was associated with that of WMLs in PD.

ADPD5-0471

RISK OF PD FOLLOWING SEVERE CONSTIPATION: A NATIONWIDE POPULATION-BASED COHORT STUDY

W. Liu[1], C. Lin[1], J. Lin[1], Y. Liu[1], C. Chang[1], R. Wu[1]
[1]NEUROLOGY DEPARTMENT, NATIONAL TAIWAN UNIVERSITY HOSPITAL, Taipei, Taiwan

Introduction: Constipation is a non-motor symptom of PD. We investigated the association between the severity of constipation and subsequent risk of PD in a population-based sample.
Methods: 551,324 participants free of PD, dementia, and stroke were retrospectively ascertained between January 1, 2005 and December 31, 2005 using the Taiwan National Health Insurance Research Database. The association between constipation at the beginning of the study and the incidence of PD was examined using a Cox regression model. Information regarding comorbidities and concomitant medications use was adjusted in the proportional hazards models.
Results: After an average follow-up of 5.5 years, 2,336 incident PD cases were diagnosed. The crude incidence rate of PD per 1,000,000 person-days was 1.57 for subjects without constipation and 4.04, 5.28, and 12.67 for mild, moderate, and severe constipation, respectively. After adjusting for age, sex, comorbidities, and concomitant medication use, patients with constipation were more likely to develop PD than subjects without constipation; the adjusted hazard ratio (aHR) was 3.28 (95% CI: 2.14-5.03), 3.83 (2.51-5.84), and 4.22 (2.95-6.05) for individual constipation severity categories. Constipation severity was also associated with an increased likelihood of PD in the time-varying analysis; the aHR was 2.84 (2.43-3.33), 5.22 (4.61-5.92), and 10.47 (9.46-11.58) for mild, moderate, and severe constipation, respectively ($p < 0.0001$). After excluding PD patients diagnosed within 3 years of constipation, the association remained significant.
Conclusions: Our study suggests that the severity of constipation is associated with a future diagnosis of PD in a dose-dependent manner.

07q. Epidemiology, Risk Factors, Genetics & Epigenetics: other

ADPD5-0503

CARDIAC CONDUCTION SYSTEM CHOLINE ESTERASE INHIBITOR HYPERSENSITIVITY IN PATIENTS WITH DEMENTIA WITH LEWY BODIES (DLB)

M. Matsumura[1]

[1]*Neurology, Geriatrics, Shibuya-ku, Japan*

Objective

Patients with DLB have shown hypersensitivity to antipsychotic drugs and a wide variety of autonomic dysfunction. To assess the potential sensitivity to choline esterase inhibitors (ChE-Is) resulting in bradycardia, we performed electrocardiography in patients with Alzheimer's disease (AD) or DLB before and after administration of a ChE-I; we then compared the changes in their heart rate (HR) changes.

Patients and Methods

Eleven patients with DLB and 24 with AD were examined. These patients had no history of drug treatment affecting the cardiac conduction system, arrhythmias, or cardiac disease. All patients were treated with a ChE-I. Electrocardiography was performed before and after administration of the ChE-I. The HR, PR interval, QRS time, and QT time were measured and the differences were computed between the pre- and post-administration time points.

Results

The mean decrease in HR after the administration of the ChE-I was 12 ± 3/min and 3 ± 5.7/min in the DLB and AD groups, respectively. This indicated a statistically significant decrease in HR in the DLB group than that in the AD group ($p < 0.05$).

Discussion

The ChE-I-induced significant decrease in the HR in patients with DLB in this study may be due to both autonomic dysfunction and hypersensitivity of the cardiac conduction system to ChE-Is in patients with DLB. When administering ChE-Is to patients with DLB, to avoid the risk of bradycardia, electrocardiography should be performed not only before, but also periodically after, ChE-I administration to monitor changes in HR.

MOLECULAR MECHANISMS UNDERLYING HAPLOTYPE-SPECIFIC REGULATION OF GENE EXPRESSION AT THE MICROTUBULE ASSOCIATED PROTEIN TAU LOCUS

M.C. Lai[1], A. Bechy[1], M. Gavriliouk[1], F. Denk[1], R. Wade-Martins[1], T.M. Caffrey[1]
[1]Physiology Anatomy and Genetics, University of Oxford, Oxford, United Kingdom

Objectives
The microtubule associated protein tau (*MAPT*) locus is defined by two major genetic haplotypes called H1 and H2. Genetic associations have been identified between H1 haplotype polymorphisms and several neurodegenerative diseases. The expression of exon 3-containing *MAPT* transcripts is two-fold higher from the H2 allele compared to H1 in brain areas highly affected by neurodegeneration. This project aims to use whole genomic locus expression vectors to identify the sequence variants responsible for the difference in splice phenotypes between the haplotypes and the splice factors that interact with the functional variants.
Methods
MAPT vectors were expressed in SK-N-F1 neuroblastoma cell line and the relative expression levels of exon 3-containing transcripts were determined by qRT-PCR. Biotin-labelled RNA oligonucleotides will be used in RNA electrophoretic mobility shift assays and affinity purification of RNA-binding proteins followed by mass spectrometry to identify trans-acting nuclear factors interacting with the haplotype-specific sequence variants.
Results
Intronic single nucleotide polymorphisms (SNPs) rs1800547 and rs17651213 were exchanged in three possible combinations between H1 and H2 wild-type *MAPT* vectors containing the whole *MAPT* locus (~143 kb). Wild-type vectors expressed in SK-N-F1 cells showed greater expression of exon 3-containing transcripts from H2 compared to H1. This expression pattern was reversed when only rs17651213 was exchanged between the H1 and H2 vectors.
Conclusions
A sequence variant responsible for the difference in exon 3 expression between the H1 and H2 MAPT haplotypes was identified through expression studies. This finding provides mechanistic insight into how sequence variations associated with neurodegeneration affect pre-mRNA transcript production.

ADPD5-0523
ESCRT REGULATES AUTOPHAGIC CLEARANCE OF PROTEIN AGGREGATES IN NEURODEGENERATIVE DISEASES

R. Oshima[1], T. Hasegawa[1], N. Sugeno[1], K. Tamai[2], E. Miura[1], A. Kikuchi[1], A. Takeda[3], N. Tanaka[2], M. Aoki[1]
[1]Department of Neuroscience & Sensory Organs,
Tohoku University Graduate School of Medicine, Sendai, Japan
[2]Division of Cancer Biology and Therapeutics, Miyagi Cancer Center Research Institute, Natori, Japan
[3]Department of Neurology, Sendai-Nishitaga Hospital, Sendai, Japan

Objectives: ESCRT (endosomal sorting complex required for transport) play a key role in the later step of the autophagosome, amphisome, and endosome maturation. The aim of this study is to investigate whether ESCRT dysfunction is associated with the abnormal accumulation of protein aggregates and subsequent neurodegeneration in animal model.
Methods: We specifically deleted the ESCRT-0 component, hepatocyte growth factor-regulated tyrosine kinase substrate (hrs), in neurons of the adult forebrain by using conditional knockout mice on calcium/calmodulin-dependent protein kinase II alpha (CaMKII)-Cre-expressing background. The locomotor activity was evaluated by footprint analysis, hind-limb extension and hanging wire tests. The neuronal cell loss was determined by hematoxyline-eosin staining. The intraneuronal accumulation of ubiquitinated proteins, autophagic substrate p62, and neurodegenerative disease-related proteins such as α-synuclein, TDP-43, tau, and huntingtin was examined by immunostaining and Western blot analyses. 8-Hydroxydeoxyguanosine (8-OHdG) and phosphorylated p38/SAPK were used as the indicators for oxidative stress and the stress-kinase activation, respectively.
Results: The locomotor performance in the hrsflox/flox; CaMKII-Cre mice was significantly impaired compared to that in hrs+/+; CaMKII-Cre mice. Histological analysis showed the prominent neuronal loss in CA1/CA3 regions of the hippocampus. Furthermore, we observed a striking accumulation of detergent-insoluble α-synuclein, TDP-43, tau, and huntingtin as well as ubiquitinated proteins and p62 in the brain of hrsflox/flox; CaMKII-Cre mice. These histopathological changes were accompanied by the increased expression of 8-OHdG and phospho-p38/SAPK.
Conclusions: These findings suggest that the functional disruption of ESCRT machinery compromises autophagic/lysosomal degradation of aggregate-prone proteins and acquires cytotoxic activity leading to neuronal cell death.

THY-1 ALPHA-SYNUCLEIN MICE – DISEASE PROGRESSION AFTER WEANING

D. Havas[1], J. Neddens[1], M. Farcher[1], R. Rabl[1], C. Schweinzer[1], B. Hutter-Paier[1]
[1]Neuropharmacology, QPS Austria GmbH, Grambach, Austria

Objectives

Thy-1 Alpha-Syn mice are characterized by strong alpha-synuclein pathology combined with severe and stable motor deficits. Although early affliction was described (Chesselet et al. 2012), only little is known about early post weaning disease progression and nothing is published about brain pathological correlates of the progressive PD motor symptomatic.

Methods

Male Thy-1 Alpha-Syn mice completed a comprehensive behavioral test battery at 1.5*, 2, 3 and 6 months of age. Brains of 2 and 6 months old mice were sampled and investigated for soluble and insoluble alpha-synuclein load, neuro-inflammation, tyrosine hydroxylase (TH) levels, lysosomes (Lamp-1) and agyrophilic neurons by Campbell Switzer (CS) staining. Pathology in relevant brain regions was correlated to behavioral deficits.

Results

Motor deficits appear age-dependently and deficits are measurable as early as at 6 weeks of age in wire suspension. Those are followed by impaired nest-building, beam walk and marble burying performance (2 months), RotaRod and pasta gnawing deficits (3 months) and hyperactivity (6 months). Deficits in predominantly CNS related tasks correlated with progressive intrasomal alpha-synuclein accumulation and aggregation in the substantia nigra, while deficits with peripheral involvement such as wire suspension were unrelated to brain pathological changes.

Conclusions

Peripherally triggered deficits e.g. diminished wire suspension, precede deficits with CNS involvement e.g. reduced RotaRod stamina or hyperactivity in the Open Field paradigm. The latter directly correlate with certain brain pathological changes, whereas perinuclear accumulation of alpha-synuclein as well as agyrophilic aggregates turned out to be the crucial drivers during early disease progression.

*only in wire suspension test

ALPHA SYNUCLEIN OVEREXPRESSION LEADS TO DOPAMINERGIC AND CHOLINERGIC DEFICITS AND REDUCED LOCOMOTOR ACTIVITY IN A MOUSE MODEL OF PD

K. Schwab[1], S. Frahm[1], M. Magbagbeolu[1], V. Melis[2], G. Riedel[3], C. Wischik[2], C. Harrington[2], F. Theuring[1]

[1]Institute of Phamacology, Charite University Medicine Berlin, Berlin, Germany
[2]School of Medicine and Dentistry, University of Aberdeen, Aberdeen, United Kingdom
[3]School of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom

Objectives: Parkinson´s disease (PD) is the second most common neurodegenerative disease and the most common movement disorder in humans, with yet no therapy available beside symptomatic treatment. PD is characterized by accumulation of alpha synuclein aggregates at presynaptic sites and loss of midbrain dopamine neurons. However, several other neurons degenerate in the course of the disease and different transmitter systems are affected.

Methods: To investigate PD related neuronal dysfunction a novel transgenic mouse model overexpressing human alpha synuclein under the control of the mouse Thy 1 promotor was generated.

Results: Transgenic animals exhibited widespread alpha synuclein accumulation in brain and spinal cord. We observed neuronal cell loss in the motor cortex and a decrease in the number of cholinergic interneurons in the striatum as well as lower extracellular striatal dopamine levels, with no changes in vesicular dopamine content. Further, transgenic mice showed deficits in motor functions that progress during ageing. Accordingly, the inhibitory and stimulatory effects of dopaminergic and cholinergic agonists/antagonists on locomotor activity were more pronounced in sensitized transgenic mice compared to control animals.

Conclusions: Our results indicate that alpha synuclein overexpression can alter cholinergic and dopaminergic functions and provides a useful model to test new drugs and therapeutic strategies for the treatment of synucleinopathies.

BEHAVIORAL, GASTRO-INTESTINAL AND HISTOPATHOLOGICAL FINDINGS IN A53T a-SYNUCLEIN MOUSE MODEL OF PARKINSON'S DISEASE AFTER LPS EXPOSURE

J. Oksman[1], C. Buensuceso[2], M. Cerrada-Gimenez[1], A. Nurmi[1], T. Huhtala[1], J. Harris[2], U. Herzberg[2]

[1]Discovery Services Finland, Charles River, Kuopio, Finland

[2]Cellular Therapeutics, Celgene, Warren, USA

Multiple transgenic animal lines exist for Parkinson's Disease (PD). However, many of the models show only a mild phenotype or do not express non-motor changes associated with PD. However, there is evidence that PD affects various non-motor related changes in clinical disease, including disturbances in colon motility and fecal output.

We attempted to enhance disease progression of A53T mouse model by using additional LPS challenge followed by behavioral monitoring and nuclear imaging. In addition, we monitored colon motility as a non-motor endpoint.

Twelve month-old A53T transgenic mice and corresponding wild type mice were tested for baseline behavior followed by LPS challenge over 3 consecutive weeks. Behavioral monitoring by beam balance test and beam traversing were performed and non-motor effects of the A53T transgene as well as additional challenge by LPS were monitored by a fecal output assay. Peripheral TSPO ligand (CLINDE) binding activity was analyzed by SPECT/CT imaging over time. Brains were collected and processed for dopamine and its metabolites from the striatum and histological evaluation of tyrosine hydroxylase and GAP 43 positive cells from substantia nigra (SN). Expression of α-synuclein was monitored and evaluated between non-challenged and LPS-challenged A53T mice.

This study focused on the validation of a previously published mouse model of PD in mice with novel endpoints and additional challenges. We present data on the progression of the PD phenotype up to 16 months of age, the effect of LPS on the phenotype, and whether biochemical, histopathological, and nuclear imaging markers correlate with behavioral changes.

ADPD5-2164
A NOVEL PARK14 TRANSGENIC MOUSE MODEL OF AGE-DEPENDENT PARKINSON'S DISEASE.

Q. Zhou[1], A. Yen[1], T. Ikezu[2], B. Wolozin[2], V. Bolotina[1]
[1]Medicine, Boston University School of Medicine, Boston, USA
[2]Pharmacology, Boston University School of Medicine, Boston, USA

One of the major limitations in the field of Parkinson's disease (PD) is the absence of a mammalian model that closely mimics progression of age-dependent human PD. Our recent studies focused on a poorly understood PARK14 (PLA2g6), and store-operated Ca^{2+} signaling. Here we present *in vivo* and *in vitro* evidence for progressive loss of dopaminergic (DA) neurons in substantia nigra pars compacta (SNpc), and age-dependent PD-like motor dysfunction in a new PLA2g6 (PARK14) $Ex2^{KO}$ mouse model, in which specific Ca^{2+} signaling function of PLA2g6 was genetically impaired. Comparative analysis of ageing $Ex2^{KO}$ and WT littermates (using balance beam, pole, rotarod, open field and other behavioral tests) showed progressive PD-like motor dysfunction at the age that closely mimics the onset of idiopathic PD in humans. Importantly, L-DOPA reversed the motor deficits in KO^{Ex2} mice in dose and age-dependent manner. Motor dysfunction in $Ex2^{KO}$ animals was not a result of muscle, or neuroaxonal dystrophy. Stereological analysis of TH-positive neurons in SNpc revealed progressive loss of dopaminergic neurons in ageing $Ex2^{KO}$, but not WT animals. Thus, PLA2g6 $Ex2^{KO}$ mice develop age-dependent PD-like neurodegeneration with progressive loss of DA neurons in SNpc, as well as specific motor dysfunction that closely mimic parkinsonism in humans. This mouse offers a novel mammalian model of age-dependent PD.

BEHAVIOURAL DEFICITS IN THE SYNERGY MOUSE: A BI-GENIC MODEL OF PARKINSONISM AND DEMENTIA WITH LEWY BODIES

M.E. Fitzpatrick[1], *J.J. Tomlinson*[2], *D.C. Lagace*[1], *M.G. Schlossmacher*[2]
[1]*Neuroscience Graduate Program Department of Cellular and Molecular Medicine, University of Ottawa, Ottawa, Canada*
[2]*Program in Neurosciences, Ottawa Hospital Research Institute, Ottawa, Canada*

Objective: Our goal is to recapitulate several pathogenetic features of human Lewy body disorders, including behavioural and biochemical abnormalities, in a pre-clinical mouse model. SYNERGY mice combine three disease-causing traits (4 insertions of PAC1-*SNCA*^{A53T} alleles*; homozygous Gba1*^{D409V} alleles; *Snca*-null). We hypothesized that SYNERGY mice will show age-dependent behavioral deficits that correlate with elevated expression of human alpha-synuclein (SNCA) in the brain downstream of mutant *Gba1* function.

Methods: Comprehensive motor, cognitive and olfactory testing is being carried out at 1½, 3, 6 and 9-12 months of age (moa). SYNERGY mouse performance is compared to both littermate controls (PAC1-*SNCA*^{A53T}; *Gba1*$^{wt/wt}$; *Snca*$^{-/-}$) ('SYNERGY controls') and wild-type mice bred in parallel on the same mixed background (*Snca*$^{+/+}$*; Gba1*$^{wt/wt}$) ('WT mice'). Behavioural performance will be correlated with SNCA load in the brain.

Results: At 1½, 3 and 6 moa SYNERGY mice and SYNERGY controls showed significant deficits in task-dependent motor performance, as seen in the rotarod, vertical pole, and nest building tests. At 3 moa, SYNERGY mice displayed normal cognition; based on our characterization of both parental strains, we expect the onset of cognitive deficits by 6 moa.

Conclusions: Our behavioural analyses to date suggest that SYNERGY mice have motor deficits as early as 1½ moa that correlates with the increased expression of human SNCA. A significant mutant *Gba1* effect on motor outcomes is not yet apparent by 6 moa. Further behavioural, biochemical and histopathological characterizations are ongoing. We propose that SYNERGY mice have the potential to be a relevant model of Lewy body disorders.

TARGETED OVER-EXPRESSION WITH AAV-MEDIATED HUMAN a-SYNUCLEIN IN A RAT MODEL OF PARKINSON'S DISEASE – VALIDATION OF NOVEL FINE MOTOR FUNCTIONAL EFFECTS

R. Pussinen[1], T. Huhtala[1], P. Sweeney[1], A. Nurmi[1]
[1]Discovery Services Finland, Charles River, Kuopio, Finland

Targeted over-expression of human α-synuclein using viral-vector mediated gene delivery into the substantia nigra of rats and non-human primates has been reported to lead to dopaminergic cell loss and the formation of α-synuclein aggregates reminiscent of Lewy bodies. In the context of these findings, we further validate long term functional and motor deficits in AAV-mediated α-synuclein transfection model in rats during chronic follow-up period.

Recombinant AAV expressing human α-synuclein (A53T) was stereotaxically injected unilaterally into substantia nigra of Wistar rats. Rats were allowed to recover for 3 weeks prior to initial baseline behavioral testing with rotational asymmetry test, stepping test and cylinder test. Similar behavioral test battery was applied again at weeks 5, 8 and 12. In addition to traditionally used rat PD model tests, MotoRater test system, a high speed kinematic motor performance monitoring was applied at multiple time-points during the follow-up period. Evaluation focused on animal gait, swimming, wading and ladder climbing between groups. Furthermore, integrity of the dopamine active transport (DAT) system was evaluated by using ^{123}I- β-CIT and SPECT/CT imaging on weeks 3, 8 and 12 after AAV- α-synuclein transfection.

This study focused on the validation of previously published AAV- α-synuclein transfection model in rats but with the addition of novel end-points. We describe the long term phenotype of AAV- α-synuclein transfected rats with traditionally used behavioral tests but also by using novel fine motor analysis techniques and DAT imaging which provide new insight to uni- and bilateral effects of AAV α-synuclein transfection.

IDENTIFICATION OF COGNITIVE IMPAIRMENTS IN MPTP-TREATED MARMOSETS USING THE WISCONSIN GENERAL TESTING APPARATUS

S. Rose[1], M. Jackson[1], R. Fisher[1], L. Lincoln[1], P. Jenner[1], D. Virley[2]
[1]Pharmacology and Therapeutics, King's College London, London, United Kingdom
[2]Scientific and Business Development, Transpharmation Ltd, London, United Kingdom

Objectives: Most patients with PD develop dementia, including impairments in attention, executive and visuospatial functions. Although the motor symptoms are well modelled in animals, the cognitive dysfunction is poorly defined, and there are limited treatment strategies. Therefore, the purpose of this study was to characterise cognitive performance in the MPTP-treated marmoset model of PD using the Wisconsin General Testing Apparatus.

Methods: Naïve (n=6) and MPTP-treated (n=6) common marmosets were tested on a series of cognitive tasks using the Wisconsin General Testing Apparatus (WGTA). Marmosets were evaluated on a simple visual discrimination (VD) task, followed by 2 reversals of this newly learnt VD task and a visuospatial (VS) conditional discrimination task. The mean number of trials and response latencies to criteria (90% correct) were recorded for each marmoset.

Results: Both groups of marmosets performed the VD task similarly to criteria ($P>0.1$, NS; Figure 1). However, when the VD task was reversed, MPTP-treated marmosets were significantly impaired on both the first ($P<0.05$) and second reversal ($P<0.05$). During the VS test, MPTP-treated marmosets demonstrated robust impairments in learning this task ($P<0.01$). Response times per trial for each test were not different between the groups ($P>0.1$, NS), suggesting that MPTP-treated marmosets were motivated and not impeded by their motor deficit to perform the cognitive tasks.

Conclusions: MPTP-treated marmosets demonstrated cognitive impairments on tasks sensitive to executive function and visuospatial conditional learning using the WGTA. This cognitive battery in the MPTP-treated primate may offer the opportunity of validating novel therapeutic strategies for PD-dementia.

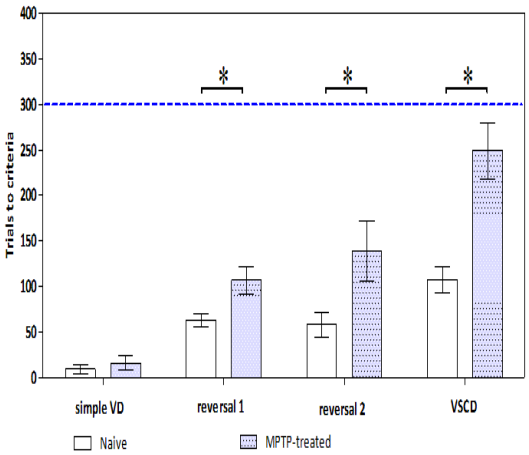

Figure 1. Total number of trials to criteria for naive and MPTP-treated common marmosets following simple VD task, two reversals and a VS conditional discrimination task. Data are mean ± SEM (n=6). * P<0.05 vs naive

[3]Neuroscience, Feinstein Institute for Medical Research, Manhasset, USA

[4]PET Center, Huashan Hospital, Shanghai, China

[5]Movement Disorders Clinic, University Health Network, Toronto, Canada

Objectives. To develop a new non-human primate model of PD based on viral vector mediated overexpression of A53T alpha-synuclein (aSyn) to serve as a preclinical testing platform for evaluating potential therapeutics.

Methods. 12 cynomolgus macaques were enrolled in the study (female, 9yrs old). Each received baseline behavioural assessments on motor activity, non-human primate parkinsonian disability rating scale (MPPrs) and were trained to conduct a fine motor task (mMAP test). Behaviour was assessed once monthly. Baseline PET scans were obtained using 18F-labelled AV133 (VMAT-2) and FDG (fluorodeoxyglucose) and were both conducted every 2 months. Animals were bilaterally injected with either AAV1/2 A53T aSyn or empty vector (EV) (1.7 x 10exp12 gp/ml) into each hemisphere of the substantia nigra (SN). Animals were sacrificed 8 months post surgery.

Results. By 5 months post surgery, A53T aSyn macaques showed 45% less motor activity in the 2-4 hr period of a 4 hr observation, compared to EV controls ($P<0.05$). This deficit persisted through to the final month (53%, 56% and 60%, respectively, to month 8, [all, $P<0.05$]). No significant effect was observed on mMAP performance at any time point. PET imaging showed a reduction in striatal VMAT-2 signal in A53T aSyn macaques compared to controls that emerged by month 2 and persisted to month 6. Further PET imaging and postmortem analyses are ongoing.

Conclusions. These data begin to form the basis of a macaque model of PD alpha-synucleinopathy that can be employed to evaluate disease modifying potential of novel disease modifying therapeutics.

Introduction: Parkinson´s disease (PD) is a neurodegenerative disorder and it is characterized by a progressive degeneration of nigral dopaminergic neurons followed by motor deficits. The use of MPTP treatment for PD models causes the similar effect in the brain and the central dopaminergic system has a crucial role in regulation of the immune processes as well as hematopoiesis. The possible role of this regulation in the hematopoieses must be investigated in animal models for PD treated with MPTP to evaluate the health status of the animals used in PD researches.

Objectives: Evaluate the hematological parameters in cappuchin monkey treated with MPTP.

Methods: 10 male capuchin monkey (mean age=12 years) received MTPT injection (0.4mg/kg, twice a week) during 1 month. Blood samples were collected before and after each treatment, the following parameters were were: red blood cells numbers, hemoglobin, platelets, MCV, MCH, MCHC, white blood cells, neutrophils, lymphocytes, monocytes, eosinophils, basophils. Intra-individual comparisons were made with T test and p value < 0.05 was considered as significant.

Results: Intra-individual comparisons showed that there were no significant differences between in the most all hematologic parameters evaluated before and after the treatment in each monkey, with an exception to the values of lymphocytes were we observed a significant decrease after MPTP treatment ($p<0,05$) (Figure 1).

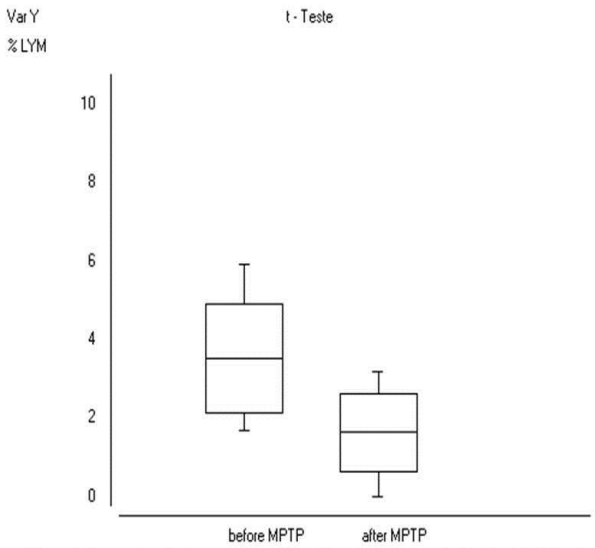

Figure 1: Comparison between values of lymphocytes before and after the MPTP treatment in capuchins monkeys (T Test /p<0,05)

Co**nclusions**: We observed that MPTP treatment in capuchins monkeys causes a significant decrease in lymphocites values.

ADPD5-2212

COGNITIVE EFFECTS OF ATOMOXETINE IN THE CHRONIC LOW-DOSE (CLD) 1-METHYL-4-PHENYL-1,2,3,6-TETRAHYDROPYRIDINE (MPTP)-TREATED MACAQUE MODEL OF PARKINSON'S DISEASE

E. Pioli[1], J. Schneider[1], Y. Jianzhong[1], Q. Li[1], A. Crossman[1], E. Bezard[2], W. Martin[3]
[1]Cognition, MOTAC, Manchester, United Kingdom
[2]Institut des Maladies Neurodegenratives, Universite de Bordeaux - CNRS, Bordeaux, France
[3]Pharmacology, Theravance Biopharma US Inc, Bordeaux, France

Objective. Atomoxetine (ATX), a selective norepinephrine reuptake inhibitor, is approved for the treatment of attention deficit hyperactivity disorder and has shown beneficial effects on working memory in healthy monkeys. Parkinson's disease (PD), in which there is widespread degeneration of the catecholamine system, is characterized by both motor symptoms and impairment of cognitive performance. The purpose of the study was to examine the effect of ATX in the gold standard primate model of cognitive defects in PD, the so-called chronic low-dose (CLD) MPTP macaque model.
Methods. The cognitive effects of ATX were assessed in 5 CLD macaques, displaying cognitive deficits and mild parkinsonian motor deficits. Three doses of ATX (0.3, 1.0 or 3.0 mg/kg) were tested in the Variable Delayed Response (VDR) and the Continuous Performance Task (CPT) on a touch-screen computerized system.
Results. No significant overall effect of ATX was reported on the VDR or CPT tasks. However, when using a best dose analysis, ATX significantly increased the percent of correct responses at a medium delay in the VDR task and decreased the number of commission errors on both the easy and difficult versions of CPT task.
Conclusion. Although no clear cognitive improvement was found after ATX administration in the CLD macaque, the best dose analyses reflected a small positive effect on working memory and on the control of impulsive responding. These modest effects of ATX are consistent with the available clinical literature seem to suggest of lower likelihood of response to ATX for patients with PD-MCI.

ADPD5-0742
SUPPRESSION OF SNCA EXPRESSION IN THE BRAIN ARRESTED PATHOLOGY PROGRESSION IN DROSOPHILA MODELS OF FAMILIAL AND SPORADIC PD
P. Melentev[1,2], *I. Golomidov*[1], *S. Sarantseva*[1]
[1]*Molecular and Radiation Biophysics Division,*
B.P. Kontantinov Petersburg Nuclear Physics Institute, Gatchina, Russia
[2]*Department of Genetics and Biotechnology, Saint-Petersburg State University, Saint-Petersburg, Russia*
Objectives. Parkinson disease (PD) is a neurodegenerative disorder characterized by the dysfunction and loss of dopaminergic neurons in the substantia nigra and accompanied by the presence of cellular inclusions known as Lewy bodies. An important component of the Lewy bodies is the protein α-synuclein (*SNCA*). SNCA is normally present in the human brain, but is physically altered in PD. However, the biological functions are worthy of investigation.
Methods. In our study, transgenic *Drosophila melanogaster* was established as a model to analyze PD-like pathology caused by *SNCA* overexpression. The following fly strains were used in this study: *UAS-SNCA.WT* carries human SNCA gene; *UAS-SNCA.A30P* carries human SNCA with A30P mutation; *UAS-SNCA.A53T* carries human SNCA with A53T mutation. We used the TARGET system, a method for temporal and regional gene expression targeting in *Drosophila*. Flies were raised at the restrictive temperature 18^{o}C throughout their development, two weeks of adult life at 29^{o}C to induce the expression of SNCA and next two weeks at restrictive temperature 18^{o}C to stop the expression SNCA.
Results. We showed a strong deficit of synaptotagmin 1 and n-synaptobrevin mRNA in brain of flies that expressed *SNCA*. Transgenic lines of *Drosophila* that expressed wild type *SNCA* and mutant *SNCA* exhibited a progressive neurodegeneration of dopaminergic neurons. After the stop expression of *SNCA* the level mRNA presynaptic proteins is not restore but the neurodegeneration is slightly slowed.
Conclusions. We found that suppression of transgene expression in the brain arrested in part alpha-synuclein pathology progression.

ADPD5-0367

SYMPTOMATIC AND NEUROPROTECTIVE EVALUATION OF A CANDIDATE COMPOUND IN THE UNILATERAL 6-OHDA LESION RAT MODEL OF PD

S. Robelet[1], E. Bettendorf[1], D. Revy[1], A. Bouzereau[1], V. Girod[1]
[1]Neurosciences, SYNCROSOME, Marseille, France

Parkinson's disease (PD) is the second most common neurodegerative disease, affecting 1% of the population over 55 years of age. PD is characterized by the loss of dopaminergic neurons and a decline in striatum dopamine content and is associated to motor symptoms: akinesia, bradikinesia, rigidity and tremor and postural abnormality. Key neurotoxic models of PD were produced by the unilateral intranigral administration of the toxin 6-OHDA representing the most commonly used. The hallmark of this rat preclinical model is the high reproducibility of the dopaminergic lésion >90% dopamine content (attested by a immunoTH study in the striatum) allowing to test the symptomatic efficacy of a candidate compound as well as neuroprotective effect in preventive condition. In our experimental conditions, the symptomatic efficacy of a test compound is tested with the three different akinetic tests 2 weeks after 6-OHDA administration: initiation time, stepping and cylinder tests, in comparison with the reference compound L-DOPA. The neuroprotective effect of the test compound is evaluated by counting the number of TH positive cells in the SNc. Finally, the mechanism of neuroprotection of the test compound is investigated by two neuroinflammation biomarkers (GFAP and IBA1) by immunohistochemical studies.

ADPD5-1155

PROLYL OLIGOPEPTIDASE INHIBITION ATTENUATES THE TOXICITY OF PROTEASOMAL INHIBITION IN ALPHA-SYNUCLEIN OVEREXPRESSING CELLS AND IN PARKINSON'S DISEASE MOUSE MODEL

M. Savolainen[1], K. Albert[2], M. Airavaara[2], T. Myöhänen[1]
[1]Division of Pharmacology and Pharmacotherapy, University of Helsinki, Helsinki, Finland
[2]Institute of Biotechnology, University of Helsinki, Helsinki, Finland

Objectives: A model for PD based on proteasome inhibition was studied in cell culture and in mice. The properties of a prolyl oligopeptidase (PREP) inhibitor, KYP-2047, that has autophagy enhancing and alpha-synuclein (aSyn) aggregation inhibiting features, was tested in these models.
Methods: SH-SY5Y cell lines overexpressing A53T or A30P aSyn were exposed to a proteasome inhibitor, lactacystin (LC, 10 µM) for 24 hours ± 1 µM KYP-2047. LDH test was done to measure cell viability. Aggregation and ubiquitinylation markers were quantified by western blot.
LC (2µg) was injected stereotaxically above the mouse substantia nigra. KYP-2047 was administered for 5 days and week after the surgery motor tests (cylinder and 2-hour locomotor activity) were performed. Immunohistochemistry was used to examine changes in aSyn, tyrosine hydroxylase (TH) and glutamate decarboxylase (GAD).
Results: In aSyn overexpressing cells, KYP-2047 reduced the LC-induced increase in aSyn oligomers and ubiquitin levels leading to improved cell viability
In mice, LC reduced the distance travelled and rearing in locomotor test but not in KYP-2047 treated mice. Immunohistochemical analysis revealed significant accumulation of aSyn and GAD increase in substantia nigra, and significant striatal TH loss.
Conclusions: Our results show that nigral stereotaxic injection of LC in mice produces rapid loss of dopaminergic cells with aSyn accumulation and motor deficits making it a suitable PD model. Moreover, PREP inhibition prevented the LC induced behavioral changes in mice and improved cell viability in aSyn cellular model, proposing a role for PREP inhibition as a potential drug therapy in PD.

DEVELOPMENT OF A TEST-SYSTEM BASED ON PARKINSONIAN MICE FOR A SEARCH OF NEUROPROTECTORS

A. Kolacheva[1], *M. Ugrumov*[1]
[1]*Laboratory of Neural and Neuroendocrine Regulations,*
Koltzov Institute of Developmental Biology, Moscow, Russia

Objectives were to specify (i) timing characteristics of the degeneration of nigrostriatal dopaminergic neurons, axons and cell bodies, separately in MPTP-treated mice, (ii) functional characteristics of surviving neurons, (iii) validity of a test system for screening of neuroprotectors.

Methods. The study was performed in C57BL/6 mice at the symptomatic stage of parkinsonism induced by 4-fold s.c. injections of MPTP at the individual dose of 12 mg/kg. Dopaminergic neurons were studied by using quantitative and semi-quantitative immunocytochemistry for tyrosine hydroxylase (TH) and HPLC for DA assay.

Results. According to our data, the number of TH-immunoreactive striatal axons begins to decrease shortly after the first injection of MPTP going down up to 43% by the 6th h following the last injection. This was accompanied with a decrease of TH content in individual axons under maintaining of DA at the control level. The number of the nigral TH-cell bodies decreased for 43% from the 3rd to the 6th h following the last MPTP injection in parallel with a slight decrease of DA content in the substantia nigra and the maintaining of intraneuronal TH at the control level. Neurodegeneration was almost prevented by the nomifensine injection 30 min prior to MPTP administration confirming the validity of this parkinsonian model as a test system for a search of neuroprotectors.

Conclusions. Thus, a test-system for a search of neuroprotectors was developed in this study.

[3]Pathology Laboratory, Ufcspa, Porto Alegre, Brazil

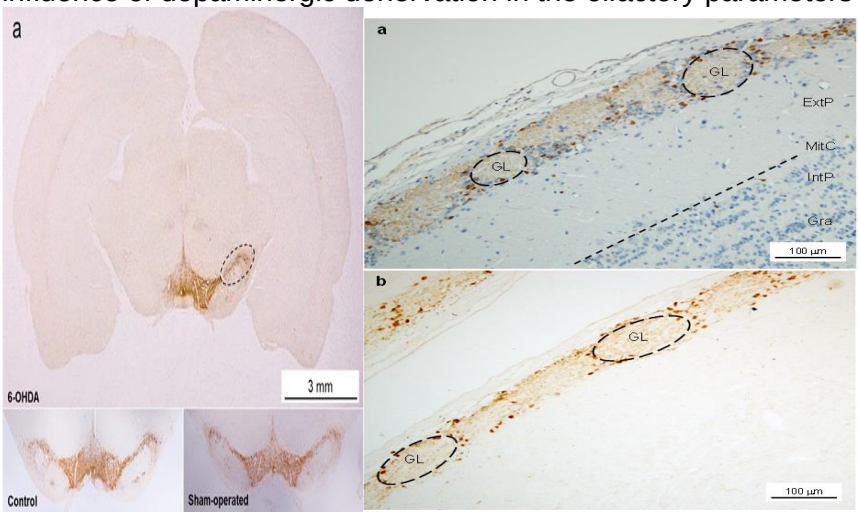
[4]Basic Science, UFCSPA, Porto Alegre, Brazil

OBJECTIVE: Evaluate the histopathology and behavior of the olfactory system in rats submitted to dopaminergic lesion induced by 6-hydroxydopamine (6-OHDA),

METHODS: Forty eight adult male Wistar rats were divided into groups: (1) 6-OHDA lesioned, (2) sham-operated and (3) control group (without any procedure). Groups 1 and 2 were submitted to stereotaxic surgery for unilateral microinjection of 6-OHDA and ascorbic acid solutions in the medial forebrain bundle. The extension of the dopaminergic lesion was evaluated at 21, 28 and 57 days after surgery. During each time period, motor function (rotational behavior and open field) and olfactory discrimination function (Coconut milk test) were evaluated. We performed both cell counting in the substantia nigra pars compacta (SNpc) and measured optical density (OD) in the OB, for tyrosine hydroxylase (TH) immunoreactivity.

RESULTS: All 6-OHDA groups of each time period exhibited a reduction of dopaminergic neurons in the SNpc ($p<0.001$, compared to control and sham-operated groups) with a mean reduction of 73%. Pearson's correlation demonstrate a modest, non-significant, negative correlation ($p= 0.33$) between the number of TH positive cells and rotations. We did not detect olfactory dysfunction ($p=0.31$, for treatment and time factors) or any significant alterations in the amount of TH positive cells in the glomerular layer of the ipsilateral OB ($p=0.80$, compared to contralateral OB).

CONCLUSION: The 6-OHDA model still represents a very useful tool in PD pathophysiology research, regarding DA denervation. However, we did not observed influence of dopaminergic denervation in the olfactory parameters investigated.



ADPD5-1692

DESYMPATHYZATION OF THE HEART IN MPTP-TREATED MICE AT THE PRESYMPTOMATIC AND SYMPTOMATIC STAGES OF PARKINSONISM

R. Nigmatullina[1], V. Kudrin[2], G. Khakimova[3], T. Fedoseeva[1], S. Zemskova[1], O. Kuzmina[1], M. Ugrumov[3]

[1]Physiology Department, Kazan State Medical University, Kazan, Russia

[2]Laboratory of Neurochemical Pharmacology, Institute of Pharmacology RAMS, Moscow, Russia

[3]Laboratory of Neural and Neuroendocrine Regulations, Institute of Developmental Biology RAS, Moscow, Russia

Objectives were to determine the noradrenaline (NA) concentration in the heart and the heart force in response to NA in C57BL/6 mice at the presymptomatic and early symptomatic stages of parkinsonism two weeks following 2-fold and 4-fold s.c. injections of MPTP, respectively, at the individual dose of 12 mg/kg. NA was assessed with HPLC ex vivo, while the heart force was measured with tensometry in vitro. According to our data, NA concentration decreased by 23% in the atria and by 21% in the ventricles at presymptomatic stage and by 34% and 31%, respectively at the symptomatic stage suggesting a heart desympathyzation. NA strengthens the atrium force by 86% and the ventricle force by 61% at the presymptomatic stage, whereas this reaction slightly decreased at the symptomatic stage up to 15% and 35%, respectively. It means that the heart sensitivity to NA increased significantly under desympathyzation that is more prominent at the presymptomatic stage. Thus, the heart desympathyzation is developed in MPTP-treated mice at the presymptomatic stage of parkinsonism being even more prominent at the early symptomatic stage.

08f. Animal Models: pharmacological & lesion models

ADPD5-2046
REGULATION OF TYROSINE HYDROXYLASE IN A LOW DOSE ROTENONE MODEL OF PARKINSON'S DISEASE

M. Johnson[1], M. Senthilkumaran[1], L. Bobrovskaya[1]
[1]Sansom Institute for Health Research, University of South Australia, Adelaide, Australia

Objectives:
Tyrosine hydroxylase (TH, the rate limiting-enzyme in catecholamine synthesis) is regulated acutely via phosphorylation of 3 serine residues – Ser19, 31 and 40, and chronically via changes in TH protein levels. In this study we aimed to investigate how TH is regulated in the brain and adrenal gland in a low dose rotenone model of Parkinson's disease (PD).
Methods:
Male Sprague-Dawley rats received intraperitoneal injections (2 mg/kg) of rotenone (*n*=5) or vehicle (*n*=4) 5 days/week for 4 weeks. The rearing test was performed weekly. Adrenal glands and selected brain regions were collected postmortem for western blot analysis of TH protein and TH phosphorylation.
Results:
Rearing behaviour decreased in the rotenone group by week 3 (*p=0.003*), with further decreases in rearing by week 4 (*p<0.0001*). TH was unchanged in the substantia nigra (SN) and striatum but pSer40 was decreased in the striatum (*p=0.04)* of rotenone rats. In the olfactory bulb, TH protein levels decreased by 60% (*p=0.01*) while pSer31 levels increased by 40% (*p=0.02)* in the rotenone group. In the adrenal gland, TH and phenylethanolamine-N-methyltransferase (another catecholamine synthetic enzyme) levels increased by 80% (*p=0.02) and 100% (p=0.02)* respectively in the rotenone rats.
Conclusions:
This study provides evidence that TH regulation in the olfactory bulb and adrenal gland (the hypothesised early regions affected in PD) are altered before any changes in TH regulation are detected in the SN. The low dose rotenone via intraperitoneal injections therefore may have potential to model the early changes of PD.

ADPD5-2074

FUNCTIONAL STATE OF THE NIGROSTRIATAL SYSTEM IN MICE AT THE PRESYMPTOMATIC AND EARLY SYMPTOMATIC STAGES OF PARKINSONISM

A. Kolacheva[1], A. Medvedev[2], A. Bazyan[3], G. Khakimova[1], M. Ugrumov[1]
[1]Laboratory of Neural and Neuroendocrine Regulations,
Institute of Developmental Biology RAS, Moscow, Russia
[2]Laboratory of Pharmacoproteomics, Institute of Biomedical Chemistry RAMS, Moscow, Russia
[3]Laboratory of Neurochemical Mechanisms of Learning and Memory,
Institute of Higher Nervous Activity and Neurophysiology of RAS, Moscow, Russia

The objective was to evaluate functional state of the nigrostriatal system in parkinsonian mice at presymptomatic and early symptomatic stages, induced by 2-fold and 4-fold MPTP injections (12 mg/kg per injection). We evaluated in substantia nigra (SN) and striatum uptake, spontaneous and stimulated release of 3H-dopamine (DA) on slices; D2 and MAO A&B gene expressions; enzymatic activity of MAO A&B. Moreover, intercellular DA was measured in striatum with microdialysis.
At presymptomatic stage, despite a loss of 29% neurons in SN, most parameters were unchanged though MAO A&B gene expressions decreased. In striatum, intercellular DA decreased by 61% as a result of: (i) a decrease of DA spontaneous release, gene expression and activity of MAO B; and (ii) an increase of MAO A gene expression, DA stimulated release and uptake. When converting the data on the number of cell bodies and axons, it was found that DA spontaneous release compensatory increased by 43% and 216%. In SN at symptomatic stage, no differences in most parameters were observed compared to presymptomatic one, though D2 and MAO B gene expressions decreased. We observed in striatum a decrease of DA intercellular level, DA stimulated release and uptake, MAO A&B gene expressions, and an increase of MAO A&B activity. Thus, an absence of motor disorders at presymptomatic stage is partly explained by an increase of DA spontaneous release and decrease of MAO B activity in striatum whereas motor dysfunctions appeared to be triggered by a decrease of DA release and increase of MAO A activity.

ADPD5-2103

BIOCHEMICAL AND BEHAVIORAL EFFECTS OF COMBINED TREATMENT WITH PAROXETINE AND L-DOPA IN UNILATERALLY 6-OHDA-LESIONED RATS

K. Kamińska[1], T. Lenda[1], J. Konieczny[1], Z. Rogóż[2], E. Lorenc-Koci[1]
[1]Department of Neuro-Psychopharmacology, Institute of Pharmacology PAS, Krakow, Poland
[2]Department of Pharmacology, Institute of Pharmacology PAS, Krakow, Poland

The aim of the present study was to examine rotational behavior and monoamine metabolism in motor (striatum, substantia nigra) and limbic (prefrontal cortex, hippocampus) brain structures of 6-OHDA-lesioned rats, treated chronically with paroxetine jointly with L-dopa. The experiment was performed on male Wistar rats injected unilaterally with 6-OHDA (16ug/4ul) into the medial forebrain bundle. Two weeks later, the animals were tested for the rotational behavior induced by apomorphine. Rats exhibiting more than 100 contralateral turns/1h were administered paroxetine (5mg/kg) or L-dopa (12mg/kg), alone or in combination, once daily for 21 consecutive days. Rotational behavior was recorded after the first and the penultimate doses of the examined drugs. Dopamine (DA), serotonin (5-HT) and their metabolites were determined using HPLC in the motor and limbic brain structures 1h after the last drug injections.
Combined administration of paroxetine and L-dopa resulted in decrease in the number of contralateral rotations compared to the L-dopa-treated group. Joint treatment with paroxetine and L-dopa increased DA levels on the ipsi- and contralateral side of the substantia nigra and on the contralateral side of the remaining structures more visibly than did L-dopa alone. Paroxetine alone enhanced 5-HT level in the contralateral striatum and substantia nigra while combined treatment decreased it. In limbic structures paroxetine+L-DOPA lowered 5-HT content compared to the effect of L-DOPA alone. The obtained data are discussed in the context of PD therapy.

Objective: Parkinson's disease (PD) is a complex genetic disorder, associated with environmental risk factors and aging. Current animal genetic or toxin-based models have so far failed to recapitulate all of the features of PD, thus impeding attempts to develop neuroprotective or disease-modifying treatments. Here we describe a new chemical for induction of PD in mouse, with a slower kinetics than other toxins, thus more relevant regarding physiopathology.

Methods: The effect of 96h exposure to the Pyridinium on a neuroblastoma cell line (SH-SY5Y) was investigated on cell death (caspases activation, oxidative stress), and on α-synuclein aggregation. The consequences of a 7-day *per os* exposure to Pyridinium (20mg/kg/day) in mouse were evaluated by biochemical (mitochondrial dysfunction) and histological studies (phosphorylated α-synuclein, Tyrosine hydroxylase, Tau (using an antibody that recognizes an early pathological conformation)).

Results: Pyridinium exposure induced SH-SY5Y cell death, increased alpha-synuclein aggregation, and inhibited mitochondrial complex I. The EC_{50} of Pyridinium on cell survival was in the millimolar range but these effects appeared after 96 hours versus 24 hours for MPP+.

Five weeks after mice exposure to Pyridium, mitochondrial respiratory control ratio, and complex I activity were decreased (24% and 48% respectively) simultaneously to an increase of Ser-129-phosphorylated α-synuclein and loss of striatal dopaminergic neurons. Misfolded Tau in hippocampus indicated an associated tauopathy.

Conclusion: With its slower kinetics, the use of Pyridium can significantly address critical gaps in our understanding of the etiology of PD, in the identification of new early biological markers and development of novel effective treatments currently lacking.

DECREASED SPREADING DEPRESSION SUSCEPTIBILITY IN PARKINSON RAT MODEL

M. Lotfinia[1]
[1]*Neuroscience, Shefa Neuroscience Research Center, Tehran, Iran*

Parkinson disease (PD) is known by a major loss of dopaminergic nigrostriatal neurons and by an increased turnover of neurotransmitter by surviving neurons of the nigrostriatal tract. The clinical diagnosis of PD is based on the identification of some combination of the cardinal motor signs of bradykinesia, rigidity, tremor, and postural instability. Spreading depression (SD) known as an evoked neuronal activity and changes in ionic, metabolic and hemodynamic characteristics of the brain. Pronounced release of dopamine during SD and the probable role of dopamine in SD process suggests that disruption of dopaminergic pathway in PD may cause SD to behave differently. To test this possibility, we induced dopaminergic lesion by bilateral intracerebral stereotactic injection of 6 µL of 6-hydroxydopamine in the medial forebrain bundle (MFB). After 4 days, SD was induced by the injection of 3M KCl and SD propagation was followed using two ion-sensitive microelectrodes placed in the parietal and occipital cortex. Eliciting SD in rat model was associated with a significant increase in the threshold of SD and a decrease in the propagation velocity and duration of accompanying extracellular DC changes. The present data show that rat model of Parkinson's disease are less prone to SD.

[3]Applied Physiology, Mossakowski Medical Research Centre PAS, Warsaw, Poland

PD is neurodegenerative motor disorder, the symptoms of which are partly due to the progressive degeneration of the nigrostriatal dopaminergic pathway. In the initial stages, motor symptoms of PD can be controlled by pharmacological intervention, however as the disease progresses, this is associated with loss of efficacy and emergence of side effects. Therefore, the first step of an ideal therapy must be to prevent this cell death. Accumulating clinical evidence suggests that physical exercise can provide this much needed treatment, and studies of PD animal models of dopamine deficiency associated with the motor symptoms support this hypothesis. It is suggested that these neuroprotective effects are likely to involve the activation of signaling cascades by neurotrophic factors. The aim of this study was to investigate the effects of treadmill exercise-induced behavioral and neurochemical changes in C57/BL6 mice treated for five weeks with 12,5mg/kg 1-methyl-4-phenyl1,2,3,6-tetrahydropyridine (MPTP) in combination with 250mg/kg probenecid. Mice were subdivided into four groups: (i) control, (ii) sedentary (non-exercised with induction of PD), (iii) exercised before during and after the induction of PD, and (iv) exercised only after the induction of PD. Brains were collected for immunohistochemistry for tyrosine hydroxylase, VMAT-2 transporter, BDNF and GDNF neurotrophins in substantia nigra and striatum. Exercised groups exhibited reduced damage to the dopaminergic system and excessive increase of BDNF and GDNF expression. These results suggest that the chronic MPTP protocol is a model of progressive PD, which may be suitable to investigate chronic pathological processes and neuroprotective strategies in PD.

Introduction: Stem cell therapy has the potential to significantly impact the development of disease-modifying treatments for PD. However, it´s very important the development of new animal models of PD, before the scientific comunity start to speculate the use of stem cell therapy.

Objectives: This study was design to propose capuchin monkey (*Sapajus apella*) as model of PD and also to evaluate the potential use of autologus mesenchymal stem cells (MSC) therapy in PD treatment.

Methods: 10 male capuchin monkey (mean age=12 years) received MTPT injection (0.4mg/kg, twice a week) during 1 month. After this period, the animals were divided in 2 groups One group (n=5) received a single dose of MSC via intracarotid and the other (n=5) received the vehicle solution instead of MSC. During all period MPTP treatment (30 days) and for 30 days after MSC therapy the clinical aspects were evaluated in accordance with the UPDRS scale adapted.

Results: Clinical aspects related with PD were present in almost all of the MPTP-animals (Figure 1). Futhermore, after MSC therapy, most of the animals present significant reduction (p>0,005 – t test) of the evaluated clinical asptects of PD (Figure 2).

Co**nclusions**: Capuchin monkeys seems to be a promise new animal model of PD. The use of autologus MSC therapy shown to have a great potential on the treatment of PD.

[4]Parkinson's Disease Pharmacology, UCB Pharma S.A, Braine L'Alleud, Belgium

Objective: Animal models are an essential asset for pathophysiological research as well as validation of therapeutic strategies of human diseases. The absence of adequate in vivo experimental models has severe repercussions for therapeutic intervention success. Despite progress in animal modelling, no mammalian model recapitulates the required age-dependent phenotypes associated with Parkinson's disease (PD).

Methods: We selected an elegant series of models of ascending complexity with three different strains of mice (C57Bl/6J, SAMP8 and SAMR1 for senescence-accelerated mouse prone or resistant, respectively), adult rats and marmoset monkeys at various ages. Each model received a stereotatic injection in the substantia nigra pars compacta of adeno-associated virus (AAV) serotype 9 carrying mutant human alpha-synuclein (A53T; 10^{10} GC/ml) under the neuron specific synapsin promoter including a WPRE enhancer element. Sixteen weeks after injection, we systemically investigated species and age-dependent differential susceptibility of dopamine neurons regarding the extent of neuronal loss. We also assessed alpha-synuclein spreading.

Results: We successfully induced dopaminergic degeneration in all species. Mice were less susceptible to alpha-syn-mediated toxicity compared to rats and monkeys. Both SAMP8 and SAMR1 present a strong alpha-synuclein staining which was not correlated with the occurrence of degeneration. High-resolution kinematic analyses revealed that rats exhibited the hallmarks of Parkinsonian syndromes during gait, including periods of freezing, postural instability, and reduced speed of motion. In marmosets, old animals were more susceptible to degeneration at both fibers and cell body levels.

Conclusion: According to the species used, we observed differences in the PD-related neurodegeneration progression over time associated with alpha-synucleinopathy.

ADPD5-0370
QUALITY OF LIFE EVALUATIONS IN PD: SELF/CAREGIVER AGREEMENT
Y. Balash[1], A. Korczyn[1], Y. Knaani[1], T. Gurevich[1]
[1]Neurology, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel
Background: Self-reports about quality of life (QoL) of patients with Parkinson's disease (PD) themselves and of their spouses as caregivers may be subjective, and not always reliable. Objective: To examine patient-spouse agreements on the items of the PD Quality of life Questionnaire (PDQ-39), the Scale of Quality of Life of Care Givers (SQLC), and the Multidimensional Caregiver Strain Index (MCSI). Methods: Patients and their spouses were separately interviewed and completed the same questionnaires for mutual characterization of each other. Their scores were examined with approximate agreement coefficients and interclass correlations (ICC).Results: 12 patient-spouse pairs were assessed. Spouses were younger (age: 70.6 ± 5.3 vs. 75.8 ± 6.7 years, P=0.06), both groups had a similar education level (14.7 and 14.3 years). Approximate agreements among QoL items were strong for PDQ-39, SQLC and MCSI (75.4 ±14 %; 78.1 ±14.1 % and 78.2 ±14.3 %, respectively), as well as within each of the couples: 75.8-78.6%. Patient-spouse opinions had better concurrence for physical condition (PDQ items: 3, 8, 12-15, ICC 95% CI – 0.637-0.713) and depression in sick persons (PDQ items: 17, 23, 24, ICC 95% CI – 0.6-0.874). Divergences in assessments in the items of SQLC and MCSI, designed for spouses were considerable (averaged ICC – 0.1)). Individual agreements within each of the couples were modest (averaged ICC– 0.41 for PDQ, and 0.429 for SQLS). Conclusions: PD patients and their spouses-caregivers had accetable approximate agreements for most of QoL items oriented to patients. However, the inner patient-spouse interrelationships have appeared complex.

ADPD5-0629

A COMPARISON OF CAREGIVING OUTCOMES IN PARKINSON'S DISEASE AND PARKINSON'S DISEASE DEMENTIA

K. Roland[1], *N. Chappell*[1]
[1]*Centre on Aging, University of Victoria, Victoria, Canada*

The growing incidence of cognitive impairments in persons with Parkinson's disease (PD) creates unique challenges for caregivers. Therefore, the relationship between symptom presentation and caregiver outcome deserves to be investigated.

OBJECTIVE: determine the different contribution of stressors to role strain, mediators and outcomes in PD compared to PD dementia (PDD) caregivers.

METHODS

Community-living PD and PDD spouse caregivers providing 3^{+}hour of care/week for >1-year were recruited (N=55). Caregivers' completed questionnaires that assessed: characteristics (age, sex, duration), stressors (ADL, cognitive impairment, motor dysfunction, memory-behaviour problems), role-strain (care-hours), mediators (assistance, self-efficacy, coping) and outcomes (depression, burden, life-satisfaction). ANOVAs determined PD-PDD group differences, while individual stepwise regression models determined stressors that best-explained caregiver outcomes.

RESULTS

Persons with PDD had greater cognition impairment, ADL and IADL disability, motor dysfunction, and more bothersome memory and behaviour problems ($p<0.01$). PDD caregivers provided more care-hours ($p=0.04$); experienced greater burden, depression and decreased life-satisfaction than PD ($p<0.006$). There were no differences in characteristics, assistance, formal/informal supports, coping strategies and self-efficacy between groups. IADL ability and cognitive impairment best-explained PDD caregiver outcomes ($F(1,51)=29.9;R^2=0.55;p=0.02$). Specific IADL (shopping, food-preparation, household-chores, transportation, medication) that best-explained cognitive decline were food-preparation and shopping ($R^2=0.53;p=0.003$). For caregiver outcomes, food-preparation explained 32% of burden, household-chores explained 16% of depression, and food-preparation and transportation explained 35% of life-satisfaction ($p<0.02$).

CONCLUSIONS

PDD dementia caregivers experience declining IADL ability due to cognitive impairments, leading to negative outcomes. This research supports the importance of equipping caregivers with coping skills relevant to symptom presentation to decrease negative outcomes and improve life-satisfaction.

09a. Patient Care & Support: caregiver support

ADPD5-1593
UNDERSTANDING OF THE DISEASE AND THE CARE GIVER BURDEN IN PARKINSON'S DISEASE

S. Cheon[1], S.Y. Lee[1], J.W. Kim[1]
[1]Neurology, Dong-A University College of Medicine, Busan, Korea

Parkinson's disease (PD) is progressive degenerative disorder and the management of PD is aiming for the improvement of daily activities of patients and their family. The purpose of this study is to evaluate the patients and their caregivers' understanding of the disease and its impact on the caregiver burden.

Caregivers of PD patients were consecutively recruited from outpatient clinic. Caregivers were confined to one of patients' family member, who were main member in patients' care. Questionnaire to evaluate the understanding PD was developed by movement disorder specialists based on current reviews and guidelines, covering pathology and nature of the disease, symptomatology, and treatment. Structured interview about demographic and socioeconomic characteristics was also done with questionnaire covering caregiver burden, understanding the disease, general quality of life (QoL), and depression.

Total 83 caregivers were recruited (age 62.2 ± 12.2 years, 55 men) and most of them were spouses of patients (79/83). Caregivers' understanding showed significant difference according to sex (men better than women). Caregiver burden was significantly correlated with their understanding, especially economic aspect of burden and understanding about pathology and nature of the disease. Depression and QoL of caregiver showed significant correlation with caregiver burden. Patients' understanding and QoL was also correlated with caregiver burden.

Understanding of patients and caregivers about their disease showed negative correlation with caregiver burden. Education about the disease to patients and their caregivers could improve daily burden of the disease and should be an essential part of the proper management of PD.

ADPD5-2196
FACTORS INFLUENCING MUTUALITY IN PARKINSON´S DISEASE DYADS
M. Karlstedt[1], S.M. Fereshtehnejad[1], D. Aarsland[1], J. Lökk[1]
[1]NVS, Karolinska Institutet, Stockholm, Sweden
Objectives
The aim of this ongoing project is to explore the quality of the relationship (mutuality) between patients with Parkinson´s disease (PD) and their partners and how it is affected by the motor and non-motor symptoms, other perceived difficulties, caregiver burden, and health-related quality of life (HRQoL).
Methods
The dyads (n=34) completed validated scales measuring mutuality (MS), caregiver burden (CBS), caring difficulties (CADI), depression (GDS), activities in daily life (ADL) and Parkinson´s disease HRQoL (PDQ8). Associations were evaluated using Pearson´s correlations to identify variables significantly related to mutuality. Multiple regression analysis was used to estimate the associations between independent factors and mutuality.
Results
Mean age of the PD patients was 69.6(SD=8.3) and for the partners 69.2(SD=8.3) years. Most of the partners 21/34 (62%) were women and had been cohabiting with the PD patient for 38.9(SD=14) years. The mean Hoehn & Yahr score was 2.5(SD=.7) with an average PD duration of 9.4(SD=6.5) years. Mutuality score was significantly negatively associated with CBS (r=-.71), CADI (r=-.73), GDS (r=-.64), ADL (r=-.41), PDQ8 (r=-.41). Mutuality did not strongly correlate with motor and non-motor symptoms, or disease duration. CBS, GDS, PDQ8 and ADL explained 55 % of the variance in mutuality and of the included variables CBS had the largest contribution (beta =-.56, p =.008).
Conclusion
Neither severity of symptoms nor disease duration were associated with impaired mutuality as were higher depression and caregiver burden scores in dyads with mild to moderate PD. Further attempts are needed to improve mutuality in dyads with depression.

NEW MOBILE HEALTH SYSTEM FOR AT-HOME REHABILITATION OF WALKING IN PERSONS WITH PD

A. Ferrari[1], M. Dorfman[2], P. Ginis[3], E. Gazit[2], L. Chiari[1], A. Mirelman[2], A. Nieuwboer[3], J.M. Hausdorff[2]

[1]Department of Electrical Electronic and Information Engineering — Guglielmo Marconi, University of Bologna, Bologna, Italy

[2]Center for the study of Movement Cognition and Mobility Department of Neurology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

[3]Department of Rehabilitation Sciences, KU Leuven, Leuven, Belgium

Background: Mobile health technologies have the potential to empower patients with PD to exercise on their own while receiving online supervision on the correctness of their motor output, thereby promoting long-term adherence and enhancing training effects. Aim of this study was to test the effectiveness of a newly developed auditory bio-feedback system (ABF) for gait training.

Methods: ABF was developed within the FP7/CuPiD project (grant agreement n°288516) and consists of three wireless inertial sensors (easily wearable on shoes and trunk) able to accurately measure in real-time gait spatio-temporal parameters and trunk inclination. The sensors connect to a smartphone and ABF as a whole acts as a 'virtual clinician' continuously assessing and vocally correcting patients' ineffective or unsafe gait patterns. 20 PD subjects were enrolled to participate in a 6-week at-home program in which they train with ABF for 30 minutes at least 3 times/week. Gait analysis pre-post training was performed to assess system efficacy.

Results: The first 14 patients (mean age: 64.5±8.3 yrs; 3 women, disease duration 10.84±5.84 yrs) who completed training using the system were able to successfully use ABF and reported high satisfaction. Comfortable walking speed improved by 9.34%±2.79% (p=0.01), step length improved by 7.05%±1.74% (p=0.03) and the 2-minute walk test improved by 11.65%±3.93% (p=0.03).

Conclusion: Initial findings suggest that patients with PD are able to autonomously use ABF and that it is a promising tool for teaching effective gait patterns. This now needs confirmation in a controlled study.

ADPD5-0985

THE QIGONG APPROACH FOR INPATIENTS WITH PD: TWO CASE REPORTS

H. Yamaji[1]

[1]*Faculty of Rehabilitation, Hiroshima International University, Higashi-hiroshima, Japan*

Introduction

Qigong is an exercise based on traditional Chinese medicine. Qigong combines fast or slow motions and motions at rest such as those during meditation. Qigong is beneficial for the mind and body. Qigong exercise relieves stress and ensures relaxation. Further, Qigong reduces muscular strain and suppresses ataxic movement.

Objective

We aimed to investigate the effect of Qigong exercises in two inpatients with PD.

Description

1. Procedure

Two inpatients with Parkinson's disease underwent a Qigong session for 30 minutes every week. In addition, we taught them Qigong self-exercises to be performed for 5 minutes.

2. Case reports of inpatients with Parkinson's disease

(1) Case A: Female, 75 years

This patient had a 20-year clinical history of Parkinson's disease. She performed all Qigong exercises eagerly. After 6 months, she achieved body balance and stability, and her ataxia improved. Therefore, she was moved from the hospital to a welfare facility.

(2) Case B: Male, 65 years

This patient had a 10-year clinical history of Parkinson's disease. Despite his initial hesitation to undergo Qigong exercises, the patient practiced these exercises every week. His activities of daily living (especially visiting the toilet and bathing) improved after performing Qigong. Subsequently, he started performing the Qigong exercises eagerly. After four months, he was discharged from the hospital, and currently, because of Qigong, he is able to perform his hobbies (painting and karaoke) at home.

Conclusion

These cases suggest that Qigong may reduce muscular strain stress and help cope with Parkinson's disease.

Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil
[5]Neurologia, Hospital Nossa Senhora da Conceição, Porto Alegre, Brazil
[6]Departamento Cirurgia e Ortopedia, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

Objective: To evaluate quality of life (QOL) in individuals with Parkinson's disease (PD) before and after therapy for swallowing disorders. **Methods:** Patients with PD who accepted to participate in all intervention sessions and research steps were selected from the Movement Disorders Outpatient Clinic at Hospital de Clínicas de Porto Alegre. Patients with language and/or hearing conditions that prevented therapy comprehension were excluded. Four individual sessions of 30 minutes each with orientations concerning feeding and a postural maneuver (head down) were performed. Quality of Life in Swallowing Disorders (SWAL-QOL) were also applied before and after therapy. **Results:** Ten individuals were evaluated, 80% male, mean age of 62,2 years (±11,3), mean of 7,5 (±4,3) years of education and mean disease duration of 10,7 (±4,7) years. 30% were classified as H&Y 2, 50% as H&Y 3 and 20% as H&Y 4. It was identified an increase in scores of all domains, including a significant difference in domain 4 (symptom frequency) p=0,025. In domain 5 (food selection), there was a trendp=0,95. Correlations between the differences before and after therapy of each domain and variables as gender, age, H&Y and education were tested. There were significant correlations between domain 10 (sleep) and gender (p=0,047), and H&Y (p=0,024). Besides, a tendency to correlation was seen between domain food selection and H&Y (0,051). **Conclusion:** From these results, an improvement in QOL concerning swallowing of PD patients after phonoaudiologic therapy can be observed. Furthermore, the lower the disease stage, the greater are the improvements after therapy.

CORRELATION BETWEEN QUALITY OF LIFE AND ALTERATIONS IN SPEECH, SWALLOWING AND COGNITION IN INDIVIDUALS WITH PARKINSON'S DISEASE

A. Ayres[1], A.C. Oliveira[2], M.S. Medeiros[3], C.R.M. Rieder[3], M.R. Olchik[2]
[1]Graduate studies: Health Sciences,
Federal University of Health Sciences of Porto Alegre, Porto Alegre, Brazil
[2]Department of Speech Pathology, Federal University of Rio Grande do Sul,
Porto Alegre, Brazil
[3]Neurology, Clinical Hospital of Porto Alegre, Porto Alegre, Brazil

Objective: to evaluate the impact of clinical alterations in speech, swallowing and cognition in the quality of life (QL) of patients with Parkinson's disease.
Methods: This is a quantitative, transversal, descritive study. Patients with Parkinson's disease participated in this study and all individuals under went speech, swallowing and cognitive evaluation, they answered the PDQ-39 questionaire and had their disease severity definied according to the Hoehn&Yahr scale.
Results: 51 PD individuals were evaluated, 28 (54,9%) were male. Average age was 61,7 years (±10,4) and mean disease duration since diagnosis was 10,2 years (±5,5). In the phonoaudiologic evalatuation, 28 (54,9%) had speech disturbancesand 38 (74,5%) hadswallowingimpairment. QL scoreswerelower as disease severity stage sincreased. Among all evaluated aspects, only cognition had na impact in the perception of QL of these individuals, even though speech alterations were the main reason to seek phonoaudiologic treatment.
Conclusion: Cognitive alterations directly reflect the perception of QL of patients with PD. Speech disturbances, however, are the main complaint, but with no impact on QL. Swallowing impairment does not have an impact on QL.

ADPD5-1493
COMPARISONS OF COGNITIVE DEFICITS IN PD AND METHAMPHETAMINE TOXICITY
Y. Sung[1], P. Renshaw[1], E. McGlade[1], D. Yurgelun-Todd[1]
[1]Department of Psychiatry, Univerity of Utah, Salt Lake City, USA
Objectives: A growing body of literature suggests that mild cognitive impairment is present at the time of diagnosis of PD. In animals, MPTP administration produces significant cognitive deficits even in the absence of Parkinsonian motor impairment. Studies of methamphetamine users also have reported impaired cognitive function without motor symptoms. This may be due to potential similarities in pathophysiology between PD and methamphetamine toxicity. This study examined the profile of cognitive deficits in methamphetamine users compared to those observed in PD patients.
Methods: Fifty-two abstinent methamphetamine and thirty-two healthy subjects completed cognitive assessments including Wisconsin Card Sorting Test (WCST), Stroop Test, and Wechsler Memory Scale (WMS). Performance on several functional domains including executive function, cognitive flexibility, attention, and memory was compared to cognitive impairment found in PD patients from prior studies.
Results: Relative to controls, methamphetamine users made more errors ($p=0.04$) on the WCST and required more time on Stroop Interference ($p=0.03$). WMS revealed that both immediate and delayed memory as well as auditory and visual working memory were significantly decreased in methamphetamine users (all $p<0.01$). Cognitive profiles in early PD are notable for attentional, executive, and visuospatial deficits (Svenningsson, 2012).
Conclusions: These results suggest similar cognitive deficits in both PD patients and methamphetamine abusers, and lend support to the evidence that PD and methamphetamine toxicity share common features of alterations in the frontal dopaminergic systems. Further research is needed to identify the neurophysiological basis of these deficits in order to develop novel pharmacotherapeutics to address these shared symptoms.

E-MOTION: A RELIABILITY ASSESSMENT FOR A PROTOTYPE SOFTWARE TO COMPLEMENT THE CLINICAL EVALUATION OF PATIENTS WITH PARKINSON'S DISEASE

Y. Ariza-Araujo[1], J. Arango[2], B. Muñoz[3], W. Agredo[4], A. Navarro[2], J. Orozco[5]
[1]Facultad de Ciencias de la Salud, Universidad Icesi, Cali, Colombia
[2]Facultad de Ingenieria, Universidad Icesi, Cali, Colombia
[3]Neuropsicologia, Fundacion Valle del Lili, Cali, Colombia
[4]Ingeniería Biomedica, Universidad Autonoma de Occidente, Cali, Colombia
[5]Neurologia, Fundacion Valle del Lili, Cali, Colombia

Objective: To compare a software prototype, e-Motion with a benchmark reference, multiple-camera 3D motion capture system to track a gait pattern.
Background: Parkinson's disease (PD) is characterized by alterations in gait pattern that may increase the risk of falls. The gait pattern's variations cannot be objectively measured in the clinical examination, therefore, is necessary to adapt devices to measure objectively, valid and replicable changes in gait patterns.
Methods: we developed the "e-Motion Capture System", a prototype software able to calculate motor (stride and step length) and spatiotemporal (velocity and acceleration), parameters that are affecting quality of life in patients with PD. This analysis was performed to compare the spatial locations of the ankles from a volunteer under indoor controlled conditions.
Results: The index for the reliability to both systems and both laterality (N=599) averaged together 0.96 (IC95% 0.94 - 0.97). To left ankle, (N=103), the index was 0.96 (IC95% 0.88 - 0.98), and to right ankle, (N=112) the index was 0.97 (IC95% 0.85 - 0.99). According to guideline for the evaluation of intra-class correlation coefficients, the inter-rater agreement between e-Motion and 3D motion capture system shows an excellent agreement.
Conclusions: The e-Motion Capture System could develop and quantify measurements of motor and spatial-temporal variables sensitive to change in the timeline of the disease. In addition, this tool is useful to complement the clinical assessment and measure efficacy of pharmacological and non-pharmacological interventions of patients with PD.

ASSESSMENT OF NONVERBAL AND VERBAL APRAXIA IN PATIENTS WITH PARKINSON'S DISEASE
A. Ayres[1], M. Presotto[2], A.F.S. Shuh[3], M.R. Olchik[4], C.R.M. Rieder[3]
[1]Post-graduate: Health Sciences, University of Health Sciences of Porto Alegre, Porto Alegre, Brazil
[2]Graduate School of Medicine: Medical Sciences, Federal University of Rio Grande do Sul, Porto Alegre, Brazil
[3]Neurology, Clinical Hospital of Porto Alegre, Porto Alegre, Brazil
[4]Department of Speech Pathology, Federal University of Rio Grande do Sul, Porto Alegre, Brazil
Objective: To assess the prevalence of nonverbal and verbal apraxia in patients with Parkinson's disease (PD), and analyze the correlation between these conditions and patient age, education, duration of disease and PD stage, as well as to evaluate the correlation between the two types of apraxia and the frequency and types of verbal praxic errors made by patients in the sample. **Method:** This was an observational prevalence study. The sample comprised 45 patients with PD seen at the Movement Disorders Clinic of the Clinical Hospital of Porto Alegre, Brazil. Patients were evaluated using the Speech Apraxia Assessment Protocol, and PD stages were classified according to the Hoehn and Yahr (H&Y) scale. **Results:** The prevalence of nonverbal apraxia and verbal apraxia in the present sample was 24.4%. There was no significance between the nonverbal apraxia with age, education, duration of disease, PD stage (H&Y), and genre. The correlation between verbal apraxia and education was significant ($p \leq 0.05$), but there was no significance with age, duration of disease, PD stage (H&Y) and genre. The most frequent types of verbal praxic errors were omissions (70.8%). The analysis of mode and place of articulation showed that most errors occurred during the production of vibrant (57.7%) and dentoalveolar (92%) phonemes, consecutively. **Conclusion**: patients with PD presented nonverbal and verbal apraxia, and made several verbal praxic errors. Verbal apraxia, but not nonverbal apraxia, was correlated with education levels.

6-HYDROXYDOPAMINE CAUSES CELL DEATH IN RETINOIC-ACID INDUCED DIFFERENTIATED SH-SY5Y CELLS VIA DOPAMINE TRANSPORTER

F.M. Lopes[1,3,4], G.F. Londero[1], L.L. Motta[1], C. Chatain[1], M.A. De Bastiani[1], L. Marengo[1], F. Kapczinski[2], R. Parsons[3], F. Klamt[1]

[4]CAPES foundation, Ministry of Education, Brasilia, DF 70.040-020, Brazil

Objectives: 6-hydroxydopamine (6-OHDA) is the most used neurotoxin to study Parkinson's Disease (PD). Even though this neurotoxin disrupts the nigrostriatal pathway in vivo by uptake via dopamine transporter (DAT), the toxicity mechanism of 6-OHDA in vitro remains controversial. This may be related to lower levels of DAT in cell lines, such as the human neuroblastoma SH-SY5Y. Our group established a dopaminergic differentiation induced by retinoic acid (RA) treatment in SH-SY5Y cells. Herein, we aim to validate RA-differentiated SH-SY5Y cells as model for PD studies and evaluate the role of DAT in 6-OHDA-induced neurotoxicity.

Methods: SH-SY5Y cells differentiation was induced by the combination of ten micromolar of RA in cell culture medium supplemented with one percent of fetal bovine serum during seven days. We evaluated cellular proliferation, neurite outgrowth, gene expression, dopamine transporter (DAT) immunocontent and 6-hydroxydopamine cytotoxicity.

Results: We found that SH-SY5Y differentiation decreases cellular proliferation and increases neurite outgrowth. Moreover, RA-differentiated cells express higher levels of dopaminergic synapse markers, DAT immunocontent and is more sensitive to 6-OHDA compared to undifferentiated SH-SY5Y cells. Later, we observed that the pharmacological inhibition of DAT significantly reduces hydrogen peroxide production and cell death in response to 6-OHDA. Thus, demonstrating a pivotal role for DAT in 6-OHDA neurotoxicity in RA-differentiated SH-SY5Y cells.

Conclusions: Our data support that RA-differentiated SH-SY5Y cells is a suitable in vitro model to study PD pathophysiology since not only it mimics the dopaminergic cell features but also the 6-OHDA-induced cytotoxicity in vivo.

THE COMMUNITY DRIVEN PD MAP PROJECT: FROM A KNOWLEDGE REPOSITORY TO A RESEARCH TOOL

S. Gebel[1], M. Ostaszewski[1], P. Gawron[1], K. Fujita[2], C. Trefois[1], P. Antony[1], D. Coowar[1], R. Balling[1]

[1]Luxembourg Centre for Systems Biomedicine, University of Luxembourg, Esch-Sur-Alzette, Luxembourg

[2]Kitano Unit, The Systems Biology Institute, Tokyo, Japan

Objectives: As the knowledge on molecular mechanisms involved in Parkinson's disease (PD) is complex and heterogeneous it needs to be efficiently organized. Therefore the "PD map" compiles literature-based information on PD into an easy to explore and freely accessible molecular interaction map (http://pdmap.uni.lu). The involvement of the scientific community is crucial for such a resource. To further promote the use of the PD map, we developed new, research-facilitating functionalities.

Methods: PD map content curation and development of associated tools are community-driven. Therefore the PD map offers straightforward, interactive online features to provide feedback on content and functionalities. Furthermore, direct interaction with the scientific community in hands-on curation workshops facilitate the development of user-oriented functionalities.

Results: Here we present applications of new PD map research tools. (1) With the drug interaction tool user can now search for drug names or brands. Potential targets are fetched from drug databases and displayed in the PD map. (2) To visualize user data on the PD map, experimental data-sets can now be uploaded and displayed, thus putting large scale data into the context of PD-related molecular pathways. (3) The export function enables to export selected areas of the PD map as xml.file, preserving annotations and information on the underlying literature.

Conclusion: By forming a resource for computational analysis and a platform for community interactions, the PD map will become a hub for the PD-community to deal with the exponentially increasing information on PD and allowing the research community to open new avenues in PD research

ADPD5-0337
REWARD SENSITIVITY DEFICITS UNDERLIE APATHY IN PD
K. Muhammed[1], S. Manohar[1], M. Husain[1]
[1]Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom
Objectives
Apathy is present in up to 70% of Parkinson's disease (PD). Its mechanisms are poorly understood and objective detection methods that do not rely on questionnaire reports are lacking, often leading to a misdiagnosis of depression, inadequate disease monitoring and poor outcomes. Here we used eye movement and pupil modulation in response to reward as objective metrics of motivation. Differences in reward sensitivity in PD patients ON dopaminergic medication were compared to OFF, and the relation to apathy assessed.
Methods
20 patients with idiopathic PD, tested ON and OFF medication, and healthy age-matched participants made saccadic eye movements for different monetary rewards. Eye position, saccadic peak velocity and pupil diameter were measured using an infrared eye tracker, while apathy was indexed by Lille Apathy Rating Scale (LARS) scores.
Results
Controls and PD patients ON demonstrated increased saccadic velocity and pupil diameter as reward magnitude increased. This reward sensitivity was blunted in PD patients OFF dopaminergic medication. Crucially, PD cases who were more apathetic on the basis of LARS scores, exhibited significantly less reward sensitivity than more motivated PD patients.
Conclusions
Saccadic velocity and pupil diameter are influenced by reward magnitude, with the degree of modulation varying with motivation levels across individuals. These indices provide novel, objective behavioural measures for assessing apathy in PD. The use of dopaminergic medication may be an effective treatment for apathy by increasing reward sensitivity, independent of effects on motor control.

ADPD5-0463
DYSFUNCTIONAL PROCESSING OF TIME IN PARKINSON DISEASE
M. Honma[1], T. Kuroda[1], A. Futamura[1], A. Sugimoto[1], H. Murakami[1], M. Kawamura[1]
[1]Department of Neurology, Showa University School of Medicine, Tokyo, Japan
Objectives: Temporal information processing is inefficient in patients with Parkinson' disease (PD). This results in perception of shortened time (Riesen & Schnider, 2001). The pathophysiology of PD has been described as linked with the basal ganglia (Lalonde & Hannequin, 1999), and patients have tremor (Yanagisawa & Nezu, 1987) and muscular rigidity (Lee, 1989). We hypothesized that disordered basal ganglia are linked to time counting dysfunction and this in turn leads to abnormal estimation of mental time. Methods: Nineteen PD patients and 19 age-matched controls (AC) took part. Temporal function was measured by subjective time production (TP) in 0.5–300 seconds tasks, subjective time by tapping (TPT) for 60 seconds, and one second cycle tapping (CT) for 60 seconds. Results: TP in PD was shorter than in AC. An average cycle per second of TPT in PD was shorter than AC (Fig. 1A). While the CT cycle in AC was longer than PD (Fig. 1C), the AC cycle was closer to one second compared with TPT (Fig. 1B). The CT cycle in PD was similar to TPT. Conclusions: The results suggest that shorter time estimation in PD is caused by a shortened time counting cycle. Furthermore, normal time estimation in AC depends on flexible time counting within a given time, while abnormal time estimation in PD depends on stabilized time counting.

ADPD5-1199
NIGRAL CELL LOSS FOLLOWING NORADRENERGIC DENERVATION
S. af Bjerkén[1], R. Stenmark Persson[1], A. Barkander[1], N. Nevalainen[1], I. Strömberg[1]
[1]Integrative Medical Biology, Umea University, Umeå, Sweden
Objectives: In Parkinson's disease, besides dopaminergic cell loss, there is an extensive noradrenergic cell loss in the locus coeruleus. Although the noradrenaline system have been recognized as part of the pathology in Parkinson's disease, the consequence of noradrenergic degeneration as well as the temporal relation between noradrenergic and dopaminergic cell loss remains unclear. There are also implications of noradrenaline acting as a neuroprotector. We aim to investigate the effect of reduced noradrenergic input on nigral dopamine neurons.
Methods: Sprague-Dawley rats were injected with DSP4 [N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine], causing selective degeneration of noradrenergic neurons. The effects were analyzed with *in vivo* voltammetry and post-mortem tissue analysis.
Results: Assessment of the noradrenergic nerve fiber density demonstrated, on average, 90 % denervation 3 months post DSP4-treatment. Evaluation of the dopaminergic system using *in vivo* chronoamperometry showed significantly increased striatal dopamine release in DSP4-treated rats compared to controls. *In vivo* amperometry with enzyme-based multisite microelectrodes was performed to test whether the increased dopamine release was due to an altered striatal glutamatergic input. The recordings revealed significantly decreased glutamate release in denervated rats. After sacrifice, the brains have been collected and processed for immunohistochemistry. Stereological cell counts of tyrosine hydroxylase-positive neurons in DSP4-treated rats demonstrated a significantly reduced number of noradrenergic locus coeruleus neurons and most interestingly also a significantly reduced number of nigral dopamine neurons compared to controls.
Conclusions: These findings support the hypothesis of noradrenaline acting as a neuroprotector for nigral dopamine neurons, as well as its plausible role in the etiology of Parkinson's disease.

A NOVEL DINUCLEOTIDE COMPLEX REPEAT IN THE SNCA GENE CONFERS RISK FOR LEWY BODY PATHOLOGY IN ALZHEIMER'S DISEASE AND AFFECTS SNCA EXPRESSION PROFILES

O. Chiba-Falek[1], M. Lutz[1], R. Saul[2], C. Linnertz[1], O. Glenn[1], A. Roses[1]
[1]Neurology, Duke University Medical Center, Durham, USA
[2], Polymorphic DNA Technologies, Alameda, USA

Genetic association of the *SNCA* gene with several Lewy-body (LB) related disorders were reported. However, the actual genetic variant/s that underlie the observed association remains largely elusive. Structural variants (SVs), particularly microsatellites are among the most polymorphic loci in the human genome and have been implicated in many Mendelian diseases, including neurodegenerative conditions. However, studies about their possible role in complex human disorders are underrepresented. We recently showed that tagging-SNPs across *SNCA* locus were significantly associated with increased risk for LB-pathology in AD. Building on these results, herein, we embarked on an effort to identify SVs within *SNCA* that contribute to LBV/AD-risk. Using an algorithm to catalogue and score SVs in *SNCA*-intron4, followed by deep sequencing, we identified a novel, highly polymorphic, complex CT-microsatellite. We showed in autopsy cases with LBV/AD compared with AD-only controls that certain alleles at this complex CT-microsatellite conferred risk to develop LBV/AD ($p<0.0001$). We further correlated the genetic association with biological functions, and expression analysis demonstrated that the CT-microsatellite site acts as a splicing regulator of exon5, whereas the risk allele was significantly associated with elevated levels of exon5 skipping ($p=0.01$). We also detected significantly higher levels of the alternative-splicing event in LBV/AD brains compared to AD controls ($p=0.0002$). In conclusion, we discovered a novel complex CT-microsatellite in *SNCA* that contributes to LB-pathology, possibly via splicing regulation of *SNCA*. Studies of the relevant of this CT-microsatellite to other LB-spectrum disorders and experiments using biological system and genome-editing approach to validate its regulatory effect are underway.

QUANTITATIVE AND FIBER-SELECTIVE EVALUATION OF PAIN AND SENSORY DYSFUNCTION IN PATIENTS WITH PARKINSON'S DISEASE

Y.L. Wang[1], Y. Chen[1], C.J. Mao[1], C.F. Liu[1]
[1]Second Affiliated Hospital, Soochow University, Suzhou, China

Introduction: Pain and sensory disturbances affect many patients with Parkinson's disease (PD). The present study aimed to evaluate the pain and sensory sensitivity of each class of afferent fibers in PD patients and determine the effects of dopaminergic therapy on pain and sensory sensitivity.

Methods: Current perception threshold (CPT) and pain tolerance thresholds (PTT) at three frequencies, 2000 Hz, 250 Hz, and 5 Hz, to stimulate Aβ fibers, Aδ fibers, and small C-polymodal fibers, respectively, were measured in 72 PD patients and 35 healthy controls.

Results: CPT was higher at all three frequencies and PTT was lower at 2000 Hz and 250 Hz in PD patients with pain versus healthy controls ($P < 0.05$). CPT was higher at 2000 Hz and 250 Hz and PTT was lower at 2000 Hz and 250 Hz in PD patients without pain versus healthy controls ($P < 0.05$). PD patients with pain exhibited higher CPT at 5 Hz and 250 Hz than PD patients without pain ($P < 0.05$). Dopaminergic therapy did not affect CPT or PPT in PD patients ($P > 0.05$). Conclusions: Abnormal Aδ fiber- and Aβ fiber-dependent sensory inputs may exist in PD. Abnormal sensory inputs via C fibers and Aδ fibers might be associated with the presence of pain in PD. Because dopaminergic therapy failed to mitigate these sensory and pain dysfunctions, mechanisms not involving the dopaminergic pathway are likely to be implicated

EVIDENCE FOR SUBTYPE-SPECIFIC IMPAIRMENT IN EMOTION PROCESSING IN PARKINSON'S DISEASE

J. Heller[1], I. Dogan[1], H. Staggenborg[1], S. Mirzazade[1], J.B. Schulz[1], K. Reetz[2]
[1]Department of Neurology University Hospital Aachen & Jülich-Aachen Research Alliance (JARA Brain), RWTH Aachen University & Research Center Jülich, Aachen, Germany
[2]Department of Neurology University Hospital Aachen & Jülich-Aachen Research Alliance (JARA Brain) & Institute of Neuroscience and Medicine (INM-4), RWTH Aachen University & Research Center Jülich, Aachen, Germany

Objectives
Impaired facial emotion recognition in Parkinson's disease (PD) has been reported for negative basic emotions. However, results are heterogeneous and to our knowledge none of the studies investigated impairment in different PD subtypes, although previous reports suggest a more benign course of disease in tremor-dominant compared to akinetic-rigid PD. The aim of the present study was to evaluate emotion recognition abilities of PD patients considering the variable of motor subtype.
Methods
Detailed clinical and neuropsychological assessments (e.g. Unified Parkinson's Disease Rating Scale, UPDRS; Hoehn-&-Yahr-Scale; cognitive tests; questionnaires on quality of life, anxiety and depression) were acquired in tremor-dominant and akinetic-rigid PD patients and healthy controls matched for age, gender and education. Emotion recognition abilities were assessed with the Ekman-60-faces-test.
Results
Our preliminary behavioral data showed worse performance in 17 akinetic-rigid (mean age: 67.6±6.7 years; 9 male; mean UPDRS-motor: 26.8±9.7) compared to 12 tremor-dominant patients (62.8±14.2 years; 6 male; UPDRS-motor: 20.4±6.2) in the recognition of surprise (p=.008) and anger (p=.008). There were no significant differences regarding age, education, disease duration, UPDRS scores and IQ. L-dopa dose was significantly higher (p=.009) in akinetic-rigid PD but did not correlate with performance in emotion recognition. Compared to the 17 healthy controls (62.1±7.5 years; 8 male), recognition of surprise (p=.005) and anger (p=.035) was enhanced in tremor-dominant patients.
Conclusion
Our results indicate that disease-related motor subtypes may play a role in emotion processing in PD. Enlargement of the study sample and the identification of respective neural correlates using functional MRI will provide further insight.

[3]Department of Molecular Medicine, IRCCS San Matteo Foundation University of Pavia, Pavia, Italy
[4]Laboratory of Neurophysiology of Integrative Autonomic Systems Headache Science C entre, C. Mondino National Neurological Institute, Pavia, Italy
[5]Department of Internal Medicine and Therapeutics, University of Pavia, Pavia, Italy
Objectives: gastrointestinal (GI) dysfunction, constipation in particular, is the most common nonmotor symptom of PD. In this study we explored the relationship between central dopaminergic denervation, GI dopaminergic function and GI motility in a PD-like model of nigrostriatal lesion, focusing on the potential role of the dorsal motor nucleus of the vagus (DMV).
Methods: Sprague-Dawley rats received a stereotaxic injection of saline or neurotoxin 6-hydroxydopamine (6-OHDA) into the medial-forebrain-bundle. Peristalsis was evaluated in isolated colonic segments, in baseline conditions and following exposure to combinations of D2 receptor (DRD2) agonist sumanirole and antagonist L-741626. Dopamine levels, DRD2 and choline acetyltransferase (ChAT) expression were assessed in the ileum and colon of all animals. Investigation of neuronal activity in the dorsal motor nucleus of the DMV was studied by analysis of FosB/Delta FosB expression in tyrosine hydroxylase and ChAT positive neurons.
Results: peristalsis showed no differences at basal recording between 6-OHDA and control groups. However, 6-OHDA lesioned animals completely lost the inhibitory response to sumanirole. A trend toward a reduced expression of DRD2 was observed in the colon of 6-OHDA lesioned rats, which was associated with increased tissue levels of dopamine and enhanced ChAT expression. A slight, but consistent, increase in FosB/Delta FosB expression was observed in the DMV of 6-OHDA lesioned rats.
Conclusions: our results demonstrate that selective lesion of the nigrostriatal dopaminergic pathway triggers alterations of GI dopaminergic system. Neuronal activations within the DMV may be the link between nigrostriatal lesion and neurochemical/functional changes in the GI tract.

NANOSCALE CAPILLARY ISOELECTRIC FOCUSING FOR THE DETECTION OF DIFFERENTIALLY SIALYLATED SERPINA1 IN CEREBROSPINAL FLUID AS AN EARLY DIAGNOSTIC MARKER FOR PD DEMENTIA

S. Halbgebauer[1], U. Haussmann[2], H.W. Klafki[2], H. Tumani[1], J. Wiltfang[3], M. Otto[1]
[1]Neurology, University Hospital Ulm, Ulm, Germany
[2]Department of Psychiatry and Psychotherapy University of Duisburg-Essen, LVR-Klinikum Essen, Essen, Germany
[3]Department of Psychiatry and Psychotherapy, University Medical Center (UMG) Georg-August-University, Göttingen, Germany

PD with dementia (PDD) encompasses together with dementia with Lewy bodies (DLB) 10-15% of all degenerative dementia. About 30% of patients with Parkinson's disease (PD) develop a dementia in the course of the disease which in turn drastically reduces quality of life and does often lead to an earlier hospitalization of the patients. However, up to date, diagnosis of PDD is merely done by clinical parameters. Recently, we described by using two dimensional gel electrophoresis (2D and 2D immunoblot) that isoforms of the serine protease inhibitor Serpin A1 are differently sialylated in the cerebrospinal fluid (CSF) of healthy individuals and PD compared to PDD. However, 2D electrophoresis is time-consuming and therefore not suited as a high-throughput approach. To overcome this problem we used a new nanoscale capillary isoelectric focusing (CIEF) approach for the detection of differentially sialylated Serpin A1 isoforms. So far we analyzed 102 patients with PDD, PD and non-demented controls. The CIEF approach gave mainly similar results like the 2D immunoblots. In addition using the CIEF approach we were able to specifically quantify each SerpinA1 isoform's expression level. We found a significant difference in the expression levels of certain SerpinA1 isoforms between PDD, PD and controls. By CIEF we are now able to analyze up to 96 samples per day compared to 4-8 samples by our 2D immunoblot. The detection of different Serpin A1 isoforms by CIEF is rapid, sensitive and allows a large scale analysis of biosamples.

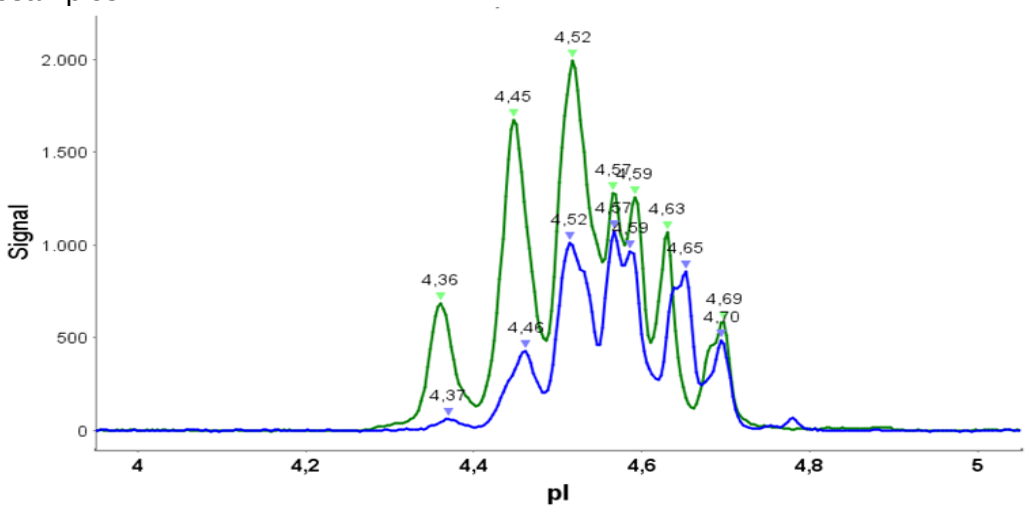

Figure: Analysis of CSF SerpinA1 using CIEF. Overlay of a control (blue) and PDD (green) electropherogram showing the difference in the SerpinA1 expression level of certain isoforms between the two groups. pI, isoelectric point.

ADPD5-0812

GASTRIC DYSFUNCTION AND PARKINSON'S DISEASE: EVIDENCE FROM AN IN VITRO STUDY IN 6-OHDA RATS.

G. Vegezzi[1], G. Levandis[2], F. Al Harraq[1], F. Tripodi[1], F. Saccani[3], L. Flammini[1], G. Domenichini[1], S. Bertoni[1], V. Ballabeni[1], S. Cerri[2], F. Blandini[2], E. Barocelli[1]
[1]Pharmacy, University of Parma, Parma, Italy
[2]Center for Research in Neurodegenerative Diseases "C. Mondino", National Neurological Institute, Pavia, Italy
[3]Clinical and Experimental Medicine, University of Parma, Parma, Italy

OBJECTIVES: Gastroparesis is frequently observed in patients with Parkinson's Disease (PD). To investigate *in vitro* the mechanisms underlying PD-associated gastric dysmotility, pharmacological/electrical field stimulation (EFS) responses were studied in preparations from 6-hydroxydopamine (6-OHDA) rats.
METHODS: Thiopental-anaesthetized male Sprague Dawley rats were injected intracranially with 6-OHDA or saline and sacrificed after 8 weeks. Stomach circular/longitudinal strips and pylorus were pharmacologically-stimulated with increasing concentrations of bethanechol/prostaglandin F2 alpha (PGF2). The relaxing effect of dopamine (DA) was studied on hypertone induced by PGF2α/bethanechol. EFS was performed on pre-contracted tissues in the absence/presence of atropine plus guanethidine (NANC-conditions), L-NAME (NO-synthase inhibitor) and protease alpha-chymotrypsin. The experiments were carried out in the respect of Italian Law on the use of animals for experimental ends (D.Lgs26/2014).
RESULTS: Pharmacological stimuli**:** Maximal responses to bethanechol/PGF2-alpha were markedly reduced in gastric circular muscles of 6-OHDA rats. In gastric longitudinal strips/pylorus from 6-OHDA rats, DA induced a smaller relaxation compared to controls. EFS: EFS-induced relaxation of pylorus was lower and insensitive to L-NAME in 6-OHDA rats compared to control. EFS relaxation of gastric longitudinal muscle was almost abolished by L-NAME and alpha -chymotrypsin in 6-OHDA rats.
CONCLUSIONS: The data obtained in rat tissues excised after 8 weeks from 6-OHDA administration indicate that the loss of responsiveness to contractile agents in gastric circular muscles, the impairment of pyloric nitrergic control and the increase of inhibitory peptidergic neurotransmission in longitudinal strips can altogether contribute to the gastric dysmotility we observed *in vivo* in the same experimental model and detected in PD patients.

ADPD5-1570
PREVALENCE OF SMELL IMPAIRMENTS AND SUBSTANTIA NIGRA HYPERECHOGENEICITY IN LITHUANIANS, BORN IN 1964

J. Janusauskaite[1], P. Puzinas[1], D. Rastenyte[1]
[1]Neurology, Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Kaunas, Lithuania

Objectives: to determine the prevalence of smell impairments and changes in substantia nigra (SN) echogeneicity on TCS in healthy adult population and to evaluate the link between the two.
Methods: 295 subjects – 59% women and 41% men, born in 1964 (aged 48,42 ± 0,04 at the moment of the study) , participating in a population study "Connection between genetic and lifestyle risk factors for chronic disease risks since childhood" were screened for smell impairments, using Sniffin' Sticks 12 test, as well as for SN echogeneicity changes using TCS. They all underwent neurological examination with focus on extrapyramidal signs and none was found to have PD at the moment of the study.
Results: sufficient acoustic temporal bone window allowed complete TCS results to be obtained in 90.5% of cases. In 6.1% of examined cases unilateral or bilateral enlargement of SN area (hiperechogeneicity) was detected (using the cutoff value of 0.26 cm^2). In additional 18.8% of cases SN area was found to be marginal unilateraly or bilaterally (0.20-0.26 cm^2). 24.1% of participants had at least mild hiposmia. Changes in SN echogeneicity correlated positively with smell impairments ($p<0.05$). 9.8% of participants were found to have both - smell and SN echogeneicity impairments.
Conclusions: almost ¼ of the studied population was found to have at least mild smell impairments. In similar proportion of cases hyperechogeneicity of SN was detected. A positive correlation between those symptoms was observed.

NEUROPROTECTIVE TRIALS IN PRODROMAL PARKINSON'S DISEASE AND DEMENTIA WITH LEWY BODIES WITH REM SLEEP BEHAVIOR DISORDER

R.B. Postuma[1], N.A. REM Sleep Behavior Disorder Study Group[2], J.F. Gagnon[3], J.A. Bertrand[3], D. Grenier-Marchand[3], J.Y. Montplaisir[3]
[1]Neurology, McGill University, Montreal, Canada
[2]N/A, REM Sleep Behavior Disorder Study Group, Marburg, Germany
[3]Centre d'Études Avancées en Médecine du Sommeil, Hôpital du Sacré-Cœur de Montréal, Montreal, Canada

Objective
To delineate risk and risk factors for conversion from idiopathic REM sleep behavior disorder (RBD) to Parkinson's disease, Dementia with Lewy bodies, and Multiple System Atrophy, in order to enable practical planning of neuroprotective trials against neurodegenerative synucleinopathy.
Methods
In a 10-year prospective cohort, we tested prodromal Parkinson's markers in 89 patients with idiopathic RBD. With Kaplan-Meier analysis we calculated risk of neurodegenerative synucleinopathy, and compared our values to recent estimates from a 300-patient RBD study group multicenter study. Using Cox proportional hazards, we tested the ability of prodromal markers to identify patients at higher disease risk, and then designed stratification strategies to optimally select patients for definitive neuroprotective trials.
Results
The risk of defined neurodegenerative synucleinopathy was high; 30% developed disease at 3 years, rising to 66% at 7.5 years. This was similar to the RBD study group's multicenter estimate (25% at 3 years, 41% at 5 years). Age (HR=1.07), olfactory loss (HR=2.8), color vision (HR=3.1), and subtle motor dysfunction (HR=3.9) identified higher risk of disease conversion. Stratification with prodromal markers increased risk of neurodegenerative disease conversion by 200%, and combining markers allowed sample size reduction in neuroprotective trials by >40%. With a moderately-effective agent (HR=0.5), a 2-year trial can demonstrate definitive reductions in neurodegenerative disease with only 80 patients per group.
Conclusions
Using stratification with simply-assessed markers, RBD patients can identify extremely high likelihood of prodromal synucleinopathy, enabling design pf neuroprotective trials against Parkinson's disease and Dementia with Lewy bodies.

PARKINSON'S UK TISSUE BANK: A UNIQUE TISSUE RESOURCE FOR PARKINSON'S DISEASE RESEARCH
D. Dexter[1], R. Reynolds[1], F. Roncaroli[1], D. Gveric[1], S. Gentleman[1]
[1]Division of Brain Sciences, Imperial College London, London, United Kingdom
Background: Parkinson's UK Tissue Bank was established in 2002 to collect and supply high quality human brain, spinal cord, DNA and CSF samples to researchers. Tissue is collected through a donor programme with almost 10,000 potential donors. To date we have collected almost 800 Parkinson's related brains and we are currently collecting ~110 cases per year with short post-mortem delays. Neuropathological examination utilise the latest international criteria, are graded according to Braak along with the degree Alzheimer's type co-pathology. Extensive medical histories exist on all cases.
Objectives: To act as an open access tissue resource for researchers so as to foster research towards a better understanding/cure for Parkinson's. We have supplied tissue to hundreds of key research projects e.g. GWAS sequencing project. A number of different tissue formats are available i.e. snap frozen, formalin fixed - paraffin embedded, and formal fixed – cryopreserved tissue.
Access: The Tissue Bank welcomes applications from both for profit and not for profit organisations. Tissue request forms can be requested via the tissue bank manager, all applications are reviewed by an independent scientific review board. The Tissue Bank via its review board can issue its own ethical approval for the use of tissue, under the MREC scheme, thus saving the need for researchers to get separate ethical permission in many cases. We encourage potential users to discuss their requirements with the Tissue Bank manager Dr D. Gveric or its Scientific Director Professor D Dexter. e-mail us at pdbank@imperial.ac.uk or Tel: +44 207 594 9732

FOLLOW-UP STUDY OF MCI PATIENTS DEVELOPING AD OR DLB (2): CHARACTERISTICS OF NEUROPSYCHOLOGIAL EXAMINATIONS AT BASELINE

K. Ota[1], D. Kondo[1], K. Kasanuki[1], H. Fujishiro[1], N. Murayama[1], K. Sato[1], Y. Hirayasu[2], H. Arai[3], E. Iseki[1]

[1]PET-CT Dementia Research Center, Juntendo Tokyo Koto Geriatric Medical Center, Tokyo, Japan

[2]Department of Psychiatry, Yokohama City University School of Medicine, Yokohama, Japan

[3]Department of Psychiatry, Juntendo University School of Medicine, Tokyo, Japan

Objective: We conducted a long-term follow-up study to investigate the characteristics of neuropsychological examinations on MCI patients who developed Alzheimer's disease (AD) or dementia with Lewy bodies (DLB) during the follow-up period.

Methods: The subjects were 96 elders who visited our memory clinic between November 2006 and December 2012 and were diagnosed as MCI (FAST lower than 3, CDR lower than 0.5, MMSE higher than 24). All the subjects underwent neuropsychological examinations (MMSE, WAIS-III, WMS-R) within a month from their first visit to memory clinic and were followed the mean of 44.8 months. The subjects were divided into three groups; AD-converters (AD group: n=23), DLB-converters (DLB group: n=13) and non-converters (NC group: n=60). We compared the results of neuropsychological examinations at baseline among three groups.

Results: Compared to NC group, AD group exhibited significantly lower scores in MMSE, Verbal comprehension in WAIS-III, Verbal memory, Visual memory and Delayed recall in WMS-R, and DLB group showed significantly lower scores in Processing speed in WAIS-III and Visual memory in WMS-R. There was no significant difference between AD group and DLB group.

Conclusion: Specific patterns of cognitive decline can be observed in MCI patients before they fulfill clinical diagnostic criteria of AD or DLB. Detailed neuropsychological examinations can be helpful for early detection of AD or DLB in MCI patients.

ADPD5-0308
FOLLOW-UP STUDY OF MCI PATIENTS DEVELOPING AD OR DLB (1): COMPARISON OF [18]F-FDG PET IMAGES AT BASELINE

D. Kondo[1], K. Ota[1], K. Kasanuki[1], H. Fujishiro[1], N. Murayama[1], K. Sato[1], Y. Hirayasu[2], H. Arai[3], E. Iseki[1]
[1]PET-CT Dementia Research Center, Juntendo Tokyo Koto Geriatric Medical Center, Tokyo, Japan
[2]Department of Psychiatry, Yokohama City University School of Medicine, Yokohama, Japan
[3]Department of Psychiatry, Juntendo University School of Medicine, Tokyo, Japan

Objective: We conducted a long-term follow-up study to investigate the patterns of hypometabolism on MCI patients who developed Alzheimer's disease (AD) or dementia with Lewy bodies (DLB) during the follow-up period.
Methods: The subjects were 96 elders who visited our memory clinic between November 2006 and December 2012 and were diagnosed as MCI (FAST lower than 3, CDR lower than 0.5, MMSE higher than 24). All the subjects underwent [18]F-FDG PET within a month from their first visit to memory clinic and were followed the mean of 44.8 months. The subjects were divided into three groups; AD-converters (AD group: n=23), DLB-converters (DLB group: n=13) and non-converters (NC group: n=60). We compared the patterns of hypometabolism at baseline among three groups.
Results: Compared to NC group, AD group exhibited significant hypometabolism in the posterior cingulate cortex, and DLB group showed significant hypometabolism in the precuneus. DLB group exhibited significant hypometabolism in the occipital lobe compared to AD group.
Conclusion: The present study indicated that specific patterns of hypometabolism can be observed in MCI patients before the patients fulfill clinical diagnostic criteria of AD or DLB; MCI patients who progress to AD tend to show hypometabolism predominantly in the posterior cingulate cortex, and those who progress to DLB are likely to exhibit hypometabolism predominantly in the precuneus and occipital lobe. [18]F-FDG PET can increase the opportunities for early detection of AD or DLB in MCI patients.

ADPD5-0421

THE RELATIONSHIP BETWEEN MONTREAL COGNITIVE ASSESSMENT AND BIOCHEMICAL BIOMARKERS IN PATIENTS WITH PARKINSON'S DISEASE

T. Shinoda[1], T. Maeda[1], R. Muraoka[1], M. Sugawara[1], M. Yamamoto[2]
[1]Neurology and Movement Disorder Research,
Research Institute for Brain and Blood Vessels, Akita, Japan
[2]Neurology, Takamatsu Neurology Clinic, Takamatsu, Japan

Objectives: To clarify the relationship between Montreal cognitive assessment (MoCA) and blood biochemical biomarkers in patients with Parkinson's disease (PD).
Methods: MoCA and Mini-Mental State Examination (MMSE) were examined in PD patients and apolipoprotein E (APOE) phenotypes, serum β-amyloid 1-40 (Aβ40) and 1-42 (Aβ42) and plasma homocysteine (Hcy) were measured. These cognitive scores and serum or plasma levels were statistically analyzed among 3 groups divided with APOE4 or APOE2 phenotypes at first and then 3 groups divided with Aβ ratio (Aβ42/Aβ40) tertiles.
Results: Total of 150 PD patients were enrolled (65 males and 85 females). Their mean age were 67.9 y. Mean total scores of MoCA (23.2) was significantly lower than those of MMSE (28.2) ($p<0.01$). In total scores of MMSE, APOE4 homozygous group scored significantly lower than heterozygous group ($p<0.05$) although there was no significant difference among APOE2 groups. In total scores of MoCA, there was no significant difference in both APOE4 and APOE2 groups. In total scores of MoCA or MMSE, there were no correlations with serum Aβ40, Aβ42, and plasma Hcy. Among groups with lower, middle and higher tertiles of Aβ ratio, there was no significant difference in total scores of MoCA, MMSE and plasma Hcy.
Conclusions: MoCA is a sensitive battery to detect mild cognitive impairment in PD but there was no significant relationship with well-known biochemical biomarkers in patients with dementia in our preliminary study. It was suggested that cognitive dysfunctions in PD detected with MoCA could be different from those in other dementias.

ADPD5-0506

ASSESSMENT OF NEUROPSYCHOLOGICAL FEATURES IN MILD DEMENTIA WITH LEWY BODIDES

H. Tabuchi[1], M. Konishi[1], B. Yamagata[1], M. Oka[1], M. Mimura[1]
[1]Neuropsychiatry, Keio University School of Medicine, Tokyo, Japan

Objectives)
Dementia with Lewy bodies (DLB) is frequently accompanied by visual hallucination, parkinsonism, or cognitive fluctuation. However, discerning DLB from Alzheimer's disease (AD) without these prominent clinical features is difficult and challenging for clinicians, particularly at the beginning of disease. This study aimed to investigate the validity of neuropsychological testing in differentiating DLB from AD.
Methods)
The participants included 30 mild DLB and 211 mild AD outpatients of the memory clinic at Keio University hospital (Clinical Dementia Rating = 0.5 or 1, age from 60 to 89). All the participants received brain MRI and neuropsychological testing including mini mental state examination (MMSE), Raven's colored progressive matrices (RCPM), Rey auditory verbal learning test, logical memory (LM) subtest of Wechsler memory scale-revised, Rey-Osterrieth complex figure test (ROCFT), modified Stroop test, trail-making test, and verbal fluency test (VFT). The geriatric depression scale (GDS) was used to evaluate the subjective mood.
Results)
No significant differences were obtained between DLB and AD in age (77.8±5.4 years in DLB and 76.1±8.0 years in AD), education (13.0±3.3 years and 12.9±2.8 years, respectively), GDS scores (5.1±3.3 and 4.9±3.9, respectively), and scores of MMSE (21.3±4.5 and 21.1±4.8, respectively). Analysis of neuropsychological testing scores demonstrated that DLB showed significantly lower scores in RCPM, copy of ROCFT and VFT, while they showed significantly higher scores in LM than AD.
Conclusions)
DLB patients performed poorer visuospatial functions and executive functions than AD. In contrast, they performed better cognitive functions in logical memory. These findings are compatible with an analysis of previous studies.

COGNITIVE AND AFFECTIVE THEORY OF MIND IN DEMENTIA WITH LEWY BODIES

C. Heitz[1], V. Noblet[2], C. Phillipps[3], B. Cretin[1], N. Vogt[3], N. Philippi[1], J. Kemp[3], X. De Petigny[4], M. Bilger[3], C. Demuynck[4], B. Jung[3], C. Martin-Hunyadi[4], J.P. Armspach[2], F. Blanc[1]
[1]Neurology, University Hospital of Strasbourg, STRASBOURG Cedex, France
[2]ICube Laboratory, Integrative Multimodal Imaging in Healthcare (IMIS) team, STRASBOURG Cedex, France
[3]Neuropsychology, University Hospital of Strasbourg, STRASBOURG Cedex, France
[4]Geriatry, University Hospital of Strasbourg, STRASBOURG Cedex, France

Introduction: "Theory of mind" (ToM) refers to the ability to attribute thoughts (cognitive component) or feelings (affective component) to others. This function has been studied in many neurodegenerative diseases but not in dementia with Lewy bodies (DLB). The aim of our study was to assess ToM in patients with DLB and to search neural correlates of deficits.
Methods: Twenty-nine patients with DLB (DLB group), on early stage of the disease, and 15 healthy elderly adults (HC group) were included in the study. We used the Faux Pas recognition (FPR) test, the Reading the Mind in the Eyes (RME) test and the facial emotion recognition of Ekman's test to assess the two components of ToM. We studied correlations between ToM scores and gray matter volume and we compared DLB impaired and not impaired patients using voxel-based morphometry.
Results: DLB group performed significantly worse than HC group for the FPR test ($p=0.02$) and the RME test ($p=0.02$), but there was no significant differences for the Ekman's test ($p=0.60$). The main region associated with ToM impairments was the prefrontal cortex but we also found correlations with orbitofrontal cortex, precuneus, superior temporal sulcus, occipital cortex, fusiform gyrus, insula, amygdala, cerebellum and basal ganglia ($p<0.001$, uncorrected, minimum cluster size of 25 voxels).
Conclusion: This study is the first to show early impairments of affective and cognitive ToM in DLB. Among patients with ToM difficulties, we found atrophy in brain regions classically involved in ToM but also in less reported regions, as basal ganglia and cerebellum.

ADPD5-0701

UTILITY OF SELF-ADMINISTERED QUESTIONNAIRE TO ASSESS OLFACTORY DYSFUNCTION IN JAPANESE PATIENTS WITH PD

I. Kawasaki[1], T. Baba[1], A. Takeda[2], E. Mori[1]
[1]Department of Behavioral Neurology and Cognitive Neuroscience, Tohoku university Graduate School of Medicine, Sendai, Japan
[2]Department of Neurology, National Hospital Organization Sendai-Nishitaga Hospital, Sendai, Japan

Objective
Olfactory dysfunction is a common non-motor feature in PD. Recent study reported the usefulness of a questionnaire-type olfactory test in the evaluation of olfactory dysfunction in PD, however its utility for Japanese PD patients is not validated. The aim of this study was to analyze the usefulness of a recently developed self-administered odor questionnaire (SAOQ) in assessment of olfactory function in Japanese PD patients.
Methods
Twenty-nine PD patients (14 females and 15 males) were recruited in this study. General cognitive function was examined using the Addenbrook's Cognitive Examination-Revised. Motor impairment was assessed using the Hoehn and Yahr stage and Unified Parkinson's Disease Rating Scale. Olfactory function was measured using the SAOQ, which consisted of 20-smell items familiar to Japanese, and the Open Essence (OE, Wako Pure Chemical Industries, Tokyo, Japan). Internal consistency of SAOQ in PD patients was assessed using Cronbach's alpha. Internal validity was assessed using Pearson's correlation coefficient by correlating SAOQ scores with OE values. The level of statistical significance was set at $p < 0.05$.
Results
Cronbach's alpha was 0.90. SAOQ scores correlated significantly with OE values ($r = 0.45$, $p < 0.05$), but not with age ($r = -0.02$, $p = 0.93$). Furthermore, there was no significant difference in SAOQ scores between female and male in the Chi-square test ($p = 0.46$).
Conclusion
This SAOQ is useful in evaluating olfactory dysfunction in Japanese PD patients.

ADPD5-0779

CONVENTIONAL ALZHEIMER'S BIOMARKERS IN CSF (ABETA42, TAU AND PHOSPHORYLATED-TAU) ARE NOT PATHOLOGICAL IN MILD COGNITVE IMPAIRMENT PATIENTS WITH PRODROMAL DLB

O. Bousiges[1], B. Cretin[2], T. Lavaux[1], N. Philippi[2], B. Jung[2], C. Heitz[2], C. Demuynck[3], X. de Petigny[3], C. Martin-Hunyadi[3], F. Blanc[2]

[1]Laboratory of biochemistry and molecular biology, University Hospital of Strasbourg, STRASBOURG Cedex, France

[2]Neuropsychology Unit Neurology Service, University Hospital of Strasbourg, STRASBOURG Cedex, France

[3]Day hospital of geriatric Geriatry Service, University Hospital of Strasbourg, STRASBOURG Cedex, France

1) Objectives

Dementia with Lewy bodies (DLB) is the second most frequent dementia after Alzheimer's disease (AD). The differential diagnosis between these two diseases is particularly difficult especially early in the disease. AD biomarkers (Aβ42, Tau and Phospho-Tau181) in cerebrospinal fluid (CSF) appear to be also disrupted in other neurodegenerative diseases such as DLB. In the literature, DLB patients present an isolated Aβ1-42 decreased. However, all these results were obtained in demented patients. So, we propose to explore conventional Alzheimer's biomarkers in DLB patients with a prodromal stage.

2) Methods

Patients were classified according to the criteria of McKeith for DLB patients and the criteria of Dubois for Alzheimer's patients. The results of lumbar puncture were not considered for the classification of patients. The patients were categorized according to their pathology: AD, DLB, or mixed AD and DLB pathology and depending on their state of dementia: prodromal or dementia stage. Once every patient classified in a group, we analyzed the results of their biomarkers.

3) Results

For demented patients, we find a decrease of Abeta42 in CSF patients with DLB. However for the prodromal stage of DLB, the levels of Abeta42 are identical to those of controls.

4) Conclusion

For the first time, we show an analysis of the levels of AD biomarkers in DLB patients with prodromal stage. Thus, we have shown that at this stage the DLB patients had no pathological profile. The profile changes at the demented stage, with an isolated decrease of Abeta42.

ADPD5-0899
IMPROVING THE CLINICAL DETECTION AND DIAGNOSIS OF LEWY BODY DEMENTIA USING A COMPOSITE RISK SCORE

J. Galvin[1], M. Tolea[2], J. Sidhu[3]
[1]Neurology and Psychiatry, NYU Langone Medical Center, New York City, USA
[2]Neurology, NYU Langone Medical Center, New York City, USA
[3]Psychiatry, NYU Langone Medical Center, New York City, USA

Lewy Body Dementia (LBD) is a challenge to diagnose, particularly outside of expert centers with delays in diagnosis approaching 18 months leading to significant burden to patients and caregivers. While consensus criteria have excellent specificity, there is no standardized way to assess symptoms. We developed the Lewy Body Composite Risk Score (LBCRS) to improve the ability to detect LBD in clinic and research populations. The LBCRS was derived from clinical features of LBD in autopsy-verified cases. We tested the LBCRS in a consecutive series of 204 patients presenting for initial evaluation of memory, mood, motor and behavioral complaints. Patients (mean age 77.5±8.0y, mean education 15.5±3.6y, 52% female) received comprehensive evaluations including Clinical Dementia Rating, Unified Parkinson's Disease Rating Scale, Neuropsychiatric Inventory, Functional Assessment Questionnaire, Mayo Fluctuations and Sleep Questionnaires, Epworth Sleepiness Scale and Neuropsychological testing. Diagnoses include subjective cognitive impairment (6), MCI (58), AD (79), LBD (39), vascular dementia (5), FTD (9), and other dementias (8). The LBCRS was completed independent of the clinical evaluation. Mean LBCRS scores were significantly different between LBD and AD (6.2±2.2 vs. 2.5±1.3, p<.001) and between MCI-LBD vs MCI-AD (3.2±1.0 vs. 1.1±0.7, p<.001). The LBCRS was able to discriminate between different causes of dementia. Using a cut-off score of 3, Area under ROC for LBD vs. AD 0.93 (0.88-0.98), Area under ROC for MCI-LBD vs. MCI-AD 0.96 (0.91-1.0). The Lewy Body Composite Risk Score increases diagnostic probability that Lewy bodies are a contributing dementia pathology and should improve clinical detection and enrollment for clinical trials.

10d. Other: diagnostics

ADPD5-1269

DIFFERENTIAL DIAGNOSIS BETWEEN ALZHEIMER'S DISEASE AND DEMENTIA WITH LEWY BODIES: PLANNING SUPPORT DURING THE COPY OF THE REY COMPLEX FIGURE.

B. Jung[1], M. Bilger[2], L. Dupont[2], T. Albasser[1], X. De Petigny[2], F. Blanc[1], C. Phillipps[1]
[1]CMRR-Neurology, Hôpital de Hautepierre, Strasbourg, France
[2]CMRR-Geriatrics, Hôpital de la Robertsau, Strasbourg, France

Objectives: Patients with Lewy Bodies Dementia (DLB) present more constructive deficits and also earlier executive impairment than Alzheimer's disease (AD) patients (Metzger-Baddeley, 2007). We aim to demonstrate that mechanisms affected in the constructive apraxia are different in AD and DLB.
Methods: 12 patients (mean age: 82.5 years +/-5.65) and 10 patients DCL (mean age: 83.08 +/-3.12) matched for education level and dementia severity (MMSE score) made the copy of the Rey Complex Figure under two conditions: with or without planning support. The Boston Qualitative Scoring System (BQSS) was used.
Results: Constructive apraxia (AC) frequency is about 80 % for DLB group against 33 % for AD patient. Qualitative approach shows higher planification impairments for DLB patients (BQSS planning score = 0.90/4*). Planning support permitted to normalize the performances of all AD patients. On the contrary, disorders persist for half of DLB patients.
Discussion: Constructive disorders involve planning impairment in AD. Even if planning disorders are commune in DLB, we suppose that other visuo-perceptive, visuo-spatial or purely constructive processes may be damaged in DLB.
Conclusion: Planning support is useful to differentiate DLB from AD patients. Constructive disorders which remain in copy condition with planning support are a strong argument for DLB.

ADPD5-1305

NEUROPSYCHOLOGICAL CORRELATES OF PAREIDOLIAS IN DEMENTIA WITH LEWY BODIES

I. Sala[1], E. Morenas-Rodríguez[1], B. Sánchez-Saudinós[1], D. Alcolea[1], M. Carmona-Iragui[1], R. Blesa[1], J. Fortea[1], A. Lleó[1]

[1]Neurology, Hospital De La Santa Creu I Sant Pau, Barcelona, Spain

Background

Pareidolias are complex visual illusions frequently experienced by patients with Dementia with Lewy bodies (DLB) that are considered an analogous phenomena to visual hallucinations. Few studies have explored the neuropsychological correlates of pareidolias.

Objective

To study the neuropsychological correlates of pareidolias in DLB patients in a Memory Disorders Unit.

Methods

We included 43 subjects (55.8% women) with a clinical diagnosis of mild to moderate DLB evaluated in our Memory Unit between October 2013 and July 2014. All subjects underwent formal cognitive evaluation with an extensive neuropsychological battery including behavioral (NPI) and functional (IDDD) scales. The Scenery and Noise Pareidolias test was performed to evaluate the presence of pareidolias (Uchiyama et al., 2012). Correlations and group comparisons (Mann-Whitney U-test) between patients with or without pareidolia, were performed.

Results

Mean age was 79.2 years and mean education was 8.6 years. Mean MMSE score was 24.6 with a moderate functional interference (IDDD: 54.07). Scenery pareidolias were present in 79.1% and Noise pareidolias in 81.4% of the patient sample. DLB patients with pareidolias (scenery) performed worse in visuoperceptive, visuoespacial, frontal task and language ($p<0.05$). Visual illusions (scenery and noise) were correlated with visual hallucinations (NPI) ($p=0.002$ and $p=0.008$ respectively).

Conclusions

The presence of pareidolias in DLB is associated with lower cognitive performance. Pareidolias parallel hallucinations in DLB. Further studies are required to determine the underlying mechanisms.

MEMORY AND NAMING PERFORMANCE DISTINGUISHES SUBTYPES OF DEMENTIA WITH LEWY BODIES FROM ALZHEIMER'S DISEASE

O. Pedraza[1], G. Smith[2], B. Boeve[3], R. Uitti[4], J. Van Gerpen[4], Z. Wszolek[4], D. Dickson[5], N. Graff-Radford[4], D. Knopman[3], R. Petersen[3], T. Ferman[1]
[1]Psychiatry and Psychology, Mayo Clinic, Jacksonville, USA
[2]Psychiatry and Psychology, Mayo Clinic, Rochester, USA
[3]Neurology, Mayo Clinic, Rochester, USA
[4]Neurology, Mayo Clinic, Jacksonville, USA
[5]Neuroscience, Mayo Clinic, Jacksonville, USA

OBJECTIVE: To determine whether learning, memory, and naming performance distinguishes subgroups of dementia with Lewy bodies (DLB) from those with Alzheimer's disease (AD) dementia.
METHODS: Patients with probable DLB (n=206) and AD dementia (n=343) were recruited through the Mayo Clinic Alzheimer's Disease Research Center. All patients had MMSE ≥ 20. DLB patients were subdivided into impaired versus normal naming performance. Age-adjusted scores from the Auditory Verbal Learning Test (learning over trials, delayed recall, recognition memory) and Boston Naming Test were examined.
RESULTS: The DLB group was older than the AD dementia group (mean years = 73.3(9.4) vs. 71.8(6.9), $p<0.05$), with no difference in education. Learning efficiency, delayed recall, and recognition memory was significantly better in DLB than in AD dementia ($p<0.01$). DLB patients with impaired naming were indistinguishable from patients with AD dementia on delayed recall, while DLB patients with normal naming had significantly better delayed recall, learning, and recognition memory ($p<0.01$). Unlike delayed recall performance, learning efficiency and recognition memory was not dependent on naming performance in DLB.
CONCLUSIONS: As a group, DLB outperforms AD dementia in learning efficiency, delayed recall and recognition memory. Nonetheless, there is a subgroup of patients who meet criteria for probable DLB but who demonstrate a pattern of impaired naming and impaired delayed recall that is indistinguishable from AD dementia. Further work is needed to determine if DLB patients with this memory and naming profile are more likely to have co-morbid AD pathology.

ADPD5-1681
COGNITIVE DYSFUNCTION IN PARKINSON'S DISEASE WITH SWEDDS
S.J. Kang[1], J.Y. Ahn[2], H.T. Kim[2]
[1]Neurology, Hanyang University Medical Center, Seoul, Korea
[2]Neurology, Seoul Medical Center, Seoul, Korea
Background : Patient diagnosed with Parkinson's disease (PD) on clinical grounds who subsequently turn out to have normal dopamine transporter imaging have been referred to as SWEDDs (scans without evidence of dopaminergic deficits). Cognitive dysfunction is frequent manifestation in Parkinson's disease. In this study we determined the similarities and differences in the cognitive dysfunction between PD and SWEDDs.
Objective : To assess cognitive dysfunction in patients of Parkinson's disease with SWEDDs, in comparison with Parkinson's disease and age-matched controls.
Method : This study enrolled 34 patients with SWEDDs, 104 patients with early PD and 29 healthy controls. Neuropsychological tests covering different cognitive domains were performed on all subjects for evaluation of cognitive function.
Results : PD with/without SWEDDs patients reported lower cognitive performances than healthy controls in several cognitive domains (attention, executive function, verbal and visual memory). But there are only one test of attention (digit span_forward) shows difference between PD and PD with SWEDDs group. Other cognitive domains were nealy correspond with two groups.
Conclusions : Cognitive dysfunction in PD with SWEDDs were not previously reported. This study shows that parkinson's disease have multi-domain cognitive dysfunction, additionally presynaptic dopaminergic deficits were not contributed cognitive dysfunction in early parkinson's disease.

10d. Other: diagnostics

ADPD5-1717
RISK SCORE APPROACH FOR THE PREDICTION OF PROGRESSION TO DEMENTIA IN NON-DEMENTED PATIENTS WITH PD
B.S. Ye[1], J.H. Ham[1], J.J. Lee[1], P.H. Lee[1], Y.H. Sohn[1]
[1]Neurology, Yonsei University College of Medicine, Seoul, Korea
Backgrounds: Parkinson's disease (PD) is often associated with mild cognitive impairment and dementia. We investigated the individual risk of PD patients to develop dementia using baseline neuropsychological tests.
Methods: A total of 274 non-demented patients with PD underwent baseline neuropsychological evaluation and followed for mean duration of 2.2 (1.1) years. Each neuropsychological score was categorized with cut-offs at 1.0 standard deviation (SD) as well 1.5 SD below age- and education-matched norms. Cox regression analysis was used to make a risk score system combining baseline neuropsychological tests predicting future progression to dementia.
Results: Twenty-two patients (8.0%) progressed to dementia during follow-up period. Univariate Cox regression analyses adjusted for age, sex, and education showed that digit span forward (-1.0 SD), digit span backward (-1.0 SD), Rey-Osterrieth Complex Figure (RCFT) copy test (-1.0 SD), Controlled Oral Word Association Test (COWAT) animal (-1.0 SD), COWAT phonemic (-1.0 SD), contrasting program (-1.0 SD), go-no-go test (-1.0 SD), and RCFT delayed recall (-1.5 SD) significantly predicted progression to dementia. Calculated risk score (range 0-13) based on multivariate Cox regression analysis predicted progression to dementia well (area under curve = 0.74, 95% CI = 0.63-0.86).
Conclusion: Risk score system is a useful approach for the prediction of dementia risk among PD patients, but should be validated and further improved to increase its predictive value. This approach showed that baseline neuropsychological score in PD patients significantly predict future progression to dementia and could help to identify candidates for future interventional studies for PD dementia.

ADPD5-2047
A CHALLENGING CASE : IS IT PARKINSON PLUS SYNDROME, UNIPOLAR MAJOR DEPRESSION WITH PSYCHOTIC FEATURES OR AN OVERLAP SYNDROME?

S.S. Talapatra[1], C. Lui[2], C. Bush[1]
[1]Internal Medicine, Sir Charles Gairdner Hospital, Perth, Australia
[2]Geriatric Medicine, Swan District Hospital, Perth, Australia

A 63 year old lady presented to the hospital with 6 months worsening paranoid delusions, visual hallucinations and bilateral leg pain. She was treated with dopaminergic agents for presumed Parkinson's Disease for 8 years (initially diagnosed based on unilateral hand motor symptoms limited to pincer grip and unscrewing a bottle cap). She was subsequently diagnosed with restless leg syndrome and in the past 3 years her dopaminergic agents had been up-titrated to treat restless leg syndrome; in spite of which she continues to report disabling leg pain. After detailed examination and investigations, it was deemed that the pain was inconsistent with restless leg syndrome and was thought to be a functional problem. It became increasingly evident that her symptoms were related to Unipolar Major Depression with psychotic features. She had insight but exhibited a myriad of neuropsychiatric symptoms predominantly paranoia, manipulative and attention seeking behaviors and selective augmentation of behavioral symptoms in the presence of her husband. A Single-photon emission computed tomography (SPECT) of the brain revealed generalized symmetrical posterior parietal and occipital lobes hypoperfusion, which in the current clinical setting favored a possible diagnosis of Lewy Body Dementia. Dopaminergic agents were weaned off successfully and, despite some signs of Parkinsonism (mild bradykinesia and rigidity), her functionality was not affected. Citalopram and Quetiapine were carefully up-titrated concomitantly. She was transferred to the Elderly Mental Health Service for ongoing in-patient care, where she continues to exhibit neuropsychiatric symptoms with an emerging functional mobility difficulty.

NONMOTOR SYMPTOMS IN DE NOVO PARKINSON DISEASE COMPARING TO NORMAL AGING

P. Bago Rozankovic[1], *L. Vucak Novosel*[1]
[1]*Dpt of neurology, University Hospital Dubrava, Zagreb, Croatia*

Introduction: Nonmotor symptoms (NMSs) are common in Parkinson disease (PD), affecting patient's quality of life. The prevalence and domains of NMSs in untreated de novo PD remains unclear, especially comparing to normal aging. The objective was to determine NMSs in untreated de novo PD patients.
Methods: We performed a case-control study to evaluate the frequency and severity of NMSs in untreated de novo PD patients (n=71) and age-matched normal controls (n=60) using the Non-Motor Symptoms Scale (NMSS). The motor section of the Unified Parkisnon Disease Rating Scale (mUPDRS) and the Hoehn and Yahr (HY) stage were also obtained in PD patients
Results: The number of NMSs and the NMSS scores were significantly higher in the PD patients than in controls ($p<0.001$). There was no correlation of the NMSS scores with age and sex in both group and additionally with mUPDRS score and HY stage in PD patients group. Mood/cognition, attention/memory and gastrointestinal domains are the most frequent in PD patients and rarely seen in controls.
Conclusion: NMSs in untreated de novo PD patients are more prevalent and severe with different domain involvement comparing to normal aging.

University of Florida Institute for Food and Agricultural Sciences, Gainesville, USA

This study was a continuation of a pilot study of a quick, non-invasive, and reliable diagnostic test for early Alzheimer's disease (AD) (Stamps, Bartoshuk, Heilman, 2013) that included more advanced stages of AD as well as Parkinson's disease (PD) patients. The participants included controls (N=31), patients with probable AD (N=36), mild cognitive impairment (N=33), other causes of dementia (N=30), or PD (N=22). Patients with a comorbid dementia or history of a brain tumor, stroke, seizures, nasal polyps, or severe head injury were excluded. Odor detection was tested one nostril at a time. A container of 14g of peanut butter was raised up from the bottom of a 30 cm ruler 1cm at a time. Upon detection, the distance from their nostril to the stimulus was measured. Patients with AD were significantly more impaired at detecting an odor with their left nostril (mean detection distance = 6.2 cm) than with their right (mean detection distance = 14.3 cm) ($p<0.001$). The mean difference of the left nostril's detection distance minus the right nostril's detection distance was -8.3 cm which was significantly different from patients with other types of dementia, controls, and Parkinson's patients ($p<0.0001$). As AD progressed, the asymmetry decreased as the right nostril became more impaired until both nostrils were symmetrically impaired at the more severe stages. The odor detection distance of the left nostril did not change with disease progression. Parkinson's patients were bilaterally and significantly impaired across both nostrils compared to the other groups ($p<0.001$) independent of disease stage.

ADPD5-1043
THE AUTONOMIC SCALE IN PD AND MULTIPLE SYSTEM ATROPHY PATIENTS : CORRELATIONS BETWEEN ONE SCALE TO THE OTHER.
S. Kim[1], T. Lee[1], J. Kim[1], J. Park[1], S. Park[1]
[1]Neurology, Soonchunhyang University, Bucheon, Korea
Background : PD is classically diagnosed with motor deficits, but wide range of non-motor symptoms, especially autonomic symptoms, commonly affect patients with PD and multiple system atrophy (MSA). There are several scales to assess autonomic symptoms in PD and MSA . The aim of this study is to determine equation models for the conversion of scores from one scale to the other.
Methods : 14 patients who first visited to our movement clinic with parkinsonism (bradykinesia, resting tremor, rigidity, postural instability) were evaluated with the Movement Disorder Society-Unified Parkinson's Disease Rating Scale (MDS-UPDRS) Part I and Scales for Outcomes in Parkinson's Disease-autonomic symptoms (SCOPA-AUT), and Unified MSA rating scale(UMSARS) I-IV. Linear regression was used to develop equation models. Spearman's rho was used to assess the relation between autonomic scales. 9 patients finally diagnosed to PD and 5 patients to MSA.
Results : MDS-UPDRS PART I and SCOPA-AUT sacle have strong correlation (r=0.743) and UMSARS and SCOPA-AUT have very strong correration (r=0.848) coefficients.
Conclusion : SCOPA-AUT scale is briefer and shorter than UMSARS and more practical to administer than UPDRS. And it can be performed by patient or observer without involvement of researcher or doctor. With the equation models identified in this study, scores from UPDRS non-motor examination or UMSARS can be converted to SCOPA-AUT scale score.

ANOSOGNOSIA IN AMNESTIC-MILD COGNITIVE IMPAIRMENT AND MILD COGNITIVE IMPAIRMENT IN PD

J. Pillai[1], A. Bonner-Jackson[2], D. Floden[2], J. Leverenz[1]
[1]Neurology, Cleveland Clinic, Cleveland, USA
[2]Neuropsychology, Cleveland Clinic, Cleveland, USA

A diagnosis of Mild Cognitive Impairment (MCI) often starts with cognitive concerns raised by the patient or a caregiver although patients often lack awareness of the cognitive changes they are experiencing. It is unclear what neuropsychological characteristics among MCI subjects relate to reduced insight into their cognitive and behavioral changes. We hypothesized that subjects with amnestic MCI (a-MCI) would be more likely to lack awareness of their cognitive deficits (anosognosia) than individuals with MCI related to Parkinson's disease (MCI-PD).
Methods: Subjects included 18 a-MCI and 10 MCI-PD subjects in an ongoing study. Anosognosia was assessed by comparing responses of patients and caregivers on a questionnaire in 3 domains (cognitive, physical, behavioral), with higher scores indicating a higher level of anosognosia. Depression assessed by Beck Depression Inventory II.
Results: Anosognosia scores did not differ significantly between the groups (all p's > .11). No relationship between depression and anosognosia was noted in the a-MCI group, while a greater severity of depression was associated with lower anosognosia scores (better insight) in the MCI-PD group. In the a-MCI group, poorer delayed recall and recognition of a word list were associated with a higher score for cognitive abilities and with the total anosognosia scores. Among MCI-PD subjects, poorer word list learning was associated with a higher rate of anosognosia for cognitive abilities.
Conclusions: Findings from this study are preliminary, pending further data collection. However they do suggest an association between depression and greater insight, and between certain types of memory impairment and greater anosognosia.

ADPD5-2033
OPTIMIZING THE PLACEBO RESPONSE IN PARKINSON'S DISEASE CLINICAL TRIALS
M. TRAD[1], L. Hughes[2], C. VanBelle[3], A. Del Medico[4], D. Stein[5]
[1]Center of Excellence Neurology, Quintiles, Levallois-Perret, France
[2]Center of Excellence Neurology, Quintiles, Reading, United Kingdom
[3]Therapeutic strategy, Quintiles, Mieregemstraat, Belgium
[4]Therapeutic strategy, Quintiles, Fairhaven, United Kingdom
[5]Therapeutic strategy, Quintiles, San Diego, USA
Background: Substantial improvement of Parkinsonian symptoms is observed in placebo groups of many clinical trials leading to a number of negative and failed studies.
Objectives: To analyze the factors contributing to increased placebo responses in PD clinical trials conducted at Quintiles between 2000- 2014.
Methods: Quintiles has been involved in the development of multiple PD medications available on the market. Of the 70 trials conducted only the large phase III pivotal studies were selected for the purposes of this analysis.
Results: Twenty Pivotal Phase III studies were performed of which 15 in Advanced and 5 in Early PD patients. All studies compared investigational product to placebo in a parallel design. Of the total number of pivotal studies, 12 were positive, while 8 were either negative or failed. Of these, 5 presented with high placebo responses. The most frequent factors potentially contributing to improvements on placebo were: high patient/rater expectations, study methodology, investigational product mechanism of action and rater dependent factors. Regional differences in the placebo response, observed in some of the studies, were not necessarily related to ethnicity but rather to the lack of awareness of the placebo effect in clinical trials.
Conclusion: The assessment of PD pivotal studies conducted at Quintiles has shown that 60% of these were positive while 25% had high placebo responses. This is in concordance with the literature were placebo improvements were observed in up to 50% of patients. Controlling some of the factors contributing to this effect, would improve the chance of successful trials.

ADPD5-0281
PATTERNS OF NEUROPSYCHOLOGICAL PROFILES ACCORDING TO SEVERITY OF DEPRESSIVE SYMPTOMS IN NEWLY DIAGNOSED PD

S. Kim[1], J. Kim[2]
[1]Neurology, Busan Paik Hospital Inje University, Busan, Korea
[2]Neurology, Chosun University Hospital Chosun University, Gwangju, Korea

Objectives: Depression is common non-motor symptoms in patients with Parkinson's disease (PD). Depression is not only associated with only poor quality of life, but also associated with decreased cognitive functions and motor decline. In our study, we analyzed clinical neuropsychological profiles according to severity of depressive symptoms in newly diagnosed Parkinson's disease patients.
Methods: 90 newly diagnosed PD patients were enrolled. We divided 38 patients of depressive group and 52 patients of non-depressive group according to their geriatric depression scale by score of 18. Age, sex, education, age at onset, disease duration, Korean mini-mental status examination and Hohen and Yahr stage were analyzed by t-test. Each neuropsychological tests were analyzed with analysis of covariance (ANCOVA) controlled by educational years. Pearson's correlation coefficient was calculated to assess the correlation between depression scores and Z-scores of neuropsychological tests.
Result: There was no difference between depressive group and non-depressive group in age, education years, disease severity, age at onset and disease duration. The score in semantic fluency was lower in depressive group compared with non-depressive group. The depression scores were correlated with semantic fluency scores and there was a trend that depressive scores were correlated with semantic memory scores.
Discussion: Although depressive symptoms are generally associated with executive dysfunctions, it is also recognized that depression relates to poorer semantic fluency ability. Our result suggests that depressive symptoms in newly diagnosed PD patients are associated with frontotemporal dysfunction, revealed by impairment in semantic fluency and semantic memory tests.

ADPD5-0545

CLINICAL EVALUATION OF PATIENTS WHO HAD DEMENTIA WITH LEWY BODIES IN THE PSYCHIATRIC WARD OF A GENERAL HOSPITAL

T. Odawara[1], T. Nishio[2], S. Hattori[1], Y. Hirayasu[2]
[1]Psychiatric Center, Yokohama City University Medical Center, Yokohama, Japan
[2]Psychiatry, Yokohama City University School of Medicine, Yokohama, Japan

Objectives: As the number of elderly patients with dementia in Japan increases, the number of inpatients with dementia with Lewy bodies (DLB) is also expected to increase. We performed a retrospective investigation of patients with DLB who were admitted to our hospital and examined issues encountered during treatment.
Methods: Subjects included 25 patients who were admitted to our center and who received a diagnosis of probable DLB at the time of discharge. The medical records of these patients were used to obtain information regarding their diagnoses, clinical manifestations, treatment and outcome.
Results: On admission, 52% of patient was diagnosed having DLB and 36% having mood disorders. Most common BPSD was depression. A decrease in body weight due to diminished food intake was noted in 13 patients. The symptoms of dysautonomia included constipation, orthostatic hypotension or changes in blood pressure, and abnormal sweating. Deep vein thrombosis (DVT) was diagnosed in four. Acetylcholinesterase inhibitors (ChEIs) ameliorated BPSD in 72% of patients. Antidepressants were effective in seven out of 13. 16 patients had positive outcomes, three worsened, and nine were transferred to a different hospital.
Conclusions: It is important to distinguish cases of DLB among cases of mood disorders diagnosed in elderly patients. ChEI was useful in many patients with BPSD, but a wide variability in the treatment response was observed in patients who received psychotrohics. More than half of patients also manifested physical complications. Therefore, it is important to take both the physical and psychological needs of the patient into account.

ADPD5-0991
EXECUTIVE FUNCTIONING AND CAREGIVER AND SELF-REPORT OF NEUROPSYCHIATRIC SYMPTOMS IN PD
C.A. Manning[1], J.H. Stenclik[1], M.H. Park[2], S. Tsang[3], M.J. Barrett[1], S.A. Sperling[1]
[1]Neurology, University of Virginia Health Systems, Charlottesville, USA
[2]Neurology, Korea University College of Medicine, Ansan, Korea
[3]Psychology, University of Virginia, Charlottesville, USA
Objectives: To examine patient and caregiver reports of current neuropsychiatric behaviors on the Frontal Systems Behavior Scale (FrSBe) and their relationship to objective measures of executive functioning.
Methods: Data from 58 patients with Parkinson's disease (PD) were examined. An Executive Composite Score was created using T-scores from four cognitive measures of executive functioning (Wisconsin Card Sorting Test Perseverative Errors, Letter Fluency, Trails B, and Stroop Color-Word Test Interference). Correlations between patient and caregiver-derived FrSBe subscale scores (Apathy, Disinhibition, and Executive Dysfunction) and the FrSBe Total Score were examined. All FrSBe scores were ratings of current functioning. Multiple linear regression analyses were used to predict executive functioning based on FrSBe ratings while controlling for depression.
Results: Patient and caregiver Total Score (.470), Apathy (.306), Disinhibition (.430), and Executive Dysfunction (.469) were significantly correlated ($p<.05$). Patient Total Score (beta = -.535, $p<.005$), Apathy (beta = -.493, $p<.001$), Disinhibition (beta = -.532, $p<.005$), and Executive Dysfunction (beta = -.565, $p<.001$) were significant predictors of the Executive Composite Score. Caregiver ratings of the same behaviors did not predict the Executive Composite Score. Given these findings, patient FrSBe subscale scores were entered into a stepwise multiple regression equation while controlling for depression. Patient self- report of executive dysfunction alone was found to be a significant predictor of the Executive Composite Score (Beta = -.461, $p<.001$).
Conclusions: PD patients had better insight into their cognitive and behavioral limitations than caregivers. Patient self-assessment of behavioral symptoms of executive dysfunction predicted objective neuropsychological performance.

MILD COGNITIVE IMPAIRMENT IN PARKINSON DISEASE AND PROGRESSION TO DEMENTIA

D. Ferreira[1], A. Nieto[2], J.N. Lorenzo[3], J. Barroso[2], I. Galtier[2]
[1]Neurobiology Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden
[2]Clinical Psychology Neurobiology and Methodology, University of La Laguna, La Laguna, Spain
[3]Unidad de Trastornos Estrapiramidales. Servicio de Neurologia, Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain

Objective: Cognitive impairment and dementia are frequent in PD. New diagnostic criteria for PD-MCI have recently been proposed by the Movement Disorder Society (MDS) Task Force (Litvan et al., 2012). Our aim was to study the rate of PD-MCI according to new criteria and the progression to dementia.
Methods: 43 patients with idiopathic PD and 20 normal controls. All patients met the clinical criteria for the diagnosis of PD. Those who met the criteria of MDS for the diagnosis of dementia associated with PD were excluded. PD-MCI diagnosis was based on level 2 of the criteria proposed by MDS Task Force. Neuropsychological testing includes two tests for each of the following five cognitive domains: attention and working memory, executive, language, memory, and visuospatial functions. Cognitive impairment was operationalized as 1,5 standard deviations or more below the mean of the control group. Follow-up assessments were conducted 6-8 years after base-line in 39 patients.
Results: Fifteen patients (34.9%) were diagnosed as PD-MCI at base-line. Follow-up assessment showed that eight of PD-MCI patients (20,5%) developed dementia. In addition, 17.9% of patients without MCI at base-line also developed dementia at follow-up.
Conclusions: Our preliminary results show that the percentage of PD-MCI patients in this study and rate of progression to dementia are comparable with previous studies. In our study an important number of patients with PD will develop dementia in 6-8 years (38,4%). The percentage of patients developing dementia was slightly higher in the PD-MCI group compared to patients without MCI at baseline.

ADPD5-1144
DEPRESSION SEVERITY IN PD PATIENTS MODULATES PATIENT AND INFORMANT PERCEPTIONS OF NEUROPSYCHIATRIC BEHAVIORS AND EXECUTIVE DYSFUNCTION

S.A. Sperling[1], J.H. Stenclik[1], S. Tsang[2], M.H. Park[3], M.J. Barrett[1], C.A. Manning[1]
[1]Neurology, University of Virginia, Charlottesville, USA
[2]Psychology, University of Virginia, Charlottesville, USA
[3]Neurology, Korea University College of Medicine, Ansan, Korea

Objectives: PD patients and informants differ in their perceptions of non-motor symptoms. The effects of time and depression on their perceptions remains unclear. We investigated 1) the relationship between patients' and informants' ratings on the Frontal Systems Behavior Scale (FrSBe) and 2) the effects of time and depression on symptoms. ***Methods:*** Using linear mixed effects models, controlling for differences in perceived pre-PD symptomatic functioning, we examined the relationship between 83 PD patients' and informants' ratings on the FrSBe Total and subscale scores (Apathy, Disinhibition, and Executive Dysfunction) as well as effects of patient depression on ratings of current (CURRENT scores) and Pre-PD symptomatic behaviors (BEFORE scores). Depression was categorized as absent, mild, or moderate/severe using established cutoff scores on the Geriatric Depression Scale or Beck Depression Inventory-II. ***Results:*** Patient and informant FrSBe Total and subscale scores were significantly correlated (p<.0001). Patients with moderate/severe depression at the time of evaluation had higher BEFORE Total FrSBe scores than those without depression (p<.001), but they did not differ on subscale scores. More severely depressed patients had significantly higher CURRENT Total FrSBe and subscales scores than those without depression (p<.01 - p<.0001). Patients' level of depression did not affect informant BEFORE FrSBe scores, but informant CURRENT Total FrSBe and subscale scores were significantly higher when patients were moderately/severely depressed (p<.001 - p<.0001). ***Conclusions:*** Patient-perceived neuropsychiatric symptoms and executive impairment were associated with informant observations. Patient depression levels at evaluation significantly modulated patients' and informants' perceptions of behavior, particularly in more severely depressed patients.

ADPD5-1611
RESTLESS LEGS SYNDROME IN CELIAC DISEASE PATIENTS.
S. Kopishinskaya[1], S. Svetozarskiy[1], A. Gustov[1]
[1]Neurology, Nizhny Novgorod Medical Academy, Nizhny Novgorod, Russia
Objectives: Celiac disease is an autosomal recessive autoimmune enteropathy triggered by ingestion of gluten. Celiac disease has a prevalence of 1-2% and is associated with various neurological syndromes, including neuropathy, cerebellar ataxia, migraine, restless leg syndrome (RLS). RLS is a disease of unknown etiology. RLS has a prevalence of 5 to 15% in a population. Purpose of the study is the prevalence of RLS among patients with celiac disease.
Methods: We examined 200 patients with celiac disease and 100 patients of control group with reflux esophagitis. The diagnosis of RLS was made according to the diagnostic criteria of the International RLS Study Group. Patients underwent neurological examination and instrumental examination, and they are filled with RLS rating scale.
Results: We found that RLS occurs more than 5 times more often in patients with celiac disease compared with the control group (21 ± 2,9 and 4 ± 2, respectively, p <0,001). The proportion of men with RLS and age older than 40 years was significantly predominated in the group of celiac disease patients. In patients with celiac disease and RLS statistically significant prevailed male gender, by age - persons older than 40 years.
Conclusions: RLS occurs frequently in patients with celiac disease. Probably, celiac disease is a risk factor for the development of RLS syndrome. The role of iron deficiency, inflammation and immune dysfunction in the pathogenesis of RLS in celiac disease should be revealed.

ADPD5-1612
SEVERE RESTLESS LEGS SYNDROME AS AN EARLY NON-MOTOR SIGN OF THE PD.
M. Radyuk[1], S. Svetozarskiy[2], S. Kopishinskaya[2]
[1]Neurology, The Volgograd State Medical University, Volgograd, Russia
[2]Neurology, Nizhny Novgorod State Medical Academy, Nizhny Novgorod, Russia
Objectives: Restless legs syndrome (RLS) is a common sensory-motor disorder. Undiagnosed and untreated RLS leads to serious disruption of sleep. The pathophysiology of RLS is multifactorial. One of the causes of secondary RLS is Parkinson's disease. Purpose of the study is the prevalence of severe RLS in patients with early Parkinson's disease (disease duration of less than three years).
Methods: We examined 57 patients with early PD (study group) and 100 patients of the control group without Parkinson's disease. The diagnosis of RLS was made according to the diagnostic criteria of the International RLS Study Group. Patients underwent neurological examination and instrumental examination, and they are filled with RLS rating scale and the Johns Hopkins' assessment scale of the RLS severity.
Results: We found that RLS occurs in more than 4 times more likely in patients with early Parkinson's disease compared with the control group (26% and 6%, respectively). The proportion of patients with the third degree of RLS severity was significantly prevailed in the study group.
Conclusions: Severe RLS may be an early sign of Parkinson's disease.

ADPD5-1926
CHANGES IN RETINAL MORPHOLOGY AND VISUAL FIELD IN EARLY PARKINSON'S DISEASE
C. Mao[1], L. Li[1], X. Ji[1], J. Wei[1], J. Chen[1], S. Guo[1], Y. Chen[1], S. Li[1], C. Liu[1]
[1]Department of Neurology, The Second Affiliated Hospital of Soochow University, Suzhou, China
Visual symptoms are common non-motor symptoms of idiopathic Parkinson's disease (PD). Here, we investigated changes in retinal morphology and visual field in early PD patients and control individuals. Peripapillary retinal nerve fiber layer (RNFL) thickness, macular thickness and volume, and foveal thickness were measured using optical coherence tomography (OCT), and mean deviation of visual field (MD) was measured using an automatic visual field analyzer. PD patients were in an 'ON' period during ophthalmic evaluation, and their clinical characteristics were evaluated using the Unified Parkinson's Disease Rating Scale (UPDRS) and Hoehn & Yahr (H&Y) scale during an 'OFF' period. Compared with control individuals, PD patients showed a decrease in RNFL thickness on average and in specific regions (i.e., inferior and superior quadrants; 5-, 7-, 10- and 11-o'clock positions). Mean total macular thickness and volume was also significantly decreased in PD patients compared with control individuals, but there was no difference between groups in foveal thickness. MD scores were significantly lower in PD patients than in control individuals. Average RNFL thickness was negatively correlated with PD duration and H&Y stage, macular thickness and volume were negatively correlated with UPDRS motor score and H&Y stage, and MD score was positively correlated with PD duration and H&Y stage. Our results show that patients with early PD exhibit retinal dysmorphology and visual field defect.

[5]Neurology, Clinique romande de redapttion SUVA, Sion, Switzerland

Objective: Parkinson's disease (PD) patients experience progressive motor impairments, including severe gait deficits. MPTP-treated monkey model of PD played a pivotal role for the safe and efficacious translation of therapeutic interventions developed in rodents to viable clinical applications for humans. However, the lack of consensus on a methodology and the almost exclusive reliance on clinical scores of PD has often hindered successful translation of interventions to clinical settings. There is a critical need to develop translational methodologies to enable robust and reliable evaluation of therapies across species.

Methods: The connection-free platform allowed us to monitor muscle synergies and kinematics while the subjects walked on a treadmill, along a corridor, and across horizontal ladders of varying complexities. Using principal component analysis (PCA) applied on a large number of parameters; we could objectively quantify and rank task-specific deficits of gait patterns across a wide range of PD severities. To assess the translational value of the developed analyses, we recorded Parkinsonian patients and rats with alpha-synuclein-mediated nigrostriatal degeneration under the same conditions as MPTP monkeys.

Results: This analysis also uncovered kinematic parameters that were specifically improved after the administration of L-DOPA and others that remain resistant to dopamine replacement therapy. We found striking similarities in the pattern of gait deficits across species, and on the therapeutic effects mediated by L-DOPA.

Conclusion: The developed methodologies establish a highly-sensitive analytic framework to evaluate safety and efficacy of therapeutic interventions to alleviate locomotor deficits in animal models of PD and in Parkinsonian patients.

[2]Illawarra Health and Medical Research Institute, The University of Wollongong, Wollongong, Australia

[3]Department of Chemistry, The University of Cambridge, Cambridge, United Kingdom

Objectives

Under certain stress conditions clusterin, a normally secreted chaperone, can be redirected from the secretory pathway to intracellular compartments. Here we investigate whether clusterin plays an active role in intracellular proteostasis under these conditions.

Methods

We generated a model of extracellular clusterin expression in *Drosophila* in order to probe the effects of clusterin on the neurodegeneration associated with the cytosolic aggregation of the amyotrophic lateral sclerosis (ALS)-associated 43 kDa TAR DNA-binding protein (TDP-43). We then extended these studies to evaluate the ability of clusterin to suppress cytosolic aggregation of other intracellular proteins, and to investigate the ability of clusterin to localise to the cytosol in response to TDP-43 aggregation in both a human glial cell line and in the neurons and glia of the human spinal cord.

Results

We demonstrate that co-expression of clusterin significantly reduces the aggregation and neurotoxicity of TDP-43 in *Drosophila* motor neurons. These effects are accompanied by a dramatic reduction in clusterin secretion and its redistribution to the cytosol, processes which depend on the ability of TDP-43 expression to induce ER stress. Furthermore, the aggregation and neurotoxicity of mutant tau R406W and extended polyglutamine tracts are also rescued by clusterin expression. We also observe intracellular clusterin in motor neurons of ALS-patient postmortem tissue and in human cultured astrocytes, where clusterin and TDP-43 physically interact in the cytosol.

Conclusions

Clusterin is first identified chaperone to exhibit intra- and extracellular activity, rescuing the neurotoxicity associated with the intracellular aggregation of TDP-43, mutant tau and extended polyglutamine tracts.

[8]Professor, Belvitge, Porto Alegre, Brazil

Introduction: In the last few years, the TDP-43 protein (TAR DNA-binding protein 43) has been implicated in some neurodegenerative diseases pathogenesis. It's an intranuclear protein involved in many distinct cellular processes, like: gene transcription, alternative splicing, mRNA stabilization, microRNA biogenesis, apoptosis and cell division. Its molecule, when altered, shows modified pattern of distribution, as well as functioning, along the Central Nervous System (CNS) structures. The Fronto temporal Lobar Degeneration (FTLD) and the Amyotrophic Lateral Sclerosis (ALS) are two examples of TDP-43 proteinopathy.

Material and methods: We studied two donated brains from patients with clinical diagnosis of FTLD , one associated with ALS. Both patients had been followed by the *Neurology Clinic of ISCMPA.* After fixation, macroscopic examination with sampling of different encephalic regions were performed. Specific regions were chosen to immunohistochemistry (IHC) technics with anti-Aβ, AT8, anti-α-syn and anti-phospho-TDP-43 on the *Laboratory of Pathology of UFCSPA*.

Results: Both brains showed anti-phospho-TDP-43 positivity but not equally distributed over the encephalic zones. FTLD case presented TDP-43-phosphorylated on the frontal cortex, hippocampus and entorhinal cortex; in ALS-FTDL case the abnormal protein was also seen on brainstem. ALS-FTDL also presented Aβ and AT8 positivity in hippocampus and entorhinal cortex (Braak I and II).

Discussion: The hypothesis supported by scientific literature that these neurodegenerative diseases can have the same etiology with distinct encephalic region involvement is also corroborated by the present study.

[3]Faculty of Medicine University of Rouen, Inserm U614, Rouen, France
[4]Institut du Cerveau et de la Moelle, CR-ICM Inserm UMRS 975, Paris, France

1.Objectives
Frontotemporal dementia (FTLD) is a clinical syndrome characterized by progressive deterioration in behaviour, personality and/or language. Molecular basis of FTLD is very heterogeneous and leads to a classification based on the composition of protein aggregates made of TAU proteins, TDP-43 or FUS/TLS. Using biochemical approaches, we showed that some cases presenting with TDP-43 pathology (FTLD-TDP) display a partial or total loss of TAU proteins expression that can be referred as “TAU less”. Our goal is to determine if this “TAU less” group can be a part of the current FTLD classification.
2.Methods
FTLD brains (n=34) were obtained from the Lille Neurobank and the GIE NeuroCEB of Paris. Western Blot was performed on frontal area with antibodies directed against TAU and TDP-43. In order to assess neuronal death, protein expression of the NSE, Aconitase, Histone H3 and Neurofilaments was studied as well. Human Tau mRNA was analysed by QPCR. Finally, 2D-DIGE was performed on FTLD brains with or without loss of TAU proteins.
3.Results
We demonstrate that loss of TAU proteins mainly affects FTLD-TDP brains with specific genetic background. However, neither a decrease in TAU mRNA level nor a massive neuronal death were able to explain this phenotype suggesting a dysfunction in post-transcriptional and/or -translational regulation of TAU. Interestingly, proteomic analysis highlighted 15 proteins deregulated in “TAU less” brains including synaptic and astrocytic proteins.
4.Conclusion
In conclusion, our results suggest that “TAU less” group may define a new variant in the FTLD classification.

FLUORESCENCE-BASED ASSAY DEVELOPMENT TO SCREEN DRUGS AGAINST AMYOTROPHIC LATERAL SCLEROSIS DISEASE

D. Kortazar[1], R.M. Mella[1], M. Roura-Ferrer[1], A. Castilla[1], J. Herrero[1], G. Saracibar[1], A.C. Salado[1], P. Villace[1]

[1]INNOPROT, INNOPROT SL, DERIO, Spain

Amyotrophic Lateral Sclerosis disease (ALS) is characterized by the death of both upper and lower motor neurons in the motor cortex of the brain, the brain stem, and the spinal cord. Prior to their destruction, motor neurons develop intracellular protein inclusions in their cell bodies and axons. These inclusions often contain ubiquitin, and generally incorporate one of the ALS-associated proteins like SOD1, TAR DNA binding protein (TDP-43, or TARDBP) or FUS. Innoprot has developed a novel fluorescence cell-based assay for High Content Screening to screen compounds that can prevent or decrease the protein TDP43 or FUS aggregation into the stress granules after induction a cytotoxic stress. In this work we used both models to screen a library of 1200 compounds. Arimoclomol and Riluzole compounds were used as positive controls for the fluorescent TDP43 and FUS aggregation model. After the screening campaign, positive compounds were chosen for further testing, based on the strength of the initial response and the lack of cytotoxicity. Our results indicated that the pharmacological inhibition or modulation TDP43 or FUS aggregation implicated in ALS is a valid strategy for drug screening.

MODELLING MOTOR NEURON EXCITOTOXICITY IN THE AXON

K.A. Southam[1], C.A. Blizzard[1], A.E. King[2], T.C. Dickson[1]
[1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, Australia
[2]Wicking Dementia Research and Education Centre, University of Tasmania, Hobart, Australia

Objectives

Amyotrophic lateral sclerosis (ALS) is characterised by degeneration of upper and lower motor neurons. Evidence suggests that excitotoxicity may play a major role in this process. It remains unclear how motor neurons become exposed to excitotoxicity and whether this may be mediated by more than one cellular compartment (dendrites or axons).

Methods

Spinal motor neurons were obtained from the spinal cords of E13.5 mice and plated into microfluidic chambers with distal skeletal myocytes. Kainic acid (KA, 100µM) was delivered to either the somatodendritic or axonal compartment for 24 hours. Targeted excitotoxicity *in vivo* was delivered to the spinal cord (10mM kainic acid) or skeletal muscle (10mM glutamate) in Thy1-YFP mice. Pathology was assessed at 28 days post-surgery.

Results

KA delivered to the somatodendritic compartment *in vitro* resulted in a significant ($P<0.05$) increase in distal axon degeneration (55.8%±2.58% KA; 43.4%±2.08% control). This was accompanied by widespread cellular degeneration within the treated somatodendritic compartment. Distal axon excitotoxicity resulted in no significant ($P>0.05$) degeneration (41.0%±3.22%). KA delivered to the spinal cord *in vivo* resulted in a significant ($P<0.05$) increase in neuromuscular junction degeneration (30.85%±0.07% KA; 2.20±0.59% control). Somatodendritic KA resulted in a significant ($P<0.05$) loss of motor neuron cell bodies and motor deficits. Excitotoxicity delivered to the skeletal muscle did not induce degenerative or functional changes.

Conclusions

This work identifies specific vulnerability of the motor neuron cell bodies to excitotoxicity. These results suggest that therapeutics aimed at reducing excitotoxicity could be more effective if targeted to the motor neuron cell bodies.

ADPD5-2016

THE MECHANISM OF TDP-43 SPREADING IN ALS

S. Peled[1], Y. Bram[1], D. Sade[1], E. Gazit[1], D. Segal[2]
[1]Molecular Microbiology & Biotechnology, University, Tel-Aviv, Israel
[2]Molecular Microbiology & Biotechnology and the Interdisciplinary Sagol School of Neuro sciences, University, Tel-Aviv, Israel

1. Objectives: One hallmark of ALS is cytotoxic aggregates of the TDP-43 protein in neurons, comparable to aggregates of bona-fide amyloidogenic proteins in other neurodegenerative diseases, such as Aβ, tau and α-synuclein. Biophysical studies have shown that TDP-43 is indeed amyloidogenic. Recently, the aggregates of these amyloids, as well as of TDP-43, were shown to spread in the brain during disease progression. Experimental evidence indicates that this occurs via a cell-to-cell transfer, apparently comparable to prion transmission. However the mechanism of this intercellular transmission is unknown and may not necessarily be shared by all amyloids. Our goal is to characterize the mechanism of intercellular transmission of TDP-43 in ALS and to identify proteins mediating it.
2. Methods: We have generated neuronal SH-SY5Y cells expressing TDP-43 (full length and A315T mutant) tagged with either GFP, HA or APEX, the latter being based on enzymatic activity hence confers enhanced sensitivity.
3. Results: We found that tagged TDP-43 localizes to the nucleus like endogenous TDP-43, and that tagged TDP-43 is transferred to naïve cells. We shall focus on the use of APEX as a tag and employ GFP and HA for corroborating APEX-tagged TDP-43 results. Notably, the APEX tag allows labeling (by biotin) of proteins located in close proximity (but not distant) to the TDP-43-APEX fusion protein and we have shown its feasibility.
4. Conclusion: This novel cell culture model should shed light on the details of the mechanism of cell-to-cell transmission of TDP-43 and may suggest candidate targets for ALS therapeutics.

LINKING OF AUTOPHAGY AND UBIQUITIN-PROTEASOME SYSTEM (UPS) IN NEUROTOXIC YEAST CELL DEATH MODELS

C. Leibiger[1], *R. Braun*[1]

[1]*Cell Biology, Institute of Cell Biology, Bayreuth, Germany*

Introduction: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease with progressive degeneration of motor neurons, resulting in atrophy of musculature and death. Mutations in the gene TDP-43 have been associated with ALS. The RNA-binding protein TDP-43 accumulates in the cytoplasm of neurons of ALS patients as abnormal ubiquitinated, phosphorylated and insoluble inclusions.

We investigate the link between the cytotoxicity of TDP-43, UPS and autophagic activities in an easy to handle *S. cerevisae* cell death model.

Methods and Results: To determine the cytotoxicity of TDP-43 we measured growth deficiency in drop dilution assays. Yeast wild type (wt), *atg* (autophagy related) and UPS knock-out strains were transformed with human TDP-43 or vector control plasmids. In order to increase autophagy, growth media contained rapamycin blocking the TORC1 signalling pathway. We observed enhanced TDP-43 cytotoxicity with increased autophagy and with decreased UPS. TDP-43 cytotoxicity was relieved by deletion of *ATG* genes. We used the GFP-Atg8 processing assay to study autophagic turnover upon TDP-43 expression. wt and Δ*atg1* were transformed with TDP-43 and GFP-Atg8. We found an increase of processed GFP upon expression of TDP-43.

Conclusions: Our results suggest that autophagy and UPS influence TDP-43-triggered cytotoxicity. UPS plays a cytoprotective role whereas autophagy plays a detrimental role. We believe that insights gained by applying yeast as cell death model promote a better understanding of the relation between autophagy and UPS in ALS.

ADPD5-0520
THIAMINE DEFICIENCY – UNEXPECTED CAUSE OF DEATH IN TWO PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS

S. Jesse[1], D. Thal[2], A. Ludolph[1]
[1]Department of Neurology, University of Ulm, Ulm, Germany
[2]Laboratory of Neuropathology, University of Ulm-Institute of Pathology, Ulm, Germany

Objectives: Hypovitaminoses by virtue of undernourishment still represent clinical relevant diseases with a broad spectrum of symptoms. We discuss two patients with amyotrophic lateral sclerosis (ALS) who unexpectedly died not because of respiratory failure, but central dysregulation traced back to acute Wernicke Encephalpathy (WE), surprisingly found by autopsy.
Methods: The two ALS patients underwent neuropathological examination after death that was performed with permission and according to German law.
Results: The sole macroscopic abnormality was a reddish colouration of the corpora mamillaria and the periventricular thalamus. The spinal cord was macroscopically unremarkable. Microscopically, the hypothalamus featured multiple fresh hemorrhages in the mammillary body, exhibiting the pattern of an acute WE. The Prussian blue staining did not detect siderophages as sign of resorption of a former bleeding. As neuropathological correlate for ALS, we found a reduced number of spinal cord motor neurons, phospho-TDP43-positive preinclusions in pyramidal neurons of the frontocentral and parietal cortex and pTDP43-positive skein-like inclusions in few ventral horn neurons of the thoracic spinal cord, confirming the clinical diagnosis of ALS.
Conclusions: Here, we report thiamine deficiency causing acute WE with fatal outcome in two patients with ALS. Both objected parenteral gastrostomy that predestines them to the high risk group due to their dysphagia. As thiamine deficiency represents a potential life threatening complication in the course of ALS, it is important to raise awareness for possible prevention by supplementation.

ADPD5-0782

OVERACTIVATION OF WNT5A SIGNALING IN FTLD-TDP: CROSS-TALK OF PROGRANULIN AND TNF-ALPHA SIGNALING PATHWAYS.

C. Alquezar[1], A. de la Encarnación[1], A. Martín-Requero[1]
[1]Cellular and Molecular Medicine, CIB CSIC, madrid, Spain

Objectives: Frontotemporal lobar degeneration with TDP-43 pathology (FTLD) is the most common cause of dementia in people under 65 years of age. Loss-of-function *progranulin* gene (*GRN*) mutations have been identified as the major cause of FTLD-TDP, however little is known about the relationship between progranulin (PGRN) deficiency and neuronal loss in FTLD-TDP. Previously we reported enhanced proliferative activity associated with the activation of Wnt5a signaling in PGRN deficient cells. The objective of this work has been elucidating the relationship between PGRN deficiency, Wnt5a signaling and cell proliferation in immortalized lymphoblasts from carriers of the c.709-1G>A *GRN* mutation (Asymptomatic and FTLD-TDP).
Methods: Cell proliferation was assessed by cell counting. mRNA levels were evaluated using real-time PCR and protein levels by immunoblotting. Co-Immunoprecipitation Assay was used for analyze the interaction between PGRN and its receptors.
Results: PGRN deficient cells showed increased expression of Wnt5a that seems to be related with overactivation of the TNF/NF-κB signaling. We observed a competition between PGRN and TNFα for binding both TNFα receptors. Blocking TNFa signaling with antibodies against TNFRI or TNFRII, as well as inhibiting NF-κB with wedelelactone, resulted in a decrease of both Wnt5a expression and proliferation in PGRN deficient lymphoblasts. In other hand, the addition of exogenous TNFα increased the Wnt5a expression and proliferation in control cells.
Conclusion: Our results revealed an important role of NF-κB signaling in PGRN-associated FTLD-TDP and confirm that PGRN can binds to TNFα receptors regulating the expression of genes, such as Wnt5a, implicated in the onset and progression of FTLD-TDP.

ADPD5-1013

CUMULATIVE FUNCTIONAL COPPER DEFICIENCY IN SPINAL CORDS OF AMYOTROPHIC LATERAL SCLEROSIS (ALS) MODEL MICE AND POST-MORTEM HUMAN ALS TISSUE

J. Hilton[1], P.J. Crouch[1], A.R. White[1]
[1]Pathology, The University of Melbourne, Melbourne, Australia

Objectives: We recently reported that increasing copper bioavailability both therapeutically and genetically acted to protect spinal cord motor neurons, whilst concomitantly improving locomotor function and survival of ALS model mice. These outcomes indicate that copper deficiency contributes to the pathogenesis of ALS. For the present study we directly assessed the extent of copper deficiency in ALS. **Methods:** We assessed levels and copper-dependent activity of the anti-oxidant SOD1, the ferroxidase ceruloplasmin and mitochondrial cytochrome c oxidase in the spinal cords of SOD1G37R ALS model mice from pre-symptom through to late symptom stages of disease progression. We also assessed post-mortem spinal cord samples from human cases of sporadic ALS. For mouse tissue analyses, non-transgenic littermate and wild-type SOD1 overexpressing mouse spinal cords, and non-disease affected livers were used as controls. Spinal cords from healthy controls were included in the human tissue analyses. **Results:** All analyses revealed a strong disparity between protein levels measured and their copper-dependent activity, consistent with a broad functional copper deficiency in ALS. This disparity was evident at an early age in the ALS model mice and was cumulative as disease progressed. **Conclusions:** These results indicate the cause of ALS phenotype in mutant SOD1 mice is not restricted to mutant SOD1 toxicity and may be driven, at least in part, by broader consequences of functional copper deficiency. The fact that the human ALS tissue we examined included only sporadic cases of the disease indicates the role of functional copper deficiency in ALS extends beyond mutant ALS cases.

An Anti-misfolding TDP-43 Proteins Drug with New Mechanism

Hsiang-Yu Chang[1,2] & I-Fan Wang[1]

[1] Garage Brain Science, Taichung, Taiwan 413 [2]Department of Biological Science and Technology, College of Life Sciences, China Medical University, Taichung, Taiwan 404

Our strategy is to maintain the functional conformation of the prone-to-aggregate domain of disease proteins throughout lifespan, could result in improved therapeutic outcomes. The functional substitution of the non-amyloid prion-like domain TDP-43 with the amyloid prion domain sup35 revealed a potent common structure for treating TDP-43 proteinopathies by using off-amyloid stabilizers[1,2,3]. These stabilizers may simultaneously prevent prion-like spread in neurodegenerative diseases. We selected few off-amyloid compounds from compound library and examined the effects of redirecting non-amyloid, misfolded TDP-43 protein into functional proteins. We successfully obtained two compounds via cell-based disease models. In this presentation, we will discuss mechanism-based target identification, drug discovery and pharmacological interventions for TDP-43 proteinopathies.

04e. Therapeutic Targets & Mechanisms for Treatment: TDP-43

ADPD5-1589
REGULATION OF NUCLEAR TDP-43 BY NMDA RECEPTOR
J. Chen[1], Q. Wan[1]
[1]Physiology, Wuhan University School of Medicine, Wuhan, China
The dysfunction of TAR DNA-binding protein-43 (TDP-43) is implicated in neurodegenerative diseases. However, the function of TDP-43 is not fully elucidated. Here we show that the protein level of endogenous TDP-43 in the nucleus is increased in mouse cortical neurons at the early stage but return to basal level at the late stage after glutamate accumulation-induced injury. The elevation of TDP-43 level is resulted from a downregulation of phosphatase PTEN. We further demonstrate that activation of NR2A-containing NMDA receptors (NR2ARs) leads to PTEN downregulation and subsequent reduction of PTEN import from cytoplasm into the nucleus after glutamate accumulation. The decrease of PTEN protein level in the nucleus contributes to a reduced association of PTEN with TDP-43 and thereby mediates the elevation of nuclear TDP-43. We provide evidence that the elevation of nuclear TDP-43, mediated by NR2AR activation/PTEN downregulation, confers protection against cortical neuronal death at the late stage after glutamate accumulation. Thus, this study reveals a NR2AR/PTEN/TDP-43 signaling pathway by which the nuclear TDP-43 promotes neuronal survival. These results suggest that upregulation of nuclear TDP-43 represents a self-protection mechanism to delay neurodegeneration at the early stage after glutamate accumulation and that prolonging the upregulation process of nuclear TDP-43 may have therapeutic significance.

[2]Otto-von-Guericke University, Department of Neurology, Magdeburg, Germany

[3]Hannover Medical School, Department of Neurology, Hannover, Germany

[4]German Center for Neurodegenerative diseases (DZNE), Neurodegeneration and brain plasticity, Magdeburg, Germany

OBJECTIVE

Assess the sensitivity of cortical thickness measurements versus diffusion tensor imaging to detect pathologic changes in ALS.

METHODS

Twenty-six ALS-limb onset patients (mean age=57.4) and twenty-nine matched controls were included. Patients were divided into two groups of 13 according to severity (ALS-Mild ALSFRS-R > 38, ALS-Severe ALSFRS-R<=38). MRI measurements were performed in a Siemens Verio 3T scanner. DTI data used TBSS to evaluate white matter integrity while cortical thickness in structural images was measured using Freesurfer. Statistical comparisons were done in regions of interest comprising the corticospinal tracts for DTI and the precentral gyrus for cortical thickness.

RESULTS

Corticospinal DTI analysis showed significant fractional anisotropy (FA) differences between the ALS groups' means compared to controls (fig. 1-left) with a non-significant trend that the more advanced had lower values than the mild group. Significant differences in cortical thickness were not identified and there was no suggestion of greater reduction in the more advanced group.

CONCLUSIONS

The results indicate that corticospinal FA reductions are more sensitive, and more closely aligned to disease severity than cortical thickness of the motor strip. This should not, however, be interpreted as meaning degeneration of white matter is more biologically pronounced than grey matter—it is quite possible that results are due to differential sensitivities of the two scan modalities.

CORTICOSPINAL TRACT INTEGRITY IN RELATION TO EXTRA-MOTOR NEUROCOGNITIVE IMPAIRMENT IN AMYOTROPHIC LATERAL SCLEROSIS: A DIFFUSION TENSOR IMAGING AND NEUROPSYCHOLOGICAL STUDY

F. Christidi[1], I. Zalonis[1], E. Karavasilis[2], M. Rentzos[1], P. Ferentinos[3], S. Kyriazi[2], V. Zouvelou[1], T. Alexakis[1], N. Karandreas[1], I. Evdokimidis[1]
[1]A' Department of Neurology Aeginition Hospital,
Medical School National & Kapodistrian University of Athens, Athens, Greece
[2]Radiology Research Unit Medical Imaging Department Evgenidion Hospital,
Medical School National & Kapodistrian University of Athens, Athens, Greece
[3]A' Department of Psychiatry Aeginition Hospital,
Medical School National & Kapodistrian University of Athens, Athens, Greece

Objectives: Diffusion tensor imaging (DTI) is a most promising structural MRI method to detect amyotrophic lateral sclerosis (ALS) changes both in pyramidal tracts and in extra-motor regions. Thus, we evaluated motor and extra-motor involvement in non-demented patients with ALS using DTI and their relation to neuropsychological measures.
Methods: We included 21 patients with definite or probable ALS (revised El Escorial Criteria) and 11 healthy controls. Using 30-directional DTI at 3T MRI scanner, we analyzed fractional anisotropy-(FA), apparent diffusion coefficient-(ADC), axial diffusivity-(D_A) and radial diffusivity-(D_R) for corticospinal tract-(CST), corpus callosum-(CC) and uncinate fasciculus-(UF). Neuropsychological evaluation included tests of executive (Trail Making Test part B-TMTB; Stroop Test-SNST; Digit Span Forward and Backwards; Wisconsin Card Sorting Test-WCST) and memory functions (Babcock Story Recall Test-BSRT; Rey Auditory Verbal Learning Test-RAVLT).
Results: We found significant ($p<0.05$) between-group differences in FA (CC), ADC (bilateral CST,CC), D_A (right CST,CC,bilateral UF), and D_R (right CST,CC). Within the ALS group, CST DTI indices (FA,ADC,D_A,D_R) did not correlate with CC or UF indices. CST indices were related to memory but not executive performance. CC FA was negatively associated with BSRT, whereas CC diffusivity indices were negatively associated with Digit Span Forward and RAVLT. UF integrity was positively associated with TMT-B, SNST and several memory scores.
Discussion: DTI identifies degeneration in both motor and extra-motor white matter tracts in ALS, with CST integrity being unrelated to extra-motor integrity (CC, UF). Motor integrity is associated to memory performance while extra-motor integrity is related to patients' both executive and memory cognitive profile.

SUBCORTICAL SHAPE SEPARATES ALZHEIMER'S DISEASE, FRONTO-TEMPORAL DEMENTIA AND HEALTHY ELDERLY SUBJECTS

B. Gutman[1], C.R.K. Ching[1], J. Looi[2], P.M. Thompson[1]

[1]Keck School of Medicine, Imaging Genetics Center University of Southern California, Los Angeles, USA

[2]Academic Unit of Psychiatry & Addiction Medicine, Australian National University Medical School Canberra Hospital, Woden, Australia

Data: 118 T1-weighted MR images of Alzheimer's (AD), Fronto-temporal dementia (FTD) patients and controls were parcellated with FreeSurfer. These structures were meshed, enforcing consistent topology: amygdala, hippocampus, pallidum, nucleus accumbens, thalamus, putamen, caudate.

Methods: Shapes were registered to a previously generated shape atlas, using the spherical fluid registration. Radial thickness (RDM) and surface Tensor-based Morphometry (TBM) were computed at homologous points. Mass-univariate group comparisons were performed: AD vs. NC, FTD vs. NC, AD vs. FTD, all corrected using False Discovery Rate (FDR). PCA & MANOVA were performed to distinguish among the three disease categories as well as the three FTD subtypes: behavioral variant (FTD); SD: semantic dementia; PNFA: progressive nonfluent aphasia (**Figure 2**).

Results: We created P-maps over the seven structures, thresholded at the FDR critical q: AD vs. NC q = 0.017, FTD vs. NC q = 0.03, AD vs. FTD q = 0.0072 (p-maps in **Figure 1**). Widespread atrophy is apparent throughout the basal ganglia, with stronger overall effect in the FTD cohort. The dorsal striatum differentiated the AD and FTD cohorts, in particular the behavioral variant and semantic dementia, subtypes characterized by social-emotional deficits.

GLUCOSE METABOLISM IN EARLY ONSET VERSUS LATE ONSET BEHAVIORAL VARIANT FRONTOTEMPORAL DEMENTIA

E.J. Kim[1], B.C. Kim[2], D.L. Na[3]
[1]Neurology, Pusan National University Hospital, Busan, Korea
[2]Neurology, Chonnam National University Medical School, Gwangju, Korea
[3]Neurology, Samsung Medical Center, Seoul, Korea

Backgrounds
: The aim of this study was to compare the overall glucose metabolism between early onset and late onset behavioral variant frontotemporal dementia (bvFTD) to investigate whether their metabolic deterioration was different even at the same dementia severity.
Methods
: Thirty one patients with early onset bvFTD (mean age: 61.6±4.9), 12 with late onset bvFTD (mean age: 75.3±5.3) and 65 healthy volunteers (mean age: 64.9±7.3) were recruited from the dementia clinics of 3 tertiary referral hospitals. Glucose hypometabolic patterns were evaluated by comparing patients with early onset bvFTD and late onset bvFTD with 65 healthy controls using voxel-based statistical parametric mapping.
Results
: There were no significant differences in Korean version of Mini-Mental State Examination, clinical dementia rating (CDR), and sum of boxes scores of FTD-CDR between early onset and late onset bvFTD patients. However, overall glucose hypometabolism of early onset bvFTD patients was much greater in magnitude and extent involving bifrontal and anterior temporal areas than that of late onset bvFTD patients.
Conclusions
: The results of greater hypometabolism in early onset than late onset patients with bvFTD even at the same severity of dementia were consistent with those of our previous research comparing glucose metabolism between patients with early onset and late onset Alzheimer's disease, reflecting greater functional reserve in younger than in older subjects.

[6]Department of Clinical Neurosciences,

Scientific Institute and University Hospital San Raffaele, Milan, Italy

Objective. To assess the patterns of cortical thinning and white matter (WM) tract abnormalities in relation to cognition and behavioural symptoms in patients with motor neuron disease (MND).

Methods. 101 patients with motor neuron disease (MND) and 56 healthy subjects were studied. Patients were classified into MND with a pure motor syndrome (MND-motor) and those with cognitive/behavioural symptoms (MND-plus). A surface-based morphometry analysis was used to assess cortical thickness. Corticospinal tract (CST), corpus callosum (CC), and major association tracts diffusion tensor (DT) metrics were obtained. A Random Forest (RF) approach was used to identify the set of image features correlated with cognitive/behavioural deficits.

Results. There were 48 MND-motor and 53 MND-plus patients. Relative to controls, both patient groups showed cortical thinning of the bilateral precentral and postcentral gyri, cingulate cortex, inferior temporal and parietal areas. In all regions, there was a trend towards a more extensive involvement in MND-plus *vs* MND-motor. Both patient groups showed a damage of the motor CC fibers, but such a damage was greater in MND-plus cases. MND-plus patients also showed a severe involvement of the extra-motor WM tracts bilaterally. RF analysis showed that the best predictors of cognitive deficits and behavioural symptoms in MND patients were the DT MRI metrics of the frontotemporal tracts.

Conclusions. Cortical thinning and WM degeneration are highly dependent upon neuropsychological and behavioural symptoms in patients with MND. WM tract damage contributes to the severity of selective cognitive and behavioural manifestations more than cortical thinning.

CONNECTED SPEECH PRODUCTION IN THE NONFLUENT VARIANT OF PRIMARY PROGRESSIVE APHASIA AND ITS RELATIONSHIP WITH WHITE MATTER DAMAGE

E. Canu[1], F. Agosta[1], S. Galantucci[1], E. Catricalà[2], P.M. Ferraro[1], G. Magnani[3], A. Marcone[2], G. Comi[3], A. Falini[4], S.F. Cappa[2], M. Filippi[1]
[1]Neuroimaging Research Unit, San Raffaele Scientific Institute and University, Milan, Italy
[2]Department of Clinical Neurosciences, San Raffaele Scientific Institute and University, Milan, Italy
[3]Department of Neurology, San Raffaele Scientific Institute and University, Milan, Italy
[4]Department of Neuroradiology and CERMAC,
San Raffaele Scientific Institute and University, Milan, Italy

Objective. To investigate the association between the different components of the connected speech and white matter (WM) damage in nonfluent variant of primary progressive aphasia (nfvPPA).
Methods. To assess the connected speech, we recorded speech samples from 11 nfvPPA patients while they described the image of the picnic picture subtest of the Western Aphasia Battery and analyzed them considering: lexical production rate and phonological/articulatory errors; pauses and repetitions; lexical typology; and syntactic structure. Diffusion tensor (DT) MRI metrics were obtained from the interhemispheric and major long association WM tracts.
Results. Speech samples in nfvPPA patients were characterized by slow rate, distortions, syntactic errors and reduced complexity of sentence production. The lexical production rate was positively related with the integrity of the left superior longitudinal (SLF) and inferior longitudinal (ILF) fasciculi and cingulum bilaterally; the Italian phoneme distortions were related with damage of the corticospinal tracts; the false starts were related with damage of the corpus callosum (CC); the lexical selection (such as the use of nouns, verbs, or prepositions) was related with DT MRI metrics of left SLF and CC genu; the syntactic complexity (i.e., mean length of utterance, ratio between number of words per sentence and number of sentences) and presence of morpho-syntactic errors were related with damage of the left SLF and ILF, and CC body.
Conclusions. We reported associations between particular aspects of connected speech and specific WM tract integrity in nfvPPA. This study underlines the relevant role of WM in nfvPPA.

Objective. To identify overlapping and unique grey (GM) and white matter (WM) signatures within the frontotemporal lobar degeneration (FTLD) continuum, and discriminate likely FTLD-TAU and FTLD-TDP patients using structural and diffusion tensor (DT) MRI.

Methods. T1-weighted and DT MRI were collected from 121 subjects: 35 motor neuron disease (MND), 14 behavioral variant of frontotemporal dementia, 12 semantic and 11 nonfluent primary progressive aphasia, 21 progressive supranuclear palsy syndrome and 28 controls. GM atrophy was established using voxel-based morphometry. Tract-based spatial statistics was used to perform a WM voxel-wise analysis.

Results. All patient groups, with the exception of MND cases with a pure motor syndrome, shared a focal GM atrophy centered around the dorsolateral and medial frontal cortex and a largely overlapping pattern of WM damage involving the genu and body of the corpus callosum and ventral frontotemporal and dorsal frontoparietal WM pathways. Surrounding this common area, phenotype (symptom)-specific GM and WM regions of damage were found in each group. Patients with a high likelihood of an underlying FTLD-TAU had more severe WM damage relative to patients who are likely to harbor FTLD-TDP pathology, despite a similar pattern of GM atrophy.

Conclusions. In the FTLD spectrum, WM damage is more severe than GM atrophy. Frontal cortex and WM pathways represent the common target of neurodegeneration in these conditions. The topographic pattern of damage supports a 'prion-like' protein propagation through WM connections as underlying mechanism of the stereotyped progression of FTLD.

Scientific Institute and University Hospital San Raffaele, Milan, Italy

[5]Department of Neuroradiology, Scientific Institute and University Hospital San Raffaele, Milan, Italy

Objective. To test a multimodal MRI-based approach, comprising cortical thickness and white matter (WM) damage metrics, to discriminate the nonfluent (nfvPPA) and semantic (svPPA) variants of primary progressive aphasia (PPA).

Methods. T1-weighted and diffusion tensor (DT) MRI were obtained from 13 nfvPPA and 13 svPPA patients, and 23 controls. Cortical thickness and DT MRI indices from the long-associative and interhemispheric WM tracts were obtained. A random forest analysis was used to identify the image features associated with each clinical syndrome. Individual patient classification was performed using ROC analysis with cortical thickness, DT MRI, and a combination of the two modalities.

Results. Random forest analysis showed that the best markers to differentiate the two PPA variants at an individual patient level were diffusivity abnormalities of the left inferior longitudinal and uncinate fasciculi and cortical thickness measures of left temporal pole and inferior frontal gyrus. A combination of cortical thickness and DT MRI measures ('grey matter [GM]&WM' model) provided the best classification pattern (area under the curve 0.91, accuracy 0.89, sensitivity 0.92, specificity 0.85). Leave-one-out analysis validated these findings demonstrating that the 'GM&WM' model had an higher accuracy (0.86) compared with 'GM-only' (0.73) and 'WM-only' (0.69) models.

Conclusion. A combination of structural and DT MRI metrics provides a quantitative procedure to distinguish nfvPPA and svPPA at an individual patient level. The discrimination accuracies obtained are high enough to suggest that the 'GM&WM' model is potentially relevant for the differential diagnosis of PPA in the clinical practice.

QUANTITATIVE SUSCEPTIBILITY MAPPING (QSM) IN AMYOTROPHIC LATERAL SCLEROSIS

J. Acosta-Cabronero[1], A. Cardenas-Blanco[1], J. Machts[1], S. Abdulla[2], K. Kollewe[3], S. Petri[3], H.J. Heinze[2], R. Dengler[3], S. Vielhaber[2], P.J. Nestor[1]
[1]Brain Plasticity and Neurodegeneration Group,
German Center for Neurodegenerative diseases (DZNE), Magdeburg, Germany
[2]Department of Neurology, Otto-von-Guericke University, Magdeburg, Germany
[3]Department of Neurology, Hannover Medical School, Hannover, Germany

OBJECTIVE

Determine whether there are alterations in metal content in ALS as measured with QSM.

METHODS

Twelve ALS patients (age=62±9 years) and thirty-four matched controls were analysed. All MRI measurements were performed in a Siemens Verio 3T scanner. T2* images were inspected to exclude cases with vascular pathology. Susceptibility weighted images—chiefly sensitive to the magnetic properties of metals—were reconstructed, post-processed and analysed using *state-of-the-art* quantitative methods.

RESULTS

Increased magnetic susceptibility (blue), suggesting metal accumulation, was found in the primary motor cortex as well as, putamen, substantial nigra and prefrontal areas. In addition, reduced magnetic susceptibility (orange) was identified in white matter including the cortico-spinal tract that co-localised with previously reported diffusion tensor abnormalities (Cardenas-Blanco et al. J Neurol in press).

CONCLUSIONS

QSM identified *in vivo* evidence for metal (most probably iron) misregulation in ALS. Notably the results suggest pathological accumulation in the primary motor cortex which could be contributing to a toxic insult; reduced susceptibility in white matter tracts suggests reduction of ferritin binding sites due to myelin/axonal loss. Increased susceptibility effects in the putamen, in contrast, appear to be common to a range of degenerative states, as we have previously observed them in Alzheimer's and in normal aging.

ADPD5-0522
THIAMINE DEFICIENCY – RELEVANT IN PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS

S. Jesse[1], D. Thal[2], A. Ludolph[1]
[1]Department of Neurology, University of Ulm, Ulm, Germany
[2]Laboratory of Neuropathology, University of Ulm-Institute of Pathology, Ulm, Germany

Objectives: By chance, we detected two patients with amyotrophic lateral sclerosis (ALS) who unexpectedly died because of central dysregulation traced back to acute Wernicke Encephalpathy (WE). Due to the two cases and their contingent cause of death, we were interested in prevalence of thiamine deficiency among ALS patients.
Methods: During two years, we examined laboratory markers of thiamine deficiency in 122 ALS inpatients without clinical symptoms of B1 deficiency to estimate prevalence. Here, transketolase and thiamine-pyrophosphat-effect (TPP-effect) were investigated in an external laboratory using EDTA-blood samples. Reference value was appointed to an increase of the TPP-effect >15% for slight and >20% for severe thiamine deficiency.
Results: We found a prevalence of B1 deficincy in 28% of ALS. Interestingly, none of the patients showed symptoms of WE. Contrary to our expectations, there was no different prevalence in the ALS-subgroups of bulbar versus spinal forms and no correlation between thiamine deficiency and severity of ALS symptoms, graduated by the ALS-functional rating score ALS-FRS-R.
Conclusions: ALS patients belong to the risk group for developing WE due to their dysphagia. In spite of absent typical WE-symptoms, prevalence of thiamine deficiency is 28% in our collective. Regarding the two patients who died due to WE and the prevalence we found for B1 deficiency, it is recommendable to pay attention to this possible fatal metabolic disease and to analyze thiamine levels in ALS patients at a low threshold.

ADPD5-0893

NGS RESEQUENCING USING A PANEL OF GENES ASSOCIATED WITH NEURODEGENERATIVE BRAIN DISEASE EXPLAINS 43% OF FAMILIAL FTLD PATIENTS

J. van der Zee[1], C. Robberecht[1], L. Dillen[1], A. Laureys[1], M. Cruts[1], C. Van Broeckhoven[1], . BELNEU consortium[1]

[1]Neurodegenerative Brain Disease Group of the Department of Molecular Genetics, VIB and University of Antwerp, Antwerp, Belgium

Objectives: We aimed at determining the contribution of mutations in genes casually associated with neurodegenerative brain diseases (NBD) in a Belgian cohort of patients with frontotemporal lobar degeneration (FTLD).

Methods: To expedite the screening we designed a NBD gene panel for amplicon-based resequencing of all exons of 30 known genes. Targeted exons are amplified in multiplex PCR panels followed by massive parallel sequencing.

Results: In 423 FTLD patients we identified 146 rare protein-modifying variants. These included 50 variants that were definitely or probably pathogenic: 35GRN, 4MAPT, 5VCP, 1FUS, 2TARDBP, 1CHMP2B, 2PSEN1, and 4 possibly pathogenic: 2VCP, 2FUS. Together with C9orf72 repeat expansions, this explained 43% of familial FTLD patients and up to 62% of pathology confirmed cases. Interestingly, we detected 2 carriers with two mutations: one with a GRN together with a C9orf72 expansion mutation and another with a VCP and a C9orf72 expansion mutation. In our Belgian FTLD cohort the 2 most frequently mutated genes are GRN (8.3%) and C9orf72 (7.3%). Further, we identified novel missense mutations in APP (n=6), MAPT (n=13) and in LRRK2 (n=17) of which the impact on the FTLD phenotype is yet unclear.

Conclusion: The NBD gene panel considerably increased the speed and efficacy of mutation screening of causal genes, and will substantially improve molecular diagnostic testing in a medical setting. The assay is a highly accurate and cost-effective screening method offering a more complete genetic output. At this moment, exome sequencing cannot offer the same amount of coverage and fidelity for targeted gene screening.

08a. Animal Models: transgenic mice

ADPD5-2161

A NOVEL TDP-43 TRANSGENIC MOUSE MODEL OF FRONTOTEMPORAL LOBAR DEGENERATION AND AMYOTROPHIC LATERAL SCLEROSIS

A. van Hummel[1], Y. Ke[1], S. Ippati[1], C.H. Stevens[1], F. Delerue[1], L. Ittner[1]
[1]Dementia Research Unit School of Medical Sciences,
The University of New South Wales, Sydney, Australia

Objectives: To generate and characterise a novel neuronal-specific inducible TDP-43 transgenic mouse model with both neurodegeneration and behavioural deficits for the study of Frontotemporal Lobar Degeneration (FTLD) and Amyotrophic Lateral Sclerosis (ALS).
Methods: A novel mouse model was generated using the Tet-OFF Advanced system (ClonTech) driven by the neuronal-specific Thy1.2 promoter, to induce non-leaky expression of human TDP-43 with the A315T mutation. Neuronal expression of the mutant TDP-43 was confirmed with Western blot, degeneration was assessed by immunofluorescence, and mice were subjected to a battery of behavioural studies at 3 months of age.
Results: Western blot and immunofluroesence analysis confirmed expression of mutant TDP-43 in the cortex, hippocampus and, to a lesser degree, spinal cord and cerebellum of transgenic mice, which was absent in wild-type littermates. Transgenic mice showed considerable early onset degeneration of the cortex and hippocampus, and significant deficits in a number of behavioural tests compared to wild-type littermates: Morris Water Maze; Elevated Plus Maze; Rotarod; Pole Test. Interestingly, treatment of three-month-old transgenic mice with doxycycline (to suppress TDP-43 expression) reduced the behavioural deficits of the transgenic mice.
Conclusions: Our novel TDP-43 mouse model shows early onset of degeneration, behavioural deficits both in memory-based and motor-based tests, and decreased anxiety, similar symptoms to those experienced by FTLD and ALS patients. The alleviation of behavioural deficits in the absence of TDP-43 expression suggests that the presence of toxic TDP-43, as well as existing neurodegeneration, contribute to the neurodegenerative process underlying FTLD.

INTEREST OF CSF BIOMARKER RATIOS IN THE DIAGNOSIS OF LATE ONSET BV-FRONTOTEMPORAL LOBAR DEGENERATION (BV-FTLD) VS ALZHEIMER'S DISEASE (AD)

C. Marelli[1], N. Menjot de Champfleur[2], C. Charroud[3], D. De Verbizier[4], J. Touchon[1], S. Lehmann[5], A. Gabelle[1]

[1]Department of Neurology and CMRR, Gui de Chauliac University Hospital, Montpellier, France

[2]Department of Neuroradiology, Gui de Chauliac University Hospital, Montpellier, France

[3]Inserm Unit 583 "Plasticity of Central Nervous System Stem Cells and Glial Tumors", Institut of Neurosciences of Montpellier, Montpellier, France

[4]Department of Nuclear Medecine, Gui de Chauliac University Hospital, Montpellier, France

[5]INSERM-UM1 1040, Bio-therapy Research Institute (IRB), Montpellier, France

Background: Late-onset bv-FTLD (>65 ys) accounts for 3-18% of all bv-FTLD. New bv-FTLD clinico-radiological criteria show low sensibility for late-onset cases; AD is the main misdiagnosis. We investigated whether CSF biomarkers could help in diagnosing late-onset bv-FTLD.

Methods: a retrospective study (2007-2013) on clinically suspected amnestic AD or bv-FTLD with onset after 65 ys and no severe psychiatric or vascular burden. Patients were re-classified as AD or bv-FTLD according to the revised criteria (McKhann, 2011; Rascovsky, 2011); the CSF T-Tau/Abeta42 (>1.06) and P-Tau/Abeta42 (>0.2) cut-offs for diagnosis of MA *vs* FTLD (Bian, 2008; De Souza, 2011) were then applied.

Results: Fifty-seven patients were included. According to the international criteria diagnoses were AD (N=37; 65%), bv-FTLD (N=12; 21%), executive AD (N=4; 7%) or "neither AD nor bv-FTLD" (N=4; 7%). After applying MA *vs* FTLD CSF cut-offs the diagnoses were AD (N=22, 39%), FTLD (N=29, 51%) or undetermined (N=6, 10%). Most of the probable/possible AD with high/intermediate biomarker probability were confirmed as AD; all bv-FTLD were confirmed as bv-FTLD; some of the probable/possible AD with undetermined biomarkers had CSF cut off in the FTLD range or had conflicting CSF results; the undetermined cases had CSF cut off in the range of "non-AD".

Conclusions: Late onset bv-FTLD is possibly under diagnosed: CSF analysis, notably combined biomarkers and ratios, could suggest this diagnosis and differentiate it from AD. The actually proposed cut-off could possibly be further improved in relation to the population on study (late-onset disease) and the specificity of the differential diagnosis (bv-FTLD *vs* AD).

ADPD5-0219

DISEASE PROGRESSION MODEL TO CHARACTERIZE THE AMYOTROPHIC LATERAL SCLEROSIS TIME-COURSE USING THE ALSFRS RATING SCALE

R. Gomeni[1], F. Bressolle[1]
[1]R&D, Pharmacometrica, Villefranche de Rouergue, France

Objectives

To develop a longitudinal model describing Amyotrophic Lateral Sclerosis Functional Rating Scale (ALSFRS) scores in ALS patients, to evaluate factors affecting disease progression, to detect presence of clusters in disease progression, to evaluate if data collected in an observational period (3 months) can predict disease deterioration at 12 months.

Methods

Patients (n=3936 with 29688 ALSFRS measurements) from PRO-ACT database (https://nctu.partners.org/ProACT/) were included in the analyses. A non-linear Weibull model described the ALS disease progression using 3 parameters: baseline ALSFRS, disease progression rate, rate of change in response. The presence of clusters in disease progression trajectories was investigated using a mixture modeling approach.

Results

Two clusters of disease deterioration trajectories were identified: slow progressors (56% of patients with 15% change from baseline); fast progressors (44% of patients with 46% change from baseline). Gender statistically affected disease progression rate: the woman progress ~10% faster than man. Logistic regression identified model predicted ALSFRS (change from baseline and value at week 3) as statistical significant predictors of slow/fast disease deterioration at 12 months ($p<0.0001$ and $p<0.005$, respectively).

Conclusions

The results confirmed previous analysis on ALSFRS-R scale [1] regarding: heterogeneity of measurements, presence of clusters in disease progression, and predictive power of measurements collected in an observational period on disease deterioration at 12 months. These findings indicate the interest of disease progression model for implementing population enrichment strategy to control the level of heterogeneity in patients included in a new trial.

ASSOCIATION OF TAU WITH TIA-1 REGULATES STRESS GRANULE BIOLOGY AND TAU MISFOLDING

T. Vanderweyde[1], K. Youmans[1], D. Apicco[1], P. Ash[1], C. Cook[1], A. Citro[1], K. Jansen-West[2], L. Petrucelli[2], B. Wolozin[1]

[1]Pharmacology and Neurology, Boston University, Boston, USA

[2]Neuroscience, Mayo Clinic, Boston, USA

Increasing evidence links neurological disease processes to dysfunctional n of neuronal RNA binding proteins (RBPs), RNA granules and stress granules (SGs). RBPs, such as T-cell intracellular antigen 1 (TIA1), contain prion-like, poly-glycine rich domains, which promote a process of protein aggregation that is normally physiological and reversible. Disease-linked mutations in RBPs increase the tendency of these proteins to aggregate, leading to formation of pathological SGs. Importantly, TIA1 and other SG proteins, co-localize with neuropathology in brain tissue of subjects with AD and ALS.

We now report a novel role for tau in regulating SG dynamics, and an equally novel ability of TIA-1 to induce misfolding of tau. Tau associates with TIA-1, a core nucleating RBP, promotes SG formation and reduces the movement of RNA granules containing TIA1, while deleting tau inhibits stress granule formation. TIA1 also regulates tau biology. Overexpressing TIA1 stimulates misfolding and phosphorylation of tau, formation of SGs that co-localize with insoluble tau. Live cell imaging indicates that TIA1 stabilizes granular tau and prolongs its half-life. Importantly, this system is modulated by translational signaling, being potentiated by puromycin or salubrinal, but inhibited by cycloheximide, which points to translational control as a novel tau regulatory pathway. The interaction of TIA1 with tau also stimulates neuronal degeneration, which is potentiated by oligomeric Ab. These results indicate tau contributes to the translational stress response, and raise the possibility that the association of tau with SGs contributes to the pathophysiology of tauopathies.

SWEET NEUROBIOLOGY: THE ROLE OF ALTERATIONS IN PROTEIN GLYCOSYLATION IN ALZHEIMER'S DISEASE PATHOLOGY

Y. Solovey[1], M. Frenkel-Pinter[1], S. Stempler[2], T. Sharon[1], A. Singh-Anand[1], D. Escobar[1], J. Lezmy[1], Y. Waldman[2], E. Ruppin[2], E. Gazit[1], D. Segal[1]

[1]Molecular Microbiology & Biotechnology, Tel Aviv University, Tel Aviv, Israel

[2]The Blavatnik School of Computer Science, Tel Aviv University, Tel Aviv, Israel

Human neurodegenerative diseases are associated with pathogenic oligomers and aggregates of misfolded proteins, eventually causing the progressive loss of neurons in the brain. One process which might be affected in neurodegenerative disorders is post-translational protein modification, known to be derailed during aging. Protein modifications such as phosphorylation, acetylation and glycosylation are critical to normal function of many proteins.

We focus on protein glycosylation. The majority of proteins synthesized in the rough ER undergo glycosylation, which is an enzyme-directed site-specific process. Protein glycosylation also occurs in the cytoplasm and nucleus as the O-GlcNAc modification, which, interestingly, competes with phosphorylation for the same amino acids.

We explore the role of glycosylaition in Alzheimer’s disease (AD), where several reports indicated vast alterations in protein glycosylation in AD.

Using an *in silico* approach we found that many genes encoding glycosylation-related enzymes exhibited different expression profile in brains of human AD patients as compared with healthy subjects. We next studied the effect of enhancing or reducing expression of the glycosylation-related genes in transgenic *Drosophila* over-expressing human tau which serve as an established AD model. We thus identifyed leading glycosylation enzymes, both augementing and ameliorating neurodegeneration in the *Drosophila* eyes which serve as a model. For example, overexpression of the *Drosophila* homolog of human RPN2 (involved in N-glycosylation) partially corrected eye neurodegeneration caused by over-expression of tau. We will next verify these effects of alterations in global protein glycosylation on AD pathology using human cultured cells over-expressing Aβ or tau as well as AD model mice.

ADPD5-0737

SWEET INHIBITION: TAU-DERIVED GLYCOPEPTIDES AS NOVEL INHIBITORS OF AMYLOID AGGREGATION

M. Frenkel-Pinter[1], A. Belostozky[2], M. Richman[2], A. Abu Mokh[1], E. Gazit[1], S. Rahimipour[2], D. Segal[1]

[1]Dept. Molecular Microbiology & Biotechnology, Tel Aviv University, Tel Aviv, Israel

[2]Department of Chemistry, Bar Ilan University, Ramat Gan, Israel

Harmful amyloid oligomers and fibrils of certain disease-specific proteins are the hallmarks of various neurodegenerative diseases, e.g. Aβ and tau in Alzheimer's disease (AD). Inhibiting the misfolding and aggregation of these proteins is an attractive strategy for developing disease modifying therapeutics for these maladies.

In this study we rationally designed glycopeptides as novel inhibitors of tau aggregation. In this strategy the 'two-component' aggregation inhibitory molecules contain (i) the peptide backbone as an aromatic core that would target and bind the aromatic residues in the amyloidogenic monomer, thus confering target specificity, and (ii) sugar moieties that would provide steric hindrance component thus preventing aggregation of the target protein . Sugars were chosen as steric hindrance motif since sugar moieties on proteins have been shown to promote correct folding, and prevent aggregation, of the glycosylated proteins. Capitalizing on the specificity of peptides to bind target proteins we have synthesized various glycopeptides that target specifically the hexa-peptide core domain of tau (PFH6) and have shown their ability to inhibit its aggregation in vitro.

In the future we shall continue to study the tau-specific inhibitory effect of the novel glycopeptides and will assess their ability to disassemble per-formed PHF6 amyloid fibrils. In addition, we plan to feed the various inhibitory glycopeptides to available transgenic flies over expressing human tau, which serve as an established model of AD, and examine their ability to reduce tau aggregation in the treated flies and to ameliorate their AD-related symptoms.

ADPD5-0748

REGULATION OF TAU LOCALIZATION TO STRESS GRANULES

C.A. Brunello[1], X. Yan[1], N.P. Nykänen[1], H.J. Huttunen[1]
[1]Neuroscience Center, University of Helsinki, Helsinki, Finland

Objectives: Stress granules (SG) are cytoplasmic messenger ribonucleoprotein particles (mRNP) that form when translation initiation needs to be inhibited, which typically occurs during a stress response. SGs contain RNA-binding proteins with self-aggregating properties, such as TIA-1, TTP and TDP-43. Recent evidence indicates that SGs colocalize with neuropathological Tau inclusions in Alzheimer's disease, and that TIA-1 and TTP bind to phosphorylated Tau. The objective of this study was to characterize the basic mechanisms underlying recruitment of Tau to SGs.
Methods: We have used protein-fragment complementation assay (PCA)-based Tau(0N4R) reporter dimers to follow subcellular localization of Tau derived from intracellular or extracellular sources in HEK293T cells. Arsenite was used as a positive control for induction of SG formation. SGs were revealed by TIA-1 immunostaining.
Results: In Tau overexpressing cells, Tau remains mostly cytosolic but it is strongly recruited to TIA-1-positive SGs upon arsenite treatment. The pseudohyperphosphorylated form of Tau (TauE14) displays partial TIA-1 colocalization also without arsenite treatment. Cells that do not express Tau but are exposed to Tau reporter dimer-containing conditioned media show intracellular Tau inclusions that colocalize with TIA-1, with and without arsenite treatment. Expression of TIA-1 shRNA in acceptor cells decreases the amount of Tau/TIA-1-positive SGs.
Conclusions: Cytosolic Tau can be recruited to stress granules upon stress or hyperphosphorylation. Internalized extracellular Tau dimers appear to escape from endocytic vesicles, followed by recruitment to the SGs. SGs may provide a novel therapeutic target in tauopathies.

ADPD5-0814

ASSESSING THE EFFECT OF A BRAIN-DERIVED TAU FRAGMENT ON MICROTUBULE BINDING AND TAU LOCALISATION IN CELLS

T. Guo[1], *D.P. Hanger*[1], *W. Noble*[1]
[1]*Department of Basic and Clinical Neuroscience,*
Institute of Psychiatry Psychology and Neuroscience, London, United Kingdom

Objectives

We have previously described a C-terminal tau fragment present in human tauopathy brain. Here we investigated the effects of this tau fragment (termed tau35) on microtubule binding and tau distribution in cells.

Method

Chinese hamster ovary (CHO) cells were transiently and stably transfected with plasmids expressing full-length (2N4R) human tau, tau35, or co-expressing full-length tau and tau35. Microtubule binding assays were used in these cells to compare the microtubule-binding ability of tau35 with that of full-length tau. The degree of microtubule bundling was also assessed using immunocytochemistry. Subcellular fractionation was used to isolate fractions containing either membrane-bound or cytosolic tau from the transfected cells.

Result

In stably transfected CHO cells, ~25% of 2N4R tau binds to microtubules, which reduces to ~15% when Tau40 and tau35 are expressed together. These results indicate a degree of competition by tau35, despite its reduced ability to bind to microtubules. Expression of full-length tau induces moderate bundling of microtubules in CHO cells. This bundling is strongly enhanced when tau35 is co-expressed with 2N4R tau, resulting in the formation of thick microtubule bundles under the plasma membrane and a smaller, more rounded, CHO cell morphology. Subcellular fractionation revealed that both 2N4R tau and tau35 associate with membranes in a similar proportion and this is unaffected by co-expression.

Conclusion

Our results suggest that the N-terminal half of tau is involved in tau-microtubule interactions. Tau35 associates with membranes similarly to 2N4R tau, although the distribution pattern of these two forms of tau may be altered.

IDENTIFICATION AND FUNCTIONAL ANALYSIS OF MISSING MOLECULES LINKING ABETA TO TAU

H. Isshiki[1], P. Nilsson[1], J. Takano[1], K. Sato[1], S. Hashimoto[1], S. Muramatsu[2], T. Saito[1], T.C. Saido[1]

[1]Laboratory for Proteolytic Neuroscience, RIKEN Brain Science Institute, Wako-shi, Japan

[2]Division of Neurology Department of Medicine, Jichi Medical University, Shimotsuke-shi, Japan

It has not yet been clarified what are the molecular mechanisms and the causal relationship between Aβ aggregation, i.e. senile plaques, and the neurofibrillary tangles containing tau protein, both of which are pathological characteristics found in Alzheimer's disease (AD) brains. To identify the molecule(s) and the molecular mechanism(s) linking Aβ to tau, focusing on how Aβ induces tau aggregation, we have performed OMICS analysis of a newly generated AD model mouse, APP knock-in mouse (Saito *et al.*, *Nat. Neurosci.*, 2014). This is a mouse model free of APP overexpression and the induced pathologies are therefore associated with increased Aβ levels. In parallel, we performed a tau interactome analysis. This analysis was based on transgenic expression of tagged-tau in mice, which enabled the pull down of proteins interacting with tau *in vivo*. Several upregulated and downregulated proteins were identified by the two approaches. After *in vitro* validation of the targets, we have carried out an *in vivo* analysis of these proteins using adeno-associated virus system to overexpress the proteins in the mouse brains. In an alternative approach, transgenic mice of selected proteins were generated. Using these two systems, we have found one protein that is phosphorylated in an Aβ dependent manner, and which affects the phosphorylation status of tau. In addition, this protein is co-localized with phosphorylated tau in AD brains. We are currently analyzing the molecular mechanisms of this protein and how it induces tau phosphorylation and aggregation.

ADPD5-1054

DEVELOPMENT AND CHARACTERIZATION OF A GENE TRANSFER-BASED RAT MODEL OF TAUOPATHY

M. d'Orange[1], A.P. Bemelmans[1], G. Auregan[1], C. Joséphine[1], M.C. Gaillard[1], M. Colin[2], L. Buée[2], E. Brouillet[1], P. Hantraye[1], K. Cambon[1]

[1]URA2210 CEA/CNRS, Molecular Research Center (MIRCen) CEA-FAR, Fontenay aux Roses, France

[2]Inserm U837, Université Lille-Nord de France, Lille, France

With a prevalence of 40 million cases worldwide, Alzheimer's disease (AD) has become a major public health issue. Although the disease has been well characterized from an anatomo-pathological point of view, its causes remain elusive and an effective disease-modifying therapy is still awaited. The recent failure of several clinical trials suggests that orienting patients towards treatments at a prodromal stage would probably be more efficient. In this context, *in vivo* positon emission tomography (PET) imaging of neurofibrillary tangles (NFTs) would be of great use. Our aim is to generate a fast-developing model of tauopathy in the rat brain, independently of the beta-amyloid component of AD. This will help establish the biological substrate of current Tau-specific positron emission tomography (PET) probes and validate new ones. To that purpose, adeno-associated viral vectors (AAV) encoding the human Tau protein were injected in the hippocampus of adult rats. Overexpression of either the wild-type or the mutant protein induced Tau hyperphosphorylation and its abnormal misfolding, characteristics of early stages of tauopathy. In addition, NFT-like lesions were observed, as early as 2 months post-injection, both in animals expressing P301L mutant species and rats co-expressing a pro-aggregating peptide along with WT Tau. Further histochemical characterization of the model is ongoing and will be presented. This model, the first in rats to show fast aggregation of the wild-type form of Tau, will be useful to decipher the affinity of Tau tracers for different species of Tau fibrils.

ADPD5-1157

UBIQUITINATION-DEPENDENT AND -INDEPENDENT TAU CLEARANCE VIA P62/SQSTM1

S.A. Park[1], J. Im[1], Y.J. Kim[1]
[1]Neurology, Soonchunhyang University College of Medicine, Bucheon, Korea

Objectives: For the clearance of tau proteins both the ubiquitin-proteasome system and autophagy are involved. Polyubiquitination of tau proteins would be an early and essential step for these processes. There is ubiquitin binding domains (UBA) within p62/SQSTM1 through which p62/SQSTM1 binds to tau proteins thereby transferring these into clearance machinery. To understand the exact underlying molecular mechanisms we performed this study.
Methods: Various mutant constructs of p62/SQSTM1 including p62ΔUBA, were established. Under the condition of ubiquitin overexpression the efficacy of wild type p62 and p62ΔUBA on tau clearance were evaluated.
Results: P62/SQSTM1 was demonstrated to enhance the clearance of tau proteins in neuronal cells, both total and phosphorylated form. The deletion of UBA within p62/SQSTM1 markedly diminished its efficacy on tau clearance, but not completely. Under the condition of ubiquitin overexpression, to some extent, the overall increased ubiquitination was linked to enhanced clearance of tau proteins. The remaining clearance of tau proteins even after deletion of ΔUBA constructs were thought to be mediated through ubiquitination-independent pathway. The direct physical interaction between tau proteins and p62ΔUBA were identified to be underlying mechanism.
Conclusions: We identified P62/SQSTM1 mediates the clearance of tau proteins. Both ubiquitination-dependent and –independent system are considered cooperatively mediating tau clearance.

The hyperphosphorylation of tau protein is associated with the development of the neuronal pathology of Alzheimer's disease. Capillary electrophoresis (CE) has never been used to study tau phosphorylation.
This work aims to develop and optimize simple and reliable CE-based assays to evaluate tau phosphorylation by the human kinase, glycogen synthase kinase 3-β (GSK3β).
For this purpose, a novel pre-capillary CE assay was first developed. In-capillary CE-based enzymatic assay was also used since this approach is known to be time- and cost- effective. The enzymatic reaction was monitored by detecting and quantifying the product adenosine 5'- diphosphate (ADP). The influence of two classes of glycosaminoglycan (GAG), namely heparin and heparan sulfate, on reaction kinetics was also evaluated. Enzyme (GSK3β), substrates (tau and ATP) and GAG concentrations were optimized.
Results obtained by both CE approaches were comparable and were in excellent agreement with those reported in the literature using conventional radiometric and immunoblotting methods. In fact, CE results confirmed the inductory effect of the sulfated sugars heparin and heparan sulfate on tau hyperphosphorylation probably due to exposition of new sites phosphorylatable by GSK3β.
This study shows simple (no-labeling), rapid (less than 30 minutes *per* assay), economical (few tens of nanoliters) and eco-friendly (no-radioactivity) CE-based kinase assays allowing the comprehension of the abnormal phosphorylation of tau. It can be extended to the screening of different modulators of tau phosphorylation to highlight their function and to develop effective drugs for neurodegenerative disease treatments.

There is increasing evidence for prion-like transmissibility of disease-causing amyloidogenic proteins like Tau. With age formation of Tau inclusions has been shown to develop in a stereotypical manner in particular brain regions from where they appear to spread. Injection of brain extracts from transgenic mice with Tau pathology into the brain of human Tau transgenic mice induced the formation of Tau filaments and showed spreading of pathology from the sites of injection to neighboring brain regions. The transfer of aggregated intracellular Tau was also observed between co-cultured cells.

Objectives: The aim of this study was to build a platform of complementary cellular assays to study Tau aggregation and transmission screen for genes, pathways, or small molecules that interfere with transfer, build-up, or break-down of Tau aggregates. The assays are also used to study the role of Tau phosphorylation and the different Tau isoforms on the aggregation dynamics.

Methods: Cellular Tau aggregation assays were built based on imaging, AlpaLISA, BRET, and enzyme complementation both in HEK cells and in primary neurons. The cells were used to do genome-wide siRNA and shRNA screens and a compounds screen with around 500,000 compounds. The assays were also made with different Tau isoforms and mutations.

Results and conclusions: Several chemical series were identified that interfered with the Tau aggregation phenotype in the different cellular assays. Different genes were identified that play a role in Tau aggregation in the cellular context. Some of these genes have been implicated with AD before and will be explored further.

ADPD5-1858

ACTIVITY STIMULATES TAU SPREAD IN VIVO.

W. Jessica[1], J. Wu[1], A. Hussaini[1], A. Mrejeru[1], K. Duff[1]

[1]Taub Institute, Columbia University Medical Center, New York City, USA

Tau protein can transfer inter-neuronally and trans-synaptically between neurons in cell cultures and in mouse models, which is thought to explain the anatomical distribution and progressive spread of pathology observed in human Alzheimer's Disease. Moreover, hyperactivity has been suggested to drive disease progression in Alzheimer's disease. Here, we examined the hypothesis that increase neuronal activity drives taupoathie. Specifically, we used optogenetics to stimulate specific neural circuitry in vivo, recorded neuronal activity longitudinally, and demonstrated that increase neuronal activity can lead to exacerbated distribution of tau that is consistent with enhanced release and uptake of tau. Taken together, these data may explain the observation of focal tauopathy associated with epileptic seizures and there may be negative implications for stimulation therapies such as deep brain stimulation (DBS), or transcranial magnetic stimulation (TMS) that are currently in clinical trials in AD patients.

ADPD5-1859

MICRORNA-132/212 DELETION RECAPITULATES THE PATHOLOGICAL FEATURES OF TAUOPATHIES IN MICE

S. Hebert[1], P. Smith[1], F. Jolivette[1], E. Planel[1], M.E. Tremblay[1]
[1]Neurosciences, Université Laval, Quebec City, Canada

Tauopathies are a class of neurodegenerative disorders characterized by the abnormal inclusions of Tau protein. Despite intensive research, the underlying mechanisms involved in tau metabolism dysregulation in vivo remain unclear. Recently, we and others have shown that the microRNA-132/212 cluster is strongly downregulated in tauopathy brains (e.g., Alzheimer's disease, progressive supranuclear palsy and frontotemporal dementia). In this study, we evaluated the effects of miR-132/212 deletion on tau expression, splicing, phosphorylation, and aggregation in mice. By Western blot analysis, we observed a significant increase in endogenous tau expression starting from P16 and until adulthood in miR-132/212 knockout (KO) mice. Using reporter assays and cell-based studies, we identified a functional miR-132 binding site within the tau 3' untranslated region, providing a mechanism for the abnormal regulation of tau expression. During development, 3R vs. 4R tau ratios are misregulated in the absence of miR-132/212, likely due to various mechanisms. Starting at 6 months of age, tau becomes hyperphosphorylated at several pathological epitopes (e.g., S422). At the age of 12 months, hyperphosphorylated tau was found in (sarkosyl) insoluble aggregates. Notably, similar results were obtained in miR-132/212 KO mice expressing human Tau P301L. Both biochemical and electronic microscopy analyses showed that miR-132/212 deficiency induced age-dependent changes in autophagy, as seen in tauopathy patients, which could explain in part the observed effects on tau aggregation. Collectively, these results provide strong evidence that loss of miR-132/212 function in the brain could contribute significantly to tau neuropathology in a large subset of neurodegenerative disorders.

ADPD5-1977

SELF-ASSEMBLED CYCLIC D,L-ALPHA-PEPTIDES AS CONFORMATIONAL INHIBITORS OF TAU AGGREGATION

M. Richman[1], *A. Belostozky*[1], *S. Rahimipour*[1]
[1]*Chemistry, Bar Ilan university, Ramat gan, Israel*

Alzheimer's disease is characterized by accumulation of misfolded amyloid-β (Aβ) peptides and hyperphosphorylated tau (ptau) proteins in the brain that are observed as amyloid plaques and neurofibrillary tangles, respectively**(1)**. Recent studies have shown that pathogenic amyloids share common structural features despite being composed of different proteins and amino acids, which may be responsible for their cross-interaction**(2)**. We have recently reported on the discovery of a novel self-assembled cyclic D,L-α-peptides that bind Ab, inhibit its aggregation and reduce its toxicity to rat pheochromocytoma PC12 cells by stabilizing the less-toxic form of the Ab**(3)**. We also demonstrated that the active cyclic peptides are recognized by the polyclonal antibodies that bind prefibrillar assemblies of amyloids, suggesting the immense structural similarity between the self-assembled cyclic D,L-α-peptide and the amyloids.

In this study, we further demonstrate that the active cyclic D,L-α-peptide (**CP-2)** can also bind and inhibit the aggregation of a tau-derived peptide, Ac-VQIVYK-NH_2 (AcPHF6)**(4)** that aggregates through β-sheet interactions to form toxic species similar to those formed by tau protein. Moreover, circular dichroism spectroscopy studies and cell toxicity assays suggested that upon co-incubation, **CP-2** changes the aggregation pathway of AcPHF6 to a "off-pathway" mechanism and protects PC12 cells from AcPHF6-induced toxicity, without exhibiting any toxicity by itself.

We also found that CP-2 is effective in reducing the Ab seeds – induced aggregation and toxicity of AcPHF6. Finally, co-localization studies clearly indicate that AcPHF6 and CP-2 can penetrate cells via similar mechanism through the endosome/lysosome compartment.

ADPD5-2081

NOVEL SANDWICH-ELISA FOR DETECTION OF AGGREGATED TAU PROTEIN

M. Holzer[1], I. Lachmann[2], I. Hilbrich[1], K. Flach[2], S. Karras[1], A. Mohring[1], U. Wagner[2], T. Arendt[1]

[1]Mol Cell Mechanisms of Neurodegeneration, Paul Flechsig Institute of Brain Research, Leipzig, Germany

[2]AJR Roboscreen, Analytik Jena, Leipzig, Germany

Objectives: (a) development of an ELISA measuring concentrations of aggregated tau protein in tissue and cultured cells of different species, (b) characterization of tau oligomer and tau filament stability using the ELISA, (c) application of the ELISA to quantify tau aggregation during aging of tau transgenic P301L mice.

Methods: Monoclonal tau antibodies were generated by immunization with pseudo-phosphorylated tau fragments. Tau antibodies were screened for tau specificity using brain tissue of tau knockout mice. Usefulness of this ELISA is demonstrated by the characterization of the aggregate stability of tau oligomers and tau filaments after treatment with deaggregating reagents. The emergence of aggregated tau species in P301L tau-transgenic mice is quantified during development.

Results: The epitope of detection/capture antibody resides in the C-terminal portion of tau, which is conserved across species. The detection limit of the Sandwich-ELISA using tau oligomers and filaments is 100pg/ml. The detection of tau filaments is strongly compromised by pretreatment with 6M guanidinium and incubation at 134°C. Tau oligomers are more susceptible and can be destroyed by 1% mercaptoethanol. Tau aggregates in P301L mice are present at day of birth and increased 30-fold to postnatal day 240.

Conclusions: (a) the Sandwich-ELISA revealed a good specificity for aggregated tau protein with high sensitivity; (b) its application to tau aggregate stability revealed the different properties of tau oligomers versus tau filaments; (c) the detection of aggregated tau species in the presence of monomeric tau was exemplified in the developing brain of P301L tau transgenic mice.

ADPD5-0948

TARGETING THE LYSOSOME TO REDUCE TAU PATHOLOGY

A. Nolle[1], R. Zwart[1], W. Scheper[1]
[1]Dept. of Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands

Objectives
In Alzheimer's disease, tau hyperphosphorylation leads to accumulation of soluble tau and formation of toxic oligomers, which ultimately results in aggregation. Tau oligomers can be degraded by the autophagy/ lysosomal pathway (ALP), which comprises a multi-step process starting with the formation of autophagosomes, followed by fusion with lysosomes to become autolysosomes and ultimately degradation of autophagic substrates. In the present study we are investigating how modulation of the ALP function can be employed to reduce tau phosphorylation and aggregation.
Methods
Hela cells and cortical neurons were transfected or transduced with tau constructs to study tau pathology. The ALP was modulated by using specific chemical and generic tools targeting the respective step of the pathway. Tau pathology was determined by immunocytochemistry and Western blotting to assess total tau and phospho-tau levels. A bimolecular complementation system was employed to visualize tau oligomerization in living cells and fluorescence was analyzed by confocal microscopy.
Results
In our cell models, we found that phosphorylated and aggregated tau accumulates upon lysosomal inhibition using Bafilomycin indicating that these tau species are degraded by the lysosome. Next, we are investigating the effect of ALP inhibition at different steps on tau phosphorylation and aggregation to determine potential targets for intervention. Currently, we are establishing different ALP activators targeting the autophagy initiation complex (Tat-Beclin) and lysosomal proteases (Cathepsin D and B).
Conclusions
Specific activation of the ALP may be a promising strategy to reduce tau in the pathology.

SIGMA-1 RECEPTOR REGULATES TAU PHOSPHORYLATION AND AXON EXTENSION BY SHAPING P35 TURNOVER VIA MYRISTIC ACID

S.Y. Tsai[1], M. Pokrass[2], T.P. Su[1]
[1]NIDA, National Institute of Health, Baltimore, USA
[2]Cellular Neurosciences, Max-Delbrück Center for Molecular Medicine, Berlin-Buch, Germany

Dysregulation of cyclin-dependent kinase5 (cdk5) through its activator p35 has long been implicated in the pathophysiology of neurodegenerative disease because it causes abnormal hyperphosphorylation of cytoskeletal proteins such as tau and neurofilament, which ultimately lead to the emergence of neurofibrillary tangles. P35 has a short half-life and undergoes rapid proteasomal degradation; however, neurotoxic insults promote p35 conversion to a longer half-life p25 that is no longer anchored to the PM, allowing atypical phosphorylation by cdk5. Studies have revealed that brains of Alzheimer's and Parkinson's patients are deficient in sigma-1 receptor (Sig-1R) expression or exhibit *SIGMAR1* mutations in patients with motor neuron diseases; however, the specific role of the Sig-1R in neurodegeneration is still unclear. Here we examined the role of endoplasmic reticulum (ER) chaperone Sig-1Rs in the regulation of p35. We found that Sig-1R KO neurons exhibit greater basal levels of p35 expression and that this increase is likely due to a decreased degradation rate of p35 but not dysregulated calpain activity. Sig-1R KO neurons also display shorter axonal length and decreased cortical axon density. Furthermore, we show that myristic acid competes with the Sig-1R agonist (+)-pentazocine for Sig-1R binding. Treatment with myristate mitigated the p35 protein level changes, restored axonal elongation and diminished PHF-1 in the Sig-1R KO neurons. Taken together, these findings indicate that Sig-1Rs mediate the myristoylation of p35, thereby regulating the degradation of p35, which, in turn modulates cdk5 activity. This property of the Sig-1R appears important to the structural and functional maintenance of the axon.

[2]Neuroscience Discovery, Eli Lilly and Co., Erl Wood, United Kingdom

Objectives: Increased Tau pathology is a major hallmark in Alzheimer's disease and tauopathies. However, it is unclear how the increase in Tau pathology might relate to the accumulation of CSF Tau, and what other factors may influence CSF Tau. To investigate this, we utilized the forebrain-inducible Tg4510 mice and conducted a longitudinal study to fine map the changes in Tau pathology, brain atrophy and CSF Tau.

Methods: Tg4510 mice at various ages were analyzed for Tau pathology and brain atrophy by ELISA and immunohistochemistry. CSF was collected from the same animals and subjected to ELISA to measure Tau and pT181 Tau.

Results: In the younger mice of 14 to 18 weeks of age, we observed a strong correlation between CSF levels of Tau and brain levels of insoluble Tau, but not total Tau. We also observed a strong correlation between levels of CSF Tau and CSF pT181 Tau. Surprisingly, in mice of older age (19 and 20 weeks), even though their insoluble Tau levels nearly doubled in a weekly basis, their CSF Tau levels reached plateau and did not increase further. Notably, this coincided with brain atrophy, which became significant from 20 weeks of age.

Conclusions: Our data demonstrated biphasic changes in CSF levels of Tau in the Tg4510 mice, where the initial increase in CSF Tau may attribute to increased Tau pathology while the subsequent plateau of CSF Tau in older mice may reflect a reduced Tau release from atrophied neurons.

TYPE 1 DIABETES-LIKE INDUCES TAU DEPENDENT COGNITIVE DEFICITS

D. Baglietto-Vargas[1], C. Cunha[1], J.J. Shi[1], D.M. Yaeger[1], F.M. LaFerla[1]
[1]Neurobiology and Behavior, University of California Irvine, Irvine, USA

Introduction: The etiology of Alzheimer disease (AD) is complex and multi-factorial. Further compounding this problem is the fact that AD patients often suffer from a variety of additional co-morbidities. One of the more prominent co-morbid conditions is diabetes, and epidemiological studies reveal that diabetes patients have a significant risk of developing AD compared to healthy individuals, suggesting a strong association between this medical co-morbidity and AD. However, the underlying molecular mechanisms connecting these two disorders are still not well understood. Here, we seek to determine whether tau is a key molecular factor for insulin-dependent type 1 diabetes (T1D) to impair cognitive and synaptic function.
Methods: To properly address this question, we use a combination of newly developed genetically-modified models with biochemical, histological and behavioral approaches to elucidate the underlying molecular mechanism by which T1D-like disease promote tau pathology and impair cognitive and synaptic function.
Results: Our study shows that T1D-like disease induces cognitive impairment via tau dependent mechanisms, and its dysregulation causes reduction in synaptic proteins levels and cognitive decline. Concomitantly, we demonstrate the novel finding using tau null mice, that reduction of endogenous tau mitigates behavioral and synaptic impairments induced in T1D-like mice.
Conclusions: Therefore, our data reveal that tau is a key molecular factor necessary for T1D-like disease to induce cognitive decline, and represents a potential therapeutic target for diabetes and AD patients.

ABNORMAL PLASMA MEMBRANE BLEBBING AND ACTIN CYTOSKELETON REMODELING ARE PRODUCED BY THE EXPRESSION OF TAU PROTEIN IN GLIAL CELLS

F. Garcia-Sierra[1], F.M. Torres-Cruz[1], F. Rodríguez-Cruz[1], N. Barragan-Andrade[1], J. Avila[2], G. Basurto-Islas[3]

[1]Cell Biology, Centro de Investigacion y de Estudios Avanzados del IPN, Mexico City, Mexico

[2]Centro de Biologia Molecular ¨Severo Ochoa¨, Universidad Autonoma de Madrid, Madrid, Spain

[3]Ciencias Naturales, Universidad Autonoma Metropolitana, Mexico City, Mexico

Abnormal aggregation of tau protein in glial cells has been reported in some tauopathies; however, the pathological meaning of these nonfibrillary aggregates still remains unsolved. In this study we evaluated whether full-length tau protein (Tau441) and its acid aspartic^{421}-truncated variant (Tau421) produce alterations in the normal organization of the cytoskeleton and plasma membrane (PM) when expressed in cultured C6 glioma cells. Glial cells were transiently transfected with plasmids (pcDNA3.1Zeo(-)) containing the sequence for either Tau441 or Tau421. After transfection, morphological changes and alteration in the normal organization of the cytoskeleton and PM were evaluated by multilabeling-immunofluorescence and confocal microscopy. By 48 hours after transfection, abnormal microtubule bundling was observed in most of the cells that either expressed Tau441 or Tau421. Moreover, both variants of tau produced extensive PM blebbing associated with cortical redistribution of the actin cytoskeleton (actin-F). These effects were reverted when tau-expressing cells were incubated with drugs that depolymerize the actin cytoskeleton. In addition, when glial cells showing tau-induced PM blebbing were incubated with inhibitors of the Rho-GTPase-Rho-associated kinase (ROCK) signaling pathway, both the formation of abnormal membrane blebs and the actin-F remodeling were avoided. These results may represent a new mechanism of tau toxicity, in which tau-induced microtubule bundling produces activation of the Rho-GTPase-ROCK pathway mediating the remodeling of cortical actin and MP blebbing. In the disease, this tau-induced blebbing of the PM may occur and contribute to the impairment of glial activity.

ADPD5-0995

CASPASE-2-GENERATED TAU FRAGMENT IMPAIRS MEMORY FUNCTION IN TAUOPATHIES

X. Zhao[1], L. Kotilinek[1], B. Smith[1], K. Ashe[1]
[1]Department of Neurology N. Bud Grossman Center for Memory Research and Care, University of Minnesota, Minneapolis, USA

Objectives
Neurofibrillary tangles are composed of aggregated forms of tau, a microtubule-associated protein. They correlate well with neuron loss and brain dysfunction in Alzheimer's disease and other tauopathies. However, our previous study found that neurofibrillary tangles contribute very little to cognitive dysfunction in rTg4510 mice expressing tau P301L mutant. It was the aim of this study to find tau*, the culprit responsible for memory decline in the absence of neurodegeneration or neurofibrillary tangles.
Methods
Total tau proteins purified from the brains of rTg4510 mice are subjected to mass spectrometry for tau* identification. In vitro tau* is generated by caspase-2 cleavage assay. Miniature excitatory postsynaptic current is recorded to assess synaptic function. Antisense oligonucleotides is administered to suppress caspase-2 expression in the brains of rTg4510 mice. The memory function is measured by Morris water maze. We measured brain tau* levels by western blot assay.
Results
Here, we identified a 35kDa tau cleavage product as tau*. We found that tau* is abundantly present in the brains of rTg4510 mice and its levels correlate well with memory dysfunction. Tau* is generated by caspase-2-mediated cleavage of tau protein at Asp314. It mislocalizes to dendritic spines, where it disrupts synaptic function by impairing glutamate receptor trafficking. After the suppression of endogenous caspase-2 expression in the brains of young rTg4510 mice, tau* levels decreased and memory function recovered.
Conclusions
Thus, these data demonstrate that caspase-2-generated tau* impairs memory function independently of neurodegeneration or neurofibrillary tangles, which suggests that caspase-2 is a target for developing new therapeutics.

[5]Laboratory for Cognition Memory and Aging,
Doshisha University Graduate School of Brain Science, Kyotanabe City, Japan

Tau, a microtubule-associated protein, makes up neurofibrillary tangles (NFTs) in Alzheimer's disease (AD) and related tauopathies. In normal neurons, tau binds and stabilizes axonal microtubules, and confined to axons. In AD, tau is hyperphosphorylated, accumulate in neuronal somata and dendrites, and form NFTs. tau has been extensively studied in the cell biology, but it remains to be clarified why endogenous tau localizes to axonal microtubules. In order to investigate the distribution of tau, we explored the immunohistochemical technique, which can make possible to distinguish between the endogenous and exogenous (human) tau in the brain tissues. First, we examined the distribution of endogenous tau in the hippocampus of wild-type mouse. Tau is exclusively localized to the axonal compartment but barely in dendrites or neuronal cell bodies. Endogenous tau is clustered in presumably presynaptic portions but never found in dendritic spines. Next, we compared the distributions of endogenous and exogenous (human) tau in the brains of tau-transgenic (tau-Tg) mice that developed tau deposition resembling human tauopathy and tau-knock-in (tau-KI) mice that never led to tauopathy. In tau-Tg mice, exogenous tau localizes in dendrites and cell somata in a sharp contrast to endogenous tau. Unexpectedly, exogenous tau in tau-KI mice had the normal distribution. This may suggest that the missorting of exogenous tau is involved in the NFT formation in tau-Tg mice.

HYPOTHERMIA-INDUCED HYPERPHOSPHORYLATION – A CELLULAR MODEL TO STUDY TAU KINASE INHIBITORS

N. Taub[1], C. Schweinzer[1], B. Hutter-Paier[1]
[1]Neuropharmacology, QPS Austria GmbH, Grambach, Austria

Objectives

Tau hyperphosphorylation is a known hallmark of Alzheimer's disease (AD). Hence, developing and screening novel kinase inhibitors are in a focus of current AD research. To find promising drug candidates, inducible cellular models of Tau hyperphosphorylation are useful tools for studying central nervous system drug effects.

Methods

SH-SY5Y cells (SH) or SH cells overexpressing the longest isoform of human Tau 441 carrying two well-characterized mutations (V337M/R406W) were treated with several kinase inhibitors and were either kept under normo- or hypothermic conditions to induce Tau hyperphosphorylation. Afterwards, total Tau and its phosphorylated species pSer262, pSer202, pSer396 and pThr231 were analyzed in cellular lysates.

Results

We are able to show a decrease of temperature triggered hyperphosphorylation of different Tau phosphorylation sites in SH- and SH-Tau cells. Interestingly, these effects were more prominent in SH-Tau than in SH cells, indicating that the presence of mutated human Tau increases the therapeutic window. In contrast to unaltered total Tau and pThr231´Tau, pSer396 and pSer262 Tau levels were significantly enhanced in SH and more pronounced in SH-Tau cells under hypothermic conditions. Kinase inhibitors such as LiCl were able to attenuate the hypothermia-induced hyperphosphorylation, making the model suitable for screenings of novel kinase inhibitors.

Conclusions

Hypothermia induces Tau hyperphosphorylation in SH and SH-Tau cells, an effect that can be inhibited by kinase inhibitors. Since the phosphorylation was more prominent in SH-Tau cells, this *in vitro* model serves as valuable, fast, cost-effective and high-throughput screening tool for studying novel kinase inhibitors.

FUNCTIONAL VALIDATION OF BIN1 AS AN ALZHEIMER`S DISEASE RISK FACTOR

N. Dräger[1], E. Nachman[1], T. Aljand[1], T.R. Jahn[1]
[1]Proteostasis in neurodegenerative disease,
Schaller Research Group at the University of Heidelberg and the German Cancer Resea rch Center (DKFZ), Heidelberg, Germany

Recent genome-wide association studies (GWAS) have revealed numerous Alzheimer`s Disease (AD) susceptibility loci. Many of these candidate genes such as PICALM, Bin1 and CD2AP are implicated in endocytosis and cell membrane-associated processes. However, the functional connections of the risk factors with AD mechanisms are still poorly understood. To validate potential risk factors, we have established a variety of *Drosophila* models, which mimic different aspects of AD pathogenesis, namely the accumulation and aggregation of Amyloid-beta (A-beta) peptides, the endocytosis and cleavage of the Amyloid Precursor Protein (APP) and the hyperphosphorylation and aggregation of tau. These models can be utilized to screen for pathway modulators employing RNAi and phenotypic readouts.

Using this approach we identified Amphiphysin, the *Drosophila* homologue of Bin1, as a specific modulator of tau-induced neurotoxicity. Amphiphysin binds lipid membranes and induces membrane curvature. However, its actual role in the adult brain remains elusive and little is known how Bin1 could contribute to the pathogenesis of AD. Knockdown of Amphiphysin aggravates phenotypes produced by the overexpression of tau in the fly and simultaneously increases tau level. These changes could not be detected in A-beta expressing flies. Interestingly, expression of human tau in both, the fly brain and neuronal cell culture, upregulates endogenous Amphiphysin, indicating that Amphiphysin has a novel role in alleviating aggregate stress or facilitating tau clearance. Currently we investigate the mechanism of how Amphiphysin might influence tau aggregation and degradation. This identification could shed light on novel pathological mechanisms and be a potential therapeutic target.

DOWN-REGULATION OF MAPT MEDIATED VIA RAAV SIRNA IN EXPERIMENTAL MODEL OF TAUOPATHY

M. Fecik[1], P. Filipcik[1], N. Kosikova[1], M. Novak[1]
[1]Institute of Neuroimmunology, Slovak Academy of Sciences, Bratislava, Slovakia

MAPT (Microtubule-Associated Protein Tau) is one of the principal components of neuron cytoskeletal system. It has been shown previously that differential tau isoform expression and phosphorylation regulates the assembly and stabilization of microtubules in fetal and adult neurons and participates on transport of proteinous or vesicular cargos along the microtubule. MAPT deficient animals do not show overt phenotype. However deficiency in tau protein induced in adult neurons could have serious consequences. We have therefore set to prepare siRNA for down-regulation of tau protein in terminally differentiated neurons transduced with rAAV viral vectors. We have designed and experimentally tested several small interfering (si) RNAs targeting different regions MAPT transcripts. The siRNAs were expressed from pSilencer2.1 vector under the control U6 promoter. The silencing efficiency of several *MAPT*-silencing constructs (siRNA1-siRNA7) was validated by transfection into HEK293 cell line, transiently expressing a His-tagged cDNA of *MAPT* gene. The level of tau protein down-regulation has been verified by Western blotting. The siRNA most efficiently inhibiting expression of MAPT was subsequently inserted into rAAV vector and used to produce viral particles to transduce rat primary neurons in culture. We have prepared the experimental tool for investigation of the role of endogenous tau in specific brain regions of adult rat and tool for testing the hypothesis whether or not the reduction of endogenous tau protein level could lead to alleviation of neurofibrillary degeneration seen in animal model of tauopathy.

This work was supported by grants: APVV-0677-12, VEGA 2/0194/14, VEGA 2/0161/13 and grant from Axon Neuroscience.

STRUCTURAL STUDY OF TAU PROTEIN FOCUSED ON ITS C-TERMINAL DOMAIN

O. Cehlar[1], R. Skrabana[1], M. Novak[1]
[1]Structural Immunopharmacology,
Institute of Neuroimmunology Slovak Academy of Sciences, Bratislava, Slovakia

Objectives: Microtubule-associated protein tau plays a key role in the pathogenesis of AD and other tauopathies. As it was shown that C-terminal domain of tau protein inhibits its assembly into insoluble filaments, it is important to gain insights into the structural features of tau C-terminus.

Methods: 30 amino acid long tau peptide derived from tau C-terminus was co-crystallized with the Fab fragment of monoclonal antibody. The diffraction data were collected and the structure was solved by molecular replacement.

Results: The Fab fragment of monoclonal antibody DC39C with epitope in the C-terminal domain of tau protein was crystallized alone and in complex with tau peptide. Both crystallization and co-crystallization trials produced crystals amenable for diffraction data collection and structure solution.

Conclusions: Insights into the atomic structure of physiological and pathological tau conformations, as the structure of C-terminal tau peptide, may help to unravel the unanswered questions of tauopathy pathogenesis.

Supported by: APVV-0677-12

LOSS OF TAU PROGRESSIVELY PRECIPITATES SCIATIC NERVE MORPHOFUNCTIONAL DEFICITS AND MOTOR IMPAIRMENT

I. Sotiropoulos[1], S. Lopes[1], V. Pinto[1], M.R. Guimarães[1], S. Pinheiro[1], N. Sousa[1], H. Leite-Almeida[1]
[1]University of Minho, ICVS Institute Life and Health Sciences School, Braga, Portugal

Objectives: Dementia is the cardinal feature of Alzheimer's disease (AD) but the clinical symptoms of this disorder also include a marked loss of motor function. While Tau abnormal hyperphosphorylation and malfunction are well-established key events in AD neuropathology, there is still an on-going debate on the impact of loss of normal Tau function in neuronal degeneration and subsequent behavioral deficits. Previous studies showed that animals lacking Tau (Tau-KO) exhibit motor deficits with controversial findings about motor-related CNS dopaminergic defect raising uncertainty on the underlying mechanisms. Interestingly, little attention has been devoted to a putative involvement of PNS primary afferents as the primary compartment of motor circuitry.
Methods: This study uses a battery of behavioral tests analyzing motor function in both young (4-6 months) and old (17-22 months) Tau-KO mice combined with a systematic morphofunctional analysis of their sciatic nerve.
Results: Herein, we provide evidence that the age-dependent motor impairment in Tau-KO animals is paralleled by ultrastructural and functional impairments of efferent fibers conveying motor-related information. Specifically, the sciatic nerves of old (17-22-months) Tau-KO mice showed increased degenerating myelinated fibers and diminished conduction properties in comparison to age-matched wild-type littermates and adult (4-6 months) Tau-KO and WTs. In addition, the sciatic nerves of Tau-KO mice exhibit a progressive hypomyelination (assessed by g-ratio) specifically affecting large-diameter, motor-related axons in old animals.
Conclusions: These findings suggest that loss of Tau protein may progressively impact on peripheral motor system adding to our understanding of peripheral neurological deficits in AD and other Tauopathies.

THE PRESENCE OF TAU PATHOLOGY AFFECTS THE ADAPTIVE IMMUNE RESPONSE

B. Ossola[1], C. Cossetti[2], M. Goedert[3], A. Compston[1], R.J.M. Franklin[4], S. Pluchino[1], M.G. Spillantini[1]

[2]Cambridge Institute for Medical Research, Cambridge University, Cambridge, United Kingdom

[3]Neurobiology, Laboratory of Molecular Biology, Cambridge, United Kingdom

[4]Cambridge Stem Cell Institute, Cambridge University, Cambridge, United Kingdom

Objectives:

The adaptive immune system and particularly lymphocytes, in addition to preventing and combating infections, are important in regulating brain functions like learning and memory. Importantly, Alzheimer's disease (AD) is associated with a decline in the effectiveness of lymphocytes. This work investigates the relationship between tau pathology, a pathological hallmark of AD and adaptive immunity.

Methods:

We have used a transgenic mouse that overexpresses human mutated (P301S) tau protein under the control of a neuronal-restricted Thy1.2 promoter. In this transgenic mouse, progressive tau pathology develops in several areas of the nervous system. The function of lymphocytes isolated from these mice and the *in vivo* response of lymphocytes to experimental autoimmune encephalomyelitis (EAE) were studied.

Results:

Naïve P301S mice showed a significant reduction of serum level of cytokines such as IFNgamma, TNFalpha, IL-2, and IL-10, normally associated with lymphocytic functions, compared to naïve wild-type mice. Lymphocytes isolated from naïve P301S mice released significantly less IFNgamma after stimulation with dynabeads and *Concanavalin* A. P301S mice showed a strong resistance to EAE induction with a delayed onset and a reduced magnitude of clinical symptoms. Consistently we found a significant reduction of demyelination, axonal degeneration, and microglia/macrophage activation in the spinal cord of treated P301S mice compared to treated wild-type mice.

Conclusions:

This work shows that the presence of pathological tau in the CNS affects adaptive immunity, which may explain the reduced lymphocytic functions in AD patients that could contribute to the cognitive decline.

[2]Psychiatry and Neurosciences, Université Laval Faculté de médecine, Quebec City, Canada
Alzheimer disease is characterized by the deposition of intracellular aggregates of hyperphosphorylated Tau protein. Tau hyperphosphorylation has been attributed in part to the deregulation of kinases and phosphatases activities. ERK1/2 was reported to be activated in the first stages of AD and was proposed as potential therapeutic target. However, while the phosphorylation of Tau by ERK1/2 has been demonstrated in cell-free system, it remains controversial *in vivo*. Here, we showed that pharmacological inhibition of ERK1/2 in mice and SH-SY5Y cells did not reduce basal levels of phospho-Tau or hypothermia-induced Tau hyperphosphorylation. We also found that activating ERK1/2 by hyperthermia did not correlate with increased Tau phosphorylation. Finally, ERK1/2 was inhibited but Tau phosphorylation was not altered by *Mek1* deletion *in vivo*. In conclusion, these results do not support the involvement of ERK1/2 in Tau phosphorylation under physiological conditions.

ADPD5-2006

POST-TRANSLATIONAL MODIFICATION(S) OF TAU PROTEIN IN APP KNOCK-IN MICE

K. Tsukakoshi[1], J. Takano[1], R. Fujioka[1], E. Hosoki[1], T. Saito[1], A. Takashima[2], T.C. Saido[1]

[1]Laboratory for Proteolytic Neuroscience, RIKEN BSI, Saitama, Japan

[2]Department of Aging Neurobiology, National Center for Geriatrics and Gerontology, Aichi, Japan

Objectives: Single locus amyloid precursor protein knock-in (*App*-KI) mouse models developed in our laboratory show Aβ amyloidosis without overproduction of APP and non-Aβ fragments in an age-dependent manner (Saito *et al.*, Nat Neurosci, 2014). We expect the models to be applicable to identifying neuropathological mechanism(s) for treatment of Alzheimer's disease (AD) because of essentially no artificial phenotypes compared to conventional *APP*-transgenic models. In this study, we aim to elucidate the mechanistic processes that link Aβ amyloidosis and tauopathy using *App*-KI mice.

Methods: We crossbred *App*-KI mice with Wtau-Tg mice (Kimura *et al.*, EMBO J, 2007), which express wild-type human 2N4R tau under the *Camk2a* promoter (termed App×Tau mice). Because the Wtau-Tg mice do not carry FTDP-17-causing mutations, we consider the double mutant mice as more relevant models of AD.

Results: The Wtau-Tg mice have been shown to exhibit hyperphopshorylated tau but not to form neurofibrillary tangles (NFTs). The 24-month-old App×Tau mice did not exhibit NFTs despite robust Aβ pathology. Yet, the aged App×Tau mice showed greater tau hyperphosphorylation than single Wtau-Tg mice.

Conclusions: Possibly, we need more time than 24 months to reconstitute tauopathy in the model mice because it takes approximately a decade for Aβ amyloidosis to induce tauopathy in humans. We are currently investigating other post-translational modifications of tau based on MS analysis and will present the latest results obtained.

HISTONE DEACETYLASE INHIBITORS DECREASE P35 EXPRESSION THROUGH PROTEASOME PATHWAY.

J. Seo[1], *S. Baral*[1]

[1]*Pharmacy, Wonkwang University, Iksan, Korea*

Alzheimer's disease (AD) is a neurodegenerative disorder arising from amyloid beta depositions and neurofibrillary tangles formation within the neurons with ultimate impairment on memory function. Histone deacetylase (HDAC) inhibitors have been reported to restore learning and memory in AD model mouse. Here, we investigated the molecular mechanism through which HDAC inhibitors made the therapeutic effects on taupathy using primary neuronal cells and SH-SY5Y neruoblastoma cells. We observed that the treatment of HDAC inhibitors, such as FK-228, valproic acid, and trichostatin A, decreased p35 expression and subsequent tau phosphorylation in SH-SY5Y cells and mice primary cortical neuronal cells with a dose-dependent manner. However, PCR analysis revealed there was no alteration in p35 mRNA expression under HDAC inhibitors treatment. MG-132 and lactacystin, the proteasome inhibitors, restored the HDAC inhibitor-induced downregulation of p35 expression. Furthermore, HDAC inhibitors increased mRNA and protein expression of SKP1A E3 ubiquitin ligase. Moreover, SKP1A siRNA recovered the HDAC inhibitor-induced downregulation of p35 expression. This study demonstrates that the overexpression of SKP1A by HDAC inhibitors might induce p35 degradation through proteasome activation.

MOLECULAR CHARACTERISATION OF BRIDGING INTEGRATOR 1 (BIN1) INTERACTION WITH TAU

Y. Sottejeau[1], J. Chapuis[1], A. Bretteville[1], F.X. Cantrelle[2], P. Dourlen[1], B. Dermaut[1], A. Amouyel[1], G. Lippens[2], I. Landrieu[2], J.C. Lambert[1]

[1]Santé publique et épidémiologie moléculaire des maladies liées au vieillissement, Institut Pasteur de Lille / Inserm U744, Lille, France

[2]Etude des interactions moléculaires et modifications post-traductionnelles par RMN, Université de Lille 1/UMR8576 CNRS, Villeneuve d'Ascq, France

BIN1 locus is identified as the second genetic determinant for Alzheimer's disease (AD). Bin1 involvement in the mechanism of the pathogenesis is unknown. We previously showed that BIN1 might modulate AD pathology through the Tau pathway.

To understand the functional consequences of the Bin1/Tau interaction, the present study investigates at the molecular level the details of this interaction by using GST-pull down and High resolution Nuclear Magnetic Resonance (NMR) spectroscopy approaches.

GST pull down assay were performed with GST fusion proteins of Tau or Tau domains (2N, PRD and 4R) and Bin1 and Bin1 SH3 domain. Immobilized GST fusion proteins were incubated with cell lysates overexpressing Bin1 iso1 or Tau 2N4R. Pull-downed proteins were analysed by immunodetection.

^{1}H, ^{15}N 2D NMR spectra were acquired at 900MHz on ^{15}N Tau 2N4R or ^{15}N Tau[165-245] fragment mixed with Bin1 SH3 and reversely ^{15}N Bin1 SH3 mixed with Tau and Tau[165-245]. Interaction mapping was performed based on the chemical shift perturbations observed in these 2D spectra due to the interaction.

GST pull down assays show that Bin 1 interacts with the proline rich domain of Tau (PRD, 165- 245), and reversely Tau with the Bin1 SH3 domain. Molecular details of the Bin1 SH3/Tau interaction were obtained by NMR spectroscopy that allow to define the peptide recognize by the Bin1 SH3 within the PRD.

Here, we report that BIN1 SH3 domain interacts with the PRD of Tau and mediates Bin1 interaction with Tau. The study of the regulation of this interaction is underway.

AGE-ASSOCIATED ALTERATIONS IN GLUTAMATERGIC SIGNALING IN TAUP301L MICE

M. Reed[1], H. Hunsberger[1], C. Rudy[1], D. Weitzner[1]
[1]Behavioral Neuroscience, West Virginia University, Morgantown, USA

Objectives. We previously demonstrated that rTg(TauP301L)4510 mice exhibit an increase in glutamate release and a decrease in glutamate uptake in the hippocampus prior, and that these alterations in glutamatergic signaling correlate with cognitive deficits. Because hippocampal hyperexcitability is also observed in cognitively impaired aged humans, we hypothesized that similar durations of P301L tau expression would produce exacerbated glutamate dysregulation and cognitive deficits in “aged” compared to “young” TauP301L mice.

Methods. We compared the effects of 5 months of P301L tau expression when mice were “young” (2-7M: tau expression ON) versus “aged” (15-20M: tau expression ON). To examine glutamate regulation *in vivo*, we used amperometry coupled to ceramic-based microelectrode arrays (MEAs). Hippocampal glutamate regulation was correlated with performance in the hippocampus-dependent Morris water maze and radial arm water maze.

Results. In young TauP301L mice, we observed glutamate dysregulation, which correlated with cognitive deficits, as previously reported by our lab. Despite similar durations of tau expression, in aged TauP301L mice we observed exacerbated cognitive deficits and glutamate dysregulation. We also observed age-related cognitive decline and glutamate dysregulation in aged transgene negative littermate controls.

Conclusions. When put into context of recent findings that presynaptic glutamate release is sufficient to drive tau release into the extracellular space (PMCID: PMC3949564), our findings of increased glutamate release in TauP301L mice suggests glutamate-mediated exocytosis of tau may be one mechanism for the trans-synaptic spread of tau pathology associated with synaptic activity and that hippocampal hyperactivity might be permissive for the development of AD.

CHARACTERIZATION OF TRANS-CELLULAR TAU PROPAGATION USING A DROSOPHILA NEURONAL CELL CULTURE SYSTEM

T. Katsinelos[1], *T.R. Jahn*[1]

[1]*Proteostasis in Neurodegenerative Disease,*
Schaller Research Group at the University of Heidelberg and the DKFZ, Heidelberg, Germany

One major hallmark of Alzheimer's disease (AD) is the hyperphosporylation and subsequent aggregation of the microtubule-associated tau protein. Interestingly, different tau species have recently been detected in the cerebrospinal fluid (CSF) of brains from AD patients and it has been proposed to trans-cellularly propagate, seeding further aggregation of naive tau molecules. Therefore, a major challenge in our understanding of tau abnormalities is to clarify the localization of aggregated tau, the interaction of aggregated with soluble tau within the cell as well as with neighboring cells and the toxic effects associated with this process.

We report the establishment of a *Drosophila* neuronal cell culture system to analyze the aggregation properties of different human tau variants. By expressing these phospho-tau variants, we can correlate the phosphorylation status with aggregation and toxicity, by employing cell culture and *in vivo Drosophila* models. Moreover, we demonstrate the appearance of human tau protein in the culture medium when it is expressed in *Drosophila* neuronal cells, similarly as observed in mammalian cell culture. The extracellular tau is mainly found as free soluble protein and is not vesicle associated. Additionally, tau molecules are detected in neighboring non-transfected cells, implicating a trans-cellular trafficking process. Our current work targets the question of whether tau secretion is dependent on the aggregation state as well as the identification and characterization of factors playing key roles in tau secretion and propagation. These answers will provide new insights in understanding the pathogenesis and the progression of the disease pathology.

INVESTIGATIONS ON THE ROLE OF DIFFERENTIAL AT8-PHOSPHORYLATION IN TAU-CONTAINING EXTRACELLULAR VESICLES ISOLATED FROM BRAINS OF RTG4510 TRANSGENIC MICE

J.C. Polanco[1], J. Lu[1], R. Lim[1], B.J. Scicluna[2], A.F. Hill[2], J. Gotz[1]
[1]Clem-Jones Centre for Ageing Dementia Research (CJCADR), Queensland Brain Institute, Brisbane, Australia
[2]Department of Biochemistry and Molecular Biology, Bio21 Molecular Science and Biotechnology Institute, Melbourne, Australia

BACKGROUND
TAU aggregates induce intracellular misfolding and aggregation of endogenous TAU in recipient cells (Clavaguera, 2009; Frost, 2009, Guo, 2011). In Alzheimer's Disease (AD), TAU aggregates may potentially spread from neuron to neuron via extracellular vesicles (EVs), such as exosomes (30-130nm) or microvesicles (200-1000nm). TAU has been found associated with exosomes isolated from cerebrospinal fluid of AD patients (Saman, 2012). Here we present the properties of TAU-containing EVs isolated from mouse brain tissue.
METHODS
EVs were isolated from the brain extracellular space (Perez-Gonzalez, 2012) of rTg4510 mice expressing P301L TAU (Santacruz, 2005). EVs were analysed using Western blotting, electron microscopy, and the qNano (IZON). Standard methods were used for cell-culture experiments.
RESULTS
To determine a putative role in AD pathogenesis, we isolated exosomes (precipitated at 100,000g) and larger EVs (10,000g). Both types of EVs contain TAU. Surface protein shaving assays revealed that TAU is intravesicular and protected by membranes. Interestingly, TAU was found differentially phosphorylated in exosomes. Exosomes were positive for AT180, AT270, pS262 and pS422, but negative for AT8-phosphorylated TAU. Conversely, larger EVs showed strong positivity for AT8. We will present the downstream effects of the uptake of EVs by hTAU-expressing cells.
CONCLUSIONS
We detected more phosphorylated TAU in larger EVs which might indicate that the size of TAU aggregates is more compatible with larger EVs. We speculate on the possible relevance of AT8 in seeding TAU aggregation and consider it important to investigate whether the pathogenicity of TAU in larger EVs (AT8+) differs from that in exosomes (AT8-).

TIME-DEPENDENT CHANGES IN THE SEEDING PROPERTIES OF TAU FROM TRANSGENIC P301S MICE

C. Kerridge[1], T.K. Murray[1], S. Jackson[1], A. Landi[1], B. Falcon[2], A. Cavallini[1], M. Goedert[2], M.J. O'Neill[1], M. Hutton[1], S. Bose[1]
[1]Neuroscience, Eli Lilly and Company, Surrey, United Kingdom
[2]Laboratory of Molecular Biology, MRC, Cambridge, United Kingdom

Objectives
Neurofibrilliary tangles display a progressive and characteristic distribution pattern in the AD brain consistent with a 'prion-like' spread of pathology. Misfolded tau protein has the ability to act as a nucleating template causing soluble tau to form insoluble aggregates that transmit between neurones. The tau species that initiates propagation is unknown, as is the time of pathological onset when this species is produced and becomes disease-inducing. These studies aimed to identify the time-dependent changes in tau species and characterise the tau that is responsible for the seeding phenomenon in the TgP301S mouse model.

Methods
Tau species were separated from a time-course of young to old TgP301S mouse brain homogenates using sucrose gradients. Different species were identified by non-denaturing gel electrophoresis and Western blot using antibodies for total and post-translationally modified tau. Fractions were evaluated for seeding ability in a cell-based model of tau propagation.

Results
Intracellular tau aggregation was only observed when seeded with fractions containing aggregate-derived, hyperphosphorylated tau. The amount of this pathological tau species increased over time in TgP301S mouse brain, as did its seeding efficiency. Fractions from young TgP301S mice, devoid of aggregated, AT8-positive tau did not seed in the cell-based model.

Conclusions
The present study shows that there is a time-dependent change in the seeding properties of tau in the TgP301S mouse model. The increase in aggregated, hyperphosphorylated tau species results in greater seeding propensity and tau propagation. Interestingly, the small oligomeric tau species in these mice were not seed-competent.

PATTERNS OF INVOLVEMENT OF THE VISUAL SYSTEM OF TAU AND ALPHA-SYNUCLEIN PATHOLOGY: RELEVANCE FOR SPREADING AND IN VIVO DIAGNOSTICS

J. Rahimi[1], I. Milenkovic[1], G. Kovacs[1]
[1]Neuropathology, Institute of Neurology, Vienna, Austria

Objectives: Spreading of misfolded proteins has been suggested for neurodegenerative diseases. The hierarchical distribution of protein deposits in Alzheimer`s (AD) and Parkinson`s disease (PD) supports this concept. However, the anatomical regions involved in these disorders have diverse anatomical connections. **Methods:** We evaluated the optic pathway as an excellent anatomical model, which follows a strict trajectory. We immunostained the optic nerve, lateral geniculate nucleus (LGN), and occipital cortex for AT8 (phosphorylated tau) and alpha-synuclein in AD, tauopathy, and PD cases. **Results:** Immunoreactivity for both proteins along the optic pathway was detected: the optic nerve showed immunopositivity in the majority of cases with tau (57%) or alpha-synuclein (50%) pathology. In addition, a significant number showed aggregates in the LGN (tau: 46%, alpha-synuclein: 93%). We observed a significant correlation between tau pathology in the LGN and occipital cortex and Braak stages in cases with AD-related changes. In tauopathies, which do not involve the occipital cortex, like argyrophilic grain disease or progressive supranuclear palsy, tau pathology was mainly represented by astrocytes restricted to the LGN. In PD cases, LGN alpha-synuclein pathology correlated with involvement of the optic nerve while positivity in the occipital cortex was present in 5 out of 14 cases. **Conclusion:** Our results support the concept of disease-spreading along neural pathways and have implications for the diagnostic evaluation of the visual system in neurodegenerative proteinopathies.

MODULATION OF CELL-TO-CELL PROPAGATION OF TAU DIMERS BY LATE-ONSET ALZHEIMER'S DISEASE RISK GENES

N. Nykänen[1], X. Yan[1], C. Brunello[1], M. Hiltunen[2], H.J. Huttunen[1]
[1]Neuroscience Center, University of Helsinki, Helsinki, Finland
[2]Institute of Clinical Medicine –
Neurology University of Eastern Finland and Department of Neurology Kuopio Universit y Hospital and Institute of Biomedicine University of Eastern Finland,
University of Eastern Finland, Kuopio, Finland

Objectives: Prion-like cell-to-cell propagation of misfolded proteins in common neurodegenerative diseases, such as Alzheimer's disease (AD) and Parkinson's disease, is becoming increasingly evident. Although advances in late-onset AD genetics have identified a large number of new disease-associated genes and pathways, functional characterization of these genetic susceptibility factors is clearly lagging behind. Particularly the connection of GWAS-identified risk genes to AD pathogenesis remains poorly understood. As many of the LOAD risk genes are mechanistically associated with endocytosis and vesicular trafficking, we hypothesized that some LOAD risk genes may have a role in transcellular propagation of Tau oligomers.
Methods: We have developed a novel live-cell reporter system based on protein-fragment complementation assay (PCA), using split humanized *Gaussia princeps* luciferase, to study cellular release and uptake of Tau dimers. The Tau release/uptake PCA assays were combined with an RNAi screen in HEK293T cells to study functional connections between the top 12 LOAD risk genes and cellular release and uptake of Tau dimers.
Results: Surprisingly, *APOE* RNAi showed the strongest effect on cellular uptake of Tau dimers. Knockdown of several genes, including *TREM2*, had a significant effect on cellular release of Tau dimers. Mechanistic studies further suggested that endocytic recycling pathways may play an important role in transcellulur propagation of Tau.
Conclusions: Late-onset AD risk genes may be functionally connected to cellular pathways involved in cell-to-cell propagation of Tau dimers/oligomers, and thus modulate the progression of the pathology.

ADPD5-0930

NEURON-TO-NEURON PROPAGATION OF TAU AGGREGATES

S. Calafate[1], J. De Wit[1], P. Verstreken[1], D. Moechars[2]
[1]Department of Human Genetics, KU Leuven, Leuven, Belgium
[2]Neurosciences Research and Development, Janssen Pharmaceutica, Beerse, Belgium

Tauopathies are a diverse group of neurodegenerative diseases defined by accumulation of misfolded cytosolic aggregates of microtubule associated protein Tau. AD is the most common tauopathy. Recent studies have strongly suggested that neuron-to-neuron propagation of aggregated Tau is involved in disease progression. To understand intraneuronal propagation, the mechanisms behind aggregates movement towards potential sites for transfer, exit and entry at the recipient neuron must be studied. We want to study the potential role of the synaptic connection in neuron-to-neuron propagation of Tau aggregates. Recently it was shown that uptake of recombinant Tau fibrils triggered aggregation of overexpressed Tau in mouse primary neurons. We expanded this model into a microfluidic culture device, which is comprised of three somal compartments connected by a series of microgrooves separating three distinct neuronal populations. Tau aggregates propagation was analyzed between the three distinct compartments. We observed that after triggering Tau aggregation in neurons in a first channel, Tau pathology was propagated into synaptically connected neurons in adjacent channels. This suggests that transsynaptic intraneuronal Tau transmission occurred. Our experimental set-up models the typical Tau pathology spreading patterns observed in AD human brains. Using this tool, we are aiming to further study the role of different synaptic proteins in Tau transsynaptic transmission.

MIMICKING ALZHEIMER'S DISEASE SPREADING VIA AN INTEGRATED MICROFLUIDICS-MEA DEVICE IN VITRO

Y. Ren[1], S. Huang[2], S. Mosser[3], M.O. Heuschkel[4], P.C. Fraering[3], J.J. Chen[2], P. Renaud[1]

[1]STI, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland
[2]Biomedical Engineering, National Cheng Kung University, Tainan, Taiwan
[3]SV, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland
[4]-, Qwane Biosciences SA, Lausanne, Switzerland

1. Objectives

The objectives are to model AD propagation *in vitro* and to provide a both morphological and electrophysiological observation platform to study AD spreading.

2. Methods

Using microtechnology, a Microfluidics-MEA device was designed and fabricated. It is a device combining a compartmentalized PDMS microfluidic system and a micro-electrode array (MEA) recording system. (Fig.1)

After fabrication, the device was sterilized and primary cortical neurons were plated. After 21 DIVs, Tau-hyperphosphorylation was induced via Okadaic acid (OA) to build a healthy-diseased culture model. Immunocytochemistry staining and MEA recording were applied to observe AD spreading

3. Results

The integrated Microfluidics-MEA device was successful in both morphological observation and electrophysiological recording.

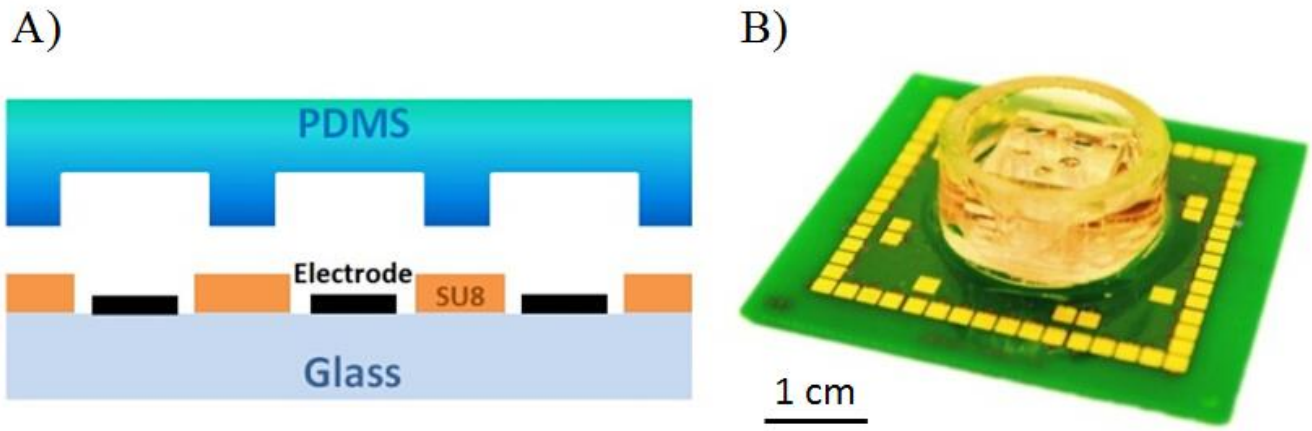

Figure 1: A) Schematic representation of the device's cross-section. B) Microfluidics-MEA device.

Inside the device, the conditions allow the soma and axon to physically connect while growing in spatially separated regions. Healthy (Fig.2, Region 3) and diseased (Fig.2, Region 1) populations were obtained, connected with axons only (Fig.2, Region 2).

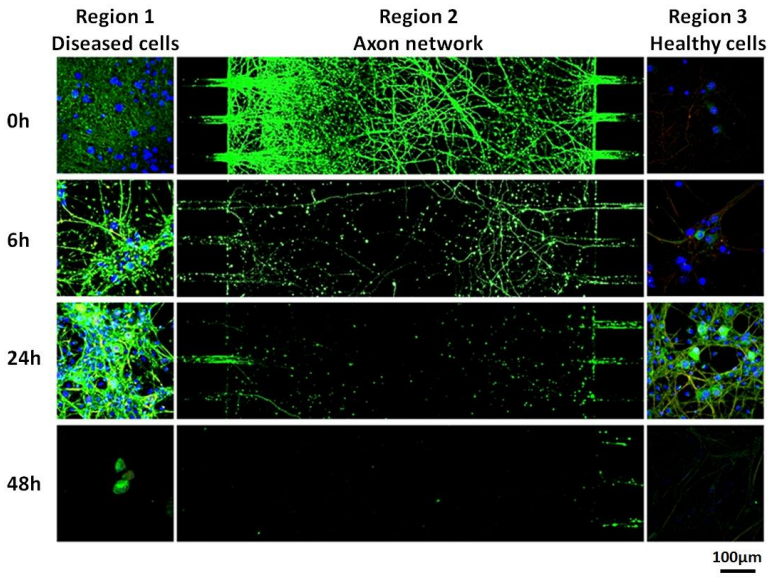

Figure 2. Disease spreading. (after 600 nM OA treatment for 75 min). Staining: hp-tau (pS262, green), nucleus (DAPI , blue)

The electrophysiological signals from the soma and axon were recorded separately and analyzed.

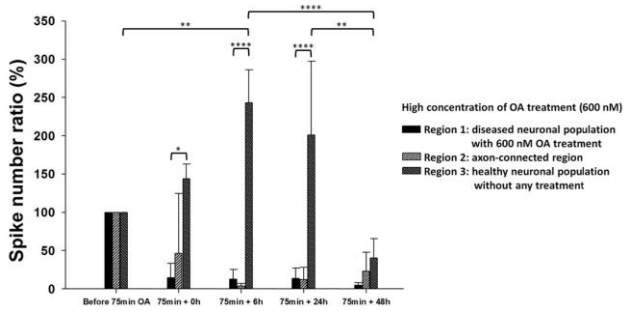

Figure 3. Spike number ratio acquired through recording. (N = 5, * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** $p < 0.005$).

4. Conclusions

We reconstituted the structural and functional patterns of AD propagation by mimicking hp-Tau spreading in our Microfluidics-MEA device. The diseased population was directly affected by OA, causing morphological and electrophysiological effects on the healthy population through axon-only connections.

FEASIBILITY OF PERIPHERAL TAU DETECTION TO DETERMINE BRAAK NEUROFIBRILLARY TANGLE STAGE

B.N. Dugger[1], C.M. Whiteside[2], C.L. Maarouf[2], T.G. Beach[1], T. Dunckley[3], B. Meechoovet[3], A.E. Roher[2]
[1]Neuropathology, Banner Sun Health Research Institute, Phoenix, USA
[2]Molecular Biology, Banner Sun Health Research Institute, Phoenix, USA
[3]Neurogenomics, Translational Genomic Research Institute, Phoenix, USA

Objectives: To determine the presence of tau in human peripheral tissues and its associated with Braak neurofibrillary tangle (NFT) stage.
Methods: Cases were chosen from a previous publication that contained phosphorylated tau deposits through the extent of their spinal cords (N=18; 16 Alzheimer's disease and 2 non-demented cases). From these cases, five peripheral postmortem human tissues samples (sigmoid colon, scalp, abdominal skin, liver, and submandibular gland) were subject to Western blot and ELISA assays for total tau species. Frontal gray matter was used as a frame of reference. In the peripheral area containing the highest total tau levels, a second confirmatory set of tissues having a variety of Braak NFT stages was examined (N=36; 12 Braak 0-II, 14 Braak III-IV, 10 Braak V-VI).
Results: The brain had the highest total tau levels, with 7889±2742ng/mg (average± standard deviation) of total protein, followed by the submandibular gland (120±25.9ng/mg), sigmoid colon (22±9.0ng/mg), abdominal skin (21±16.1ng/mg), scalp (14±5.7ng/mg), and liver (13±4.6ng/mg). Additional submandibular glands, having a variety of Braak NFT stages, showed a significant inverse association between Braak NFT stage and total tau levels (rho= - 0.55, P=0.002).
Conclusions: These results demonstrate that tau is present in measurable quantities within peripheral tissues but not to the levels that are detected within the brain. Of potential importance, there is the strong and significant inverse correlation between submandibular gland tau levels and Braak NFT stage. This study gives a glimpse into the etiopathogenesis of Alzheimer's disease from a peripheral perspective.

03b.Pathophysiology & Disease Mechanisms: prion-like mechanisms

ADPD5-1006

A FRET FLOW CYTOMETRY ASSAY DETECTS PROTEOPATHIC SEEDING

B. Holmes[1], J. Furman[1], M. Diamond[1]

[1]Neurology, University of Texas Southwestern Medical Center, Dallas, USA

Proteopathic seeding may underlie the pathogenesis of tauopathies such as Alzheimer's disease. This seeding activity is characterized by the ability of protein aggregates, or seeds, to template their conformations onto monomeric substrates, thereby amplifying the misfolded state. Via transcellular propagation, proteopathic seeds spread through the nervous system and may drive disease pathogenesis. To date, few methods can detect seeding activity in biospecimens with great specificity, sensitivity, and rapidity and thus the role of tau seeding in disease progression remains untested. We engineered an ultrasensitive, specific, and facile FRET-based flow cytometry biosensor assay based on expression of tau or synuclein fusions to CFP and YFP. These monoclonal biosensor cells specifically detect tau or synuclein seeding activity at femtomolar and picomolar levels, respectively. Due to seeding barriers, these biosensor cells are insensitive to cross seeding by heterologous amyloids and may thus serve as an ideal assay to measure specific proteinopathies from biospecimens. Our seeding assay readily detects tau seeding activity from brain lysates of the P301S tau transgenic mouse, an animal model of human tauopathy. Importantly, this brain-derived seeding activity is specific to tau, since tau immunodepletion abolishes activity. This seeding assay will permit investigations detailing the co-evolution of proteopathic seeding activity and disease progression.

Prion-like seeding and propagation of Tau-pathology have been demonstrated in in vitro and in vivo models and may underlie the stereotyped progression of neurodegenerative Tauopathies. However, the involvement of templated misfolding of Tau in neuronal network dysfunction remains to be explored in detail. We have analyzed the repercussions of prion-like spreading of Tau-pathology via neuronal connections on synaptic and cognitive function in TauP301S transgenic mice.

We have recapitulated prion-like induction of Tau-aggregation by synthetic pre-aggregated Tau fibrils (PFFs) in primary neuronal cultures and organotypic cultures derived from TauP301S mice. We recapitulated prion-like seeding by PFFs in vivo in mice along functional neuronal connections. Injection of PFFs in entorhinal cortex resulted in spreading to different brain regions including hippocampal and isocortical brain regions, reminiscent for spreading of Tau-pathology in Alzheimer's Disease. In contrast, injection of PFFs in substantia nigra induced spreading of Tau-pathology to striatum, thalamus, brain stem, motor cortex and frontal cortex affecting distinct intrinsic functional connectivity networks. We performed calcium imaging analysis and electrophysiological analysis in Tau-seeded primary neurons and organotypic cultures and in acute hippocampal slices from PFF injected mice. This demonstrated aberrant synaptic and neuronal network function induced by templated misfolding of Tau, by synthetic Tau-seeds. Furthermore, templated Tau aggregation impaired cognitive function, reflected in impaired performance in the object recognition test 6 months post-injection.

Hence, our data demonstrate that templated misfolding of Tau by Tau seeds is sufficient to affect unique neuronal networks and contributes to synaptic and cognitive dysfunction in a model recapitulating spreading of Tau pathology.

GENERATION OF A TAU PRION STRAIN LIBRARY REVEALS VAST STRUCTURAL PLASTICITY IN THE TAU AMYLOID FOLD

D.W. Sanders[1], S.K. Kaufman[1], M.I. Diamond[1]
[1]Neurology, Washington University, St. Louis, USA

Neurodegenerative tauopathies are defined by the deposition of tau amyloids (neurofibrillary tangles). Prion-like propagation of aggregation likely contributes to their stereotyped progression along discrete neural networks, which may have important implications for the phenotypic diversity seen in this group of diseases. Previously, we showed that two unique tau conformations (strains 9 and 10) are stably propagated through living systems, maintaining their properties through months of cell division and upon passage through multiple generations of transgenic mice. However, the degree to which tau is capable of forming distinct conformations has been largely unexplored. In the present work, we have created a tau prion strain library using tau aggregates derived from diverse recombinant, transgenic mouse, and patient sources as inoculates. We utilized our previously established monoclonal HEK293 cell line stably expressing a tau repeat domain-YFP fusion protein to produce more than 15 distinct tau prion strains as assessed by inclusion morphology, limited proteolysis, and seeding propensity. In preliminary studies, we find that several of these strains induce distinct pathologies when inoculated into transgenic tau P301S mice. Based on these findings, we conclude that like prion protein, tau is capable of forming structurally diverse amyloid conformations that stably propagate themselves with high fidelity in living systems. Furthermore, the current resource may prove useful for examining many fundamental questions underlying strain biology in both cellular and animal models of tauopathy.

PROTEOPATHIC SEEDING ACTIVITY IS A PROXIMAL MARKER OF TAUOPATHY

J.L. Furman[1], B.B. Holmes[2], T.E. Mahan[2], D.M. Holtzman[2], M.I. Diamond[1]
[1]Neurology, University of Texas- Southwestern, Dallas, USA
[2]Neurology, Washington University, St. Louis, USA

Transcellular propagation of toxic tau aggregates, or seeds, may underlie the stereotypic spread of pathology in Alzheimer's disease and related tauopathies. However, the critical role of tau seeding activity in disease progression remains untested. If proteopathic seeds are a causal agent in AD, we hypothesize that seeding activity is detectable in biological samples, precedes other pathological markers, and correlates with disease progression. To address these questions, we developed an ultra-sensitive and highly-quantitative FRET flow cytometry cell-based assay to measure seeding activity from brain homogenates. The assay detects robust seeding activity from AD brains, but not Huntington's or age-matched-control brains, demonstrating its utility in discriminating tauopathy vs. non-tauopathy human specimens. To address the potential causal role of seeding activity, we used P301S tauopathy mice to carry out a detailed time-course study. Using the same cohort of mice, we compared seeding activity from one hemisphere to several common histological markers of tau from the other hemisphere. All stains reliably identified tau pathology, although the age of onest was variable: Conformationally-abbarrent tau (MC1) was detected at 3 months; hyperphosphorylated tau (AT8 and PG5) was detected at 6 months; beta-sheet-rich amyloids (ThioflavinS) were detected at 9 months. Seeding activity, however, was consistently measured in four different brain regions at just 1.5 months, far preceding onset of other pathological markers. Seeding activity steadily increased with age and correlated well with all histological stains. Thus, the proximal appearance and progressive accumulation of seeding activity is consistent with a causal role of tau seeds in disease progression.

A NOVEL FIXED TISSUE SEEDING ASSAY DEMONSTRATES AGGREGATE CONFORMATION CAN AFFECT THE RATE OF SPREAD OF TAU PATHOLOGY

S.K. Kaufman[1], D.W. Sanders[1], J.L. Furman[2], B.B. Holmes[1], M.I. Diamond[2]
[1]Neuroscience, Washington University, St. Louis, USA
[2]Neurology and Neurotherapeutics, UT Southwestern, Dallas, USA

Tauopathies are a group of diseases characterized by progressive neurodegeneration and the deposition of misfolded tau. We previously showed tau can form unique prion strains that induce distinct histopathology in a mouse tauopathy model. However, it is not known whether misfolded tau shares other important characteristics with prion protein. In this work, we have found misfolded tau derived from fixed tissue is stable and capable of seeding aggregation of naïve tau protein. To test the effect of fixation on the conformation of misfolded tau, we introduced material from fixed brain slices of P301S mice inoculated with our distinct tau strains (C9 or C10) into our original tau cell line (C1). This produced secondary strains with aggregates that have the same conformation as the original inoculum, verifying the stability of tau aggregate conformation after fixation. We next developed a novel technique to quantify the degree of tau pathology in fixed tissue using our FRET-based flow cytometry biosensor assay. This allowed us to quantify the rate of spread of tau pathology after inoculation with C9 or C10 into the hippocampus of P301S mice using isolated brain regions from fixed tissue slices. We found that C9 spread to the contralateral hippocampus more rapidly than C10, suggesting conformation may affect the rate of spread of tau pathology. Furthermore, our fixed tissue biosensor assay showed positivity in the contralateral hippocampus prior to the appearance of overt tau histopathology in that region, suggesting this technique may be more sensitive than traditional histopathology techniques.

Staten Island, USA
[2]*Neurochemistry, The New York Institute For Basic Research, Staten Island, USA*

In Alzheimer's disease (AD) cognitive decline takes place over a period of several years with often a long period of mild cognitive impairment (MCI) before development of dementia probably due to synaptic loss which is interrupted with a transient compensatory increase during MCI. The (3xTg-AD) transgenic mice (hAPPSw, P301L tau, PS1 (M146V) knockin) show amyloid beta plaques and neurofibrillary pathology starting at around the age of 9-12 months. We studied the spatial reference memory of 12 week old 3xTg-AD and control mice using Morris Water Maze task, and neuronal and synaptic markers immunohistochemically in 10, 12, 13, 14, 15 and 16 weeks old animals. The 3xtg-AD mice showed impairment in reference memory accompanied by synaptic loss and reduced levels of b-III tubulin and MAP2 at 12 weeks of age. The cross-sectional analysis of the 6 different age groups showed a compensatory increase in synaptic markers relative to that in WT animals in a topographic and time manner in different regions of the brain. The WT animals were also subject to changes in the expression of the above mentioned markers. However, when studied longitudinally we found that in 3xtg-AD mice the compensatory phenomenon occurred in all the regions of the brain parallelly. These findings for the first time raise the intriguing possibility that AD causing mutated transgenes may initially cause an increase in synaptic markers as a compensatory mechanism for synaptic loss and this increase which though is transient could be the biological basis of long period of MCI.

03c. Pathophysiology & Disease Mechanisms: synapse pathology

ADPD5-0577

CSF LEVELS OF C-TERMINAL FRAGMENTS OF NEUROGRANIN ARE INCREASED AND CORRELATED WITH THE CSF ABETA1-42/ABETA1-40 RATIO IN ALZHEIMER'S DISEASE

A. De Vos[1], D. Jacobs[1], H. Struyfs[2], K. Andersson[3], H. Zetterberg[3], K. Blennow[3], S. Engelborghs[2], E. Vanmechelen[1]

[3]Clinical Neurochemistry Laboratory Institute of Neuroscience and Physiology, The Sahlgrenska Academy at Gothenburg University, Mölndal, Sweden

Objectives Abeta1-42 and protein tau are well-accepted CSF biomarkers to support early diagnosis of AD. However a robust surrogate for synaptic loss, an established correlate of cognitive decline, is not readily available. Previously a small soluble post-synaptic protein, namely neurogranin, has been shown to be such a promising surrogate CSF biomarker. Unexpectedly, deep-proteomic mass-spectrometry approaches demonstrated that neurogranin is also present in plasma/serum.
Methods We report the establishment of an ELISA for the C-terminal part of neurogranin to assess its diagnostic potential in an explorative study in paired CSF/plasma samples of cognitively healthy persons versus patients suffering from MCI due to AD (MCI), dementia due to AD (AD) or MCI/AD with high tau levels.
Results Using the new neurogranin ELISA we confirmed increased CSF levels in MCI and AD, and also observed a correlation with CSF tau. Additionally, we noted a negative relationship between CSF neurogranin (or tau) levels and the CSF Abeta1-42/Abeta1-40 ratio, as if gamma-secretase deficiency seems to correlate with axonal/synaptic loss. On the other hand, no significant differences were detected in plasma neurogranin levels between controls and the AD groups. Also, there was no correlation between CSF and plasma levels of neurogranin.
Conclusions This explorative study clearly warrants further clinical studies to address the additional diagnostic potential for AD of neurogranin in CSF. Furthermore, now a straightforward ELISA could be combined with mass-spectrometry to further advance neurogranin into a harmonized biomarker for synaptic pathology in CSF of AD patients.

03e. Pathophysiology & Disease Mechanisms: proteasome and ubiquitin

ACTIVITY OF UBIQUITIN PROTEASOME SYSTEM IN ETIOPATHOGENESIS OF TAUOPATHY

A. Opattova[1], P. Filipcik[1], M. Cente[1], M. Fecik[1], M. Novak[1]
[1]Institute of Neuroimmunology, Slovak Academy of Sciences, Bratislava, Slovakia

Common feature of neurodegenerative diseases such as Alzheimer`s disease is disturbance in protein turnover followed by intracellular accumulation of aberrant proteins. It can be caused either by impairment in the processes of protein synthesis or by aberrant posttranslational modifications accompanied with deficiency in the protein repair machinery.

In our study we characterized degradation pathways for physiological and pathologically truncated tau proteins and determined the activity of proteasome in context with the intracellular tau protein accumulation and clearance in cellular and animal models of human tauopathy.

In the cellular model we showed that pathologically truncated tau is degraded preferentially by ubiquitin-proteasome complex. Our study revealed that degradation of truncated tau is significantly inhibited (1.5x; $p<0.01$). Interestingly the over-expression of truncated tau leads to significant inhibition of ubiquitin proteasome system activity (~30%; $p < 0.001$). Our results on transgenic rats showed significant inhibition of proteasome activity in brain areas with advanced stage of neurofibrillary pathology (up to 2.15 times; $p<0.01$). Moreover the proteasome impairment negatively correlates with the load of sarkosyl insoluble tau in the afflicted brain areas of the transgenic animals.

In conclusion, our results clearly showed that truncated tau protein expressed in cellular and animal models of tauopathy caused significant impairment of proteasome. Regulation of processes involved in the intracellular protein degradation pathways may therefore represent a promising way for development of disease modifying compounds for treatment of human tauopathies.

Objectives : An increase in oxidative DNA and RNA damage occurs in vulnerable neurons during the early stages of Alzheimer disease (AD). In addition to its well-known role in microtubule stabilization, Tau is an essential nuclear key player in the protection of neuronal genomic DNA and RNA integrity under ROS-producing stress (hyperthermic stress (HS). Our objective is to test the impact of Tau pathological forms on neuronal nucleic acid integrity in vivo.

Methods : THY-Tau22 mice expressing mild, moderate or severe Tau pathology were subjected to HS. Nucleic acid integrity was analyzed in mouse CA1 hippocampal and AD cortical neurons, using a TUNEL assay and immunolabeling for 8-OHdG. Immunolabeling for TOC1 and T22 antibodies was used to identified prefibrillar Tau oligomers. Methylene blue was i.p. injected in THY-Tau22 mice to prevent Tau polymerization.

Results : HS selectively induced DNA and RNA damage in neurons expressing prefibrillar Tau pathology. HS-induced nuclear nucleic acid damage was strictly correlated to the accumulation of prefibrillar Tau oligomers. Methylene Blue prevented HS-induced Tau oligomerization and nucleic acid damage.

Conclusion : We highlighted the existence of an early and limited time window of nucleic acid vulnerability to HS during the evolution of Tau pathology. Importantly, this study emphasizes a toxic role of prefibrillar Tau oligomers in impaired nucleic acid integrity in vivo. Our findings suggest that a loss of the Tau-mediated nucleic acid protective functions participate in the DNA and RNA damage observed in AD.

[5]UCO Pathological Anatomy and Histopathology Unit, Cattinara Hospital, Trieste, Italy

Objects

Disarrangement in functions and quality control of mitochondria at synapses are early events in Alzheimer's Disease (AD) pathobiology. We reported that an AD-linked toxic 20-22 kDa NH_2-tau fragment mapping between 26 and 230 aminoacids of the longest human tau isoform (aka NH_2htau) early affects the Parkin-driven quality control of mitochondria (mitophagy) in post-mitotic neurons in correlation with bioenergetic deficits and *in vitro* synaptic pathology. However, whether the NH_2htau-enhanced autophagic turnover of mitochondria exacerbates neuronal death because of depletion of functional mitochondria or, alternatively, is a compensatory attempt to mitigate neuronal damage, still remains to be clarified.

Methods

Primary neurons; adenovirus-mediated infection; shRNA-mediated gene expression knockdown; Western blotting; immunofluorescence; immunoprecipitation; immunohystochemistry.

Results

We show that the extensive Parkin-dependent turnover of mitochondria occurring in NH_2htau-expressing post-mitotic neurons plays a pro-death role and that UCHL-1, the cytosolic ubiquitin-C-terminal hydrolase L1 which directs physiological remodeling of synapses by controlling ubiquitin homeostasis, critically contributes to mitochondrial and synaptic failure in this *in vitro* AD-model. Pharmacological or genetic suppression of improper mitophagy, either by inhibition of mitochondrial targeting to autophagosomes or by shRNA-mediated silencing of Parkin or UCHL-1 gene expression, restores synaptic and mitochondrial content providing partial but significant protection against the NH_2htau-induced neuronal death. In mitochondria from human AD synapses, the endogenous NH_2htau is stably associated with Parkin and with UCHL-1.

Conclusions

Our studies suggest that the NH_2htau fragment contributes to synaptic failure in AD neurons by aberrant recruitment of Parkin and UCHL-1 to mitochondria making them more prone to detrimental autophagic clearance.

SPECIFIC ANTIBODIES AGAINST TAU PROTEIN

M. Kolarova[1], L. Hromadkova[1], J. Ricny[1], A. Bartos[1], D. Ripova[1]
[1]Laboratory of Biochemistry and Pathophysiology of Brain, Prague Psychiatric Centre, Prague, Czech Republic

Objectives
In past years, large attention was devoted to diagnostic markers as well as therapeutic approaches to neurodegenerative diseases, especially to Alzheimer disease (AD). The n ewest clinical studies are focused on tau protein. They used monoclonal antibodies (Abs) against a specific epitope of tau protein or polyclonal Abs like intravenous immunoglob ulins (IVIg). Some studies found that IVIg products contain Abs against tau protein. Acco rding to this findings, we were interested in the isolation these Abs and their characteriza tion.
Methods
We used a commercial product Flebogamma from Grifols. Specific Abs were purified ag ainst human recombinant tau protein (the longest isoform). Tau protein was covalently b ound to epoxy-
activated agarose resin at 5 mg of protein to 1 ml of resin. Specific Abs were characteriz ed by ELISA, Dot blot and Western blot analysis.
Results
We were able to immunopurify 1,6 mg/ml (0,88%) of specific anti-
tau Abs from 8 ml of 50 mg/ml of Flebogamma IVIg.
Conclusions
We found that in the commercial product Flebogamma
were specific Abs against tau protein. It is interesting that from the plasma of healthy don ors it is possible to isolate specific Abs against one protein that is associated with AD. A ccording to this, we decided to measure levels of Abs against tau protein in different gro ups: patients with Mild Cognitive Impairment, AD and Other Dementias as well as in heal thy elderly controls. This study was supported by GACR P304/12/G069, GACR 13-
26601S, IGA NT 13183 and MH CZ - DRO (PCP, 00023752), UK 266705/SVV/2014.

[2], Institute of Experimental Endocrinology Slovak Academy of Sciences, Bratislava, Slovakia

Epidemiological studies clearly indicate a strong relationship between Alzheimer's disease (AD) dementia and obesity. However, the mechanisms behind the association of fat metabolism and etiopathogenesis of AD are still not understood. Leptin, a major adipokine of white adipose tissue is supposed to play an important role in this mechanism. We have therefore investigated the link between selected metabolic parameters in peripheral blood and pathogenic changes in brain of transgenic rat model of human tauopathy. Brain tissue of transgenic rats expressing human truncated tau protein, whose primary sequence was designed according AD-core tau protein, was analysed in different stages of pathogenesis, preferentially in early pre-symptomatic phase. The data from brain stem and hippocampus of experimental animals were correlated with metabolic parameters in peripheral plasma. We found that pathological forms of human tau protein, if expressed in rat brain, leads to significant reduction of body weight accompanied with significant decrease in level of plasma leptin in asymptomatic animals. The level of plasma leptin inversely and significantly correlated with amount of hippocampal tau proteins hyperphosphorylated on several AD-associated phosphoepitopes. Our data show, that plasma leptin could serve as a convenient peripheral marker of early stage of neurofibrillary degeneration.

PROFILING OF MICRORNA LEVELS IN RAT MODEL OF NEUROFIBRILLARY DEGENERATION

N. Kosikova[1], M. Cente[1], P. Filipcik[1], M. Novak[1]
[1]Institute of Neuroimmunology, Slovak Academy of Sciences, Bratislava, Slovakia

Neurofibrillary tangles composed of post-translationally modified protein tau are major hallmarks of neurodegenerative diseases collectively known as tauopathies. Pathogenesis of these disorders is characterized by gene expression changes resulting to altered signaling pathways. Moreover, deregulation of microRNA levels has been also associated with many neurodegenerative diseases, suggesting possible employment of miRNAs as diagnostic biomarkers. In order to identify differentially expressed microRNA molecules during neurofibrillary degeneration we have performed complex miRNA profiling in rat model of tauopathy that recapitulates major features of neurodegeneration of AD type.

Transcriptomic analysis of brain tissue samples showed significantly increased expression of several particular miRNAs involved in the regulation of neuroinflammation (4,1-fold), innate immune response (2,6-fold), intracellular trafficking (2,4-fold) and signal transduction (2,3-fold). Interestingly, correlation analysis revealed strong positive relationship between dysregulated microRNA molecules.

The data suggest that expression of truncated tau protein leads to deregulation of signaling pathways during the neurodegeneration process manifested by altered miRNA expression. Moreover, identified miRNA markers can be potentially applied for the monitoring of the neurodegenerative cascades in Alzheimer's disease and related tauopathies.

[3]CNRS UMR 8104, Université Paris Descartes Institut Cochin, Paris, France

Objective: Neurofibrillary tangles (NFTs) are the pathological hallmark of neurodegenerative diseases commonly known as Tauopathies. NFTs result from the intracellular aggregation of abnormally and hyperphosphorylated tau proteins. Recently, we demonstrated that activated AMP-activated protein kinase (AMPK) co-localized with phosphorylated Tau in pre-tangle- and tangle-bearing neurons in Tauopathies. In addition, we showed that AMPK was a tau kinase *in vitro*. The goal of this study was to determine whether *in vivo* in the mouse brain AMPK was also involved in Tau phosphorylation.

Methods & Results: In order to determine if AMPK could affect tau phosphorylation and tangle formation *in vivo*, we crossed AMPKalpha2KO mice with the PS19 tau transgenic mice. Tau and phosphorylated Tau levels in Heat stable and insoluble fractions obtained from 8 months old animals were analyzed by ELISA, Western-blot and immunohistochemistry. We did not observed any significant effect of AMPKalpha2 deficiency on total or phosphorylated Tau levels in the heat-stable preparations. However, we observed a significant reduction in insoluble total and phosphorylated Tau in the AMPKalpha2KO mice as compared to controls.

Conclusion: We found that AMPK could regulate tau phosphorylation and tau aggregation *in vivo* in the mouse brain. Our results suggest that strategies aiming at inhibiting AMPK could be of therapeutic values for Tauopathies.

[2]Immunology, Hellenic Pasteur Institute, ATHENS, Greece

Background: Alzheimer's Disease (AD) is the most common form of dementia, with two major neuropathological features, including intracellular neurofibrillary tangles (NFTs) consisting of hyper-phosphorylated tau, and extracellular amyloid plaques. Hyper-phosphorylation of tau decreases its affinity for the microtubules, resulting in accumulation of the protein in the axons and disruption of the normal neuronal function. Cerebral blood hypoperfusion and subsequent elimination of oxygen and glucose supply to the brain are believed to be involved in the development of sporadic AD. Based on these data, we investigated the effects of glucose and oxygen deprivation on tau phosphorylation and depolarization-induced signaling.
Methods: Perfusion of acute brain slices from C57BL/6 mice with artificial cerebrospinal fluid supplemented with various oxygen and glucose concentrations. Total protein extracts were analyzed by SDS-PAGE.
Results: Hypoxia reduced the phosphorylation of tau in all the examined residues. This effect was more potent when oxygen deprivation was combined with low levels of glucose in the perfusion medium. However, glucose deprivation, alone, did not affect phospho-tau levels. Finally, hypoxia, but not hypoglycemia, resulted in complete attenuation of depolarization-induced neuroprotective signaling.
Conclusions: The hypophosphorylation of tau under hypoxic conditions could be attributed to an extensive down-regulation of energy metabolism, as a temporary neuroprotective mechanism against limited oxygen supply. Although these particular stress conditions failed to induce pathological phosphorylation of tau protein, they may exert their neurotoxic effects through impairment of depolarization-induced signaling, which is vital for normal neuronal function and survival.

GENE EXPRESSION ANALYSIS OF SIGNALING PATHWAYS IN A RAT MODEL OF TAUOPATHY

M. Cente[1], P. Filipcik[1], A. Opattova[1], N. Kosikova[1], M. Novak[1]
[1]Institute of Neuroimmunology, Slovak Academy of Sciences, Bratislava, Slovakia

The process of neurofibrillary degeneration in tauopathies is inevitably accompanied by dysregulation of signaling pathways leading to cellular stress and inflammation. In order to identify molecular hallmarks involved in these cascades we have employed the transgenic rat model of tauopathy expressing human truncated tau protein (AlzTau 151-391,4R).

In this study we have analyzed gene expression levels of inflammatory markers together with heat shock proteins in the brains of transgenic animals. We observed significantly increased gene expression of small heat shock protein (2.1-fold), cell adhesion molecule (2.8-fold) and activation of complement system (3.7-fold). Interestingly, the mRNA levels of these markers strongly correlated with the amount of sarkosyl insoluble tau. Immunohistochemical staining revealed localization of protein in individual cell populations what was quantitatively determined by stereological quantification.

The results suggest that misfolded tau protein induces variety of signaling pathways including cellular stress and neuroinflammation that are associated with neurodegeneration process of tauopathies.

ADPD5-2138

EFFECT OF REG-1ALPHA ON NEURONAL CELL DEATH IN CELLULAR AND ZEBRAFISH MODELS OF TAU HYPERPHOSPHORYLATION

M. MOUSSAED[1], S. HUC-BRANDT[1], M. SILHOL[1], F. TROUSSE[1], J.M. VERDIER[1], M. ROSSEL[1], A. MARCILHAC[1]

[1]INSERM U710, University Montpellier 2 - Place E. Bataillon CC 105 34095, Montpellier, France

Objectives: We focus our interest on Reg-1alpha, a secreted glycoprotein, that is (1) differentially regulated during development, ageing and pathological processes, (2) more or less expressed in various organs depending on environmental factors, (3) specifically involved as a paracrine/autocrine factor in proliferation and differentiation of cells. The large majority of studies has been carried out in the digestive system. However, we have recently demonstrated that Reg-1alpha is involved in neurite outgrowth through its receptor EXTL3 and was able to regulate GSK-3beta pathway. Moreover, Reg-1alpha is overexpressed in human Alzheimer-disease brains and is associated with Tau intracellular inclusions. In this context, we investigated Reg-1alpha function and signaling pathway during the pathological processes in original cell culture and zebrafish models of tauopathy.

Methods: To understand the relation between Tau and Reg, we performed (1) overexpression of the human Tau cDNA corresponding to the splice variant 4R0N carrying P301L mutation and (2) pharmacological stimulation with okadaic acid to modulate the phosphorylation state of the system. We analyzed the inductive role of Reg-1alpha (recombinant protein) and the mechanisms involved in the degenerative processes. In addition, using the transgenic zebrafish hTauP301L line, injection of human Reg-1alpha mRNA effect was analyzed in embryos.

Results: Reg-1alpha overexpression in zebrafish hTauP301L resulted in severe defects during development and induced neuronal death. Moreover, we observed, in cellular models, abnormal neuritic morphologies and Reg-1alpha/hyperphosphorylated Tau colocalization. In these conditions, Reg-1alpha modifies the cellular phenotype and accelerates neuronal death in cells expressing tau-hyperphosphorylated by Akt/GSK-3beta pathway regulation and caspase3 activation.

PROPERTIES OF HUMAN OLIGODENDROCYTES GENERATED FROM IPSC LINES OF PATIENTS WITH MAPT MUTATIONS.

S. Agathou[1], M.G. Spillantini[2], R.T. Karadottir[1]
[1]Wellcome Trust-MRC Cambridge Stem Cell Institute, University of Cambridge, Cambridge, United Kingdom
[2]John van Geest Centre for Brain Repair, University of Cambridge, Cambridge, United Kingdom

Objectives Frontotemporal Dementia with Parkinsonism linked to Chromosome 17 (FTDP-17T) comprises 50% of all dementia cases under the age of 60 and involves the aggregation of the microtubule-associated protein tau. Research on tauopathies has mainly focused on the neuronal component overlooking the contribution of glial cells. Glial tangles in oligodendrocytes have been observed in various cases of FTDP-17T, and *in vivo* expression of tau in oligodendrocytes is sufficient to induce neurodegeneration and recapitulate tauopathy. Our aim is to generate oligodendrocytes from human induced pluripotent stem cells (iPSCs) of patients with FTDP-17T MAPT mutations (N279K and P301L) and to evaluate their electrophysiological and biochemical properties along side oligodendrocyte tau expression.
Methods We have optimised currently used protocols to generate human oligodendrocyte-lineage cells from iPSCs of control and FTDP-17T patients. Whole-cell patch clamp recordings were used to examine the effects of the N279K and P301L tau mutations on the membrane properties and ion-channel composition of these cells.
Results We obtained large amounts of human IPSC-derived oligodendrocyte using hypoxic culturing conditions. We managed to equally generate oligodendrocyte precursor cells (OPCs) from FTDP-17T and control iPSCs, both of which matured into myelin-interacting oligodendrocytes with neuronal axons. We are now investigating, tau expression, oligodendrocyte membrane properties, neurotransmitter signalling and the myelinating capacity of these human oligodendrocytes.
Conclusions Glial contribution to FTDP-17T has been underestimated. Relevant information can be obtained from the IPSC-oligodendrocytes that we have generated, thus helping to elucidate the role of glia in diseases with tau pathology.

THE PSP-RELATED TAU MUTATION A152T CAUSES HIPPOCAMPAL EXCITOTOXICITY

L. Krüger[1], J.M. Decker[1], E. Mandelkow[1], E.M. Mandelkow[1]
[1]Neurodegenerative diseases,
(1) German Center for Neurodegenerative Diseases (DZNE) (2) CAESAR Research Cen ter (3) Max-Planck-Institute for Metabolism Research Hamburg Outstation, Bonn, Germany

Objectives:

We investigated the consequences of human full-length Tau with the rare point mutation A152T (hTau40/A152T, related to progressive supranuclear palsy) on hippocampal function.

Methods:

For pathophysiological characterization a combination of aged hTau40/A152T transgenic mice and cultured organotypic hippocampal slices was used.

Results:

Transgenic mice show Tau pathology including hyperphosphorylation, aggregation, neuronal loss and behavior deficits. In cultured slices Tau was found in both presynaptic and somato-dendritic compartments including dendritic spines. Furthermore we observed mossy fiber sprouting, an indicator for increased epileptiform activity. Pronounced epileptiform activity was indeed observed in such slices. In cultures extracellular glutamate started to rise early followed by neurotoxicity. In parallel we detected elevated levels of intracellular calcium in CA3 neurons, characterized by an enhanced calcium influx after membrane depolarization, sensitive to NR2B blockade. Glutamate increase was reduced to control levels by either inhibition of neurotransmitter release or blockade of voltage-gated sodium channels. In line with these changes, we observed enhanced basal synaptic transmission in the mossy-fiber pathway of acute hippocampal slices from aged hTau40/A152T mice with no change in short and long-term plasticity. Excitotoxic cell death in slices was ameliorated by long-term application of low-dose memantine and by administration of ceftriaxone, which stimulates glutamate uptake via glial Excitatory Amino-Acid-Transporter-2.

Conclusions:

hTau40/A152T causes pronounced excitotoxicity mediated by extrasynaptic NMDAR containing NR2B subunits due to an increase of extracellular glutamate, which is caused by enhanced presynaptic transmitter release.

IN VIVO IMAGING OF NEURONAL CIRCUIT'S DYNAMICS IN THE MOUSE TAUOPATHY MODEL

P. Marinkovic[1], S. Blumenstock[1], I.C. Stancu[2], I. Dewachter[2], J. Herms[1]
[1]Translational Brain Research,
German Center for Neurodegenerative Diseases (DZNE) Munich, Munich, Germany
[2]Institute of Neuroscience, Catholic University of Louvain, Brussels, Belgium

OBJECTIVES:

In Alzheimer's brains, neurofibrilary tangles (NFTs) and tau pathology spread in stereotypical manner. Recent studies demonstrated that similar spreading pattern could be reproduced in animal models by injecting tau fibrils in specific brain areas where they serve as seeds for aggregation of endogenous tau. It is not fully clear what are the effects of tau pathology spreading on neuronal activity and functioning. In present study we address this question using two-photon in vivo imaging in tau seeding mouse model.

METHODS

We are able to induce NFTs formation by injecting recombinant tau fibrils in cortex of P301S transgenic mice. To study neuronal activity and neuronal circuit's dynamics we have established an approach which combines two-photon calcium imaging through cranial window with imaging in awake, head-fixed mice. In that way, we follow same neuronal populations over prolonged periods of time. Furthermore, by applying FSB, a dye which labels NFTs, we can directly visualize NFTs formation and spreading *in vivo*.

RESULTS

Our results suggest that formation of NFTs takes place in first two weeks after tau fibrils injection in cortex of P301S mice. NFTs could be detected throughout all cortical layers. Using *in vivo* two-photon calcium imaging we can reliably record activity from layer 2/3 neurons for more than 2 months after seeding.

CONCLUSIONS

In conclusion, our method enables *in vivo* investigation of tau pathology effects on neuronal functioning. Identifying and preventing early tau pathology induced changes in neuronal functioning could be potential therapy strategy for Alzheimer's disease and other tauopathies.

HOW DOES AGEING CONTRIBUTE TO ALZHEIMER'S DISEASE?

M. Sealey[1], *C. Proud*[1], *A. Mudher*[1]
[1]*Centre for Biological Sciences, Institute for Life Sciences, Southampton, United Kingdom*

Ageing is the biggest risk factor for dementia of which Alzheimer's Disease (AD) is the most common form. There are currently no effective treatments that can halt the progression of AD, and despite decades of research the pathogenesis of the disease is poorly understood. AD is characterized by two pathological hallmarks: intracellular tau tangles and extracellular Abeta plaques. It is unclear how cellular changes that occur during ageing predispose us to the formation of these pathologies. Increasingly, the same cellular pathways that are implicated in ageing are also found to be altered in AD. These pathways include, among others, mTOR signaling, insulin signaling and autophagy.

In this study, the impact of these age associated pathways on tau mediated phenotypes and pathologies will be investigated. Components of the different cellular pathways will be assessed for age related changes in *Drosophila* expressing human tau. The tau mediated phenotypes that will be assessed include; longevity, climbing ability, circadian rhythms and memory function. Levels of tau, its phosphorylation state and solubility will be determined biochemically to assess tau pathology.

Preliminary results show that the expression of human tau induces the activation of dTOR (the TOR pathway in *Drosophila*), this effect becomes greater with age. Inhibiting dTOR using rapamycin significantly increases the lifespan of tau expressing flies. Conversely, activation of dTOR by dietary means, exacerbates tau-mediated locomotor deficits and shortens lifespan.

These findings demonstrate that a pathway implicated in ageing can influence tau-mediated phenotypes and pathology.

HYPERPHOSPHORYLATED TAU MAY PLAY A CRUCIAL ROLE IN THE PATHOGENESIS OF WHITE MATTER LESIONS IN ALZHEIMER'S DISEASE

K.E. McAleese[1], M. Firbank[2], M. Dey[1], S. McParland[1], M. Johnson[1], J.T. O'Brien[3], J. Attems[1]

[1]Neurodegenerative diseases and stroke, Institute of Neuroscience, Newcastle upon Tyne, United Kingdom

[2]Neuroimaging, Institute of Neuroscience, Newcastle upon Tyne, United Kingdom

[3]Psychiatry, Institute of Neuroscience, Cambridge, United Kingdom

Background: Cerebral small vessel disease (SVD) is associated with the pathogenesis of white matter lesions (WML), however, WML have been observed in the absence of SVD in white matter adjacent to cortical areas exhibiting Alzheimer's disease (AD) pathology. We investigated the influence of AD pathology (hyperphosphorylated tau (HPT) and amyloid-beta (Abeta) plaques) and SVD on white matter integrity.

Method: We evaluated 40 *post mortem* human brains (15 normal aged controls; mean age 84.4±9.1 years; 9F:6M: 25 AD; 84.4±5.4 years; 15F:10M). All cases underwent *post mortem* T2* MRI assessment of white matter hyperintensity (WMH) according to the ARWMC scale and quantitative assessment (% binary area fraction of immunopositivity) of HPT (AT8) and Abeta (4G8) pathology and vessel wall fibrosis using Sclerotic Index (SI).

Results: ARWMC scores were significantly higher in AD compared to control cases ($P<0.05$), however, no significance difference was found in SI. For the overall cohort significant correlation was seen between ARWMC scores with AT8 and 4G8 immunopositivity in all major cortical regions ($P<0.05$). Regression analysis revealed AT8 immunopositivity was a significant predictor of ARWMC score in all major cortical regions ($P<0.01$) and overall hemisphere ($P<0.05$). SI was also shown to be a significant predictor of ARWMC for the overall hemisphere ($P<0.05$).

Conclusion: HPT pathology was found to be associated with WMH independent of concomitant SVD indicating a potential independent and/or combined pathogenic role of cortical neurodegenerative pathologies and SVD in the development of WML.

TAU ANTIBODY PROFILING IN A CELLULAR SEEDING ASSAY

M. Borgers[1], S. Versweyveld[1], B. Russo[1], M. Mercken[1], A. Ebneth[1], J. Kemp[1]
[1]Neuroscience, Janssen Research & Development, Beerse, Belgium

Objectives: A cellular seeding model was used to investigate the relation between activity, epitope, binding properties and phospho-dependency of anti-tau antibodies in preventing aggregation.
Methods: Cell homogenates of a HEK cell line stably expressing 2N4R-TauP30L-GFP aggregates were used to induce aggregation in a cellular seeding model expressing K18/P301L. Induced aggregation was detected by Bioluminescent Resonance Energy Transfer (BRET) ratio. For testing activity of anti-tau antibodies, cell homogenate and antibody were co-incubated with the cells.
Results: Co-incubation of anti-tau antibodies and cell homogenates resulted in a decreased BRET ratio for several antibodies. The antibodies with the highest activity were mostly total tau antibodies and only a small percentage were phospho-specific antibodies. The total tau antibodies with the highest activity mainly have an epitope located in the N-terminal part of tau indicating this could be a more exposed part of tau when part of an aggregate. Binding properties of the antibodies indicate as well that affinity/avidity is not the only driving force for activity.
Conclusions: A high affinity antibody does not guarantee that the antibody prevents aggregation based on the results obtained with this cellular seeding model. Other players are epitope and phospho-dependency of the antigen.

ADPD5-0315

PREPARATION AND TESTING OF INHIBITORS OF THE FORMATION OF A NOVEL, NEUROTOXIC TAU FRAGMENT

M.A. Walters[1], M. Le Naour[1], K. Nelson[1], J. Strasser[1], M. Cuellar[1], X. Zhao[2], K.H. Ashe[2]
[1]Medicinal Chemistry, University of Minnesota, Minneapolis, USA
[2]Neuroscience, University of Minnesota, Minneapolis, USA

Objectives: Tauopathies are a group of incurable neurodegenerative conditions, characterized by the presence in the brain of neurofibrillary tangles composed of aggregated tau protein. Currently, *there are no disease-modifying treatments for tauopathies.* The development of such therapies requires an understanding of the molecular pathways that lead to synaptic dysfunction and neurodegeneration in tauopathies.

Methods: Our collaborators (Zhao and Ashe) recently obtained evidence that a cysteine protease cleaves tau to form a fragment believed to be tau* (35-kDa **t**au **c**leavage **p**roduct, henceforth TCP35). This fragment has been shown to mislocalize to dendritic spines in neurons and potentially disrupt synaptic function. Based on their reported cleavage site of tau, we have prepared a series of peptide aldehyde inhibitors with the goal of developing a structure-activity relationship (SAR) that will guide the further design of potent and selective inhibitors of this cysteine protease.

Results: Our initial results show that a reversible covalent pentapeptide based on the site of cleavage is a <500 nM and highly selective inhibitor of the protease target. Further SAR findings will be presented.

Conclusions: The identification of the cysteine protease responsible for the formation of a newly characterized neurotoxic tau fragment has paved the way for the development of new therapeutics for the treatment of tauopathies. We expect that preparation of potent inhibitors of the formation of TCP35 may be possible based on the cleavage sequence that has been identified.

ADPD5-0379

THE AMYLOID-BINDING AGENT BTA-EG4 REDUCES PHOSPHORYLATED TAU LOAD AND LEVELS OF SYNAPTIC AMYLOID PRECURSOR PROTEIN IN MODELS OF ALZHEIMER'S DISEASE

C. Croft[1], P. Mastrandreas[1], D. Hanger[1], W. Noble[1]
[1]Department of Basic and Clinical Neuroscience,
Institute of Psychiatry Psychology and Neuroscience King's College London, London, United Kingdom

Objectives: The tetra (ethylene glycol) derivative of benzothiazole aniline, BTA-EG_4 acts as an amyloid-binding agent to reduce levels of beta-amyloid (A-beta), increase dendritic spine density and ameliorate cognitive decline in mouse models of Alzheimer's disease (AD). The effect of BTA-EG_4 on abnormal processing of tau has not yet been explored. Here, we sought to determine the impact of BTA-EG_4 treatment on disease-associated modifications in tau including its abnormal phosphorylation and localisation. Changes in amounts of pre- and post-synaptic proteins were also assessed, since tau is closely linked with synaptic degeneration in AD.
Methods: Primary cortical neurons and organotypic brain slice cultures from 3xTg-AD mice were treated with BTA-EG_4. Levels of tau and phosphorylated tau at several AD-relevant epitopes were quantified by western blotting. Crude synaptosomes were prepared from treated samples and levels of synaptic markers, tau and amyloid precursor protein (APP) were assessed by western blotting.
Results: Treatment with BTA-EG_4 was found to significantly reduce levels of total tau and tau phosphorylated at epitopes of relevance to AD. In addition, BTA-EG_4 treatment reduces levels of APP, but not tau, in synaptosomal preparations. The mechanism linking these changes in APP and tau is currently under investigation.
Conclusions: BTA-EG_4 freely permeates the blood brain barrier to bind A-beta and reduce A-beta-associated toxicity. We show here that BTA-EG_4 also reduces levels of total and phosphorylated tau, together with reducing APP load at synapses. These findings suggest that further preclinical exploration of BTA-EG_4 in models of AD is warranted.

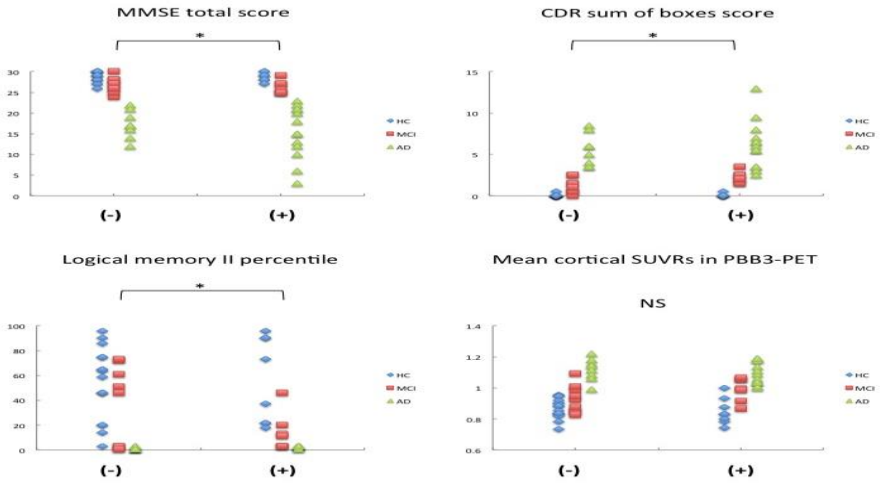
DOES HYPERTENSION CONTRIBUTE TO TAU LOAD IN ALZHEIMER'S DISEASE? CROSS-SECTIONAL POSITRON EMISSION TOMOGRAPHY STUDY USING [11C]PBB3

F. Niwa[1], H. Shimada[1], H. Endo[1], S. Kitamura[1], H. Shinotoh[1], M. Higuchi[1], T. Suhara[1]
[1]Molecular Imaging Center, National Institute of Radiological Sciences, Chiba, Japan

Objectives: Hypertension is known to be a risk factor for dementia, including Alzheimer's disease (AD). However, its pathological role in AD is unclear. This study aimed to investigate the influence of hypertension on the brain using tau deposition detectable by a novel positron emission tomography (PET) ligand, [11C]PBB3.
Methods: Brain magnetic resonance imaging scans, PET scans with the [11C]PBB3, and neuropsychological tests, such as the Mini Mental State Examination (MMSE), were performed on 61 subjects, including those with AD and mild cognitive impairments (MCI) and healthy controls (HCs). Subjects diagnosed with other types of dementia, such as vascular dementia, and those aged <50 years were excluded. In [11C]PBB3-PET imaging, standardized uptake value ratios (SUVRs) were determined as measures of radioligand retention using the cerebellar cortex as reference. Subjects were divided into hypertension-positive (HP) and negative (HN) groups based on clinical history, and comparisons were performed.
Results: The HP group included 13 subjects with AD, 7 with MCI, and 8 HCs, while the HN group included 8 subjects with AD, 9 with MCI, and 16 HCs. The MMSE scores in the HP group were significantly lower than those in the HN group. No significant difference was observed in the mean cortical SUVRs between the groups, not only in subjects with AD, but also in those with MCI and in healthy controls.
Conclusion: Although hypertension may be associated with cognitive decline, hypertension did not contribute to tau load in [11C]PBB3-PET. Further hypotheses involving other pathological mechanisms would be required.

Figure.



Comparisons between the hypertension-positive (+) and negative (–) groups among healthy controls (HC), subjects with mild cognitive impairment (MCI), and subjects with Alzheimer's disease (AD). MMSE, Mini Mental State Examination; CDR, Clinical Dementia Rating; SUVRs, Standardized uptake value ratios; *, $p < 0.05$ (Total group comparison using t-test); NS, Not statistically significant in the comparison.

MOLECULAR AND FUNCTIONAL ANALYSIS OF AD-DERIVED PAIRED-HELICAL FILAMENTS

K. Van Kolen[1], A.F. Marreiro[1], K. Plasman[2], D. Van Dam[3], M. Mahieu[1], E. Peeraer[1], G. Daneels[1], M. Vandermeeren[1], P.P. De Deyn[3], S. Engelborghs[3], K. Gevaert[2], L. Ver Donck[4], D.W. Moechars[4], J. Kemp[4], M. Mercken[4]
[1]Neuroscience, Janssen Research & Development, Beerse, Belgium
[2]VIB Department of Medical Protein Research, UGent, Gent, Belgium
[3]Biomedical Sciences, University of Antwerp, Antwerp, Belgium
[4]Neurosciences, Janssen Research & Development, Beerse, Belgium

Objectives: Although several studies demonstrate that Tau aggregates spread via transsynaptic transport, little is known about the molecular signature of the seed. The aim of this study is to characterize the biophysical and molecular profile of PHFs derived from *postmortem* AD brain and evaluate their seeding properties *in vivo*.
Methods: PHFs are enriched from p*ost mortem* AD brain tissue and analysed by Western blotting and ELISA. Immunopurified extracts are analysed by SDS PAGE and mass spectrometry to determine protein components and post-translational modifications. On the other hand, enriched PHFs are used for stereotactic injections of P301L mice.
Results: IP/MS analysis of Tau from *postmortem* AD brain confirmed phosphorylation of a number of epitopes including Ser202/Ser205 and Thr231. Besides Tau, a number of interacting proteins including heat-shock proteins, kinases, phosphatases and cytoskeleton proteins were identified. When PHFs are injected in the cortex, Tau pathology (confirmed by native PAGE, Western Blot and IHC) is observed from one to three months after injection in injected and non-injected hemispheres.
Conclusions: This study further characterized the molecular properties of PHFs from AD brain. Further analysis is required to identify other post-translational modifications including ubiquitination and acetylation. Injection experiments in Tau transgenic mice show that purified PHFs can trigger Tau aggregation *in vivo*. Further injection studies with fractionated AD brain samples are needed to get more insight in the molecular properties of this type of seed.

[4]Neuropathology, Doshisha University, Kyotanabe, Japan

[5]Alzheimer's Disease Project Team, National Center for Geriatrics Gerontology, Obu, Japan

[6]Graduate School of Brain Science, Doshisha University, Kyotanabe, Japan

[Objective] Neurofibrillary tangles (NFT) are a pathological hallmark of Alzheimer's disease (AD); neuronal and synapse loss are key events during the process of NFT formation. With a view of developing a new therapy for AD, we screened an array of small molecules for their potential to inhibit the aggregation of toxic tau in an animal model of tauopathy, focusing on the mechanism of inhibitory action

[Methods] Tau-binding molecules were identified in a first screening of a natural compound derivatives library. Screened tau-binding compound was then tested by several tau aggregation assays, and confirmed a reducing granular tau oligomer level.

[Results] Epinephrine and pyrocatecholviolet that share 1,2-dihydroxybenzene in their structures, bound to tau and inhibited the toxic tau aggregation; compounds lacking 1,2-dihydroxybenzene did not show the latter capacity, indicating the requirement of 1,2-dihydroxybenzene for the inhibition of toxic tau aggregation. Binding assays revealed that 1,2-dihydroxybenzene bound to Cys residues in tau. Furthermore, tau modified by 1,2-dihydroxybenzene was not polymerized by heparin. They suggest that Cys residues contribute to tau aggregation. To confirm that 1,2-dihydroxybenzene-containing compounds penetrate the brain, we administered isoprenaline to P301L-tau transgenic mice. The treatment significantly decreased levels of Sarkosyl-insoluble tau, and neuronal loss.

[Conclusions]

1,2-dihydroxybenzene binds and caps the Cys residues in tau. Capped tau cannot interact with other tau molecules, thus inhibiting toxic tau aggregation. Administration of brain permeable 1,2-dihydroxybenzene inhibits Sarkosyl-insoluble tau and neuronal loss, and thus has the potential to alleviating brain dysfunction. These results suggest Cys as an important therapeutic target for AD.

ADPD5-1147

EFFECTS OF METHYLENE BLUE AND ANOTHER OXIDANT ON HUMAN TAU TRANSGENIC FLY MODELS

S. Sheik Mohideen[1], Y. Yamasaki[2], L. Tsuda[3], Y. Yoshiike[1]
[1]Alzheimers Disease Project Team Center for Development of Advanced Medicine for Dementia, National Center for Geriatrics Gerontology, Obu, Japan
[2]Department of Drug Discovery Center for Development of Advanced Medicine for Dementia, National Center for Geriatrics Gerontology, Obu, Japan
[3]Animal Models of Aging Center for Development of Advanced Medicine for Dementia, National Center for Geriatrics Gerontology, Obu, Japan

Objective: Neurofibrillary tangles formed by aggregated tau are well correlated with the extent of cognitive decline in Alzheimer patients. Methylene blue (MB) is known to inhibit tau aggregation *in vitro*. However, the mode of action *in vivo* is still unknown. Using the fly models that express human wild type tau (hTau), we investigated the effects of MB and another oxidant that has similar oxidizing property on the tau accumulation and behavioral deficits caused by hTau expression. Methods: hTau flies were treated with 1 mM compound for 1 month. In prior to biochemical analysis of tau accumulation, their behavioral activity was analyzed. Results: We found that MB effectively reduced the tau accumulation and ameliorated the climbing deficits of hTau flies. However, it didn`t rescue the climbing ability completely and induced climbing deficits in wild type flies. Oxidizing property of MB is implicated in the dose-response effects of MB. To find a safer compound, we selected a compound that works similarly to MB but at the same time that is less toxic. Treatment with this compound reduced the tau accumulation and ameliorated the climbing deficits to the smaller extent than MB. Unlike MB, this compound didn`t affect the climbing ability of the wild type flies. Conclusion: These results suggest that the common oxidizing property play roles in the mode of action for suppressing tau accumulation *in vivo.* Compounds that have the similar oxidizing property, as MB and that are also nontoxic may become good therapeutic candidates for tauopathies including AD.

04c. Therapeutic Targets & Mechanisms for Treatment: tau

ADPD5-1386

PRO-AGGREGANT FULL-LENGTH TAU-DELTA-K280 CAUSES A TORPOR-LIKE PHENOTYPE IN HIPPOCAMPAL SLICE CULTURES: TREATMENT WITH TAU AGGREGATION INHIBITORS AND ADENOSINE A1-RECEPTOR ANTAGONISTS

F.J.A. Dennissen[1], *E.M. Mandelkow*[1]
[1]*Neurodegenerative Diseases,*
(1) German Center for Neurodegenerative Diseases (DZNE) (2) CAESAR research cent er (3) Max Planck Institute for Metabolism Research Hamburg Outstation, Bonn, Germany

Objectives:
To investigate the mechanism of toxicity of pro-aggregant Tau and possible modes of treatment.

Methods:
Organotypic hippocampal slice cultures (OHSCs) from full-length pro- and anti-aggregant Tau (Delta-K280 or Delta-K280-PP) transgenic mice and littermate controls were prepared from P8 pups and cultured for 30 days *in vitro*. Treatment was applied for the entire *ex vivo* period. The OHSCs were analyzed using immunostaining, live cell imaging, qPCR and electrophysiology.

Results:
Both pro-and anti-aggregant Tau transgenic OHSCs show Tau missorting and phosphorylation (12E8, PHF-1, AT8, etc.). Local accumulations ('grains') of Tau in a pathological conformation (MC-1) are found in the neuropil of pro-aggregant Tau transgenic OHSCs only. The ATP level and (axonal) mitochondrial density was reduced in these OHSCs. Pro-aggregant Tau did not colocalize with 'classical' protein aggregation markers like P62, HSP70, vimentin or Tia-1. Instead, a qPCR based miniscreen pointed towards an impaired activity of neurons and astrocytes. Using a paired-pulse protocol (electrophysiology) we found impairment of the presynapse which could be counterbalanced by Tau aggregation inhibitors (BSC3094) or by preventing the downregulation of cellular activity using an adenosine A1-receptor antagonist (Rolofylline).

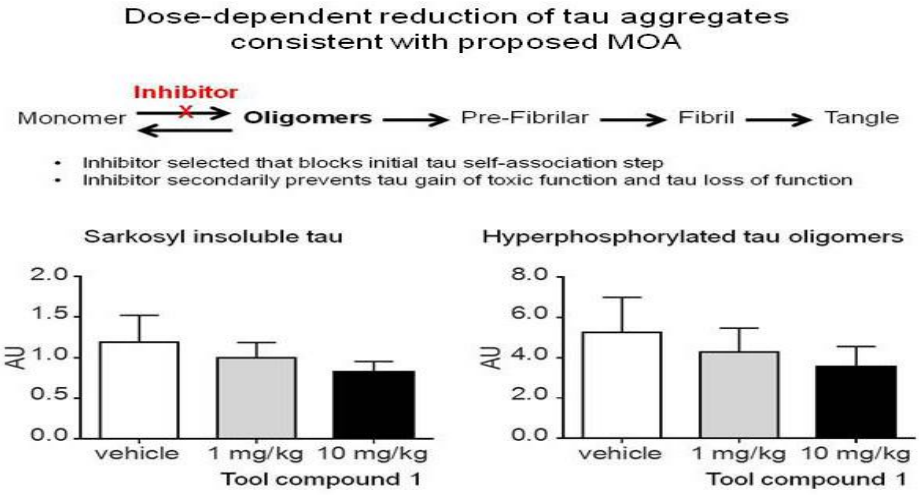
Conclusions:
In OHSCs, pro- and anti-aggregant Tau become missorted into somata and dendrites whereas pathological (MC-1 positive) Tau accumulates locally in pro-aggregant slices as grains. These grains do not colocalize with known aggregation markers. Instead, full length pro-aggregant tau but not its anti-aggregant tau counterpart causes a downmodulation of cellular activity and metabolism. This can be impaired by preventing aggregation or adenosine signaling via the adenosine A1-receptor.

04c. Therapeutic Targets & Mechanisms for Treatment: tau

ADPD5-1437
IN VIVO CHARACTERISATION OF A TOOL COMPOUND TARGETING TAU OLIGOMERS

P.K. Krishnamurthy[1], D. Romero[1], P. Lopez[1], G. Papiani[1], A. Yehaskel[1], E.J. Davidowitz[1], J.G. Moe[1]
[1]R & D, Oligomerix Inc., New York City, USA

Objective: Tau oligomers are toxic to neurons, inhibit long term potentiation in hippocampal slices, impair the formation of associative fear memory in mice, and transmit tau pathology. Recent advances in research at Oligomerix and in the AD field strongly support targeting tau oligomers for drug discovery for the development of both symptom-modifying and disease-modifying therapeutics. Proof-of-concept studies in a mouse model of tauopathy were initiated with a tool compound inhibitor of tau oligomer formation to demonstrate target engagement in vivo and to validate the screening approach.
Methods: A highly diverse library of 100,000 drug-like small molecules was screened using AlphaLISA for detection of tau self-association, hits were validated and dose response and neurocytotoxicity assays were performed. Medicinal chemistry and secondary assays were used to select tool compounds for in vivo validation studies. Acute toxicity of selected tool compounds was assessed in wild type mice, and the JNPL3 mouse model (Taconic) was used to test compound efficacy for reduction of tau aggregates.
Results: Preliminary testing with Tool Compound 1 in wild type mice showed that it was non-lethal at the high, medium and low doses tested. Biochemical analysis of the brains of 5 month old JNPL3 mice treated with Tool Compound 1 for 8 weeks showed a dose dependent reduction in sarkosyl insoluble tau levels and also phospho tau levels.
Conclusions: These results are consistent with demonstration of target engagement in vivo. Based on the results of this initial study, a larger study has been initiated with 16 weeks of treatment.



04c. Therapeutic Targets & Mechanisms for Treatment: tau

ADPD5-1510

EPITOPE CHARACTERIZATION OF THE ANTI-TAU ANTIBODY AT8 THROUGH A PHOSPHOPEPTIDE CO-STRUCTURE AND PEPTIDE BINDING STUDIES

T.J. Malia[1], A. Teplyakov[1], J. Luo[1], R. Ernst[1], S.J. Wu[1], M. Vandermeeren[2], R.W. Sweet[1], M. Mercken[2], G.L. Gilliland[1]
[1]Biologics Research, Janssen R&D, Spring House, USA
[2]Neuroscience Discovery, Janssen R&D, Beerse, Belgium

Alzheimer's disease (AD) pathology is characterized by the development of hyperphosphorylated neurofibrillary tangles, which are comprised of extensively phosphorylated filamentous tau protein, or paired-helical filament tau (PHF-tau). AT8 is a PHF-tau specific monoclonal antibody that is a commonly used marker of neuropathology because of its recognition of abnormally phosphorylated tau. Previous reports described the AT8 epitope to include pS202/pT205. Our studies support and extend previous epitope findings by also identifying pS208 as part of the binding epitope. We characterized the phosphoepitope of AT8 through both peptide binding studies and with a co-structure with a phosphopeptide. A co-structure of AT8 Fab with a pS202/pT205 peptide shows that the interaction interface involves all six CDRs and tau residues 201-209. Both phosphorylation sites are recognized by AT8, with pT205 acting as the anchor. The structure further shows that phosphorylation at S208 can be accommodated by AT8. Crystallization of the Fab/peptide complex under acidic conditions shows that CDR-L2 is prone to unfolding and precludes peptide binding, and may suggest a general instability in the antibody. Phosphopeptide binding studies were performed using ELISA and surface plasmon resonance and it was found that AT8 bound to the triply phosphorylated tau peptide (pS202/pT205/pS208) 30-fold stronger than to the pS202/pT205 peptide, supporting the role of pS208 in AT8 recognition. The epitope characterization and binding analysis of AT8 further enhance the knowledge of this important diagnostic antibody and provide insight into the sequence of tau phosphorylation in the progression of AD and other tauopathies.

26S PROTEASOME DYSFUNCTION AND COGNITIVE IMPAIRMENT DUE TO ABNORMAL TAU ACCUMULATION IS ATTENUATED BY RAISING CAMP

N. Myeku[1], C. Clelland[1], S. Emrani[1], N. Kukushkin[2], W. Yu[1], A. Goldberg[2], K. Duff[1]
[1]Pathology/Taub Institute, Columbia University Medical Center, New York City, USA
[2]Cell Biology, Harvard Medical School, Boston, USA

Tau inclusions are a feature of tauopathies, implying a deficit in the cell's ability to clear tau either as a cause or consequence of the disease. Therefore, therapeutic activation of proteolytic pathways can be an effective treatment for tauopathies

Objective

The goal is to first investigate the status of proteasome clearance in tauopathy and to identify what type of tau species cause proteasome dysfunction. Secondly, to apply a therapeutic strategy by activating cAMP/PKA pathway to rescue proteasome activity *in vivo*.

Methods

The effects of tau accumulation on proteasome were studied in a model of tauopathy (rTg4510) and in a cross to a UPS reporter mouse (rTg4510/UbG76V-GFP). The function of affinity purified proteasomes was assessed by different assays. Immunohistochemistry analyses were performed to examine the proteolysis of UbG76V-GFP in tauopathy. To test whether activation of PKA/cAMP pathway by rolipram could prevent overt tauopathy development, we administered 0.03mg/kg rolipram for 21 days to mice at an early stage tauopathy.

Results

Accumulation of insoluble tau correlated with progressive decrease in the peptidase activity of 26S proteasomes, while levels of ubiquitinated proteins and undegraded UbG76V-GFP increased. Affinity purified proteasomes were less active in hydrolyzing ubiquitinated proteins. Loss of proteasome activity was prevented by administering rolipram, which activates cAMP/PKA and proteasome subunit phosphorylation. Enhancing proteasome function led to reduced levels of aggregated tau and improved cognitive performance in early stage tauopathy.

Conclusion

Proteasome function and proteolysis by the UPS decrease with worsening tauopathy, and stimulating proteasome activity through cAMP/PKA is a promising therapy for tauopathy.

[2]Department of Biotechnology, Indian Institute of Technology Madras, India

Introduction: Alzheimer's disease (AD) is a neurodegenerative disease characterized by the appearance of tau-associated neurofibrillary tangles. We found a novel function of protopine (PRO), a brain permeable isoquinoline alkaloid, isolated from the Chinese medicinal herb Rhiozma Corydalis (Yanhusuo in Chinese), reduces tau aggregates by inhibiting HDAC6 and by inducing proteasomal mediated degradation in certain neuronal cells.

Methods: Primary cortical neurons, N2a and SHSY5Y–Tau-P301L cells were treated with PRO in the presence or absence of autophagy and proteasome inhibitors. Cell lysates were investigated for Tau-5, PHF-1, acetylated (Ac)-α-tubulin, Ac-histone 3 and Hsp70. Three-month old male JNPL3 mice received PRO (10mg/kg/day) or saline by intraperitoneal injection until 6 months. Rotarod was performed to assess the motor function of mice. The docking studies of PRO with HDAC6 was performed using Autodock program.

Results: We found that PRO induces acetylation of α-tubilin without influencing the levels of Ac-histone 3 in cells. From docking study, the binding affinity of PRO with HDAC6 was calculated to be -7.65kcal/mol with a Ki value of 2.5μM. PRO reduces the accumulation of tau and ubiquintinylated conjugates, and simultaneously increases the level of Hsp70 in SHSY5Y-P301L. PRO enhances tau degradation via proteasomal degradation, but not via autophagy. In JNPL3 mice, PRO treatment did not significantly influence animal body weight. Three months of PRO treatment significantly attenuated motor dysfunction of JNPL3 mice. Immunohistochemical and immunblot analyses of various tau proteins in mice brains are underway.

Conclusion: Based on our results, PRO deserves further exploration as a promising therapeutic agent for AD.

RESCUE OF IMPAIRED LONG TERM DEPRESSION IN THY-TAU22 TRANSGENIC MICE

T. Ahmed[1], D. Blum[2], S. Burnouf[2], D. Demeyer[2], V. Buée-Scherrer[2], R. D'Hooge[1], L. Buee[3], D. Balschun[1]
[1]Lab Biological Psychology, KU Leuven, Leuven, Belgium
[2]Université Lille-Nord de France UDSL F-59000, Inserm UMR837 Jean-Pierre Aubert Research Centre F-59000 Lille France, Lille, France
[3]Université Lille-Nord de France UDSL, Inserm UMR837 Jean-Pierre Aubert Research Centre F-59000, Lille, France

Objectives: Cognitive decline, a hallmark of Alzheimer's disease (AD), and accompanying neuropsychiatric symptoms share dysfunctions of synaptic processes as a common cellular pathomechanism. Long-term potentiation (LTP) has been found to be a sensitive indicator for such synaptic dysfunctions. However, much less is known about how other forms of synaptic plasticity are affected by AD progression.
Methods: We used long-term field recordings of long-term depression (LTD) in the CA1-region *in vitro* and tested the effects of inhibitors of glycogen synthase kinase-3 beta (GSK3β) and of sodium selenate.
GSK3ß phosphorylation sites were analyzed by Western blotting.
Results: We found that an impairment of long-term depression (LTD), an alternative cellular mechanism for memory storage, can be reversed in THY-Tau22 mice by either inhibition of glycogen synthase kinase-3 (GSK3β) activity or application of the protein-phosphatase 2A (PP2A) agonist selenate. In agreement with these results we observed increased phosphorylation of GSK3β at Y216 and reduced total phosphatase activity in biochemical assays of hippocampal tissue of THY-Tau22 mice. Notably, L-LTD induction and pharmacological inhibition of GSK3ß appeared to downregulate GSK3ß-activity via a marked upregulation of phosphorylation at the inhibitory Ser9 residue.
Conclusions: Our results point to alterations in phosphorylation/ dephosphorylation homeostasis as key mechanisms underlying the deficits in LTD and hippocampus-dependent learning found in THY-Tau22 mice.

PATHOLOGY AND HIGH-THROUGHTPUT PHENOTYPING OF THE INDUCIBLE TG4510 TRANSGENIC MODEL

D. Brunner[1], H. Hain[1], E. Sabath[1], M. Mazzella[1], R. Avila[2], Z. Kurowska[2], J. Beltran[1], V. Alexandrov[1], M. Windisch[1], A. Ghavami[1]
[1]PsychoGenics, New York, USA
[2], Renovo Neural Inc, Cleveland, USA

Objective: The rTg4510 mice, overexpressing human tau with the P301L mutation under control of a tetracycline responsive transacting element, exhibit many salient characteristics of fronto-temporal dementia and Alzheimer's disease in an age-dependent manner including cognitive impairment, motor deficits, tau hyperphosphorylation, neurofibrillary tangles, and neuronal loss in the forebrain.
Methods: PhenoCube® NeuroCube® and SmartCube® are high-throughput platforms that assess circadian, cognitive, motor behavior, anxiety, gait, and other domains using PGI's proprietary Computer Vision automated scoring system and machine learning algorithms to define phenotypic signatures. Other standard test followed published protocols. Immunohistochemistry with fluorescence or with DAB labeling was used to detect epitopes of interest in hippocampus and cortex.
Results: Using our proprietary behavioral testing platforms we have confirmed the phenotype described by other labs including hyperactivity and cognitive deficits. We also found deficits in a procedural learning and reversal T-maze, in addition to a pronounced nocturnal hyperactivity. The deficits in the Tg4510 are-age dependent unlike those of the tTa control, which are significant at the earlier ages. We present an assessment of pro-inflammatory transcripts expression, synaptophysin and phosphorylated Tau levels in the transgenic mice.
Conclusion: The tg4510 mouse represents a highly reproducible model of tauopathies that allows sensitive testing of drug effects on brain pathology and behavior. The option to switch off tau expression by doxycycline is a most suitable calibration for assessment of effects of new treatments.

ADPD5-1910
MIRROR IMAGE PHAGE DISPLAY FOR SELECTION OF TAU-BINDING D-ENANTIOMERIC PEPTIDES FOR THERAPEUTIC APPLICATIONS IN NEURODEGENERATIVE DISEASES

S. Funke[1], C. Dammers[2], D. Yolcu[2], L. Kukuk[2], S. Rudolph[2], D. Willbold[2]
[1]Bioanalytik Fakultät Angewandte Naturwissenschaften, Hochschule Coburg, Coburg, Germany
[2]Institute of Complex Systems (ICS-6), Forschungszentrum Jülich, Jülich, Germany

Objectives: A variety of neurodegenerative disorders, including Alzheimer's disease, are associated with neurofibrillary tangles composed of the tau protein. Inhibitors of pathological tau fibril formation could be useful for the development of therapeutics, provided that the inhibitors were specific enough to avoid interference with physiological processes.
Methods: We have developed biotechnological strategies to identify specific peptides out of large phage displayed peptide libraries by specialized selection procedures. In order to avoid disadvantages of natural peptides (e.g. protease sensitivity, immunogenicity), we have applied mirror image phage display to yield D-enantiomeric peptides that are extremely protease stable and not or less immunogenic than L-peptides.
Results: Employing mirror-image phage display with a large peptide library (> 1 billion different peptides), we have identified tau-fibril binding peptides consisting of D-enantiomeric amino acids. Here, we report on various D-enantiomeric peptides which bind to aggregating tau variants as well as full length tau fibrils and modulate the aggregation thereof.
Conclusions: These peptides might be an interesting starting point for therapy development.

TAU PROTEOLYTIC ACTIVITY: A MECHANISTIC TARGET FOR DRUG DISCOVERY

J. Moe[1], G. Papiani[2], P. Lopez[2], D. Romero[2], E. Davidowitz[2]
[1]R&D, Oligomerix Inc, Valhalla, USA
[2]R&D, Oligomerix Inc, New York, USA

Objectives: The particular structure and mechanisms by which tau oligomers exert their deleterious effects is an important focus of current research. The oligomeric forms of tau appear to be most closely associated with neuronal loss and memory impairment in mouse models of tauopathy and accumulate in AD brain. Importantly, extracellular tau oligomers have been shown to impair memory formation and to inhibit long-term potentiation in hippocampal slices. The general aim of this work is to elucidate and target toxic mechanisms of tau oligomers for drug discovery.
Methods: Recombinant human tau oligomers were purified. Autoproteolytic fragments were sequenced to determine cut sites. Peptides spanning a cut site were used as a substrate for assaying tau protease activity and for screening inhibitors. Protease inhibitors were used to characterize the class of protease. Truncated constructs and mutagenesis were used to localize the active-site region of tau. A cell assay was developed to screen inhibitors of tau protease activity.
Results: Tau acquires proteolytic activity enabling it to cut itself and other proteins upon formation of certain tau oligomer species. Tau oligomers belong to the class of serine proteases and are labeled with a functional probe for serine hydrolases. Antibodies specific for autoproteolytic tau fragments were developed. A point mutation in tau blocks tau cleavage in a cell assay for tau protease.
Conclusions: Tau protease activity may provide a mechanism for some of the toxic characteristics associated with tau oligomers. Peptide and cell based assays for targeting tau protease have been developed for drug discovery.

[2]Department of Anatomy Cell and Developmental Biology, Eotvos University, Budapest, Hungary

1. Objectives: The aggregation of Tau is linked to the onset and pathology of Alzheimer's Disease (AD) and other neurodegenerative diseases. In this study, we over-express full-length human Tau protein in motoneurons of Drosophila melanogaster and apply it as an *in vivo* model to test novel drug-like compounds that we have shown to reduce Tau aggregation *in vitro*.
2. Methods: We expressed full-length human Tau protein in motoneurons of Drosophila using the UAS-Gal4 system. Climbing tests were carried out on cohorts of six larvae or adult flies. Kruskal-Wallis test was used for statistical analysis.
3. Results: Compared to the wild type animals, overexpression of Tau in motoneurons caused a strong impairment in the locomotion capabilities of both larvae and adult animals. Oral administration of two novel compounds to flies overexpressing Tau resulted in a statistically significant increase in the climbing ability of treated versus untreated animals.
4. Conclusions: The presented Tau Drosophila model is a practical *in vivo* model for the functional screening of drug candidates for their ability to restore locomotion activity. On the basis of our results, the two compounds that restore locomotion in Drosophila are promising lead candidates for efficacy studies in relevant mouse models of AD.

1. *Objectives.* A potential strategy to alleviate the aggregation of intrinsically disordered proteins (IDPs) is to maintain the native functional state of the protein by small molecule binding. However, the targeting of the native state of IDPs by small molecules has been challenging due to their heterogeneous conformational ensembles.
2. *Methods.* To tackle this challenge, we applied a high-throughput binding screen using chemical microarrays, to screen monomeric full length Tau ($hTau^{2N4R}wt$) for small molecule binders. Next, small molecule binders were tested for their ability to inhibit the aggregation of different tau constructs *in vitro* and in N2a cells.
3. *Results.* The screen identified a diverse set of novel fragment and lead-like small molecules capable of binding $hTau^{2N4R}wt$, some of which had the ability to inhibit the aggregation of $hTau^{2N4R}wt$, three repeat Tau construct, and pro-aggregant mutant four repeat Tau construct $Tau^{4RD}DK280$ *in vitro* and in N2a cells. a novel set of drug-like fragment and lead-like compounds that bound to Tau.
4. *Conclusion.* These results demonstrate that Tau is a viable receptor of small drug-like molecules. Moreover, these results support the potential and practical feasibility of the therapeutic strategy to target the early phases of the aggregation pathway of IDPs by a small molecule to reduce initial nucleation events, thereby eliminating the formation of potential toxic oligomers.

We thank the Wellcome Trust (UK), Medical Research Council (UK), Elan Pharmaceuticals (USA), the Canadian Institutes of Health Research (Canada), Hungarian National Brain Research Program (KTIA_NAP_13-2014-0009, Hungary) for funding this project.

ADPD5-1287
CASEIN KINASE 1 INHIBITORS BENEFICIALLY MODULATE TAU PHOSPHORYLATION AND CELL SIGNALLING PATHWAYS IN A TRANSGENIC MODEL OF HUMAN TAUOPATHY

I. Pike[1], C. Russell[1], D. Britton[1], V. Mitra[1], E. Lahert[1], M. Ward[1]
[1]Research & Development, Proteome Sciences plc, London, United Kingdom

Non-proline-dependent casein kinase 1 delta (CK1d) is highly elevated in Alzheimer's disease (AD) brain tissue where it plays an important, early role in phosphorylation of tau, and regulates aspects of the cell cycle which are re-activated in AD neurons leading to cell death. CK1d represents a potentially important target for drug development in AD and further analysis of the activity of different CK1d-mediated pathways is required.
We have developed two selective CK1d inhibitors, PS110 and PS278-05, that are orally available and enter the brain at therapeutic levels. We have undertaken in vivo studies in the TMHT mouse model of tauopathy and monitored the effects on tau and downstream CK1d targets using targeted mass spectrometry, western blotting and immunohistochemistry, and applied SysQuant®, a global phosphorylation workflow, to determine the cross-pathway effects of CK1d inhibition in mouse brain tissue.
Both CK1d inhibitors improved cognitive performance in the TMHT mouse.
The compounds have reduced overall phosphorylation of tau, reduced tangles and increased cell count in hippocampus, and reduced active CDK5 levels. CK1d compounds have modified key pathways including those linked to amyloid processing, oxidative phosphorylation and energy production. In vitro toxicity studies confirm that neither compound showed adverse effects, and in vivo trials show the compounds have good stability and absorption, and are long-lasting.
Inhibition of CK1d affects multiple cell signaling pathways and we will present data showing which pathways are most active in a mouse model of tauopathy and the relevance of these findings to CK1d as a target in human disease.

ADPD5-1563

CHRONIC O-BETA-N-ACETYLGLUCOSAMINYLASE INHIBITION WITH THIAMET-G PREVENTS TAU PATHOLOGY AND HYPERACTIVITY IN RTG4510 MICE

C. Volbracht[1], N. Rostgaard[1], P. Jul[1]
[1]Neurodegeneration, Lundbeck A/S, Valby, Denmark

The abnormal hyperphosphorylation of the microtubule-associated protein tau plays a crucial role in neurodegeneration in Alzheimer's disease (AD) and aggregation of hyperphosphorylated tau into neurofibrillary tangles is a hallmark in AD. Besides kinases and phosphatases tau phosphorylation is regulated by O-GlcNAcylation, a posttranslational modification of proteins on the serine or threonine residues with β-N-acetylglucosamine (GlcNAc). O-GlcNAcylation is dynamically regulated by O-GlcNAc transferase, the enzyme catalyzing the transfer of GlcNAc to proteins, and N-acetylglucosaminidase (OGA), the enzyme catalyzing the removal of GlcNAc from proteins. Thiamet-G is a specific and brain permeable OGA inhibitor.
rTg4510 mice overexpress inducible human 4R0N mutant P301L tau and displayed age-dependent progression of tau pathology with tau hyperphosphorylation at AD-relevant epitopes, accumulation of the 64 kDa tau species, and neurofibrillary tangles in cortex and hippocampus. A subset of rTg4510 mice displayed a hyperactive phenotype both in a novel environment and during the diurnal cycle in the home cage, reminiscent of agitated behaviour. The percentage of hyperactive rTg4510 mice increased with age and was prevented by suppression of tau transgene indicating that this phenotype correlates with the progressive tau pathology. Treatment of rTg4510 mice with Thiamet-G increased overall O-GlcNAcylation levels in the brain indicative for sufficient target engagement. Further, Thiamet-G increased O-GlcNAcylation levels on mutant tau isolated from rTg4510 brains. Chronic Thiamet-G treatment significantly reduced soluble and insoluble 64 kDa hyperphosphorylated tau levels and reduced the number of hyperactive rTg4510 animals.
These results support OGA inhibition by Thiamet-G as possible treatment concept to reduce tau pathology and dysfunction.

[6]ULB, IRIBHM, Brussels, Belgium

Objectives. Consumption of caffeine, a non-selective adenosine A_{2A} receptor ($A_{2A}R$) antagonist, reduces the risk of developing Alzheimer's Disease (AD) in Human and mitigates both amyloid and Tau burden in transgenic mouse models. However, the impact of selective $A_{2A}R$ blockade on the progressive development of AD-related lesions and associated memory impairment has not been investigated. In the present study, we explored the outcome of $A_{2A}R$ gene deletion in the THY-Tau22 transgenic mice, which progressively develop hippocampal Tau pathology and spatial memory defects.
Methods. $A_{2A}R$ KO animals and THY-Tau22 Tau transgenic mice were mated to obtain $A_{2A}R$ gene deletion in the Tau mouse model. We then analyzed the subsequent effects on both pathological (Tau phosphorylation and aggregation, neuro-inflammation) and functional impairments (spatial learning and memory, hippocampal plasticity, neurotransmitters profile).
Results. We found that deleting $A_{2A}Rs$ protects from Tau pathology-induced deficits in terms of spatial memory and hippocampal long-term depression. These effects were concomitant with a normalization of the hippocampal glutamate/GABA ratio, together with a global reduction in neuro-inflammatory markers and a decrease in Tau hyperphosphorylation. Interestingly, treatment of Tau mice with the specific $A_{2A}R$ antagonist MSX-3 also led to significant memory improvements as well as decreased Tau hyperphosphorylation.
Conclusions. By showing that $A_{2A}R$ genetic or pharmacological blockade improves the pathological phenotype in a Tau transgenic mouse model, the present data highlight A_{2A} receptors as important molecular targets to consider in Alzheimer's Disease and Tauopathies.

NEUROINFLAMMATION ENHANCES AUTOPHAGY AND ATTENUATES TAU PATHOLOGY IN A TAUOPATHY MOUSE MODEL

Y. Qin[1], C.F. Liu[2], K. Fassbender[1], Y. Liu[1]
[1]University of the Saarland, Neurology, Homburg, Germany
[2]Soochow University, The neuroscience institute, suzhou, China

OBJECTIVES:
Alzheimer's disease (AD) is pathologically characterized by extracellular amyloid-b deposits, intracellular hyperphosphoylated tau-formed neurofibrillary tangles, and microglia-dominated neuroinflammation. As the same as Ab, tau contributes to neurodegeneration. There is evidence showing that tau is degraded through autophagy, a cellular protective mechanism reported to be damaged in AD. In this project, we aimed to investigate the relationship between neuroinflammation and autophagy and the pathogenic role of neuroinflammation in tau pathology.
METHODS:
We established neuroinflammatory mouse models with both 3- and 17-month-old C57BL/6 mice by intraperitoneal injection of lipopolysacchride (LPS, 1mg/kg every two days for one week). We ablated IKKb protein in microglia in 17-month-old C57BL/6 mice using Cre-Lox technique to reduce aging-induced neuroinflammatory activation. Furthermore, we intraperineally injected human tau mutant (P301S)-transgenic mice with 0.15mg/kg LPS weekly by injection for 12 consecutive weeks to investigate the autophagy markers and the amount of phosphorylated tau with biochemical and histological methods. Additionally, we evaluated neuronal autophagy in SH-SY5Y cells expressing fusion proteins of mRFP-GFP-LC3b co-cultured with LPS-challenged macrophages.
RESULTS: We observed that, in both LPS-induced and IKKb ablation-reduced neuroinflammatory activation models, the autophagy activity as showed with protein levels of LC3-II, beclin1 and p62 in Western blot was always correlated with neuroinflammatory activity. Interestingly, the long-term administration of LPS at a low dose enhanced autophagy in P301S tau-transgenic mice, which was followed by a significant reduction of phosphorylated tau in the mouse brain. Similarly, LPS-activated macrophages enhanced LC3b-expressing cells.
Conclusion: Neuroinflammation enhances autophagy, and potentially degrading phosphorylated tau proteins in AD pathogenesis.

A MOUSE DOSING STUDY WITH PHARMACODYNAMIC AND EFFICACY OUTCOMES DEMONSTRATES THE POTENTIAL OF A NOVEL DRUG CANDIDATE TARGETING NEUROINFLAMMATION

L.J. Van Eldik[1], S.J. Webster[1], D.M. Watterson[2], A.D. Bachstetter[1]
[1]Sanders-Brown Center on Aging, University of Kentucky, Lexington, USA
[2]Pharmacology, Northwestern University, Chicago, USA

Objectives: Clinical studies and preclinical animal model investigations support the prevailing hypothesis that proinflammatory cytokine overproduction from activated glia can contribute to neuron degeneration and impaired cognitive function. Initial validation of proinflammatory cytokine overproduction as a targeted pathway raised the potential for new therapeutic approaches to acute and chronic brain disorders, such as traumatic brain injury (TBI) and Alzheimer's disease (AD). We previously reported that MW01-2-151WH (MW151), a novel small molecule candidate that can attenuate proinflammatory cytokine overproduction, is efficacious in mouse models of AD and TBI (BMCL17:414; J Neurosci 32:10201; J Neuroinfl 5:28; J Neurotrauma 27:1283). Dosing, including intervention time window, is a critically important next step.
Methods: We examined pharmacodynamic and efficacy outcomes after MW151 administration at different concentrations and post-injury time windows in a closed head injury (CHI) mouse model of diffuse TBI. Endpoints included glial activation, cytokine levels, and cognitive function.
Results: Post-injury administrations of MW151 at low doses suppressed the acute cytokine surge. MW151 ameliorated the cognitive deficits associated with the CHI, when given during the first 7 days post-injury.
Conclusions: Low dose MW151 intervention across an extended post-injury window can modify disease progression. Proinflammatory cytokine levels trending toward homeostasis is a viable pharmacodynamic endpoint.

PATIENT SATISFACTION IN A FIRST IN MAN STUDY OF A TAU IMMUNOTHERAPY AGENT

M. Scheinin[1], Z. Lovró[1], J.O. Rinne[1]
[1]Clinical Research Services Turku, CRST Ltd., Turku, Finland

Objectives: To examine the acceptability of a hospital setting for patients with Alzheimer's disease (AD), participating in an entry into man study of a novel immunotherapeutic agent, developed by AC Immune, targeting tau pathology.
Methods: It was considered necessary to conduct initial clinical testing of the vaccine in a hospital setting to maximise patient safety. Entry into man in AD patients was considered ethically acceptable and preferable compared to a study in healthy volunteers, as both the safety and the immunogenicity of the product are likely to depend on the study population.
Eight patients with mild AD were hospitalised for 24 hours in a special facility adjacent to the emergency care facility and intensive care unit of Turku University Hospital. The room was separate from other patient facilities. A member of the clinical study team accompanied the subject for the entire duration of the stay. Caregivers were allowed to stay in the same room overnight. Patient and caregiver experiences were assessed with an open interview.
Results: All subjects coped well in the facility and rated the hospital stay as pleasant and comfortable in all respects.
Conclusions: The use of an in-patient facility adjacent to the emergency and intensive care units provided an acceptable setting for AD patients participating in an entry into man study of a novel vaccine. Increased security of the setting in case of a medical emergency compared to a conventional phase I unit was achieved without compromising patient comfort and acceptability.

[3]Biochemical Screening Systems, ProQinase GmbH, Freiburg, Germany
[4]Medicinal Chemistry, Institute of Pharmacy Martin Luther University Halle-Wittenberg, Halle (Saale), Germany

Objectives Close consideration has been taken into the tau pathology as perspective field for AD drug developments. Several protein kinases have been identified to cause pathologic tau phosphorylations. Resulting tau hyperphosphorylations finally lead to neurofibrillary tangles and the loss of tau function contributes to neuronal death. Novel protein kinase inhibitors related to tau pathology have been identified and characterized in *in vitro* studies of tau phosphorylation and tau content. First *in vivo* results of effectively influencing neuronal degeneration are presented.
Methods The target kinase activity of prepared lead structures was determined in *in vitro* assays. The kinase binding mode has been demonstrated by molecular modelling in enzyme docking studies. Cellular studies of toxicity, of tau protein phosphorylation and tau amounts will be presented. First *in vivo* results in mice with tauopathy will be reported.
Results Affinities of the more lipophilic compounds towards cdk1 and cdk5 were demonstrated by amino acid hydrogen bonding and additionally reasoned with hydrophobic interactions. A selective gsk3 beta affinity was shown for a methoxylated derivative by an exclusive binding to Arg141 of gsk3 beta. Demonstrated nontoxic inhibitor concentrations reduce tau amino acid phosphorylation and tau content. The most active compound proved to prevent further neuronal decay in a tauopathy mice model.
Conclusions Lipophilic 1-aza-9-oxafluorene lead structures effectively inhibited AD relevant kinases by demonstrated kinase interactions. The neuronal degeneration in demonstrated studies of motoneuronal abilities can be attenuated thus proving effective *in vivo* activities and a positive outcome of the kinase inhibition.

DRUG CANDIDATES PROMOTING O-LINKED GLYCOSYLATION OF TAU FOR THE TREATMENT OF TAUOPATHIES

A. Quattropani[1], M. Neny[1], S. Ousson[1], J. Hantson[1], A. Sand[1], B. Permanne[1], C. Wiessner[1], D. Beher[1]

[1]Research & Development, Asceneuron SA, Lausanne, Switzerland

Objective

The presence of neurofibrillary tangles (NFTs) is a characteristic hallmark of tauopathies which include amongst others Alzheimer's disease (AD) and progressive supranuclear palsy (PSP). NFTs are composed of aggregates of the microtubule-associated tau protein, and NFT pathology can be modified by inhibition the glycoside hydrolase, O-linked beta-N acetylglucosaminidase (OGA). Mechanistically, OGA inhibition blocks the removal of O-linked N-acetylglucosamine (O-GlcNAc) moieties from serine and threonine residues. This leads to an accumulation of O-GlcNAcylated tau protein that is less prone to aggregation. Following this rationale we sought to develop novel OGA inhibitors with the final aim to test the tau hypothesis in the clinic using PSP as initial indication.

Methods

A focused medicinal chemistry lead optimization campaign was performed starting from a series of novel OGA inhibitors. Candidate molecules with drug-like profiles were identified using a stringent assay cascade.

Results

The OGA inhibitor ASN-561 has been identified as a preclinical development candidate. ASN-561 has good potencies for inhibition of recombinant and cellular O-GlcNAcase enzymes combined with excellent brain penetration. ASN-561 demonstrated pharmacodynamic efficacy in wild-type mice upon single, oral dose utilizing O-GlcNAcylation of brain proteins as a readout for CNS target engagement. In JNPL3 tau transgenic mice ASN-561 increased the levels of tau which is O-GlcNAcylated at serine 400 up to 12-fold compared to vehicle at the highest dose. Preclinical studies supporting the investigation of the molecule in human clinical trials are currently being performed.

Conclusion

ASN-561 is an advanced preclinical OGA inhibitor with the potential to enter human Phase I safety and tolerability studies in 2015.

DEVELOPMENT OF THE NOVEL SMALL MOLECULE TAU AGGREGATION INHIBITORS, PTI-51-CH3 (TAUPRO™) AND PTI-80, FOR THE TREATMENT OF TAUOPATHIES

Q. Hu[1], J. Cam[1], J. Cummings[1], K.L. Hanson[1], L.A. Esposito[1], T. Lake[1], A.D. Snow[1]
[1]Neuroscience, ProteoTech Inc., Kirkland, USA

Accumulation of intracellular neurofibrillary tangles (NFTs) composed of aggregated tau protein is a key pathological hallmark of all tauopathies. PTI-51-CH3 (Taupro™) and PTI-80 have been identified and developed two potent small molecule tau aggregation inhibitors. Both compounds target the tau repeat domains that constitute the core of tau fibrils in NFTs, and have the ability to both prevent tau fibril formation and disaggregate pre-formed tau fibrils. The robust inhibitory activities usually occur at a PTI-compound:tau protein molar ratio of 0.3-0.4 in Thioflavin S fluorometry studies. In addition, PTI-51-CH3 and PTI-80 dose-dependently inhibit tau from forming beta-sheet-containing fibrils as determined by circular dichroism spectroscopy and electron microscopy. The inhibitory potency appears to be superior than those previously reported in the literature. As drug candidates, PTI-51-CH3 and PTI-80 also possess reasonable PK parameters in plasma and brain, and have reasonable brain exposure at the Cmax exceeding the estimated free-tau concentration range in neurons. Both compounds have safe drugability profiles with no cytotoxicity observed in cell culture studies, and no significant inhibition of CYP450 enzymes. PTI-51-CH3 and PTI-80 are currently being tested for in vivo efficacy in a transgenic mouse model. These mice express a human tau isoform with the FTDP-17 P301S mutation, that has commonly been used as a tauopathy animal model. Our results suggest that PTI-51-CH3 and PTI-80 are top pre-clinical candidates for future development as tau aggregation inhibitors for the treatment of Alzheimer's disease, progressive supranuclear palsy and other tauopathies.

APPLICATION OF MICROSCALE THERMOPHORESIS (MST) TO DETECT PROTEIN FIBRIL - SMALL MOLECULE INTERACTIONS

Y. Zhao[1], R. Richardson[1], M. Janik[2], E. Fisher[1], A. Buell[3], F. Aigbirhio[1], G. Toth[1]
[1]Wolfson Brain Imaging Centre Department of Clinical Neurosciences, University of Cambridge, Cambridge, United Kingdom
[2]Institute of Organic Chemistry Research Centre for Natural Sciences, Hungarian Academy of Sciences, Budapest, Hungary
[3]Department of Chemistry, University of Cambridge, Cambridge, United Kingdom

OBJECTIVES

Identifying novel small molecules bind to protein fibrils for the development of PET imaging agents for the diagnostics of Tauopathies such as Alzheimer's disease has proven challenging. For this purpose, we developed a sensitive biophysics based free solution methodology to quantify such interactions.

METHODS

MST binding experiments were conducted on a Monolith NT. 115 instrument. NT647-NHS dye was used to label both tau fibrils, generated in vitro, and intrinsically disordered tau monomers. Measurements were conducted using 25 nM protein with 0.05% Tween HEPES buffer titrating the unlabelled binding partner from < 1 nM to 100 times the K_D for the interaction. Enhanced gradient standard capillaries were used in each experiment using settings of 90% LED power and 40% MST power.

RESULTS

Smooth binding curves and binding affinities (K_D) were obtained for the interaction between tau fibrils and thiazine red (22±21 nM), lansoprazole (29±24 nM), a novel drug-like compound with K_D about 48 nM and between tau monomers and heparin (131±8 nM), consistent with data reported in the literature.[1,2,3]

CONCLUSIONS

MST shows promise as practical methodology for quantification of ligands binding to tau fibrils. K_D can be obtained with very small amounts of protein with repeatability of measurement results. The outlined MST methodology may be applied to other protein fibril systems and used for screening for small molecule binders of protein fibrils.

Objectives.
Human A_{2A} adenosine receptor belongs to the superfamily of G protein coupled receptors and its blockade is highly relevant for therapeutics of Parkinson and Alzheimer diseases. Currently, only three compounds are still being tested in clinical phase for PD treatment. Even if they show good affinities for the receptor, there is still a need for improving their ADME properties by keeping their selectivity towards other adenosine receptors.
Methods.
Based on the recently published crystalline structure of the A_{2A} receptor complexed with ZM241385, a selective and high-affinity antagonist[1] and on a pharmacophoric model,[2] we designed new ligands using *in silico* docking studies starting from antagonists that we recently identified in our group.
Results.
Cyclic guanidine core was identified as a promising structure. We therefore developed an original 5-step synthesis enabling us to incorporate pharmacomodulations and to evaluate structure activity relationships. Affinity tests were then conducted on HEK293 cells membranes expressing A_{2A}R and cytotoxicity was evaluated on SY5Y cells.
Conclusions.
We designed a new chemical route to access our cyclic guanidine structures. For now, these molecules did not show better affinity than our firstly identified antagonist. SAR helped us to confirm the necessity of having a rigid cyclic structure and to identify substituent that seem to improve the affinity.

05t. Drug Development & Clinical Trials: medicinal chemistry approaches

ADPD5-2063
IN SILICO DESIGN OF ADENOSINE A2A ANTAGONISTS
P. Melnyk[1], N. Renault[2], V. Moas Heloire[1], D. LeBroc[3], D. Blum[4], C. Furman[3], L. Buée[4], P. Chavatte[2], L. Agouridas[1]
[1]Lille University Pharmacy Faculty, Inserm UMR-S1172, LILLE Cedex, France
[2]Lille University Pharmacy Faculty, Inserm U995, LILLE Cedex, France
[3]Lille University Pharmacy Faculty, EA4483, LILLE Cedex, France
[4]Lille University, Inserm UMR-S1172, LILLE Cedex, France
Objectives.
Human A_{2A} adenosine receptor belongs to the superfamily of G protein coupled receptors and its blockade is highly relevant for therapeutics of Parkinson and Alzheimer diseases. Co-crystallization of A_{2A} receptor with selective antagonists was further analyzed from *in silico* studies to highlight polar and aromatic inter-molecular hotspots for design of novel antagonists.
Methods.
Docking-scoring processes were performed to select a suitable crystal structure and refine a virtual screening protocol trained from a library training set including most of known A_{2A} antagonists and thousands decoy ligands. This protocol was expected to screen new test sets like academic chemical libraries and *de novo* combinatorial libraries.
Results.
A preferential crystal A_{2A} structure was identified since molecular docking predictions of reference A_{2A} antagonists fit with experimental co-crystallized poses. After the training stage, the best screening performance was reached in the top-1% scored subset in term of enrichment and yield rate of true active by filtering docking poses satisfying aromatic stacking with Trp246 and hydrogen bond with Asn253. From a 2,200 molecules in-house library, these rules were applied to screen 7 virtual hits whose one exhibited a consistent A_{2A} binding affinity in the range of µM.
Conclusions.
Rich structural material about A2A receptor structure allows the design of suitable structure-based virtual screening protocols. Preliminary results of virtual screening onto a small in-house library let us expect very successful campaigns onto larger databases.

LIGAND-INDUCED STRUCTURAL CHANGES OF THE HUMAN FARNESYL PYROPHOSPHATE SYNTHASE: IMPLICATIONS TO DRUG DESIGN FOR TAUOPATHY-ASSOCIATED NEURODEGENERATION

J. De Schutter[1], J. Park[2], C. Leung[1], P. Gormley[3], L. Théroux[3], J. Frappier[3], A. Berghuis[2], J. Poirier[3], Y. Tsantrizos[1]

[3]Psychiatry and Medicine, McGill University, Montreal, Canada

Human farnesyl pyrophosphate synthase (hFPPS) is the gate-keeper of mammalian isoprenoids and the key target of bisphosphonate drugs. However, bisphosphonates suffer from poor “drug-like” properties and are mainly effective in treating skeletal diseases. Recent investigations have implicated hFPPS in various non-skeletal diseases, including tauopathy-associated neurodegeneration and progression of Alzheimer’s disease (AD). Consequently, the development of non-bisphosphonate inhibitors of hFPPS can provide molecular tools for validating this enzyme as a therapeutic target for AD. A structure-based, multistage screening protocol, based on differential scanning fluorimetry (DSF), NMR and crystallography, was developed in order to identify non-bisphosphonate inhibitors of hFPPS. These studies led to the discovery of a novel class of hFPPS inhibitors, which bind to a catalytically relevant allosteric pocket of the enzyme near the active site cavity. The synthesis and structure-activity relationship optimization studies of these compounds will be described. In addition, preliminary biological evaluation of these compounds for their ability to block tau metabolism in human immortalized neurons will be presented. This work was supported by the Natural Sciences and Engineering Research Council of Canada (NSERC), the Canadian Institute of Health Research (CIHR) and the Fonds de Recherché du Québec-Nature et Technologies (FRQ-NT).

DETECTION OF PHF-TAU PATHOLOGY WITH [18F]T807 IN BRAIN SECTIONS FROM FRONTO TEMPORAL DEMENTIA PATIENTS

F. Gomez[1], Y.G. Lin[1], Q. Liang[1], M.A. Mintun[1], E. Bigio[2], G. Attardo[1]
[1]Discovery, Avid Radiopharmaceuticals, Philadelphia, USA
[2]Pathology, Northwestern University, Chicago, USA

Objective: To establish the ability of the radiotracer [18F]T807, also known as [18F]AV-1451, to detect Tau aggregates in postmortem human FTD and FTLD brain tissue.
Methods: Frozen sections from FTD, FTLD, Alzheimer's disease (positive control) and age matched controls subjects were exposed to [18F]T807 and examined by autoradiography. Adjacent slides from the same tissue samples were stained with PHF Tau antibodies (AT8, AT100, 3R and 4R) in order to establish the presence of pathological Tau aggregation in the [18F]T807 positive regions. In addition, several fluorescent reporter compounds that compete with [18F]T807 binding were used to double stain these tissues to identify any colocalization between the tracer and PHF Tau aggregates revealed by the antibodies.
Results: The positive signals obtained by autoradiography from [18F]T807 in FTD and FTLD brain tissue were located in areas that contained PHF tau as determined by Tau antibodies. All [18F]T807 surrogate fluorescent compounds colocalized with immunofluorescence signal obtained with antibodies that stain pathological Tau aggregations but also with those that stain the 3R and 4R variants of the protein.
Conclusions: Our autoradiography results suggest that the radiotracer [18F]T807 is capable of binding Tau in FTD and FTLD tissue. Furthermore, fluorescent signals from T807 structurally related reporter compounds colocalized with tau antibodies AT8, AT100, 3R and 4R.

Autopsy studies have shown that increasing cerebral tau pathology in Alzheimer's disease (AD) is associated with decline in cognitive functions. In contrast, the amount of amyloid plaques shows weak association with cognition in early AD, as suggested by amyloid PET imaging. So far, cerebral in vivo metabolism assessed using ^{18}F-FDG has been showing best correlations with cognitive performance, particularly memory. The recent development of novel radiotracers for in vivo assessment of tau pathology now offers a unique possibility to study the regional deposition of tau in the brain along with cognitive changes. The aim was to compare, at different stages of AD, the similarity/differences in regional hypometabolism with tau deposition measured by PET in relation to cognition.

Patients with AD as well as patients with Mild Cognitive Impairment (MCI) underwent three dynamic PET-scans using the novel tau tracer ^{18}F-THK5117, the amyloid ligand ^{11}C-PIB, and ^{18}F-FDG, as well as 3D structural MR. All participants also underwent a comprehensive neuropsychological examination covering five cognitive domains. Regional Standard Uptake Values normalized to cortical cerebellar uptake were calculated for the three PET tracers in each patient.

In this ongoing study, the relationship between PET tracers' regional uptake and cognitive scores in each clinical group is investigated.

In vivo measurement of PET tau pathology will result in new knowledge on the relationship between tau and cognitive functions across clinical stages of AD. This multi-tracer approach will give valuable information of regional brain changes and help reveal the yet unclear mechanisms linking pathological features and phenotype

[3]Department of Medicinal chemistry, Uppsala University, Uppsala, Sweden

[4]Department of Pathology, Karolinska University Hospital, Stockholm, Sweden

[5]Department of Pharmacology, Tohoku University School of Medecine, Sendai, Japan

Objectives: To facilitate the early diagnosis of AD, it is important to understand the time course of each characteristic hallmarks of AD. In this study, we aim to comprehend the time course of Tau pathology with in vitro characterization of ^{3}H-THK5117, a PET tracer currently under development for Tau in vivo imaging. To interpret the relation with the other pathological hallmarks we also compared the binding of ^{3}H-THK5117 with ^{3}H-PIB (amyloid plaques) and ^{3}H-Deprenyl (astrocytosis).

Methods: The regional distribution of ^{3}H-THK5117 was determined with single concentration binding assay in differents brain regions on AD and control cases. Autoradiographies with ^{3}H-THK5117, ^{3}H-PIB and ^{3}H-Deprenyl were performed on whole frozen hemisphere sections from AD cases that, before death, had undergone in vivo ^{18}F-FDG and ^{11}C-PIB PET imaging.

Results: ^{3}H-THK5117 binding shows a difference in regional distribution with higher binding in AD compare to control. A negative correlation was observed between in vitro manual segmentation of ^{3}H-THK5117 autoradiography and in vivo FDG PET scan. The preliminary results for the laminar in vitro distribution showed a similar pattern for ^{3}H-THK5117 and ^{3}H-Deprenyl in hippocampus while we observed a different binding pattern for ^{3}H-PIB

Conclusions: THK5117 shows a high specific binding with difference between AD and control cases. The in vitro binding pattern is in accordance with Tau distribution in the brain observed with AT8 antiTau immunostaining. A similar regional pattern are observed with Deprenyl but not PIB. Finally, the negative correlation between ^{3}H-THK5117 and ^{18}F-FDG suggests a correlation between Tau deposit and neurodegeneration.

[3]Cyclotron and Radioisotope Center, Tohoku University, Sendai Aoba-ku, Japan
[4]Department of Geriatrics and Gerontology,
Institute of Development Aging and Cancer Tohoku University, Sendai Aoba-ku, Japan

Objectives: *In vivo* imaging of neurofibrillar pathology will provide new insights into Alzheimer's disease (AD) and allow monitoring of disease progression and treatment effects. We developed [^{18}F]THK-5105 and [^{18}F]THK-5117 as tau PET tracers and successfully visualized tau deposition in the brain of AD patients. A drawback of these tracers is the non-specific white matter retention that may interfere with visual interpretation of PET images. We continued compound optimization and developed a novel tau PET tracer [^{18}F]THK-5351. **Methods:** In vitro binding of [^{18}F]THK-5351 to PHF-tau in the postmortem AD brain tissues was evaluated by in vitro binding assay and autoradiography. Binding kinetics were further evaluated and compared with [^{18}F]THK-5117. In vivo biodistribution of [^{18}F]THK-5351 in normal mice were performed. **Results:** [^{18}F]THK-5351 displayed high binding affinity with AD brain homogenates containing high amount of PHF-tau. In vitro autoradiography of [^{18}F]THK-5351 in AD brain sections showed the laminar distribution, which was completely different from that of [^{11}C]PiB. Microautoradiograpy also supported selective labeling of [^{18}F]THK-5351 to tau pathology in AD brain section. [^{18}F]THK-5351 showed faster dissociation from white matter and higher signal-to-background ratio than [^{18}F]THK-5117. Initial sufficient brain uptake of [^{18}F]THK-5351 and faster washout from normal mouse brain than [^{18}F]THK-5117 were observed. **Conclusions:** These results support [^{18}F]THK-5351 is a promising PET tracer for imaging tau pathology in humans and is expected lower background and higher contrast PET images of than [^{18}F]THK-5117.

ADPD5-2173

TAU DEPOSITION AS MEASURED BY 3H-THK5117 IN CORTICAL LAYERS OF POST-MORTEM AD BRAIN IN COMPARISON WITH AMYLOID PLAQUES AND ASTROCYTOSIS

F. Engman[1], L. Lemoine[1], L. Saint-Aubert[1], I. Nennesmo[2], P.G. Gillberg[1], A. Nordberg[1]
[1]NVS, Karolinska Institutet, Stockholm, Sweden
[2]Department of Pathology, Karolinska University Hospital, Stockholm, Sweden

Objectives
Tau pathology has been suggested to spread in Alzheimer's disease (AD) between interconnected neurons trans-synaptically. Thus, studying the distribution of tau in the different cortical layers of the brain can improve our understanding of tau's spreading patterns. Furthermore, by comparing the laminar distribution of tau, amyloid-beta and astrocytosis, the possible relationship between these pathological features can be understood.

Methods
The laminar distribution of hyperphosphorylated tau, fibrillar amyloid plaques and reactive astrocytes were assessed using the radiotracers ^{3}H-THK5117, ^{3}H-PiB and ^{3}H-L-deprenyl, respectively. The binding of each radiotracer through the cortical layers was quantified in autoradiograms of post-mortem whole hemisphere brain sections from three AD patients and one control.

Results
In a 60-year-old AD patient the ^{3}H-THK5117 binding showed a laminar distribution with highest binding in the superficial layers in most brain regions. In the temporal cortex, high ^{3}H-THK5117 binding was also observed in deeper cortical layers. The binding pattern was quite similar with that of ^{3}H-L-deprenyl (astrocytosis) while ^{3}H-PIB (fibrillar amyloid plaques) showed a more even distribution between the different cortical layers. In two other AD cases of 79 and 81 years of age, somewhat different binding patterns of ^{3}H-THK5117 were observed.

Conclusions
The present study reveals interesting patterns of cortical laminar distribution of tau deposition as measured by the tentative PET tracer THK5117 in autopsy AD brain, which coincides with astrocyte distribution but differs from amyloid deposition. The similarities and dissimilarities between these pathological markers in different cortical layers illustrate the complexity of AD pathology.

RETINA EXAMINATION FOR TAU TANGLES AND BETA AMYLOID PLAQUES IN ALZHEIMER'S DISEASE

U. Kayabasi[1], R.C. Sergott[2]
[1]Neuro- ophthalmology, World Eye hospital, Istanbul, Turkey
[2]Neuro- ophthalmology, Wills Eye hospital, Philadelphia, USA

Objective: To detect tau tangles and beta amyloid plaques in retina for the early diagnosis of Alzheimer's Disease (AD).
Methods: We examined 30 patients with mild cognitive insufficiency (MCI) and 15 age matched healthy controls. Age range was 64 - 85. Retina was examined by using fundus autofluorescence (FAF) and optical scanning tomography (OCT). FAF showed us lipofuscin which contained beta amyloid in AD and the layer of the accumulations was detected by OCT. Patients who had retinal lesions were given curcumin with Meriva for three days and FAF-OCT tests were repeated. Suspicious cases for AD were sent for brain PET- CT imaging.
Results: In 22 patients, tau tangles and plaques were observed on OCT. Curcumin stained the retinal accumulations in all 22 patients. Since curcumin binded to beta amyloid, it was proven that these plaques were related to AD. In all 22 patients, PET-CT results were consistent with bilateral temporo-parietal hypometabolism. No tangles or stained plaques were observed in the control group.
Conclusion: Our study suggests that tau tangles and beta amyloid plaques can be found in retinas of AD patients. This is the first study that reveals imagings of tau tangles and beta amyloid plaques in alive AD patients with FDA approved devices.

RETINA EXAMINATION FOR TAU TANGLES AND BETA AMYLOID IN ALZHEIMER'S DISEASE

U. Kayabasi[1], R.C. Sergott[2]
[1]Neuro- ophthalmology, World Eye hospital, Istanbul, Turkey
[2]Neuro- ophthalmology, Wills Eye hospital, Philadelphia, USA

Objective: To detect tau tangles and beta amyloid plaques in retina for the early diagnosis of Alzheimer's Disease (AD).
Methods: We examined 30 patients with mild cognitive insufficiency (MCI) and 15 age matched healthy controls. Retina was examined by fundus autofluorescein (FAF) and optical scanning tomography (OCT) tests. FAF detected lipofuscin which contained beta amyloid in AD and the layer of the accumulations was detected by OCT. Patients who had retinal lesions were given curcumin with Meriva for three days and FAF-OCT tests were repeated. All the suspicious cases for AD were sent for brain PET- CT imaging.
Results: In 22 patients, tau tangles and plaques were observed on OCT. Curcumin stained the retinal lesions in all 22 patients. Since curcumin binded to beta amyloid, it was proven that the plaques were related to AD. All 22 patients had PET- CT results consistent with bilateral temporo-parietal hypometabolism. Tau tangles and curcumin staining was not seen in the control group.
Conclusion: Our study suggests that tau tangles and beta amyloid plaques can be seen in retina in an easier way and probably earlier than brain changes in AD. This is the first study that reveals tau plaque and beta amyloid imagings in alive AD patients with FDA approved devices.

FDG-PET CT AND TRODAT-1 SPECT IN DEMENTIA: REDEFINING THE TAUOPATHIES AND ALPHA SYNUCLEIONOPATHIES

R. Ranjan[1], R.I.T.U. Verma[2], C.S. Agrawal[1], P. Pankaj[2]
[1]Neurology, Sir Ganga Ram Hospital, Delhi, India
[2]Nuclear Medicine and PET CT, Sir Ganga Ram Hospital, Delhi, India

Objectives: To investigate the potential usefulness of FDG PET CT and 99mTc-TRODAT-1 SPECT imaging in the evaluation of subjects with suspected or diagnosed dementia with the following objectives:

- Documenting the complementary role of 99mTc-TRODAT-1 and FDG PET CT imaging in various neurodegenerative disorders
- Early diagnosis of dementia and minimal cognitive impairment
- Pre clinical diagnosis of dementia in high risk groups
- Differential diagnosis of different tauopathies and alpha-synucleinopathy

Methods: 50 patients with suspected or diagnosed dementia and 10 age matched healthy volunteers were evaluated using FDG PET CT and 99mTc-TRODAT-1. 99mTc-TRODAT-1 was prepared from a lyophilized kit and SPECT imaging performed using a double-head camera. FDG PET CT was done on a separate day by GE Discovery STE PET CT system.

Results: Different patterns of cortical and sub cortical hypo metabolism was noted in the different dementia sub types on FDG PET CT. Reduced striatal uptake of 99mTc-TRODAT-1 was found in all the alpha-synucleinopathies but in only few of the tauopathy.

Conclusion: FDG PET CT in conjunction with 99mTc-TRODAT-1, may serve as useful imaging agents for the early detection of dementia and differentiation of different tauopathies and alpha-synucleinopathy

MAPPING REGIONAL GREY AND WHITE MATTER DAMAGE IN PATIENTS WITH PROGRESSIVE SUPRANUCLEAR PALSY SYNDROME

F. Caso[1], F. Agosta[1], M.A. Volonté[2], L. Sarro[1], L. Spagnolo[2], A. Falini[3], G. Comi[2], M. Filippi[4]

[1]Neuroimaging Research Unit, Scientific Institute and University Hospital San Raffaele, Milan, Italy

[2]Department of Neurology, Scientific Institute and University Hospital San Raffaele, Milan, Italy

[3]Department of Neuroradiology, Scientific Institute and University Hospital San Raffaele, Milan, Italy

[4]Neuroimaging Research Unit and Department of Neurology, Scientific Institute and University Hospital San Raffaele, Milan, Italy

Objective. To investigate the pattern of grey matter (GM) atrophy and white matter (WM) damage in patients with probable progressive supranuclear palsy syndrome (PSPs) using MRI.

Methods. We enrolled 31 patients with probable PSPs and 22 matched healthy controls. Patients underwent clinical and neuropsychological evaluation, and brain structural and diffusion tensor (DT) MRI. The regional patterns of brain GM atrophy and WM microstructural damage were assessed using voxel-based morphometry and tract-based spatial statistics, respectively ($p<0.05$ FWE).

Results. PSPs patients were in a moderate stage of disease (Hoehn and Yahr score: 3.3) and showed mild to moderate cognitive impairment involving especially attentive-executive functions. PSPs patients did not show GM atrophy relative to controls. On the contrary, they showed a reduction of fractional anisotropy (FA) and an increase of mean, axial and radial diffusivities in the main WM tracts bilaterally, including body and splenium of corpus callosum, cingulum, inferior fronto-occipital, superior longitudinal and uncinate fasciculi, anterior and superior corona radiata, corticospinal tracts, and thalamic radiations. Superior cerebellar peduncles and internal capsules showed a significant increase of diffusivity values, but no FA changes.

Conclusions. In PSPs patients, WM microstructural damage is prominent compared to GM atrophy even in the moderate stage of the disease, suggesting that diffuse WM damage in tauopathies is not merely a function of disease severity. Regional differences in DT MRI metrics might reflect a different vulnerability of WM tracts. Our finding might provide new insight in understanding the pathophysiology of the disease and the clinical progression.

NON-PHOSPHORYLATED TAU IN THE CSF AS A NOVEL POTENTIAL BIOMARKER OF ALZHEIMER'S DISEASE

P. Lewczuk[1], I. Lachmann[2], K. Flach[2], N. Lelental[1], M. Holzer[3], A. Perret-Liaudet[4], J.M. Maler[1], P. Spitzer[1], J. Kornhuber[1]
[1]Psychiatry and Psychotherapy, Universitätsklinikum Erlangen, Erlangen, Germany
[2]AJ Roboscreen, AJ Roboscreen, Leipzig, Germany
[3]Paul Flechsig Institute of Brain Research, University of Leipzig, Leipzig, Germany
[4]Neurobiologie, Hospices Civils de Lyon, Lyon, France

Objectives: (a) technical validation of a first, to our best knowledge, ELISA method measuring concentrations of non-phosphorylated (non-P-Tau) molecules in the human cerebrospinal fluid (CSF); (b) testing if the CSF concentrations of non-P-Tau can be useful for an early diagnosis of MCI/AD.
Methods: First, a novel ELISA (AJ Roboscreen, Leipzig, Germany) has been technically validated taking into consideration its detection limit, linearity, precision, repeatability of the standard curves, and recovery. In the clinical part, the hypothesis was tested if non-P-Tau could discriminate patients with MCI and early AD whose clinical diagnoses were supported by 'classic' CSF biomarkers (Aβ1-42, Aβ42/40 Ratio, Tau, and pTau181) (n=58) from neuropsychiatric Controls without alterations in the CSF biomarkers (n=42).
Results: The method characterizes with very good inter- and intra-assay precision. The imprecision of the optical densities of the standards (six repetitions) was lower than 16% for all standards with the goodness of fit higher than 0.99. Patients with MCI/AD had statistically highly significantly increased non-P-Tau concentrations compared to the Controls (p
Conclusions: (a) the ELISA presented here characterizes with good analytical performance, including precision and repeatability; (b) for the first time we were able to measure non-P-Tau concentrations in human CSF; (c) our results suggest that CSF non-P-Tau could is worth consideration as a reliable and robust candidate biomarker of Alzheimer's Disease.

PROTEIN EXPRESSION AND ACTIVITY OF MICROTUBULE AFFINITY-REGULATING KINASE (MARK2) CHANGE UPON ALTERED NUTRITION. A PROMISING LINK TO ALZHEIMER'S DISEASE?

C. Hempp[1], A. Boucsein[1], J. Benzler[1], M. Benzler[1], G. Böttiger[1], A. Waniek[1], S. Stöhr[1], A. Tups[2]

[1]Animal Physiology, Philipps-University, Marburg, Germany

[2]Physiology, University of Otago, Dunedin, New Zealand

Objectives:

MARK2 is an important kinase regarding cell polarity, cytoskeletal structure and tau phosphorylation. Several upstream kinases of MARK2 are known, however regulation of MARK2 is not completely understood.

We aimed to investigate if nutritional factors can regulate MARK2.

Methods:

Adult mouse hypothalamic cells were treated with palmitate and subsequently analyzed for cell viability and MARK2 protein expression.

To investigate effects of a high fat diet (HFD) in animal models, we performed immunohistochemical analysis of active MARK (Thr208) in brains of mice treated with HFD over a period of 3 weeks. Furthermore hippocampal mRNA expression of MARK2 was analyzed by *in situ* hybridization with brains of wild-type (WT) and leptin deficient, obese $Lep^{ob/ob}$-mice.

Results:

After 12 h of palmitate treatment hypothalamic cells lost cellular processes. MARK2-proteinexpression and metabolic activity declined dramatically after 24 h of treatment and after 48 h cell death occurred. Observation of cytoskeletal structure is under progress.

Additional animal studies in WT-mice revealed a significant reduction of active MARK (Thr208) positive pyramidal cells in hippocampal CA2 region after 3 days of HFD. Furthermore $Lep^{ob/ob}$-mice, exhibited a significantly reduced hippocampal MARK2 mRNA expression compared to WT-mice.

Conclusion:

Our results strongly indicate that MARK2 is regulated by nutritional factors. Protein expression as well as protein activity is down regulated during a HFD in cellular and animal models. Based on these results we expect dramatic alterations in the cytoskeletal structure and propose that metabolic changes can trigger pathogenesis of neurodegeneration, like Alzheimer's disease via altered MARK2 protein expression and activity.

[8]., CogState Ltd, Melbourne, Australia

Objectives: Aggregates of hyper-phosphorylated tau protein are one of the main neuropathological hallmarks of Alzheimer's disease (AD) and other neurodegenerative disorders.

The Microtubule Associated Protein Tau (MAPT) gene contains 2 haplotypes, H1 and H2. Studies show the H1 clade is diverse containing a number of sub-clades, compared to the H2 clade which has been shown to be a single non-recombining haplotype. The H1c haplotype, in particular, has been associated with an increased risk of AD and progressive supranuclear palsy, as well as increased levels of CSF tau in AD. H1 haplotypes have also been associated with an increased risk of PD and Frontotemporal dementia.

This study aimed to use endophenotypes available within the Australian Imaging, Biomarkers & Lifestyle (AIBL) Study of Aging to investigate the effect of MAPT genetic variation with regards to AD risk.

Methods: Seven SNPs within MAPT, namely rs1467967, rs242557, rs3785883, rs2471738, rs7521, rs9468 and rs1800547, were genotyped using the OpenArray® platform, in 1473 AIBL samples. Genotyping rs9468 and rs1800547 allowed for the differentiation of H1 and H2 haplotype, while the other 5 SNPs specifically tagged variation within the H1 clade.

Results and Conclusions: Cross-sectional analyses focused on associations with clinical classification of disease, levels of CSF and peripheral tau protein, neocortical amyloid burden as measured using PET imaging, hippocampal volume and cortical thickness. Further, longitudinal analyses were conducted to determine genetic influences on an individual's rate of cognitive decline.

GENETIC VARIANTS OF GSK3B ARE ASSOCIATED WITH BIOMARKERS FOR ALZHEIMER'S DISEASE AND COGNITIVE FUNCTION

P. Kettunen[1], S. Larsson[1], S. Holmgren[1], S. Olsson[1], L. Minthon[2], H. Zetterberg[1], K. Blennow[1], S. Nilsson[3], A. Sjölander[4]
[1]Institute of Neuroscience and Physiology, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden
[2]Department of Clinical Sciences in Malmö, Lund University, Malmö, Sweden
[3]Institute of Mathematical Sciences, Chalmers University of Technology and University of Gothenburg, Gothenburg, Sweden
[4]Center for Culture and Health, University of Gothenburg, Gothenburg, Sweden

Background: Glycogen synthase kinase 3 beta (GSK3B) is the major kinase phosphorylating tau protein. Hyperphosphorylated tau is one of the hallmarks of Alzheimer's disease (AD). Despite extensive research, the role of *GSK3B* in AD pathogenesis is not fully understood.
Objective: To evaluate possible associations between gene variants of *GSK3B* and risk of AD.
Methods: Twelve *GSK3B* tag single-nucleotide polymorphisms (SNPs), together with the previously AD-associated rs334558, were analyzed in 583 AD patients and 673 controls. Analyses on single marker and haplotype levels were done to relate to risk of AD, Mini Mental State Examination (MMSE) scores and cerebrospinal fluid (CSF) biomarker levels of total tau (T-tau), hyperphosphorylated tau (P-tau_{181}) and amyloid-β ($Aβ_{42}$).
Results: After correction for multiple testing, we found a number of associations of gene variants with CSF biomarker levels and cognitive function in the AD patients. Firstly, rs334558 was associated with elevated T-tau levels. Next, rs1154597 showed association with reduced $Aβ_{42}$ levels. Lastly, rs3107669 was associated with lower MMSE scores.
Conclusion: We found *GSK3B* gene variants associated with cognitive function and CSF biomarkers T-tau and $Aβ_{42}$. To our knowledge, this is the first time *GSK3B* has been associated with cognitive function or CSF biomarkers reflecting neuronal degeneration (T-tau) and brain amyloid load ($Aβ_{42}$). The regulation of *GSK3B* needs to be investigated further, to fully understand how these *GSK3B* gene variants are involved in AD pathogenesis.

[2]Neurology, Mayo Clinic, Jacksonville, USA

Objectives: PSP arises from a combination of genetic and environmental factors which lead to intermediate pathological changes in the brain, eventually causing cell death and disease. We hypothesize that there are genetic variants associated with the PSP disease process that can be identified using neuropathologic features as phenotypes in a genome-wide association study.

Methods: Tau pathology scores were assessed in 970 pathologically-confirmed PSP cases for four tau lesion types: 1) neurofibrillary tangles 2) coiled bodies 3) tufted astrocytes, and 4) tau threads by one neuropathologist from 1998 – 2013. Tau lesions were scored (0,1, 2, or 3) in 18 brain regions. This dataset was converted into latent traits using the ltm R Package, which effectively reduces the dimensionality into a single, continuous variable for regression analyses. Linear regression was employed to test for association between latent traits using genome-wide genotyping in Stage 1 (498 PSP cases), and using age and sex as covariates. The top 35 SNPs from Stage 1 ($P < 10^{-5}$), were then genotyped in Stage 2 (406 PSP cases) using Sequenom MassArray platform, and association testing was performed.

Results: Preliminary results from a meta-analysis of Stage 1 and 2 identified a strong association located at chr3q27 within *ST6GAL1* (ST6 beta-galactosamide alpha-2,6-sialyltranferase 1) with variability of tau-immunoreactive coiled bodies and tufted astrocytes in hindbrain structures having the most significant associations.

Conclusions: We have identified genetic variants which associate with clinicopathologic heterogeneity of PSP, having the potential to reveal novel molecular pathways involved in the PSP disease process.

COPY NUMBER VARIATION ANALYSIS OF THE 17Q21.31 REGION AND ITS ROLE IN ALZHEIMER'S AND PD

J. Clarimón[1], L. Cervera-Carles[1], A. Lleó[1], R. Blesa[1], O. Dols-Icardo[1], J. Fortea[1], J. Pagonabarraga[1], B. Pascual-Sedano[1], A. Campolongo[1], J. Kulisevsky[1]
[1]Department of Neurology, Institut de Recerca Biomèdica - Hospital de Sant Pau, Barcelona, Spain

Objective: The 17q21.31 inversion polymorphism (leading to H1/H2 haplotypes) has been related to Alzheimer's (AD) and PD. Recent analyses have described several copy number variants (CNV) within 17q21.31 with a high diversity range in humans. We aim to analyze the structural variation of this chromosomal region through a high-resolution approach, and test whether differences in CNV could influence the risk of AD and PD.
Methods: We recruited 390 PD patients, 505 AD patients and 388 unrelated controls from Spain, previously genotyped for the H1/H2 haplotype. A new molecular approach based on Droplet-Digital PCR was used to determine the precise genomic dosage of the three known CNV that are present on the 17q21.31 chromosomal region.
Results: Our estimation of copy number duplications revealed a high degree of variation, ranging from two to eight copies. The PD group had a significant overrepresentation of the H1 allele; although the pattern of CNV distribution was similar to controls in the whole region. The H1/H2 haplotype was not associated to AD risk. However, our preliminary results indicated an excess of CNV in controls compared to AD patients.
Conclusions: Droplet-Digital PCR is a highly precise method to analyze CNV polymorphisms with multiple alleles. Copy number variation of the 17q21.31 region does not seem to meaningfully affect the PD risk. Our preliminary data indicates that AD patients have a distinct pattern of CNV compared to controls. Further analyses are in progress in order to elucidate the role of CNV within 17q21.31 and AD risk.

[2]Alzheimer & Tauopathies, Université Lille-Nord de France UDSL Inserm U837, Lille, France
[3]Transcription and Disease Laboratory, Jawaharlal Nehru Centre for Advanced Scientific Research (JNCASR), Bangalore, India

Objectives: The underlying causes of memory loss associated with Alzheimer's disease (AD) are poorly understood and effective treatments are still under investigations. Several studies point to new therapeutic interventions by modulating brain acetylation levels with the use of histone deacetylase (HDAC) inhibitors. We recently described a new molecule (CSP-TTK21) that promotes CBP acetyltransferase activation in the brain. Herein, we used a transgenic mouse model of tauopathy (tg22) that develops neurofibrillary tangles and memory impairments, to assess the potential therapeutic effect of CSPTTK21.
Methods: we combined behavioral, biochemical and genome-wide molecular analyses.
Results: We found that CBP levels were decreased in the hippocampus of tg22 relative to WT mice. In addition, a global decrease of H2Bac acetylation (H2Bac), a CBP-targeted histone mark, was observed at a time where tg22 mice presented spatial memory impairments. ChIP-sequencing experiments confirmed that this mark was altered, showing a significant decrease of H2Bac at specific loci of genes important for synaptic plasticity and learning and memory. Remarkably, CSP-TTK21 treatment fully rescued long term retention of spatial memory performances and specifically increased H2Bac levels at learning and memory gene loci in the hippocampus of tg22 mice. How this translates on gene expression is currently being evaluated. Finally, we found that CBP levels were severely decreased in post-mortem brains from AD patients.
Conclusions: Our results strongly support that improving CBP histone acetyltransferase activity with molecules such as CSP-TTK21 could stand as a valuable epigenetic therapeutic option for the treatment of memory and plasticity dysfunctions associated with AD.

ACUTE TRAUMATIC BRAIN INJURY INITIATES EARLIER AND MORE SEVERE TAU PATHOLOGY IN P301S TRANSGENIC MICE

G. Edwards III[1], I. Moreno-Gonzalez[1], J. Zhao[2], P. Dash[2], C. Soto[1]
[1]Mitchell Center for Research in Alzheimer's disease and Related Brain Disorders Neurology, University of Texas Health Science Center-Houston, Houston, USA
[2]Neurobiology and Anatomy, University of Texas Health Science Center-Houston, Houston, USA

Background: History of traumatic brain injury (TBI) seems to be a strong epigenetic factor that can initiate molecular cascades increasing the risk of Alzheimer's disease (AD) or dementia. Following an acute TBI, individuals exhibit an elevation of A-beta and hyperphosphorylated tau (pTau) accumulation, suggesting a pathological link between TBI and AD. Furthermore, individuals with TBI experiences can develop chronic traumatic encephalopathy or dementia pugilistica having neurofibrillary tangles (NFTs) reminiscent of AD. ***Objective:*** To assess if a single, acute TBI increases the levels of pTau, which then form the first aggregates that can spread this pathology throughout the brain, resulting in early and more severe pathological changes. ***Methods:*** 3 month old P301S tau transgenic mice (n = 5/ time point) were subjected to TBI by controlled cortical impact (CCI) and sacrificed 1 day, 1 week, 1 month, and 6 months post-TBI. Coronal brain sections were immunohistochemically stained and levels of pTau and NFTs were quantified. Late stage post-TBI P301S were behaviorally characterized by Rotarod and Barnes maze tasks. ***Results:*** Injured P301S groups exhibited acceleration and augmentation of pTau brain deposition compared to aged-matched sham controls at the various time-points. TBI exacerbated the distribution of pTau as seen in different brain regions. ***Conclusion:*** Acute TBI may initiate accumulation of misfolded tau aggregates, resulting in early and exacerbated development of typical tau pathology. We are currently analyzing whether the data support the hypothesis that TBI leads to the formation of the initial tau aggregated seeds that can spread in brain by a prion-like mechanism.

THE ULTRASTRUCTURAL CORTICAL PATHOLOGY OF ADULT P301S TAU TRANSGENIC MICE WITH NEUROFIBRILLARY PATHOLOGY

K. Dikranian[1], F. Stewart[2], M. Levy[3], K. Yanamandra[2], D.M. Holtzman[2]
[1]Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, USA
[2]Neurology, Washington University School of Medicine, St. Louis, USA
[3]Cell Biology and Physiology, Washington University School of Medicine, St. Louis, USA

A classic hallmark of Alzheimer's disease (AD) is the accumulation of neurofibrillary tangles in neurons. Tauopathies are a heterogeneous group of dementias sharing a common feature, aberrant tau metabolism and tau aggregation. The most prevalent tauopathy is AD. While many transgenic (tg) animals that develop Aβ deposition have been studied at the ultrastructural (EM) level, there are relatively few systematic and comparative EM studies on tg animals with aberrant tau metabolism. Here we present a detailed study on adult P301S heterozygous tg mice and compare our EM data to tg animal models with Aβ-related pathology and prototypic taopathy. The characteristic axonal pathology observed in the hippocampus, piriform/amygdala as well as in white matter tracts was similar to that seen in APP tg animals, single tg (tau) and double (APP/tau) tg mice. Specific 12-20 nm tangle like filaments were observed in neuronal somata, dendrites, myelinated, non-myelinated axons and postsynaptic sites in tau tg mice. Neurons showing signs of non-apoptotic (necrotic) cell degeneration were often encountered while apoptotic cell death was relatively rare. Nevertheless apoptotic cells presented classic EM features of programmed cell death similar to that observed in tg mice with Aβ deposition. Compared to other APP tg models a characteristic feature of astrogliosis in P301S tau tg animals was the abundance of intracytoplasmic intermediate filaments in hypertrophic cell processes, and was similar to results observed in P301L tg mice. However, in P301S tg animals astrocytic hypertrophy was accompanied by phagocytosis of axonal debris.

ADPD5-0826

EXPRESSION OF A TAU FRAGMENT ASSOCIATED WITH TAUOPATHY INDUCES MOTOR AND COGNITIVE DEFICITS IN TRANSGENIC MICE

M.K. Bondulich[1], T. Guo[1], C. Meehan[1], W. Noble[1], J. Mitchell[1], D.P. Hanger[1]
[1]Department of Basic and Clinical Neuroscience,
Institute of Psychiatry Psychology and Neuroscience, London, United Kingdom

Objectives: Tauopathies are characterised by highly phosphorylated aggregated forms of tau, including truncated tau, associated with neuronal loss and cognitive decline. We have generated a transgenic mouse expressing a specific N-terminally cleaved fragment of human tau (Tau35). This form of tau was identified in tauopathies containing deposits of predominantly four repeat tau isoforms, but is absent from tauopathies containing mainly three repeat tau isoforms. We hypothesise that Tau35 triggers tau aggregation, leading to cellular dysfunction and cognitive impairment in transgenic mice.
Materials and Methods: *Tau35 e*xpression was assessed using RT-PCR and on western blots. The behaviour of the Tau35 mice was examined using motor and cognitive assessment tests. Pathology was identified by immunohistochemistry using a range of tau and conformational antibodies. Muscle morphology was assessed using hematoxylin and eosin staining.
Results: Tau35 mice express low levels of the transgenically expressed tau fragment, which comprises approximately 10% of total tau in these animals. Tau35 mice exhibit phenotypic abnormalities of clasping and kyphosis, reduced lifespan, and early motor deficits, followed by neuromuscular impairment and cognitive decline. Abnormal tau immuno-reactivity in the hippocampus is evident inTau35 mice from 8 months of age.
Conclusion: The relatively low expression of a disease-related tau species in Tau35 mice distinguishes these animals from over-expression of wild-type or mutant human tau in most existing tauopathy mice. Our results showcase Tau35 mice as a novel *in vivo* model in which a tauopathy-associated tau fragment causes motor, cognitive and pathological changes in the brain that parallel those seen in human disease.

ADPD5-0943

INVESTIGATING ABERRANT HYPERPHOSPHORYLATED TAU IN THE LOCUS COERULEUS

T. Chalermpalanupap[1], C. Jerome[2], T.X. Chen[3], M.G. Tansey[3], L.C. Walker[4], A.I. Levey[5], D. Weinshenker[2]
[1]Neuroscience Program, Emory University, Atlanta, USA
[2]Dept of Human Genetics, Emory University, Atlanta, USA
[3]Dept of Physiology, Emory University, Atlanta, USA
[4]Dept of Neurology, Yerkes National Primate Research Center, Atlanta, USA
[5]Dept of Neurology, Emory University, Atlanta, USA

Objective: Recent studies suggest that hyperphosphorylated tau aggregates (or pre-tangle tau) may develop first in the locus coeruleus (LC), the brainstem noradrenergic nucleus that supplies norepinephrine to the forebrain and degenerates in AD, long before other pathologies associated with AD begin to appear in the rest of the brain. In conjunction with studies demonstrating the prion-like ability of aberrant tau to spread from one cell or one brain region to another, these findings have motivated us to study the consequences of hyperphosphorylated tau in the LC. Utilizing a mutant form of human tau (P301S) that is prone to hyperphosphorylation and aggregation, we have developed tools to study both its impact on LC neuron function and survival, as well as its spread from the LC to the forebrain.
Methods: Primary cell culture. Bacterial artificial chromosome transgenic mice.
Results: By crossing mice expressing green fluorescent protein driven by the tyrosine hydroxylase promoter with mice expressing P301S tau, we have successfully isolated and cultured primary LC neurons expressing aberrant tau to study their susceptibility to toxic challenges associated with AD *in vitro*. In addition, we have created a transgenic mouse that expresses aberrant hyperphosphorylated tau selectively in the LC.Using a bacterial artificial chromosome harboring the noradrenergic-specific dopamine beta-hydroxylase gene to express P301S tau.
Conclusions: These *in vitro*/*in vivo* models will allow us to assess the effect of aberrant hyperphosphorylated tau on LC neuron function and survival, as well as its pathogenic spread from the LC to other areas of the brain.

08a. Animal Models: transgenic mice

ADPD5-1208

BEHAVIOURAL COMPARISON OF TAU TRANSGENIC MOUSE LINES DIFFERENTIATES ALZHEIMER AND FTD PHENOTYPES

P.H. Moreau[1], D. Mccall[1], V. Melis[1], C.R. Harrington[2], C.M. Wischik[2], B. Platt[3], G. Riedel[1]
[1]Institute of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom
[2]School of Medicine and Dentistry, University of Aberdeen, Aberdeen, United Kingdom
[3]School of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom

Tauopathy patients show different symptoms including a progressive cognitive decline frequently associated with Alzheimer's disease (AD) and motor and emotional/psychiatric abnormalities with Fronto-Temporal Dementia (FTD). Moreover, genetic mutations are only confirmed for FTD, but not for AD. This suggests that different genetic mouse lines could mimic different forms of tauopathies. We here compare 4 tau transgenic lines in tasks that interrogate core-features of tau-related dementias (cognition, anxiety, anhedonia, circadian activity). Included are the NMRI-derived Line1 and Line66 over-expressing a tau fragment or 301S mutated tau constructs under Thy1 control (Melis et al., 2014, CMLS in press) and C57/Bl6 derived $PLB2_{Tau}$ mice with a knock-in of a full-length 301L/406W mutant Tau gene, as well as $PLB1_{Triple}$ mice (Ryan et al., 2013, CLMS 70:2603) with mutant tau and APP and presenilin expressed under the CamKIIa regulatory element. Female mice were 5-7 months of age. Behavioural results were dependent on background strain and gene construct. Relative to controls expressing high preference for novel objects/social partners rather than familiar ones, Line 1 mice had no recognition bias and Line 66 showed signs of neophobia by preferring familiar objects. In addition, anxiety and sucrose preference was lower only in Line 66 mice, and $PLB1_{Triples}$ were hyperactive. No other phenotypes were significant. These data suggest that low and localised expression of mutant tau in PLB mice at 7 months did not lead to severe phenotypes; in contrast Line 1 showed deficits consistent with AD and Line 66 with symptoms of FTD.

ADPD5-1341

EXAMINATION OF AN IMMUNE DEFICIENT TAU TRANSGENIC MODEL IMPLICATES THE ADAPTIVE IMMUNE SYSTEM IN NEUROFIBRILLARY TANGLE PATHOGENESIS

W. Chen[1], J. Wang[1], B. Thummar[1], A. Park[1], D. Blum[2], L. Buée[2], M. Blurton-Jones[1]
[1]Neurobiology and Behavior, University of California Irvine, Irvine, USA
[2]Neurodegeneration and Restorative Research, University of Lille, Villeneuve-d'Ascq, France

Objectives:

A number of studies have shown that tau pathology can be influenced by microglia- and astrocytes-derived inflammatory signals. While these studies implicate the innate immune system in neurofibrillary tangle (NFT) pathology, there remains little data regarding the potential role of the adaptive immune system in tauopathy. To study the influence of T-, B-, and NK-cells in tau pathogenesis, we generated and examined an immune-deficient tau transgenic model.

Methods:

A well-established tau transgenic model (Thy-Tau22) was backcrossed onto a Rag2-/- il2rgamma -/- double knockout background to produce tau transgenic that lack T-, B-, and NK-cells (Rag-Tau22 mice). These mice were then compared to immune-intact tau transgenics to determine the effects of peripheral immune cell depletion on pathogenesis and cognitive dysfunction. Given the growing interest in stem cell transplantation for neurodegenerative disorders, we used these mice to examine the effects of tau pathogenesis on human neural stem cell engraftment, migration, and differentiation.

Results:

Rag-Tau22 mice lack B-cells, T-cells, and NK-cells, but otherwise appear normal and healthy. Our results suggest however that the deletion of these peripheral immune cells dramatically increases tau hyper-phosphorylation and accumulation and exacerbates behavioral dysfunction. We have also found that Human neural stem cells transplanted into RagTau22 mice can survive for at least 3 months and exhibit distinct migration and differentiation phenotypes.

Conclusions:

Thus far our studies suggest that Rag-Tau22 mice could provide a promising new approach to examine the role of the peripheral immune system in tau pathogenesis and the long-term effects of human stem cell xenotransplantation.

08a. Animal Models: transgenic mice

ADPD5-1353

NEUROINFLAMMATION AND COGNITIVE DECLINE IN A NOVEL TRANSGENIC MOUSE MODEL EXPRESSING A RARE TAU MUTATION A152T.

A. Sydow[1], K. Hochgräfe[1], S. Könen[1], D. Cadinu[1], D. Matenia[1], O. Petrova[1], E.M. Mandelkow[1]

[1]Neurodegenerative Diseases,

(1) German Center for Neurodegenerative Diseases (DZNE) (2) CAESAR Research Cen ter (3) Max-Planck-Institute for Metabolism Research Hamburg Outstation, Bonn, Germany

Objectives:

Various Tau-mutations are associated with neurodegenerative disorders. Recently, a rare Tau mutation (A152T) has been described as a novel risk factor for frontotemporal dementia spectrum disorders and Alzheimer's disease. Tau A152T shows a decreased binding to microtubules and reduced tendency to form abnormal fibers (Coppola et al., HumMolGen 2012).

Methods:

To investigate molecular mechanisms of genetically provoked tauopathies, we have generated a novel transgenic mouse model expressing human full-length Tau with a rare mutation A152T (hTau40/A152T) under the control of the neuron-specific Thy1.2-promoter.

Results:

Immunohistological analysis of young hTau40/A152T mice demonstrated the presence of pathological Tau conformation (MC1) and Tau hyperphosphorylation (PHF1, AT8) combined with Tau missorting. Tau-aggregates detected by Gallyas silver staining and sarcosyl-extraction indicate a progressive co-aggregation of endogenous mouse Tau and exogenous human Tau. Old hTau40/A152T mice show a prominent neuroinflammation in response to hTau40/A152T accumulation. To monitor and quantify neuroinflammatory changes in living Tau transgenic animals, we crossbred hTau40/A152T and GFAP-luciferase reporter mice and confirmed the age-related activation of astrocytes by in vivo bioluminescence imaging (BLI). In contrast to other Tau-transgenic models with reduced protein clearance, hTau40/A152T mice show a strong induction of autophagy. Although hTau40/A152T mice develop Tau pathology in spinal cord and motor cortex, their neuromotor performance was unaffected. Importantly, impaired spatial reference memory manifest in hTau40/A152T mice at the age of ~16 months and is accompanied by neuronal loss.

Conclusions:

The hTau40/A152T mouse model mimics pathological hallmarks of tauopathies and offers the potential to evaluate new therapeutic strategies against Tau-induced neurodegeneration.

ADPD5-1954

AMELIORATION OF SPATIAL PROBLEM-SOLVING COGNITIVE DEFICIT IN TAU TRANSGENIC MICE BY TREATMENT WITH THREE TAU-AGGREGATION INHIBITORS

V. Melis[1], P.H. Moreau[1], C.R. Harrington[1], C.M. Wischik[1], G. Riedel[2]
[1]School of Medicine and Dentistry, University of Aberdeen, Aberdeen, United Kingdom
[2]School of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom

The abnormal folding and aggregation of the microtubule-binding protein tau is a key pathogenic hallmark in Alzheimer's disease (AD) and other neurodegenerative disorders, collectively named tauopathies. AD represents a major socioeconomic problem for which more effective therapies are required. In particular, compounds aimed to prevent and/or inhibit accumulation of tau aggregates hold considerable promise for the treatment of tau-related neurodegenerative diseases.

This study examined the effect of three tau-aggregation inhibitors (TAIs) in Line 1 mice, a novel model of tauopathy, in which a truncated fragment of human tau (AA 296-390) is overexpressed. Line 1 mice present with an age-dependent histopathological phenotype and are characterized by cognitive impairments revealed in a spatial problem-solving water maze (WM) task.

Methylthioninium (MT) acts as an inhibitor of tau aggregation in vitro and in vivo whether administered as chloride salt (MTC) or in the reduced leucoMT form (LMTX®). LMTX® is now been investigated in a phase 3 programme. The activity of MTC, LMTX® and a third diaminophenothiazine, ETN, have been compared in 5-months old line 1 mice.

Mice treated orally with one of the three compounds, were assessed in the spatial problem-solving WM test. All drugs were able to ameliorate the spatial deficits in Line 1 with ETN presenting efficacy already at the dose of 5 mg/kg. These findings support the use of TAIs other than MT as a disease-modifying treatment for AD and tauopathies.

[4]Faculty of Medicine, University of New South Wales and Neuroscience Research Australia, Sydney, Australia

Objectives

Frontotemporal Lobar Degeneration (FTLD) is one of the most common causes of early-onset dementia, and approximately 50% of cases are pathologically characterised by inclusions consisting of abnormally phosphorylated tau. Transgenic mice that express human tau carrying a mutation associated with FTLD are commonly used to investigate this disorder. In this study, we characterised a novel tau-transgenic mouse line, known as TAU58/2, which expresses human tau carrying the P301S mutation.

Methods

The motor phenotype of young and aged TAU58/2 mice was assessed using the Rota Rod and vertical pole test. Brain tissue was analysed with immunohistochemistry and silver staining. Tissue from various subtypes of FTLD, Alzheimer's disease and control patients was analysed for comparison.

Results

TAU58/2 mice showed early-onset and progressive motor deficits. Pathological hyperphosphorylation of tau was found throughout the brain resulting in increased neurofibrillary tangle formation with age. Gliosis was also observed in regions associated with pathological tau deposition, with activated microglia in close proximity to neurons harboring tau-positive inclusions. Interestingly, neurofilament-positive axonal swellings were seen in the TAU58/2 brain, prior to any substantial tangle formation, but coinciding with the onset of motor deficits. Similar neurofilament-positive pathology was also observed in human FTLD-tau and Alzheimer's disease brain tissue, but not FTLD with TDP-43 inclusions or controls. Together, this may suggest a role for neurofilament in mediating tau toxicity.

Conclusion

TAU58/2 mice recapitulate behavioural and pathological aspects of human FTLD-tau, making this an excellent model for studying the underlying pathological mechanisms, and for testing therapeutics in the future.

08b. Animal Models: transgenic rats

ADPD5-0827

NOVEL APPROACH FOR TESTING OF SENSORIMOTOR DYSFUNCTION IN TRANSGENIC RAT MODEL OF ALZHEIMER´S DISEASE BY FULLY AUTOMATED SYSTEM

I. Zimová[1], S. Katina[2], V. Cubínková[1], B. Valachová[1], N. Áilka[1], M. Novák[1]
[1]Neuroscience, Institute of Neuroimmunology Slovak Academy of Sciences, Bratislava, Slovakia
[2]Neuroscience, Axon Neuroscience, Bratislava, Slovakia

Objectives

Alzheimer´s disease (AD) is the most common neurodegenerative disorder characterized by memory impairment. The aim of the study was to set up the comprehensive testing method, which would provide quantitative reflection of sensorimotor alteration, would be sensitive enough to record early clinical symptoms and would have a high-throughput format.

Material and methods

In present study were used transgenic rat line SHR 72 and non-transgenic SHR age-matched controls. Testing was performed in two consecutive days in 3 timelines (3, 5, 6 months of the age of experimental animals). In each timeline three repetitions of correct trials were performed. For testing was used CatWalk XT A system for quantitative assessment of sensorimotor function in rodents.

Results

We observed measurable progressive decline of sensorimotor function in transgenic rats. From the total number of 63 variables we selected 26 in category „dynamic variables“, 4 in category „static variables“ and 5 in category „general run variables“. Early changed (in timeline – 3 months) were variables : Run duration, Stand, Stand Index, Contact area, Swing phase and Step cycle. Variables changed in late phase of experiment (timeline 5 and 6 months) were: Initial dual stance, Intensity and Regularity Index.

Conclusion

Hereby, we demonstrate novel approach for testing of sensorimotor deficits of animal models of AD, which is sensitive enough to detect even early changed symptoms without subjective influence of researcher. Acknowledgement This work was supported by research grant APVV-0200-11. ;

Characterization of time-dependent changes in cognitive function observed in non-human primates (NHP) following hippocampal injection of adeno-associated viral (AAV) vectors overexpressing two forms of human Tau protein.
We recently demonstrated the ability of lentiviral vectors encoding Tau proteins to generate genetic models of tauopathies in rodents. These data stimulated the development of a similar model in NHP that allows for the preclinical exploration of functional deficits and offers additional opportunities for translational evaluation of innovative therapies.
Stereotaxic injections of AAVs were performed under preoperative MRI guidance in 12 adult males *Macaca fascicularis*. These NHPs were injected bilaterally into the hippocampal CA1 region with AAV2/9 vectors bearing a CBA promoter and overexpressing either the WT hTau46 (n=4), the hTau46 P301L mutated form of Tau (n=4) or a null GFP (n=4) where the reporter gene was not translated. All NHP were trained to perform a cognitive battery on tactile screens before and at 4, 8, and 12 months post-injection (p.i.) looking at performances in working memory, spatial memory and executive function.
Results suggest that overexpressing either WT hTau46 or hTau46 P301L in CA1 is sufficient to induce a cognitive deficit as early as 4 months p.i. that stabilizes at 8 months p.i. These NHPs showed no deficit in a visual discrimination task at 8 and 12 months p.i. suggesting the specificity of the impairment observed in spatial and recognition memory and executive functions.
These NHP models of sporadic or inherited tauopathies hold great promise for further investigation of novel therapeutic strategies.

[3]Department of Clinical Neurosciences (DNC), Lausanne University Hospital (CHUV), Lausanne, Switzerland

Objectives: Histological characterization of non-human primate (NHP) models of sporadic and inherited tauopathies induced by hippocampal injections of various forms of human Tau proteins overexpressed by adeno-associated viral (AAV) vectors.

Background: We recently showed the feasibility of generating genetic models of tauopathies in rodents using lentiviral vector-mediated gene transfer. These data supported the development of a NHP model offering additional opportunities for the validation of imaging and biochemical biomarkers and the exploration of innovative therapies.

Methods: 14 adult male *Macaca fascicularis* received bilateral stereotaxic injections of AAV2/9 vectors bearing a CBA promoter and overexpressing either the WT hTau46 (n=5), the hTau46 P301L mutated form of Tau (n=5) or a null GFP (n=4) into the hippocampus (CA1). CSF and plasma samples were collected at 3, 5, 7 and 12 months post-injection (p.i.). Animals were sacrificed at 3 or 12 months p.i.

Results: Brain examination showed that both constructs led to tau hyperphosphorylation (AT8) and changes in tau conformation (MC1) in the hippocampus and connected cerebral regions as early as 3 months p.i. A further progression of the pathology (AT100 staining) was observed at 12 months p.i. in both WT hTau46 and hTau46 P301L injected NHPs.

Conclusions: This NHP model recapitulates the progression of lesions and the typical pathological features observed in various human tauopathies, holding great promise for further investigation of peripheral biomarkers as well as novel therapies.

PET imaging characterization of metabolic and inflammatory dysfunctions in two non-human primate models (NHP) of progressive tauopathies.

Tauopathy is correlated with progressive brain hypometabolism, and neuroinflammation has been identified as a key player in the pathology of the disease.

8 NHP, bilaterally injected into the CA1 hippocampal region with a viral vector (AAV2/9-CBA) overexpressing either WT hTau46 (n=4) or mutated hTau46 P301L (n=4), and 4 healthy controls underwent ^{18}F-FDG and ^{18}F-DPA714 PET imaging (FOCUS220, Siemens). Blood samples were withdrawn to measure the arterial input function and metabolite correction was performed for ^{18}F-DPA714. PET images were coregistered to corresponding MR-images and quantified using Patlak and Logan for ^{18}F-FDG and ^{18}F-DPA714 respectively. WT and mutated hTau46 groups were individually compared to healthy controls.

Segmentation of the hippocampus and its projection areas did not reveal any macroscopical atrophy as compared to controls. The mean CMRglu map of the mutated hTau46 group showed a strong pattern of hypometabolism in the parieto-temporal cortical region compared to controls, which did not reach significance due to one NHP. Hypometabolism was less present in the WT hTau46 group, and only in the parietal cortex. TSPO binding showed a global increase in parieto-temporal regions in the mutated hTau46 group ($p<0.05$), but not in the WT hTau46 model. The cerebellum remained unchanged in glucose metabolism and TSPO binding in both WT and mutated hTau46 groups.

These models of tauopathy will be used as a tool to screen in vivo new radioligands presumably specific for hyperphosphorylated tau and/or tau aggregates.

DETECTION OF SOLUBLE AMYLOID BETA AND TAU PROTEINS IN THE INTERSTITIAL FLUID OF NON-HUMAN PRIMATES BY IN VIVO MICRODIALYSIS

G. Flik[1], A. Rassoulpour[2], M. Van Gaalen[3], J. Sutcliff[3], C. Schlumbohm[3], J. Folgering[3], T. Cremers[1]

[1]Neuropharmacology, Brains On-Line, Groningen, Netherlands

[2]Neuropharmacology, Brains On-Line, San Francisco, USA

[3]Neuropharmacology, Encepharm, Gottingen, Germany

Alzheimer's disease (AD) is the most common cause of age-related cognitive decline. Amyloid plaques of which amyloid is the main component and neurofibrillary tangles consisting of fibrillar tau aggregates are both hallmarks of Alzheimer's disease. Much attention has focused on the soluble forms of amyloid and tau proteins that are released by cells and can be found in the interstitial fluid (ISF). These soluble forms of the proteins are hypothesized to have a biological role on their own, and, in addition, contribute to the pathophysiology of AD. Previous work using in vivo microdialysis of the rodent brain has demonstrated the ability to detect the soluble forms of these proteins in mouse ISF as well as to modulate their levels in the CNS (Cirrito el al, 2003). In the current study we utilized push-pull microdialysis in the hippocampus and prefrontal cortex of 4-5 year old cynomologous monkeys to measure $A\beta_{42}$ and total-Tau protein in the ISF. In addition, $A\beta_{42}$ and total-Tau proteins were measured in the CSF and plasma of the same animals. We found that both $A\beta_{42}$ and total-Tau protein can be detected in the ISF from the cynomologous monkey. Studies are underway to further examine these proteins in response to pharmacological manipulation and to compare with the effects seen in rodents. Taken together with future pharmacological data in multiple species and compartments, this data may provide greater insight into the utility of in vivo microdialysis evaluation of pathogenic proteins as an impactful translational method in neurological disease drug discovery.

IMPAIRED RETROGRADE TRANSPORT BY THE DYNEIN/DYNACTIN COMPLEX CONTRIBUTES TO TAU-INDUCED TOXICITY

A. Voigt[1], M. Butzlaff[1], T. Rasse[2], J.B. Schulz[1]
[1]Neurology, RWTH Aachen University, Aachen, Germany
[2]Department of Synaptic Plasticity, Hertie-
Institute for Clinical Brain Research University of Tübingen, Tübingen, Germany

The R406W amino acid substitution in Tau is associated with Frontotemporal Dementia with Parkinsonism linked to chromosome 17 (FTDP-17) characterized by Tau-positive filamentous inclusions. These filamentous Tau-inclusions are present in a group of neurodegenerative diseases known as tauopathies, including Alzheimer's disease (AD). To gain more insight into the pathomechanism of tauopathies, we performed an RNAi-based large-scale screen in *Drosophila* to identify genetic modifiers of Tau[R406W]-induced toxicity. We screened a collection of fly lines, putatively silencing more than 7000 *Drosophila* genes using RNAi for their ability to modify Tau[R406W]-induced toxicity. This collection covers more than 50% of all protein coding fly genes and over 90% of all fly genes known to have a human ortholog. In summary, we identified 62 genes that, when silenced by RNAi, specifically modify Tau-induced toxicity. Among these modifiers were three subunits of the Dynein/Dynactin complex. Analysis on segmental nerves showed that pan-neuronal Tau[R406W] expression and concomitant silencing of Dynein/Dynactin complex member synergistically caused strong pathological changes within the axonal compartment, characterized by axonal inclusions, but only minor changes at synapses. These alterations did not cause locomotion deficits at larval stage, but manifested in adult flies. Thus our data suggest that Tau-induced detrimental effects originate from axonal rather than synaptic dysfunction. In conclusion, our findings suggest an important role of the Dynein/Dynactin complex in the pathomechanism in Tauopathies like FTDP-17 or AD.

PHOSPHORYLATED TAU AFFECTS SUNDOWNING SLEEP BEHAVIOUR IN A DROSOPHILA TAUOPATHY MODEL

T.K. Karikari[1], S. Crighton[1], R. Osgood[1], K.G. Moffat[1]
[1]School of Life Sciences, University of Warwick, Coventry, United Kingdom

Objectives

Sleep disturbance is often considered as a major risk factor in Alzheimer's and Parkinson's diseases (AD and PD); studies have linked poor sleep with both pathologies, monitoring the amyloid beta peptide (Aβ) levels in cerebrospinal fluid and brain deposits. The mechanisms underlying this possible linkage are not clear. *Drosophila* has been used to model toxicity of AD and PD aggregation. Recently, *Drosophila* has been used also to study sleep-like behaviours. Here we aimed to establish experiments to determine the effects of hyper-phosphorylated tau on sleep-like behaviours in the fly.

Methods

We expressed human 0N4R tau in combination with tau kinases in the circadian network of the fly brain. F1 progeny flies carrying the G1118GAL4 driver with or without both tau and BRSK2 were monitored for sleep-like behaviours over a seven-day period in Activity Monitors. PySolo and BeFly were used to analyse the amount, timing and duration of sleep-like episodes.

Results

Following birth, flies expressing hyper-phosphorylated tau showed sleep like defects at the beginning of evening sleep activity (zeitgeber time 13 to 14 hours). Aged flies further degenerated their sleep patterns during the daytime (zeitgeber time 0-3 hours). Additionally, aged flies showed increases in sleep-like episodes, but decreases in both the length of sleep bouts and their longest sleep-like bouts.

Conclusions

The *Drosophila* phenotypes are remarkably similar to those linking "sundowning" with dementia in humans, showing major sleep disturbances. We propose that *Drosophila* will be a good model to genetically analyse links between AD and PD toxicity and sleep defects.

GENERATION OF TAU KNOCK-OUT AND HUMAN PATHOGENIC TAU KNOCK-IN DROSOPHILA MODELS USING MIMIC TRANSPOSONS AND CRISPR/CAS9

J. McInnes[1], L. Zhou[1], S. Vilain[1], P. Verstreken[1]
[1]Center for the Biology of Disease Laboratory of Neuronal Communication, VIB-KU Leuven, Leuven, Belgium

Objectives: Abnormal accumulation of Tau has been implicated in Alzheimer's disease and more than twenty other neurodegenerative diseases. Despite its prevalence among neurodegenerative disorders, the functions of Tau in health and disease conditions remain widely elusive. We sought out to generate novel genetic models of *Drosophila melanogaster* to study the endogenous function of Tau as well as the molecular mechanisms underlying Tau-induced neuronal dysfunction and degeneration.
Methods: To generate a Tau loss-of-function model, we utilized a novel knock-out method whereby we took advantage of the vast collection of MiMIC transposon insertions in the *Drosophila* genome to insert a gene disrupting cassette. To study pathogenic Tau function, we knocked-in human wild-type and FTDP-17 clinical mutant coding sequences into the endogenous *Drosophila tau* locus. We first utilized the CRISPR/Cas9 system to replace the first exon of *Drosophila tau* with a cassette flanked by *attP* sites. In a second transformation step, we used PhiC31 integrase-mediated recombination to introduce cDNA sequences encoding human wild-type or mutant Tau, flanked by the endogenous 5' and 3' UTRs from the *Drosophila tau* transcript.
Results: Using MiMIC transposon and CRISPR/Cas9 technology, we successfully generated a Tau knock-out fly, as well as knock-in models expressing wild type or pathogenic mutant forms of human Tau. All transgenic flies were verified by sequencing, and gene expression was assessed by Western blot and immunohistochemical analysis.
Conclusions: The Tau knock-out and knock-in *Drosophila* models will serve as a powerful platform to study the physiological and pathological roles of Tau *in vivo*.

HYPOTHERMIA IN VIVO – AN ACUTE MODEL OF TAU HYPERPHOSPHORYLATION
C. Schweinzer[1], D. Havas[1], E. Auer[1], M. Farcher[1], B. Hutter-Paier[1]
[1]Neuropharmacology, QPS Austria GmbH, Grambach, Austria
Objectives
Enhanced and abnormal phosphorylation of the microtubule-associated protein Tau plays a major role in many neurodegenerative diseases, known as tauopathies. Recent evidence discloses the contribution of anesthesia-induced hypothermia in Tau hyperphosphorylation as novel, non-genetic and non-aging trigger [1]. Since Tau presents a promising therapeutic target, an acute, inducible model of Tau phosphorylation is a useful tool for studying central nervous system drug effects.
Methods
Wildtype C57BL6/J mice received either pentobarbital or vehicle under normo- or hypothermic conditions. Body temperature was evaluated every 5 minutes after treatment for a period of 30 minutes. Afterwards, brains were collected and histological and biochemical evaluations of total Tau and its phosphorylated species were performed. Additionally, cerebral pGSK3 beta, amyloid beta and alpha synuclein levels were investigated.
RESULTS
Pentobarbital induces hypothermia in mice and triggers hyperphosphorylation of different Tau sites which is attributable to enhanced GSK3beta activity. While total Tau levels remain unaltered under hypothermic conditions, amyloid beta levels in mice are significantly enhanced in contrast to unaltered alpha synuclein levels.
Conclusions
Pentobarbital induces hypothermia and Tau hyperphosphorylation in wildtype mice. Amyloid beta production is also induced under hypothermic conditions whereas alpha synuclein levels stay constant. Pentobarbital and hypothermia in wildtype mice are able to mimic pathogenic events of neurodegenerative diseases and are thus a useful non-genetic, acute model to study CNS drug mechanisms.
1. Maurin, H., et al., *Terminal hypothermic Tau.P301L mice have increased Tau phosphorylation independently of glycogen synthase kinase 3alpha/beta.* Eur J Neurosci, 2014. **40**(2): p. 2442-53.

UNIQUE NEUROPROTECTIVE TAU ISOFORMS AND PROCESSING IN THE NAKED MOLE-RAT NERVOUS SYSTEM

M.E. Orr[1], R. Buffenstein[1]
[1]Physiology, University of Texas Health Science Center, San Antonio, USA

The microtubule associated protein tau is predominantly expressed in neuronal axons and functions to stabilize microtubules. Disregulated tau phosphorylation, folding, cleavage and/or cellular distribution coincide with neurodegeneration in numerous disorders including Alzheimer's disease. While such findings engendered the widely accepted dogma for pathogenic tau processing, commonly encountered environmental changes induce similar changes in tau but without toxic consequence.

Objective: Test the hypothesis that tau phenoplasticity is primarily a reversible neuroprotective response to homeostatic disruptions.

Methods: We exploit a rodent exceptionally suited to study physiological extremes, the naked mole-rat (NMR). These mammals naturally tolerate stressors known to alter tau metabolism including hypoxia, body temperature fluctuations (15°C - 40°C), reproductive/social status changes, development and aging (maximum lifespan 32 years). We conduct histological, biochemical and molecular assessments on neural tissue from NMRs collected during normal aging and altered environmental settings.

Results: NMRs express central and peripheral nervous system tau isoforms distinct from humans and mice, though highly similar in sequence (95% identical to human). NMR tau undergoes significant changes in expression (level and isoform), phosphorylation and subcellular distribution dependent on age, social status, body temperature and toxin exposure. Remarkably, these processes are generally reversible. Overall our data suggest that tau's exceptional sensitivity to perturbations in life stages and environmental situations are healthy physiological responses. NMRs may have naturally evolved neuroprotective mechanisms in tau metabolism to preserve neuronal function and stability in extreme living conditions, and similar processes may translate to other mammals and offer new molecular targets for neuroprotection especially in tau-associated diseases.

Heparan sulfate 3-*O*-sulfotransferase-2 (HS3ST2 or 3OST2) is an enzyme predominantly expressed in neurons of some brain regions in where it generates rare 3-*O*-sulfated domains in heparan sulfates (HS). While HS persist at the cell membrane in normal brain, in Alzheimer's disease (AD) they accumulate at the intracellular level, in where they co-localize with the neurofibrillary pathology.

Objectives: We aimed to investigate whether 3OST2, and its 3-*O*-sulfated HS products, are involved in the mechanisms leading to the abnormal phosphorylation of tau.

Methods: We used two cells models and a zebrafish model of tauopathy (hTauP301L) combined with *in vitro* phosphorylation reactions, Western blot, FRET, ELISA assays, confocal microscopy, and gene silencing. Additionally, 3OST2 transcripts levels were analysed in AD brains.

Results: In cells, we show that under pathologic conditions 3-*O*-sulfated HS are internalized, co-localize with tau and favour its hyperphosphorylation, but not that of p38 or NF-kB(p65). *In vitro*, 3-*O*-sulfated HS bond to tau, but not to GSK3b, PKA or PP2A, inducing the tau abnormal phosphorylation. In zebrafish (hTauP301L), we demonstrated that inhibiting *3ost2* expression results in a strong inhibition of several abnormally phosphorylated tau epitopes in brain and in spinal cord, leading to a complete recovery of motor neuronal axons length and animal motor response to touching stimuli.

Conclusion: Upon binding to tau at the intracellular level, 3-*O*-sulfated HS produced by 3OST2 might act as tau molecular chaperons favouring its pathologic phosphorylation by different kinases. This opens a new route in the understanding of the disease mechanisms with forthcoming therapeutic possibilities.

[2]PATHOLOGY POST-GRADUATION PROGRAM, UFCSPA, Porto Alegre, Brazil

[3]PATHOLOGY LABORATORY, UFCSPA, Porto Alegre, Brazil

[4]BASIC SCIENCE, UFCSPA, Porto Alegre, Brazil

Objectives: We aimed to evaluate the presence and amount of protein deposit throughout the brainstem of donated brains from people with and without clinical dementia.

Methods: The samples were collected by convenience and with the informed consent of first-degree relatives. Fourteen brains were collected from individuals 50 years old or older who underwent death verification in the Forensics Department (FD) of Porto Alegre. We analyzed the brainstem and olfactory bulb by H&E stain and immunohistochemical techniques to AT8, beta-amyloid and alfa-synuclein.

Results: Of the 14 brains collected in this study, the tau protein was found in the brainstems of 10 (71.42%). Of the 7 individuals who had a final diagnosis of Alzheimer's disease (AD), 6 presented tau deposits in some region of the brainstem.

Conclusions: Protein deposits can pre-date the symptomatic phases of neurodegenerative diseases by years. The tau protein is particularly interesting: it might be found in the brainstem and olfactory bulb long before it reaches the limbic cortex, at which point symptoms occur.

ADPD5-0283
EVALUATION OF HIGHER CORTICAL FUNCTIONS OF SENILE DEMENTIA OF ALZHEIMER'S TYPE.
D. Tolibov[1], G.S. Rakhimbaeva[1]
[1]Neurology department, Tashkent Medical Academy, Tashkent, Uzbekistan
Purpose. Evaluate the effectiveness of diagnostic disorders of higher cortical functions in patients with senile dementia of the Alzheimer's type using scales GDR (Global Deterioration Rating) and MMSE (Mini Mental Scale Examination).
Material and methods. Study involved 42 patients (22 men and 20 women) aged 65 to 77 years (mean age 70,8 ± 3,3 years) divided into 2 groups: group 1 (basic group) - senile dementia of Alzheimer's type - 35 patients, group 2 (comparison group) - 27 patients with chronic cerebral ischemia (II- IIIst.) with mild cognitive impairment. GDR and MMSEwereused for assessing the severity of cognitive impairment.
Results. These neuropsychological studies indicate the results of cognitive functions: in group I - GDR 5,0 ± 0,5 scores, MMSE 21,8 ± 4,05 scores. In group II - GDR 2,0 ± 0,5 scores, MMSE 27,0 ± 0,5 scores. Senile dementia develops in commonly characterized by a relatively sparse confabulation products. Confabulation shifted to a more or less distant past ideas about the environmental situation and the self (ekmnestic confabulation). At the stage of mild dementia clearly identified the most features of amnestic aphasia, amnestic disorder component of praxis, and in some cases, signs of constructive dyspraxia. There is a long preservation of motor component of praxis.
Conclusions. The total scores on the MMSE and the GDR is a sensitive indicator of cognitive deficits and higher cortical functions of mild to moderate dementia of the Alzheimer's type before, is effective in determining therapeutic approaches and tactics of early prevention in patients with dementia of the Alzheimer type.

ADPD5-0290

BEHAVIOURAL VARIANT OF FTD WITH TEMPORAL PREDOMINANT DEGENERATION: A UNIQUE CLINICOPATHOLOGICAL SYNDROME MOSTLY UNDERLINED BY TAU PATHOLOGY

V. Deramecourt[1], S. Tolner[1], F. Lebert[1], C.A. Maurage[2], F. Pasquier[1]
[1]Memory Clinic, CHRU Lille & Univ. Lille Nord-de-France UDSL, LILLE, France
[2]Pathology department, CHRU Lille & Univ. Lille Nord-de-France UDSL, LILLE, France

Objective: The behavioural variant of frontotemporal dementia (bvFTD) is currently defined by a specific behavioural and cognitive phenotype associated with imaging results showing frontal or anterior temporal atrophy or hypometabolism. We aimed at characterizing bvFTD patients with predominant atrophy or hypometabolism in the temporal lobes. **Methods**: We constituted two groups of longitudinally followed up patients diagnosed with bvFTD according to the FTD-consortium criteria: (i) patients with predominant atrophy or hypometabolism in the temporal lobe and (ii) patients with predominant atrophy or hypometabolism in the frontal lobe. We compared the behavioural, neuropsychological, genetic and neuropathological features across the two groups. **Results:** 62 patients were included in the study period from 2001 to 2014. The median age at onset was 57y (IQR 53-63). 27 patients were included in the temporal group. 35 patients were included in the frontal group. The temporal group was characterized by less frequent apathy and dysexecutive profile, but more impaired episodic memory and semantic knowledge at onset. A definite FTD pathology was obtained in 15 patients from the temporal group: argyrophilic grains disease (n=5), *MAPT* mutation (n=5), FTLD-TDP (n=3), corticobasal degeneration (n=1) and Pick's disease (n=1). **Conclusions:** Patients presenting with a clinical diagnosis of bvFTD and temporal predominant degeneration may represent a specific syndrome within the FTD spectrum. Moreover, this syndrome seems to be predictive of underlying Tau pathology, especially argyrophilic grains disease in patients with a late onset, and *MAPT* mutations in patients with significant family history of FTD.

MOLECULAR DIVERSITY OF CEREBROSPINAL FLUID TAU INVESTIGATED USING QUANTITATIVE MASS SPECTROMETRY

N.R. Barthélemy[1], A. Gabelle[1], F. Fenaille[2], C. Hirtz[1], N. Sergeant[3], S. Schraen-Maschke[3], L. Buée[3], C. Junot[2], F. Becher[2], S. Lehmann[1]
[1]Biochimie - Protéomique Clinique, CHRU Montpellier, Montpellier, France
[2]iBiTec-S, CEA, Gif-sur-Yvette, France
[3]UMR 837, Inserm, Lille, France

Microtubule-associated tau proteins are major actors in tauopathies, and specifically in Alzheimer's disease (AD) where hyperphosphorylated forms aggregate into neurofibrillary tangles. Understanding tau molecular profile with its multiple isoforms and post-translational modifications represent an important challenge. Mass spectrometry (MS) has recently allowed protein quantification in complex biological samples like the cerebrospinal fluid (CSF). To study tau which is found in femtomolar concentrations within the CSF, we first had to develop an innovative pre-fractionation strategy, which was not dependent on immuno-enrichment. We then relied on the sensitive multiplex peptide detection capability of targeted high-resolution MS to quantify 19 tau-specific peptides covering its entire sequence. This new method was used on a clinical cohort of patients with AD, frontotemporal lombar degeneration and progressive supranuclear palsy. Interestingly, CSF tau expression profile was characterized by a predominance of central core fragments and 1N/3R isoform presence. AD was associated to a unique profile, and very specific modifications of the tau peptide stoichiometry. Taken together these results provide remarkable information on tau modifications for future therapeutic interventions, and improved molecular diagnosis of tauopathies.

CSF BIOMARKERS IN THE DIAGNOSIS OF SPORADIC AND GENETIC FORMS OF FRONTOTEMPORAL LOBAR DEGENERATION

I. Santana[1], I. Baldeiras[2], M.J. Leitão[3], M.H. Ribeiro[2], B. Santiago[1], M.R. Almeida[4], C.R. Oliveira[3]

[1]Neurology, Coimbra University Hospital, Coimbra, Portugal

[2]Neurology, Faculty of Medicine University of Coimbra, Coimbra, Portugal

[3]Neurochemistry Laboratory, Center for Neuroscience and Cell Biology, Coimbra, Portugal

[4]Neurogenetics Laboratory, Center for Neuroscience and Cell Biology, Coimbra, Portugal

Objectives: CSF biomarkers are increasingly used in the differential diagnosis of neurodegenerative dementias, however the accuracy of these markers to distinguish Frontotemporal Lobar Degeneration (FTLD) from Alzheimer's Disease (AD) is still controversial. Therefore the advantage of investigating cohorts with a definitive diagnosis (mutation carriers or with neuropathology) has been highlighted. Our goal is to evaluate the contribution of the CSF biomarkers for the differential diagnosis of AD and FTLD, considering specifically the genetic forms of FTLD.

Methods: Two large sporadic dementia groups: AD (n=120) and FTLD (n=120), along with 20 carriers of FTLD mutations (C9orf72=9; progranuline=7; MAPTAU=2; SQSTM1=4; two patients harbouring two mutations) were investigated. CSF levels of t-Tau, p-Tau, Ab42 (Innogenetics) were determined by ELISA.

Results: In sporadic cases we identified Ab42 and t-Tau as the best biomarker subset to differentiate FTLD from AD (sensitivity=79%, specificity=84%). However, the diagnostic accuracy was still sub-optimal, with a significant percentage (24%) of FTLD patients showing a CSF-AD biomarkers profile. These FTLD patients were more likely to be women, ApoE-e4 carriers and of the PNFA clinical subtype. Considering the genetic forms of FTLD, two cases of familiar forms with progranuline mutations also presented a CSF-AD biomarker profile, although this pattern was absent in other affected members.

Conclusions: A CSF-AD biomarker profile can be seen in patients with a clinical phenotype of FTLD as well as in pathogenic mutation carriers (definitive diagnosis), reinforcing the need for the identification of new biomarkers, namely targeted at ubiquitinated-protein inclusions founded in neurons FTLD patients.

A NEUROIMAGING RATING SCALE TO ENHANCE THE INTER-RATER RELIABILITY AND DIAGNOSTIC VALIDITY OF HUMMINGBIRD SIGN

Y.E. Kim[1], S. Kang[2], H. Ma[1], Y. Kim[3]
[1]Neurology, Hallym University Sacred Heart Hospital, Anyang, Korea
[2]Neurology, Dongtan Sacred Heart Hospital, Anyang, Korea
[3]Lab of Parkinson disease and Neurogenetics, ILSONG Institute of Life Science, Anyang, Korea

Although Hummingbird sign (HBS) is a distinctive feature of Progressive supranuclear palsy (PSP) vs. idiopathic Parkinson's disease (IPD) and other parkinsonian disorders, there are no consensus criteria. To enhance inter-rater reliability (IRR) and diagnostic validity, we developed a new radiologic rating scale for HBS (HBS-RS). Two raters blinded to the clinical diagnosis reviewed T1 midsagittal magnetic resonance images of 133 patients with IPD (n=93) or with PSP (n=40). The existence of HBS was assessed in two steps, separated by two weeks, first based on their own experience, and then according to the HBS-RS. The HBS-RS is comprised of 4 items (contour of third ventricle floor, shape of beak, shape of Hummingbird head, and midbrain atrophy), with weighted scores from 0 to 2.
IRRs of individual items in HBS-RS, and of composite scores, showed moderate to good agreement (κ, 0.479 - 0.766) and were observed to be highest in item #1. IRRs for HBS-RS total scores were better than HBSs (Cohen' κappa[κ], 0.666 VS. 0.596). Sensitivities and specificities varied depending upon the cut-off for each item or for composite scores. Sensitivities in each item were high (85.0 – 92.5) at low cut-off (0 VS. 1 or 2). Specificities reached higher than 80% by using composite scores of HBS-RS. Receiver operating characteristic curves for HBS-RS total score showed fair diagnostic accuracy for PSP (AUC, 0.76 and 0.73).
HBS-RS is a simple and measurable visual assessment tool to determine HBS with higher inter-rater agreement and adjustable diagnostic validity for PSP.

THE PATTERN OF TAU PATHOLOGY IS DISTINCT IN CREUTZFELDT-JAKOB DISEASE

B. Sikorska[1], I. Milenkovic[2], T. Petrov[3], P.P. Liberski[1], G.G. Kovacs[2]
[1]Department of Molecular Pathology and Neuropathology, Medical University of Lodz, Lodz, Poland
[2]Institute of Neurology, Medical University of Vienna, Vienna, Austria
[3]Institute of Science and Technology, Insitute of Science and Technology, Klosterneuburg, Austria

Objective: To investigate whether the pattern of tau pathology in the hippocampus is influenced by the presence of pathological isoform of the prion protein.
Methods: We compared phospho-tau immunoreactivity (AT8) in 23 hippocampal regions in 26 cases of sporadic Creutzfeldt-Jakob disease (CJD) stratified into three molecular subgroups (MM1/MV1, MV2 and VV2). We compared AT8 immunoreactivity patterns between the molecular subgroups of CJD and other neurodegenerative diseases by mathematical analysis. Subsequently, we created a heat map of phospho-tau (AT8) immuoreactivity pattern to highlight the differences between the groups.
Results: We observed differences in the pattern of tau pathology between the CJD molecular subgroups as compared to Alzheimer-related neurofibrillary degeneration (Braak stages) and other neurodegenerative tauopathies. The tau pathology pattern in the VV2 subgroup was different not only form Braak stages 1 and 2 and but also from other CJD subgroups. Interestingly, the pattern of hippocampal pathology of MM1/MV1 group was comparable to that of progressive supranuclear palsy.
Conclusion: The pattern of phospho-tau pathology in CJD brain does not match the early stages of neurofibrillary degeneration according to Braak and Braak classification and shows differences between molecular subgroups of this disease.

IATROGENIC CJD IN HUMAN GROWTH HORMONE RECIPIENTS IN THE UK

D. Ritchie[1], A. Peden[1], S. Lowrie[1], M. Le Grice[1], K. Burns[1], M. Head[1], J. Ironside[1]
[1]National CJD Research & Surveillance Unit, University of Edinburgh, Edinburgh, United Kingdom

Objectives: To date, 74 cases of accidental human-to-human transmission of Creutzfeldt-Jakob disease (CJD) have been reported in the United Kingdom (UK) in recipients of human growth hormone (hGH) derived from cadaveric pituitaries. Although hGH was withdrawn in 1985, cases of hGH-related iatrogenic CJD (hGH-iCJD) continue to occur. In this first comprehensive analysis, neuropathological features, prion protein (*PRNP*) genotype, and the biochemical properties of the disease associated prion protein (PrP^{Sc}) were determined in UK hGH-iCJD subjects. Results were compared with data from UK sporadic CJD (sCJD) cases.
Methods: Central nervous system (CNS) and peripheral tissues taken at autopsy from 38 UK hGH-iCJD patients were examined. Formalin fixed tissues were analysed by immunohistochemistry for PrP^{Sc} accumulation. Biochemical analysis of PrP^{Sc} in frozen tissue was performed by Western blot, following limited proteinase digestion.
Results: In hGH-iCJD patients, there was a strong bias towards the MV and VV genotypes at polymorphic codon-129 of *PRNP*, combined with type 2 PrP^{Sc} subtype (MV2 and VV2). In contrast, sCJD cases were predominantly of the MM1/MV1 subtype. Patterns of CNS neuropathology in hGH-iCJD showed similarities to sCJD VV2 and MV2 subtypes, but with more severe pathology in the cerebellum.
Conclusion: It has been proposed that human-to-human transmission of sCJD may be a function of host *PRNP* codon-129 genotype and the strain of agent involved. Our results suggest that in the UK hGH patients, iCJD has resulted from limited exposure to prion infectivity, most probably from hGH contaminated with either sCJD MV2 or VV2 tissue.

ADPD5-0795

FAMILIAL PRION PROTEIN MUTANTS INHIBIT HRD1-MEDIATED RETROTRANSLOCATION OF MISFOLDED PROTEINS BY DEPLETING MISFOLDED PROTEIN SENSOR BIP

S. Peters[1], M.A. Déry[1], A. LeBlanc[1]
[1]Neurology and Neurosurgery, McGill University, Montreal, Canada

OBJECTIVES

Newly synthesized misfolded glycoproteins retrotranslocate from the endoplasmic reticulum (ER) to the cytosol for proteasomal degradation. Familial prion protein (PrP) mutants retrotranslocate abnormally. Here, we determined (1) PrP's retrotranslocation mechanism, (2) how familial PrP mutants avoid retrotranslocation, and (3) the effect of familial PrP mutant expression on heterogeneous misfolded ER protein retrotranslocation.

METHODS

The role of human E3 Ubiquitin ligase, Hrd1, on PrP retrotranslocation was assessed by overexpression or siRNA knockdown of Hrd1 and proteasome inhibition in human glioblastoma CR7 cells. Cells were submitted to subcellular fractionation to assess membrane-bound and cytosolic PrP levels. The effect of PrP mutants on PrP's and other Hrd1 substrates' retrotranslocation was determined by co-expression of PrP-V210I^{129V} and -M232R^{129V} in the presence or absence of Hrd1-dependent substrates, transthyretin^{D18G} or alpha-one-anti-trypsin^{NHK}. RT-PCR and western blotting evaluated misfolded protein sensor BiP levels in whole cell extracts.

RESULTS

We identified Hrd1, as a critical regulator of glycosylated PrP retrotranslocation in mammalian cells. PrP mutants not only failed to retrotranslocate, but prevented retrotranslocation of wild-type PrP, and Hrd1-dependent substrates, TTR^{D18G} and alpha-1-anti-trypsin^{NHK}. Mutant PrP decreased BiP levels by 50% and increased BiP turnover 10-fold. Over-expression of BiP rescued PrP-induced loss of retrotranslocation.

CONCLUSION

PrP mutants block a major pathway of misfolded protein degradation by down-regulating misfolded protein sensor, BiP. The accumulation of misfolded proteins could be most detrimental to terminally differentiated neurons, which, unlike dividing cell types, cannot cope with deregulated proteostasis by self-renewal. This provides a novel mechanism for familial PrP mutant-induced pathology.

Fatal familial insomnia (FFI) and a genetic form of Creutzfeldt-Jakob disease (CJD^{178}) are clinically distinct prion disorders linked to the D178N prion protein (PrP) mutation. The disease phenotype is determined by the 129 M/V polymorphism on the mutant allele, which is thought to influence spontaneous D178N PrP misfolding, leading to formation of distinctive prion strains with specific neurotoxic properties. Transgenic (Tg) mice expressing the mouse PrP homolog of the FFI mutation, develop a neurological illness with severe sleep disruption, different from that of analogously generated Tg(CJD) mice modeling CJD^{178}. No prion infectivity is detected in Tg(FFI) and Tg(CJD) brains by bioassay or protein misfolding cyclic amplification, indicating prion-independent mechanisms of neurotoxicity and phenotypic heterogeneity. Tg(FFI) and Tg(CJD) neurons accumulate mutant PrP in different compartments of the secretory pathway and show distinct morphological abnormalities of transport organelles, suggesting that mutant PrP-specific alterations of secretory transport may contribute to determine the disease phenotype.

Prion hypothesis postulates that a protein conformation based agent is responsible for the infectivity of Transmissible spongiform encephalopathies (TSEs, also known as prion diseases). Synthetically generating prions *in vitro* with bacterially expressed recombinant prion protein strongly supports the prion hypothesis. However, it remains unclear whether the pathogenic properties of synthetically generated prion (sg-Prion) recapitulate those of naturally occurring prions, including the ability to transmit disease via routes other than the most efficient intra-cerebral inoculation, the neuroinvasion pathway, and the ability to induce specific pathological lesions of TSEs. Here we report intraperitoneal (i.p.) inoculation of wild-type mice with sg-Prion caused prion disease with an average survival time of 210 – 220 days post inoculation. Detailed pathological analyses together with a time course study revealed that the nature of sg-Prion induced lesions, including spongiform change, disease specific prion protein accumulation (PrP-d) and the PrP-d dissemination amongst lymphoid and peripheral nervous system tissues, the route and mechanisms of neuroinvasion were all typical of classical rodent prions. Moreover, the sg-Prion induced lesion profile confirmed that the sg-Prion is a unique murine prion strain, ruling out the possibility of inadvertent contamination. Our study revealed for the first time that, similar to naturally occurring prions, the sg-Prion is capable of causing prion disease via routes other than direct intra-cerebral challenge. Moreover, our results demonstrated that the *in vitro* generated sg-Prion caused neurodegenerative disorder recapitulates the pathological characteristics of naturally occurring TSEs.

Institut National de la Recherche Agronomique, Montpellier, France
[5]U1198, Inserm Université Montepllier 2 EPHE, Montpellier, France

1 . Objectives

To investigate the influence of an *endogenous factor* on the conformational conversion of the cellular prion protein into the pathogenic isoform, we focused on acetylcholinesterase (AChE). There is compelling evidence that AChE is a widely distributed enzyme in mammalian tissues and fluids with a large spectrum of functions that go well beyond the hydrolysis of acetylcholine, such as the Aβ pro-aggregating activity that might contribute to Alzheimer's disease (AD) pathogenesis.

2. Methods

We addressed the hypothesis of a broader non-enzymatic function of AChE in prion diseases by combining biochemical, biophysical, cellular and *in vivo* approaches.

3. Results

We show that PrP can bind *in vitro* to AChE. This heterologous association induces aggregation of monomeric PrP and modifies the structural properties of PrP amyloid fibrils. We address the relationships between the formation of AChE/PrP hetero-assemblies and i) their enhanced cytotoxicity in primary neuronal cultures, as well as the extended survival of prion-infected $AChE^{+/-}$ mice; ii) the interference of dual-site binding AChE inhibitors with both PrP-AChE complex formation (*in vitro*) and prion accumulation (in cell cultures); and iii) the altered AChE homeostasis in both nervous and lymphoreticular systems of prion-infected mice and in chronically infected cell cultures

4. Conclusions

Our results indicate that AChE deserves consideration as a new actor in expanding pathologically relevant PrP morphotypes and as a therapeutic target for prion diseases. This could be also extended to AD, in which the functional involvement of both proteins has been previously described.

ADPD5-0369

EXTRANEURAL ROLE OF THE CELLULAR PRION PROTEIN IN COLORECTAL CANCER CARCINOGENESIS IN VITRO

Y.H. Say[1], C.K.L. Chieng[1]

[1]Department of Biomedical Science, Universiti Tunku Abdul Rahman (UTAR), Kampar, Malaysia

This study investigated the role of cellular prion protein (PrP^C) in colorectal cancer carcinogenesis, since PrP^C was found to aberrantly overexpressed in extraneural cancer tissues like breast, gastric, prostatic and pancreatic tumours. We revealed that overexpression of PrP^C by transfection correlates with the development of a more sustainable and chemotherapeutic drug-resistant LS 174T human colorectal adenocarcinoma cells. Endogenous and overexpression of PrP^C were assessed by immunoblotting and immunofluorescence microscopy. Cell growth in anchorage-dependent manner was evaluated by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. Overexpression of PrP^C was shown to increase viable cells in a time-dependent manner. Cell growth in anchorage-independent manner was evaluated by soft agar colony formation and anoikis assay. While LS 174T cells remained resistant to anoikis, overexpression of PrP^C further exacerbated the phenomenon. Overexpression of PrP^C also increased cell motility and invasiveness of LS 174T cells. Cell adhesion to extracellular matrix (ECM) using collagen type-I and fibronectin coated surfaces revealed increased cell attachment in LS 174T cells overexpressing PrP^C. Overexpression of PrP^C was found to mitigate doxorubicin-induced cell cytotoxicity in LS 174T cells. Analysis of apoptotic and necrotic cells with annexin V/PI-FITC staining showed that PrP^C overexpression attenuated apoptosis. Human apoptosis antibody array with 35 apoptosis-related proteins revealed that three inhibitors of apoptotic proteins (IAPs) - Survivin, XIAP, and cIAP-1 - were up-regulated in LS 174T cells overexpressing PrP^C when apoptosis is induced. In conclusion, the overexpression of PrP^C could enhance the invasiveness and survival of LS 174T colorectal cancer cells, indicating that PrP^C plays a role in colorectal carcinogenesis.

ER STRESS INDUCES PRION PROTEIN GENE EXPRESSION THROUGH RECRUITMENT OF SPLICED XBP1 AND CLEAVED LUMAN TO THE ERSE26 PROMOTER REGION.

M.A. Déry[1], J. Jodoin[1], M. Misiewicz[1], B. Foveau[1], A. LeBlanc[1]
[1]Neurology and Neurosurgery, McGill University, Montreal, Canada

OBJECTIVES

The prion protein (PrP) is essential to prion disease and may contribute to Alzheimer's disease pathogenesis. Because these diseases exhibit perturbation of endoplasmic reticulum (ER) homeostasis, this study aimed at understanding the regulation of the prion gene (*PRNP*) expression by ER stress and its impact on neuronal survival.

METHODS

The impact of pharmacological ER stressors, and transcription factor overexpression on *PRNP* expression was assessed by western blot, qRT-PCR, and luciferase reporter assay. siRNA-mediated silencing highlighted the contribution of key transcription factors to ER stress-induced *PRNP* expression. *PRNP* promoter mutagenesis revealed ER stress regulatory elements (ERSE) involved in *PRNP* promoter regulation, and chromatin immunoprecipitation assessed transcription factor interaction with the *PRNP* promoter. The function of ER stress-induced *PRNP* expression on cellular survival was addressed by comparing condensed chromatin, and caspase activation levels in ER stressed PrP WT and KO hippocampal cells.

RESULTS

Pharmacological ER stressors, spliced XBP1 (sXBP1), and cleaved Luman (ΔLuman) overexpression increased *PRNP* promoter activity, PrP mRNA, and protein levels. XBP1 or Luman silencing decreased ER stress-induced PrP levels. Mutagenesis of the *PRNP* ERSE26 reduced pharmacologically-, sXBP1-, and ΔLuman-induced *PRNP* promoter activity. sXBP1 and ΔLuman interact with the *PRNP* ERSE26 promoter region, and ERSE26 homology is specifically conserved among primates. Prion knockout hippocampal cells are more vulnerable to ER stress-induced apoptosis.

CONCLUSIONS

Regulation of ER stress-induced *PRNP* expression by sXBP1 and ΔLuman constitutes an evolutionarily recent neuroprotective adaptation against ER stress-induced apoptosis that could collaterally exacerbate prion and Alzheimer's disease progression.

Centre for Prions and Protein Folding Diseases Diseases, Edmonton, Canada
[2]Chemistry and Biochemistry, University of California Santa Cruz, Santa Cruz, USA
[3]Faculty of Medicine and Dentistry, Centre for Prions and Protein Folding Diseases, Edmonton, Canada
[4]Department of Pathology, Case Western Reserve University, Cleveland, USA

Objectives: Alternative conformations of the PrP^{C} octarepeat region (OR), denoted components 1, 2 and 3, occur in the presence of different copper concentrations. We sought to test whether these different conformations cause different phenotypic properties.
Methods: Reiterative peptide mutagenesis yielded octarepeat variants with discrete component 1 or component 3 copper-binding geometries. We made transgenic (Tg) mice with component 1 PrP geometry (TgS1), component 3 geometry (TgS3) and also control Tg wt mice bearing identical 5' untranslated region leader sequences. Tg mice were phenotyped for the effects of mutant PrPs upon peripheral nerve myelination, spontaneous disease and response to prion infections.
Results: None of the Tg lines succumbed to spontaneous neurologic disease with observation periods of up to 600 days of age. S1 and S3 PrP resembled WT PrP in supporting peripheral nerve myelination. S1 and S3 Tg mice both accumulated PrP^{Sc} and infectious prion particles at levels lower than wt mice, but differed from each other in clinical presentation. Unexpectedly, S3 PrP expressed in the brain had an increased propensity to C2 (beta) cleavage adjacent to the main binding region for oligomeric forms of Abeta peptide. C2 overproduction occurred by a mechanism distinct from metal-catalyzed hydrolysis reported previously.
Conclusions: OR flexibility is concluded to impact diverse biological endpoints; it is a salient variable in infectious disease paradigms where levels of PrP^{Sc} and infectivity uncouple from the onset of clinical disease and is likely germane in familial prion disease where a single mutant OR produces multiple presentations within the same kindred.

ADPD5-0530

PRP WITH AN INFLEXIBLE OCTAREPEAT REGION HAS CONDITIONAL SENSITIVITY TO MISFOLDING

N. Daude[1], A. Lau[1], I. Vanni[2], S. Wohlgemuth[1], A. McDonald[3], G. Millhauser[3], D. Westaway[1]

[1]Department of Medicine, Centre for Prions and Protein Folding Diseases, Edmonton, Canada

[2]Department of Veterinary Public Health and Food Safety, Istituto Superiore di Sanità, Rome, Italy

[3]Department of Chemistry and Biochemistry, University of California Santa Cruz, Santa Cruz, USA

Objectives: Alternative conformations of the PrP^C N-terminal octarepeat region (OR), denoted components 1, 2 and 3, occur in the presence of different copper concentrations. We set out to test the phenotypic impact of these different N-terminal PrP conformations.

Methods: Scanning of variant octarepeat peptides identified variants with discrete, component 1 or 3 copper-binding geometries. Corresponding alleles, S1 and S3, respectively, were engineered into a full-length mouse PrP to generate lines of transgenic mice and stable cell-lines.

Results: Striking divergence was noticed for the S1 and S3 alleles transfected into RK13 cells and challenged by *de novo* infection. Unlike S1 and wild type PrP, the S3 allele did not support replication of RML prions; instead S3 PrP produced a full-length protease-resistant PrP species in uninfected cells. Subsequent to deglycosylation the S3 PrP allele was characterized by simultaneous production of 17 and 21 kDa proteinase K-resistant fragments. Assessment of the S3 allele in RK13 cells grown in different conditions defined an important role for different culture media. Analyses to define the composition of media followed by reconstitution experiments allowed us to assign the crucial nutritional components conferring the ability of S3 PrP to form two protease-resistant species.

Conclusion: Our data establish that i) different conformations of the PrP OR can be associated with different phenotypic attributes, ii) the OR's are sensitive to nutritional factors and iii) that binding of nutritional factors to the OR's transduces effects in *cis* to affect folding of the PrP C-terminal domain *in vivo*.

VALIDATION OF A NOVEL DISEASE GENE SIGNATURE IN CJD BRAINS

M. Barbisin[1], S. Vanni[1], F. Moda[2], T. Virgilio[2], F. Tagliavini[2], G. Legname[1]
[1]Laboratory of Prion Biology-Department of Neuroscience,
Scuola Internazionale Superiore di Studi Avanzati (SISSA), Trieste, Italy
[2]Neurology and Neuropathology Unit,
IRCCS Foundation Carlo Besta Neurological Institute, Milan, Italy

Objectives. Prion diseases are fatal neurodegenerative disorders whose pathogenetic mechanisms are not fully understood. In this context, we conducted a microarray-based transcriptome analysis of brains from BSE-infected macaques and we identified a five-gene signature able to distinguish infected animals from controls: *HBB* and *HBA2* were down-regulated, whereas *TTR*, *APOC1* and *SERPINA3* were up-regulated. Our objective is validating this signature in CJD brain samples and eventually confirming the results at the protein level.

Methods. We collected about 100 mg of frontal cortex of vCJD, sCJD and fCJD affected patients. RNA was extracted using TRIzol and checked for quantity and integrity. Retrotranscription was carried out using Superscript III and RT-qPCR was performed on the five selected gene transcripts. Antibodies against the five encoded proteins were first checked on mouse tissues and then utilized to perform WB or IHC in human brain slices.

Results. The collection of the samples and the quality of the extracted RNA were a challenge, but the preliminary results are very encouraging and will be thoroughly discussed.

Conclusions. Some genes related to oxygen or lipid transport and to innate immunity were found to be dysregulated in prion infected macaques and are known to be involved also in Alzheimer's and PD. Validating this gene signature in brains of CJD affected patients would shed some light not only on prion disease molecular mechanisms, but also on neurodegeneration in general. The encoded proteins may become potential biomarkers for preclinical diagnosis and therapeutic purposes of many neurodegenerative diseases.

REDUCED CIRCULATING CHOLESTEROL LEVELS IN PLASMA PHOSPHOLIPID TRANSFER PROTEIN DEFICIENT MICE INCREASE SURVIVAL TIME FOLLOWING PRION INFECTION

C. Desrumaux[1], T. Imberdis[1], M.T. Alvarez[2], J.D. Arnaud[2], L. Lagrost[3], V. Perrier[1]
[1]University of Montpellier, INSERM U710, Montpellier, France
[2]University of Montpellier, BioCampus, Montpellier, France
[3]University of Burgundy, INSERM U866, Dijon, France

- Objectives : The various pathways of lipid/lipoprotein metabolism seem to play a key role in Alzheimer's (AD) and prion (PrD) diseases. Abnormal cholesterol metabolism is frequently observed in PrD, but whether cholesterol influences the neuroinvasion process is still unclear. Plasma phospholipid transfer protein (PLTP) affects the production of lipoproteins by the liver and is a major determinant of circulating cholesterol metabolism. In the present work, PLTP deficient mice ($PLTP^{-/-}$) displaying about 30% reduction in plasma cholesterol levels, were used as a model to study the influence of circulating cholesterol during prion neuroinvasion.
- Methods : C57Bl/6 WT and C57Bl/6 $PLTP^{-/-}$ mice were challenged with 22L prion strain by either intracerebral (i.c.) or intraperitoneal (i.p.) routes, and fed either with a standard chow diet or hypercholesterolizing diet. Blood samples were collected before prion inoculation for lipid assays. Mice were sacrificed at the terminal stage of the disease and tissues were collected.
- Results : A significant increase of the survival time and a decrease of spongiosis was observed in $PLTP^{-/-}$ mice challenged with prions by i.p. route and fed with standard chow diet. Upon feeding with the hypercholesterolizing diet, a significant increase of plasma cholesterol levels was observed in $PLTP^{-/-}$ mice, associated with a reduced survival time.
- Conclusion : The $PLTP^{-/-}$ mouse model led us to underline the implication of cholesterol during the neuroinvasion process. Therapeutic strategies targeting a decrease of cholesterol levels, associated with other targets could be a good way to slow down the disease progression.

04g. Therapeutic Targets & Mechanisms for Treatment: kinases

ADPD5-2323

THE KINASE PDK1, A COMMON THERAPEUTIC TARGET FOR PRION AND ALZHEIMER'S DISEASES TO RESCUE TACE ALPHA-SECRETASE NEUROPROTECTIVE ACTIVITY

France & Pharma Research Department, Hoffmann La Roche, Basel, Switzerland

Objectives: Prion and Alzheimer's (AD) diseases make up a group of pathologies characterized by separate etiologies and distinct clinical manifestations but may share some common pathogenic cascades. The identification of such cascades would represent a biomedical challenge for therapies. How PrPSc in prion diseases or the amyloid Ab peptides in AD exert their toxicity remains elusive.
Methods: This study combines the use of prion-infected or "Alzheimer's" neurons and mouse models with prion disease or Alzheimer-like pathology (Tg2576, 3Tg-AD, 5Tg-AD).
Results: We show that PrPSc or Ab trigger the overactivation of the 3-phosphoinositide-dependent kinase-1 (PDK1) in prion-infected or "Alzheimer's" neurons, respectively. PDK1 then promotes the phosphorylation and internalization of TACE a-secretase. TACE internalization diverts TACE activity away from (i) the normal cellular prion protein, which amplifies the replication of PrPSc in prion diseases, (ii) the amyloid precursor protein, which favors the production of Ab in AD, and (iii) TNFa receptors, which accumulate at the plasma membrane and hypersensitize diseased neurons to TNFa. Inhibition of PDK1 is sufficient to target TACE back to the plasma membrane of diseased neurons, where it recovers its protective activity. Inhibition of PDK1 increases the lifespan and counteracts motor deficits in prion-infected mice and reduces memory and cognitive impairments in AD mouse models.
Conclusions: Deregulation of PDK1-dependent TACE activity emerges as a central neurodegenerative mechanism of both prion diseases and AD. Rescuing TACE a-secretase activity at the plasma membrane upon PDK1 inhibition represents a valuable entry point to combat these two diseases. Importantly, the therapeutic relevance of targeting PDK1 in AD is supported by a rise in PDK1 activity and reduced TACE a-secretase activity in the brain of AD subjects1.
1Pietri et al. PDK1 decreases TACE-mediated a-secretase activity and promotes disease progression in prion and Alzheimer's diseases. Nat. Med. (2013) 19:1224-35.

Entrance:

Crutzfeld-Jacob disease, a rare but fatal disease is a progressive neurological disruption.

Methods and Materials

52 years old man apply us with right hand tremor and speech disorder 1,5 months ago started. We found his neurological examination cognitive loss, pyramidal and exstrapyramidal signs. We were excluded metabolic and paraneoplastic disorders.
In MRI hyperintense kortikal ribbon marker in frontal area and head of caudate nucleus and anterior of basal ganglia in T2 and flair sequences .
Diffusion and ADC sequences show us hyperintense kortikal ribbon marker in frontal area and head of caudate nucleus and anterior of basal ganglia
Radiological findings were significant for this disease . Three months later myoclonic seizures began..
Clinical and radiological findings were consistent with sporadic Crutzfeld-Jacob disease .
We worked 14-3-3 protein in cerebrospinal fluid. It was negative. But neuron specific enolase was higher it is supported CJD.

Discussion

Definitive diagnosis of CJD is possible with tissue analysis..
Some types of CJD in cerebrospinal fluid 14.3.3.protein can be negative but tau and neuron specific enolase can be higher it is supported CJD.
In CJD clinical and radiological findings should be considered together.

ADPD5-0578
SERIAL MAGNETIC RESONANCE IMAGING CHANGES IN A PATIENT WITH GERSTMANN-STRÄUSSLER-SCHEINKER SYNDROME (P102L)

H. Rhee[1], S. Yoon[2], K. Park[2], E. Kim[3]
[1]Department of Neurology, Kyung Hee University Medical Center at Gangdong, Seoul, Korea
[2]Department of Neurology, Kyung Hee University Medical Center, Seoul, Korea
[3]Department of Radiology, Kyung Hee University Medical Center, Seoul, Korea

We describe serial MRI findings of a patient with Gerstmann-Sträussler-Scheinker Syndrome (GSS) with a mutation in the prion protein gene at codon 102 (Proline to Leucine) in a Korean family. A 31-year-old woman began to experience gait unsteadiness 5 months before admission. Neurological examination revealed slow saccadic eye movement and bilateral limb ataxia. Brain MRI showed no abnormality. Her family members (mother, aunt, grandfather, and great grandfather) had a history of progressive gait disturbance and becoming bedridden that had been left undiagnosed. Over a period of next 3 months, the patient developed insomnia, voiding difficulty, and cognitive impairment. MRI of the brain showed hyper-intense signal changes in the cerebral cortex, predominantly in the parieto-temporal regions, caudate head, and ventral region of putamen. CSF 14-3-3 protein was found to be weakly positive. Analysis of the PRNP gene showed a proline-to-leucine substitution at codon 102. The neurological status had worsened progressively and she had reached akinetic mutism 9 months after onset. Follow-up brain MRI with an interval of 10 months showed areas of spreading diffusion restriction in entire cerebral cortex and marked aggravation of atrophy of cerebral and cerebellar hemispheres, and brainstem. It has been reported that MRI scans may be normal during the early stage of GSS. In this case, serial MRI show the progressive extension of the high signal intensity on DWI in accordance with the neurological status, which has been attributed to the severity of spongiform degeneration and to gliosis, and marked brain atrophy following the DWI changes.

SELECTIVE DAMAGE OF STRIATAL PROJECTION CELLS OF THE DIRECT OR INDIRECT PATHWAY PRODUCES DYSREGULATION OF SLEEP AND CIRCADIAN RHYTHM IN MICE

M. Cabanas[1], L. Bellocchio[2], A. Ruiz-Calvo[2], Y. Jeantet[1], M. Guzman[2], Y. Cho[1]
[1]Institute of Cognitive and Integrative Neuroscience of Aquitaine, University of Bordeaux, Talence Cedex, France
[2]Department of Biochemistry and Molecular Biology Ice of Aquitaine, Complutense University, Madrid, Spain

Neuropathology of Huntington's disease (HD) is associated with early and selective alteration of the indirect pathway originating from a subpopulation of GABAergic projection neurons in the striatum. This cell population expresses dopaminergic D2 receptor (D2R) and projects to the substantia nigra pars reticulata via the globus pallidus and subthalamic nucleus. On the contrary, neuropathology of PD is rather characterized by dysfunctioning of the direct pathway originating from the other class of striatal projection cells, which expresses preferentially dopaminergic D1 receptor (D1R) and projects directly to the substantia nigra pars reticulata.

To evaluate the impact of the abnormalities of the indirect or direct pathway on symptomatic changes observed in patients with HD or PD, respectively, we induced excitotoxicity of striatal D2R or D1R expressing cells in mice, by using Designer Receptors Exclusively Activated by Designer Drugs associated with Gq protein. Mice were then recorded for electroencephalogram during sleep and wake cycles over 24 h for potential changes of sleep physiology and circadian rhythm, phenotypic changes observed precociously in HD and PD patients and animal models of these diseases.

Our results show that the selective perturbation of the direct or indirect pathway produces significant changes of circadian rhythm and sleep architecture. The same manipulations, however, were not sufficient to produce changes in brain rhythms during waking and sleep states.

Our data suggest an important contribution of the striatal indirect and direct pathway to circadian rhythm regulation, and the alteration of these pathways to early sleep changes in HD and PD.

ADPD5-1679
DIFFERENTIAL EFFECT OF HDAC3 ON CYTOPLASMIC AND NUCLEAR HUNTINGTIN AGGREGATES

T. Mano[1], S. Tsuji[1], A. Iwata[1]
[1]Neurology, The University of Tokyo Hospital, Bunkyo-Ku, Japan

Histone deacetylases (HDACs) are potential therapeutic targets of polyglutamine (pQ) diseases including Huntington's disease (HD) that may function to correct aberrant transcriptional deactivation caused by mutant pQ proteins. HDAC3 is a unique class 1 HDAC found in both the cytoplasm and in the nucleus. However, the precise functions of HDAC3 in the two cellular compartments are only vaguely known. HDAC3 directly binds to huntingtin (Htt) with short pQ and this interaction is important for suppressing neurotoxicity induced by HDAC3. With long pQ Htt, the interaction with HDAC3 is inhibited, and this supposedly promotes neuronal death, indicating that HDAC3 would be a good therapeutic target for HD. However, the knockout of one HDAC3 allele did not show any efficacy in reducing neurodegenerative symptoms in a mouse model of HD. Therefore, the role of HDAC3 in the pathogenesis of HD has yet to be fully elucidated. We attempted to resolve this issue by focusing on the different roles of HDAC3 on cytoplasmic and nuclear Htt aggregates. In addition to supporting the previous findings, we found that HDAC3 preferentially binds to nuclear Htt over cytoplasmic ones. Specific HDAC3 inhibitors increased the total amount of Htt aggregates by increasing the amount of nuclear aggregates. Both cytoplasmic and nuclear Htt aggregates were able to suppress endogenous HDAC3 activity, which led to decreased nuclear proteasome activity. Therefore, we concluded that Htt aggregates impair nuclear proteasome activity through the inhibition of HDAC3. Our findings provide new insights regarding cross-compartment proteasome regulation.

Helmholtz Zentrum München German Research Center for Environmental Health (Gmb H), Munich, Germany

Amyotrophic lateral sclerosis (ALS) and Frontotemporal dementia (FTLD) are severe neurodegenerative diseases with overlapping clinical and pathological features. Recently, a hexanucleotide repeat expansion in the non-coding region of the *C9orf72* gene was discovered to be the most frequent pathogenic mutation in both diseases. Although lacking an ATG start codon, the repeat is translated in all reading frames into dipeptide repeat (DPR) proteins forming insoluble p62-positive, TDP-43-negative inclusions in patients. Their role in the disease, however, is still unclear.
To distinctively analyze the role of DPR proteins, we designed synthetic genes expressing the DPR sequence with an ATG start codon but no extensive GGGGCC repeats. Only poly-GA showed insoluble p62-positive aggregates and induced apoptosis in primary neurons. Using a mass spectrometry approach we identified poly-GA coaggregating proteins. We found a significant enrichment of proteins of the ubiquitin-proteasome system and additionally Unc119, a trafficking factor, previously linked to neuromuscular function and axon maintenance. The soluble levels of Unc119 in our system were strongly reduced. Furthermore, Unc119 knockdown inhibited dendritic branching and caused neurotoxicity similar to poly-GA overexpression and the addition of Unc119 partially rescued poly-GA toxicity. These findings indicate that poly-GA overexpression causes Unc119 loss of function. Whereas Unc119 is detectable in many poly-GA inclusions in the frontal cortex and the hippocampus of *C9orf72* patients, the abundant poly-GA inclusions in the cerebellum appear to be less affected by Unc119 coaggregation. Thus, poly-GA induced Unc119 loss of function might contribute to the selective vulnerability of neurons in the pathogenesis of *C9orf72* FTLD/ALS.

CRYSTAL STRUCTURE OF THE ATAXIN-3 CARBOXY-TERMINAL REGION
V. Zhemkov[1], A. Kulminskaya[1], I. Bezprozvanny[2], M. Kim[2]
[1]Laboratory of Molecular Neurodegeneration, Saint-Petersburg State Polytechnical University, Saint-Petersburg, Russia
[2]Department of Physiology, University of Texas Southwestern Medical Center, Dallas, USA
Machado-Joseph Disease, or Spinocerebellar Ataxia Type 3 (MJD/SCA3), is a conformational disease of the brain that is genetically associated with the CAG triplet expansion in the ATXN3 gene. MJD/SCA3 development is associated with polyglutamine elongation in Atx3 beyond pathogenic threshold of 55Q. Topologically Atx3 consists of N-terminally located Josephin domain (JD) with deubiquitination enzymatic activity (1-180 a.a.r.), intermediate flexible linker containing two ubiquitin-interacting motifs (182-291 a.a.r.) and C-terminal region encompassing polyglutamine repeat (polyQ) (begins at 292 a.a.r.). While JD is quite well structurally and functionally characterized, the remaining part of the protein lacks detailed information.
Here we report crystal structures of the C-terminal region (278-329 a.a.r.) of non-expanded ataxin-3 with 13 glutamine residues fused to maltose-binding protein. Our observations show that C-terminal domain is mainly disordered, solvent exposed region that likely adopts extended random conformation. Our findings suggest that disordered polyglutamine together with its flanking sequences can adopt structured alpha-helical conformation upon protein-protein interactions. It is tempting to speculate that these helix-to-loop transitions of polyglutamine can play an important role in normal functioning of ataxin-3 and other polyQ containing proteins while glutamine expansion can lead to disruption of these transitions leading to toxic conformational switch. The recent discoveries will be discussed on the meeting.

DETECTION OF PROTEIN AGGREGATES IN BRAIN AND CEREBROSPINAL FLUID DERIVED FROM MULTIPLE SCLEROSIS PATIENTS

M. Tayebi[1], *M. David*[2]
[1]*Animal & Veterinary Science, Charles Sturt University, Wagga Wagga, Australia*
[2]*Antibody Discovery Laboratory, PRIOCAM LLC, Houston, USA*

Studies of the properties of soluble oligomers species of amyloidogenic proteins, derived from different proteins with little sequence homology, have indicated that they share a common structure and may share similar pathogenic mechanisms. Amyloid β, tau protein as well as amyloid precursor protein normally associated with Alzheimer's disease and Parkinson's disease were found in lesions and plaques of Multiple Sclerosis patients.

The Objective of the study is to investigate whether brain and CSF samples derived from Multiple Sclerosis patients demonstrate the presence of soluble oligomers normally associated with protein misfolding diseases such as Alzheimer's disease.

We have used anti-oligomer monoclonal antibodies to immunodetect soluble oligomers in CSF and brain tissues derived from Multiple Sclerosis patients.

In this report, we describe the presence of soluble oligomers in the brain tissue and cerebral spinal fluid of Multiple Sclerosis patients detected with our monoclonal anti-oligomer antibodies with Western blot.

These results might suggest that protein aggregation plays a role in Multiple Sclerosis pathogenesis although further and more refined studies are needed to confirm the role of soluble aggregates in Multiple Sclerosis.

A NOVEL NON TETRAMERIC MUTANT OF TRANSTHYRETIN PROTEIN INVOLVED IN FAMILY CARDIAC AMYLOIDOSIS.

P.S. Ferreira[1], C. Andrade[1], C. Lima[1], A.P. Neves[1], F.L. Palhano[1], C.R.U.Z. Waddington[1], D. Foguel[1]

[1]Medical Bochemistry, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Transthyretin (TTR) is one of many proteins that are capable of forming amyloid fibrils *in vivo*. This protein is associated with two distinct amyloidosis: Familial Cardiac Amyloidosis (FCA) that causes a restrictive cardiomyopathy and Familial Amyloid Polyneuropathy (FAP) that affects peripheral nerves, they are hereditary and caused by mutations in the TTR gene. The diagnosis was established at University Hospital since 2008 due to a collaboration between our group and the center of Amyloidosis CEPARM. Previously the only mutation found was V30M in 3 patients diagnosed in France. Since 2008 we discovered 5 new mutations in Brazil and a novel mutation not yet described in the world and until now 140 patients were diagnosed. The novel mutation A19D-TTR causes a severe restrictive cardiomyopathy that is certainly related to a higher profile of aggregation observed for this mutant if compared to others amyloidogenic mutants of TTR. The thermodynamic stability is lower in comparison with the WT TTR. Structural predictions using a bioinformatics tool showed that the insertion of the mutation caused an electrostatic clash that facilitates its dissociation and aggregation. Biophysical studies revealed that this protein is a dimer and not a tetramer as commonly found for the TTR. In addition the oligomers of A19D are toxic for primary culture of cardiomyocytes and fibroblast from murine heart. The recent CEPARM consolidation in our university hospital led to the identification of the rare A19D-TTR variant in a Brazilian patient, suggesting that other new, uncharacterized mutants could be identified in the coming years.

ENDOGENOUS FUNCTION OF SERF AND ITS MOLECULAR ROLE IN NEURODEGENERATION

E. Stroo[1], A. Mata Cabana[1], A. Pras[1], E.A.A. Nollen[1]
[1]Molecular Neurobiology Of Ageing,
European Research Institute For The Biology Of Ageing, Groningen, Netherlands

Objectives The formation of amyloid-like fibrils through accumulation of aggregation-prone proteins in the human brain is an important hallmark in neurodegenerative diseases. Modifier of aggregation MOAG-4 was identified as a positive regulator of aggregate formation in C. *elegans*. MOAG-4 seems to act cell-autonomously and independent from classical cellular quality control mechanisms. The exact mechanisms in which MOAG-4 and its human orthologs SERF1A and SERF2 promote protein aggregation remains unknown[1,2]. In our study, we aim to investigate the endogenous role of SERF.

Methods A Yeast-two-hybrid screen was performed for the identification of possible SERF interactors. Possible SERF interactors were (over)expressed in Human Embryonic Kidney cells to investigate the possibility of these proteins to form insoluble inclusions.

Results Will be presented.

Conclusions Will be presented.

THREE VARIANTS OF LRRK2 EXHIBIT SIMILARITIES TO MULTIPLE PATHOGENIC MUTATIONS CAUSATIVE FOR PARKINSON'S DISEASE

H. Rideout[1], E. Leandrou[1], K. Melachroinou[1], A. Memou[1], G. Hadjigeorgiou[2], L. Stefanis[3]
[1]Basic Neurosciences II, biomedical research foundation academy of athens, athens, greece
[2]Dept of Neurology, University of Thessaly Medical School, LARISSA, Greece
[3]2nd Dept of Neurology, University of Athens Medical School, ATHENS, Greece

Objectives: We set out to determine whether three distinct variants in LRRK2, identified in Greek PD patients but not in controls, exhibited certain cellular phenotypes associated with multiple other common mutations in LRRK2 that are more clearly pathogenic.
Methods: Over-expressed wild type or mutant forms of LRRK2 were assessed for their ability to induce neuronal death, kinase activity, GTP binding, oligomerization, and interaction with the cell death protein FADD.
Results: When over-expressed in primary cultured neurons, A211V, K544E, and T1410M-LRRK2 induced apoptotic death to a similar extent as the pathogenic mutants G2019S or I2020T. However, only A211V-LRRK2 exhibited greater kinase activity compared to WT, but to a lesser extent than G2019S-LRRK2. Moreover, the interaction with FADD, and the effect of each variant on oligomerization, were not dramatically different from WT-LRRK2.
Conclusions: We find that some, but not all, of the phenotypes typically reported for pathogenic mutations in LRRK2 are also displayed by three selected variants found in PD patients of Greek origin. Importantly, each was able to induce neuronal death to a similar extent as the pathogenic mutations in a primary cellular model of LRRK2-PD, however the precise mechanism remains unclear.

ADPD5-0983

THERAPEUTIC AND DISEASE-MODIFYING EFFECTS OF GANGLIOSIDE GM1 IN MOUSE MODELS OF HUNTINGTON'S DISEASE

S. Sipione[1], M. Alpaugh[1], D. Galleguillos[1], L.C. Morales[1], P. Kar[1], S. Lackey[1], P. Kar[1], B. Kerr[2], K. Todd[3]

[1]Pharmacology, University of Alberta, Edmonton, Canada

[2]Anesthesiology and Pain Medicine, University of Alberta, Edmonton, Canada

[3]Psychiatry, University of Alberta, Edmonton, Canada

BACKGROUND

Huntington disease (HD) is a neurodegenerative disorder due to the expansion of a polyglutamine stretch in the protein huntingtin. The resulting mutant protein acquires toxic conformations and aggregates within the cells, leading to neuronal dysfunction and death.

We previously showed that levels of ganglioside GM1, a lipid highly enriched in the brain, are decreased in HD models. Administration of exogenous GM1 resulted in normalization of motor behavior in a transgenic model of HD (YAC128 mice). These effects were accompanied by increased phosphorylation of mutant huntingtin at Ser13 and Ser16, a post-translational modification that was shown to decrease mutant huntingtin toxicity.

OBJECTIVES

The aim of this study was to further characterize the therapeutic effects of GM1 and to demonstrate that GM1 is a disease-modifying treatment for HD.

METHODS

We measured motor and non-motor behaviour in three different models of HD (R6/2, YAC128 and Q140 mice) during chronic intraventricular infusion of GM1 or vehicle. At the end of the treatment, filter-trap assay, immunoblotting and stereology analysis were performed to determine whether GM1 affects neurodegeneration and levels of mutant huntingtin aggregates in treated mouse brains.

RESULTS

GM1 treatment decreased levels of soluble and insoluble huntingtin in HD mouse brains, and dramatically improved both motor and non motor symptoms of the disease. In R6/2 mice, GM1 attenuated striatal neuron and white matter loss, increased body weight and prolonged survival.

CONCLUSIONS

Our data suggest that GM1 has disease-modifying properties across HD mouse models and could have therapeutic potential in HD patients.

ADPD5-2083

SYNAPTIC DYSFUNCTION IN AN IN VIVO CORTICO-STRIATAL MODEL SYSTEM OF HUNTINGTON'S DISEASE

V. Korzhova[1], D. Artamonov[1], A. Gainullina[1], O. Vlasova[1], I. Bezprozvanny[2]
[1]Medical Physic and Bioengineering Department, Saint-Petersburg State Polytechnical University, Saint-Petersburg, Russia
[2]Department of Physiology, University of Texas Southwestern Medical Center at Dallas, Dallas, USA

Huntington's Disease (HD) is caused by trinucleotide repeat expansion in the gene coding protein huntingtin. HD's pathology includes multiple motor and mental disorders. There are growing evidences that one of the manifestations of HD is abnormalities of synaptic activity between striatal and cortical neurons.

Objectives

The goal of the present study is to explore synaptic dysfunction during HD using *in vitro* model of co-cultured cortico-striatal neurons.

Methods

Cells of interest were obtained from the brain of mice YAC128 coding mutation causing HD and co-cultured. During *in vitro* cultivation cultures were characterized functionally by cell-attached patch-clamp and optogenetic stimulation and morphologically by immunocytochemistry.

Results

On the day 14 *in vitro* cultivation cortical neurons from YAC128 mice were characterized by spontaneous activity compared with wild type neuron culture. No difference in morphology of striatal dendritic spines between HD and wild type models was observed at that time.

On the day 19 *in vitro* cultivation the activity of YAC128 cortical neurons was reduced, while activity of wild type cortical neurons was increased. Spine elimination and changes in spine morphology were observed at that time.

Conclusions

Present work demonstrated synaptic dysfunction in the *in vitro* cortico-striatal model system of Huntington's Disease, which possibly resulted in reduced signal transduction activity between cortical and striatal neurons.

This work was supported by the contract with the Russian Ministry of Science 11.G34.31.0056 (Ilya Bezprozvanny).

EXTRANEURONAL ROLE OF GAMMA-SYNUCLEIN IN COLORECTAL CANCER CELL BIOLOGY

Y.H. Say[1], K.W. Goh[2]
[1]Department of Biomedical Science, Universiti Tunku Abdul Rahman (UTAR), Kampar, Malaysia
[2]Centre for Foundation Studies, Universiti Tunku Abdul Rahman (UTAR), Kampar, Malaysia

γ-Synuclein, a predominantly neuronal protein of the Synucleins family, is associated with carcinogenesis and is proposed as a putative breast cancer marker. Its role in colorectal cancer carcinogenesis is still elusive. To investigate the role of γ-Synuclein in colorectal cancer carcinogenesis from invasion, metastasis and apoptosis evasion aspects, we overexpressed γ-Synuclein in the LS 174T colon adenocarcinoma cell line. When compared with untransfected and mock transfectants, LS 174T-γsyn had higher mobility in scratch wound assay, tend to scatter more in cell-scattering assay, and had enhanced lamellipodia and filopodia formation in cell-spreading assay. Enhanced adhesion of LS 174T-γsyn to fibronectin and collagen and significantly higher proliferation rate showed that γ-Synuclein was able to increase extracellular matrix interaction and promoted proliferation of LS 174T. Higher invasiveness of LS 174T-γsyn was evidenced by enhanced invasion to the bottom of the basement membrane in the Boyden chamber assay. However, LS 174T-γsyn cells were significantly more vulnerable to doxorubicin, vincristine and hydrogen peroxide insults, via apoptotic cell death. LS 174T-γsyn cells also had reduced anchorage-independent growth as shown by reduced colonies formation and reduced anoikis resistance. Higher ROS production also signified the pro-oxidant ability of γ-Synuclein. The pro-invasive property of γ-Synuclein was mediated through enhanced CREB phosphorylation. HGF down-regulation contributed to doxorubicin-mediated pro-apoptotic property of γ-Synuclein by suppressing cell survival and proliferation signalling pathways possibly involving ERK1/2, p38α, JNK pan and STATs. Taken together, the results suggest that γ-Synuclein may be possessing pro-invasive and doxorubicin-mediated pro-apoptotic properties at the same time.

03g. Pathophysiology & Disease Mechanisms: mitochondrial dysfunction

ADPD5-2273

REGULATION OF MITOCHONDRIAL BIOGENESIS IN NEURONS EXPRESSING N-TERMINAL MUTANT HUNTINGTIN

K. Obrietan[1], *K. Hoyt*[2]
[1]*Neuroscience, Ohio State University, Columbus, USA*
[2]*Pharmacology, Ohio State University, Columbus, USA*

Huntington's disease (HD) is an autosomal-dominant neurodegenerative disease characterized by abnormal movements and affective/cognitive difficulties. Typically, HD patients experience onset of symptoms at midlife. The genetic defect responsible for the disorder is a poly-glutamine expansion in the huntingtin protein. Expression of this mutant protein ultimately leads to neurodegeneration; striatal degeneration in particular underlies the resulting movement disorder. Numerous studies have indicated an important role of mitochondrial dysfunction in the evolution of neuronal dysfunction and death in HD.

Objective: Here, we are investigating modulation of key components of mitochondrial biogenesis in cultured neurons expressing N-terminal mutant huntingtin.

Methods: Neurons cultured from PND1 HD transgenic mice (line R6/2) and WT control littermates were treated with an activator of nuclear factor, erythroid 2-like 2 dependent (antioxidant response element-driven) transcription (tert-butyl hydroquinone). To assess mitochondrial biogenesis, neurons were fixed with paraformaldehyde, co-immunolabelled for mitochondrial protein NADH dehydrogenase 1 beta subcomplex-8 and the transcriptional co-activator peroxisome proliferator-activated receptor-gamma coactivator-1alpha. Quantitative immunofluorescence analysis was used to compare protein expression levels and subcellular localization in HD neurons compared to WT control neurons.

Results: Mitochondrial protein expression was comparable under basal untreated conditions in HD and WT neurons. Upon tert-butyl hydroquinone exposure, WT neurons increased mitochondrial protein expression while HD neurons were not responsive.

Conclusions: Basal levels of mitochondrial biogenesis are comparable in early post-natal HD and WT neurons, however, coupling of antioxidant-response element driven transcription activation to mitochondrial biogenesis is deficient in HD neurons, suggesting a fundamental deficit in this signalling pathway in neurons expressing mutant huntingtin.

FIBRILLAR AND OLIGOMERIC AMYLIN DECREASES BRAIN PERICYTE GLUCOSE UPTAKE IN VITRO

N. Schultz[1], M. Fex[2], M. Wennström[1]
[1]Clinical Sciences Malmö, Clinical Memory research Unit, Malmö, Sweden
[2]Clinical Sciences Malmö, Lund University Diabetes Center, Malmö, Sweden

Background: Previous studies show degeneration of brain pericytes in patients with Alzheimer's disease (AD), a pathological event suggested to underlie the microvascular changes commonly seen in AD patients. The underlying causes to the pericyte loss are yet not defined. Interestingly, recent studies have shown depositions of aggregated hormone islets amyloid polypeptide (IAPP), also called amylin, in brain vessel walls of patients with AD. In normal conditions amylin moderates glucose metabolism, however, it is prone to aggregate and elevated secretion of the peptide leads to toxic depositions. To understand how amylin depositions may affect brain pericytes, we investigated pericyte glucose uptake in presence of different amylin aggregations forms.
Methods: Primary human brain vascular pericytes (HBVP) were exposed to fibrillar, oligomeric and monomeric preparations of amylin for 24 h. Immunocytoflourescence stainings with anti-GLUT-1 antibody were performed to assess alterations in GLUT-1 location and cell morphology. Glucose uptake, in the presence or absence of insulin, was evaluated by measuring the uptake of radiolabelled [^{14}C]-2-deoxyglucose.
Results: Exposure to fibrillar and oligomeric amylin, but not monomeric amylin, induced contracted pericyte morphology and significantly decreased glucose uptake. The decreased glucose uptake were counteracted by insulin supplement, but remained low compared to control cells.
Conclusion: Our study demonstrates an aggregation-dependent impact of amylin on pericyte glucose uptake. This finding suggests amylin depositions in the brain as a possible factor underlying the pericyte degeneration found in AD patients.

IGF-1 IS A POTENT INDUCER OF GDNF EXPRESSION, AND MAY CONTRIBUTE TO THE REGULATION OF GDNF VIA MT EXPRESSION.

T. Watanabe[1]

[1]*cell biol., Neuroscience Instit.(meguro), meguro-city, Japan*

Parkinson disease, one of most common neurodegenerative disorders is elderly, is characterized massive loss of dopamine neuron. One of the neurotrophic factors that might protect neurons in harmful micro-environment is insulin growth factor-1 (IGF-1). Our previous study indicated that the induction of glial MT(metallothinein) as scavenger and/or regenerating factor lead to activation of IGF-1R neuron.Glial cell line-derived neurotrophic factor (GDNF) has significant neuroprotect potentials in PD. and, has been identified as a potent neurotrophic factor for a variety of neuronal cell populations. At present, it is still unknown whether human gliomas in vivo are also capable of producing GDNF.

In the present study, To determine factors that would enhance GDNF expression, we analyzed the effect of IGF-1 in C6 glioma cells under MPTP-neurotoxicity. Treatment of C6 cells with IGF-1 elicited an 8.5-fold increase in the level of GDNF content with expression of MT-mRNA, and elicited 18% of effective at recovery of C6 cell under MPTP. However, m-RNA expression of GDNF is not relative increased in course of IGF-1.

These data indicate that IGF-1 is a potent inducer of GDNF expression, and may contribute to the regulation of GDNF via MT expression.

[2]Electrophysiology, PsychoGenics Inc, Montvale, USA
[3]CHDI Management/Foundation, CHDI, LA, USA

Objective: Huntington's disease (HD) is a lethal autosomal dominant neurodegenerative disorder caused by expansion of CAG repeats in the *Huntingtin (HTT)* gene. HD patient brains reveal a devastation of the caudate-putamen and cortico-striatal-thalamo-cortical circuits are thought to be particularly affected. Choreic symptoms correlate well with D2-containing medium spiny neuron (MSN) loss, which originate the indirect pathway. MSN dysfunction has been extensively studied *in-vitro* in models of HD, but the functional consequences on the immediate downstream nuclei of the indirect pathway, the external Globus Pallidus and subthalamic nucleus (STN), remains unknown.
Method: We characterized the properties of cortical to basal ganglia transmission in early symptomatic zQ175 heterozygous knock-in HD model mice (6-8 months old). Under urethane anesthesia, evoked responses of striatal MSNs and STN neurons were recorded following stimulation of primary motor cortex (M1).
Result: Evoked single unit recordings of MSNs demonstrated a reduced averaged number of spikes per stimulus but similar latency in male zQ175KI HET compared to WT. Furthermore, ~50% more spontaneously active MSNs were recorded in zQ175KI HET compared to WT. We also investigated the 'hyperdirect' cortico-STN pathway by recording evoked single unit activity in STN. Similarly to MSNs, male STN neurons in zQ175KI HET mice exhibited a reduced averaged number of spikes per stimulus compared to WT.
Conclusion: We have characterized a basal ganglia circuitry dysfunction relevant to the human HD condition. These functional *in-vivo* assays will allow for the assessment of novel compounds with potential disease modifying properties.
Study funded by CHDI Foundation, Inc.

04r. Therapeutic Targets & Mechanisms for Treatment: protein aggregation

ADPD5-1583

EVALUATION OF THE EFFICACY OF THE PEPTIDE P42B IN CELLULAR AND DROSOPHILA MODELS OF HUNTINGTON'S DISEASE

C. Marelli[1], N. Bonneaud[1], A. Paucard[1], F. Maschat[1]
[1]Molecular Mechanism of neurodegenerative Dementia, INSERM U710, Montpellier, France

Background: P42 is a 23aa peptide preventing aggregate formation in HeLa cells and in *Drosophila* HD models (Mugat, 2008; Arribat, 2013). Additionally, it reduces aggregate formation, weight loss, and brain atrophy, and ameliorates motor performances in R6/2 mice (Arribat, 2014). In P42TAT-containing brain extracts we identified a shorter 14aa fragment, P42B, still present after three hours. We tested whether P42B still harbours active properties.
Methods: P42 and P42B were tested alone, or combined with the transduction peptide TAT. HeLa cells were co-transfected with GFP-hHtt171aa-136Q and cherry-P42/P42B. Transgenic flies expressing polyQ-hHtt in salivary glands (*MS-1096*-Gal4; UAS-HA-hHtt^{171aa}-138Q/+) or eyes (*GMR*-Gal4; UAS-HA-hHtt^{67aa}-93Q/+) were crossed with flies expressing UAS-P42GFP/P42TATGFP/P42BGFP, or UAS-GFP as negative control. P42TAT or P42BTAT synthetic peptides were also tested in food of *MS-1096*-Gal4; UAS-HA-hHtt^{171aa}-138Q/+ flies. The aggregates were studied by immunostaining and quantified by filter retardation assays. The eye degeneration was studied in adult *Drosophila*.
Results: P42B prevents aggregate formation in HeLa cells and eye degeneration in adult flies. In the larval salivary glands P42B, either genetically or orally administered, does not significantly hamper aggregate formation; however, at immunostaining P42B co-localizes with the aggregates.
Conclusions: P42B harbors some of the active properties of the P42 peptide, but its efficacy varies. The entire peptide P42 may be required to fully hamper aggregate formation due to either a problem in peptide: i) stability, ii) expression or iii) cellular localization. Whereas P42B does not seem to fully prevent aggregation, its detection in aggregates further confirms a model whereby P42 might interact directly with polyQHtt.

ADPD5-1823
APPLICATION OF PROTEINOPATHY PLASMA BIOMARKERS IN NEURODEGENERATIVE DISEASES

M. Chiu[1], S.Y. Yang[2], T.F. Chen[1], K.Y. Tzen[3], L.Y. Fan[4], H.E. Horng[5]
[1]Neurology, National Taiwan University Hospital, Taipei city, Taiwan
[2]Institute of Electro-optical Science and Technology, National Taiwan Normal University, Taipei city, Taiwan
[3]Nuclear Medicine, National Taiwan University Hospital, Taipei city, Taiwan
[4]Neurology, En Chu Kong Hospital, New Taipei city, Taiwan
[5]Neurology, En Chu Kong Hospital, Taipei city, Taiwan

Protein aggregation is a common characteristic of many neurodegenerative disorders, and the interaction between pathological-toxic proteins to cause neurodegeneration is an important issue of current neuroscience research. Evidence increasingly indicates considerable overlap between synucleinopathies and tauopathies or other protein-misfolding diseases. New findings suggested synergistic effects of α-synuclein, hyperphosphorylated-tau, amyloid β, and other pathologic proteins including induction and spread of protein aggregates are possible underlying molecular pathogenic mechanisms.

We used an immunomagnetic reduction (IMR) assay to measure the plasma levels of Aβ40, Aβ42, tau proteins and α-synuclein in 20 older control participants, 10 participants who had either mild cognitive impairment due to Alzheimer's disease (AD) or early AD dementia; 5 patients with dementia of Lewy's bodies (DLB), 5 patients with Parkinson's disease dementia (PDD), 5 with Parkinson's disease and 5 with frontotemporal lobe dementia (FTLD). IMR assay works by determining the per cent of reduction in the magnetic field produced by an alternating current (ac). This reduction is due to a decrease in the magnetic susceptibility (c_{ac}) of a bio-functionalized magnetic nanoparticle reagent due to its association with target bio-molecules. All participants received ^{11}C-labeled Pittsburgh compound B PET scans to displays amyloid retention in the brain for correlation.

Results show that in comparison with normal elderly control, plasma Aβ42 (Aβ42/Aβ40) and plasma total tau proteins were both increased in early Alzheimer's disease; only plasma total tau proteins but not Aβ42 (Aβ42/Aβ40) were increased in FTLD. The results of plasma α-synuclein for patients with DLB and PDD will be also reported.

03e. Pathophysiology & Disease Mechanisms: proteasome and ubiquitin

ADPD5-0704

UBIQUITIN-MEDIATED PROTEOLYSIS IS AFFECTED IN BRAINS OF SMALL VESSEL DISEASE AND CADASIL PATIENTS.

M. Ritz[1], S. Engelter[2], M.F. Tolnay[3], N. Peters[2], P. Lyrer[2]
[1]Department of Biomedicine, Pharmacenter, Basel, Switzerland
[2]Stroke Center, University Hospital Basel, Basel, Switzerland
[3]Institut of Pathology, University Hospital Basel, Basel, Switzerland

Objectives. Sporadic cerebral small vessel disease (SVD) and its hereditary form, cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) lead to vascular cognitive impairment (VCI) and subcortical vascular dementia. This project was conducted in order to elucidate the molecular mechanisms underlying sporadic and hereditary SVD causing cerebral ischemia and consequently paresis, speech problems and cognitive decline.
Methods. We compared the gene expression in post-mortem brain specimen dissected from the frontal and occipital cortex and white matter of 5 SVD and 2 CADASIL patients with samples from 5 non-neurologically affected controls, using oligonucleotide-based microarray technology (Affymetrix® Genechips). Gene annotation and statistical analysis were performed using Partek® Genomics Suite. Genes with fold expression changes $F > 1.2$ in both directions, and $P < 0.05$ were considered significantly differently expressed between diseased and control groups. Biological functions enriched with these up- and down-regulated genes were identified using DAVID® bioinformatics resources.
Results. Functional classification revealed many cellular pathways affected in SVD and CADASIL. A common pathway involving many under-expressed genes in several brain regions of SVD and CADASIL patients was ubiquitin-mediated proteolysis. We confirmed these transcriptomic results by immunohistochemistry on brains sections, showing accumulation of mono-and poly-ubiquitinated proteins, including p62 or P-Tau.
Conclusions. These results demonstrated that, on a molecular level, SVD and CADASIL follow patterns of neurodegeneration with deregulation of the ubiquitin-mediated proteolysis, inducing formation of protein aggregates. These results suggest that activating the ubiquitin proteasome system may represent a new strategy to treat patients with cerebral small vessel diseases.

DIABETES AUGUMENTS COGNITIVE DYSFUNCTION IN CHRONIC CEREBRAL HYPOPEFUSIO BY INCREASING NEURONAL CELL DEATH: IMPLICATION OF CILOSTAZOL FOR DIABETES MELLITUS-INDUCED DEMENTIA

S. Han[1], K.J. Kwon[1], E.J. Lee[1], J.O. Kim[1], H.J. Kim[2], H.Y. Kim[1], C.Y. Shin[3]
[1]Neurology, Konkuk University Medical Center, Seoul, Korea
[2]Neurology, Hanyang University Medical Center, Seoul, Korea
[3]Pharmacology, Konkuk University School of Medicine, Seoul, Korea

Background and purpose- Many patients with diabetes are at increased risk of cognitive dysfunction and dementia. We tested whether cognitive impairment could be exacerbated in combined injury using a rat model of chronic cerebral hypoperfusion with diabetes. We also determined whether a potent inhibitor of type III phosphodiesterase could prevent the cognitive decline caused by this combined injury.

Methods- We used OLETF rats as a model of type II diabetes (T2DM) and LETO rats as a control. Chronic cerebral hypoperfusion was modeled by permanent bilateral common carotid artery occlusion. At 24 weeks, the non-diabetic and T2DM rats were randomly assigned into groups for the following experiments: (1) sham non-diabetic ; (2) hypoperfused non-diabetic ; (3) sham T2DM ; (4) hypoperfused T2DM rats. Rats were orally administered cilostazol (50 mg/kg) or vehicle once a day for 2 weeks after 24 weeks. Morris water maze tasks were used to assess behavioral test., and neuronal cell death and neuroinflammation were investigated via Western blots and histological investigation.

Results- Spatial memory impairment was exacerbated synergistically in the hypoperfused T2DM group compared with the hypoperfused non-diabetic group and sham T2DBM group ($P < 0.05$). Compared with the control group, neuronal cell death was increased in the hippocampus of the hypoperfused T2DM group. Cilostazol, a PDE-3 inhibitor, improved the memory impairments through inhibition of neuronal cell death, activation of CREB phosphorylation and BDNF expression in hypoperfused T2DM group.

Conclusion- Our experimental results support the hypothesis that there are deleterious interactions between chronic cerebral hypoperfusion and T2DM

NEUROINFLAMMATION INCREASES IN A MOUSE MODEL OF ALZHEIMER'S DISEASE FEATURING VASCULAR COMORBIDITY

A.M. Helman[1], T.L. Beckett[2], D.M. Niedowicz[2], K. Kohler[2], V.L. Reeves[2], T.L. Lee[2], D.M. Wilcock[2], M.P. Murphy[2]
[1]Molecular and Cellular Biochemistry, University of Kentucky, Lexington, USA
[2]Sanders-Brown Center on Aging, University of Kentucky, Lexington, USA

Objectives: Obesity and type 2 diabetes mellitus are risk factors for developing Alzheimer's disease (AD) and vascular dementia. This disease pathology includes small strokes, cerebrovascular occlusions, and cerebral microhemorrhages. To examine this unique disease state we developed a db/AD mouse model: a cross between the db/db diabetic mouse and the APP(ΔNL)/PS1(P264L) double knock-in model of amyloid pathology. The diabetic phenotype causes unique vascular changes, including aneurysms, microhemorrhages, and gray matter microinfarcts.
Methods: Gene expression profiles were collected using microarray data analysis and array cards probing for neuroinflammatory markers. Microglial and astrocytic activation, astrocytic dysfunction, and neurovascular coupling were assessed via immunohistochemistry on fixed hemibrains.
Results: The db/AD mice had significant differences in metabolic pathways and a general increase in neuroinflammation, including astrocyte and microglial activation. Astrocyte activation was prominent near amyloid deposits, and around some blood vessels (vascular amyloid was not required for astrocyte activation). Additionally, we saw changes in the aquaporin-4 water channel, the calcium-dependent potassium channel Kir4.1, and several matrix metalloproteinases, indicating generalized astrocyte dysfunction, particularly at astrocytic end-feet.
Conclusions: We have created a mouse that models a mixed dementia disease state, with both AD and vascular pathologies that can be used to better understand how obesity and type 2 diabetes contribute to the development of dementia. Further elucidating the role of inflammation, and the specific role that astrocytes play in the development of pathology, will be important for improving our understanding of the disease, and for the design of potential therapies. Funded by NIH (ES024158, AG045809, NS083692).

ADPD5-2045

MARKERS OF INFLAMMATION IN ISCHEMIC STROKE PATIENTS:AN ADDITIONAL CRITERION OF LONG-TERM COGNITIVE IMPAIRMENT

M. Danovska[1], M. Alexandrova[2]
[1]Department of Neurology, University Hospital, Pleven, Bulgaria
[2]Department of Biophysics, Medical University, Pleven, Bulgaria

Limited data has shown that elevated levels of some inflammatory markers in the circulation of ischemic stroke patients indicate future cognitive deterioration.The objective of the present study is to establish important determinants of cognitive deficit that can be evaluated immediately after stroke onset and prove useful in predicting cognitive decline in the first year post-stroke. Methods: We examined 47 ischemic stroke patients admitted within 48 hours of ictus. Their neurological and cognitive status, biochemical parameters and microalbuminuria level were prospectively evaluated over a 1-year period post-stroke. Results: A more severe neurological deficit was found in the cognitively impaired then in the cognitively normal patients (p=0.003). A time-varying dynamics of the MMSE score was observed in both patient groups (p=0.000). Age (p=0.000), level of education (p=0.004), gender (p=0.041), history of diabetes (p=0.045) and serum high sensitive C-reactive protein (hs-CRP) on admission (p=0.003) were significant determinants of cognitive decline 1 year after stroke. The patients with cognitive decline had persistently high WBC and granulocyte counts. The albumine-to-creatinine ratio was high during the whole follow-up period in the cognitively impaired group even after adjusting for sex and age (p=0.010). The ordinal logistic regression analysis showed that hs-CRP (p=0.005) and age (p=0.000) were independent predictors of patients' cognitive status, represented as a three level ordinal scale. Conclusion: The level of inflammatory markers could be considered as an additional criterion of long-term post-stroke cognitive impairment and a rational approach in view of treatment strategies especially among female stroke patients.

ROLE OF VON WILLEBRAND FACTOR IN EARLY DETECTION OF ACUTE ISCHEMIC CEREBROVASCULAR STROKE

D. Alsalmawy[1], *A. Fayed*[1]
[1]*Neurology, Faculty of medicine Alexandria University, Alexandria, Egypt*

Role of Von Willebrand Factor In Early Detection Of Acute Ischemic Cerebroveascular Storke

Doaa Hanafy Alsalamawy, Akram Muhammed Fayed, Muhammed Momtaz El-Sawy
Faculty of Medicine- Alexandria University - Egypt

Background: von Willebrand factor is a blood glycoprotein involved in coagulation, Its primary function is to bind to factor VII to prevent it's degradation, also it is important for platelet adhesion activity becomes elevated in both the acute and subacute phases of ischemic stroke and it may be associated with increased mortality. Objective to asses the potential diagnostic utility of blood born protein biomarkers in predicting acute ischemic stroke. Material and methods: 40 patients of both sex admitted with acute ischemic stroke and ten control normal subject for each patient complete lab investigations and clinical investigations, Von Willebrand factor was done using ELIZA technique. Results: Von Willebrand factor showed significantly more positive results among patients 74.5% than control 10%. Conclusion: Von Willebrand factor become elevated in early stage of acute ischemic stroke and is related to the stroke severity.

[4]Metabolismo e Doenças Cardiovasculares, Starmedica.Clinica, Paredes, Portugal

Objective:
Assessement between the relation of 189 patients, 132 women (69.84%) with ages between 20-55 years, mean range 37,5 years and, 57 men (60.16%) with ages between 25-55 years, mean age 40 years, bearers of dyslipidemia and depressiv syndrome (DS) for at least 3 years, with familiar priors of metabolic and CV risk.
Design and method:
All patients involved in this study had a previous anthropometric, biochemical, clinical and vascular evaluation. Therapeutic response was initiated with serotonin reuptake inhibitors (SRI) and statin, associated a modification in lifestyle.
In 67 women (50.75%) between 20-30 years, an important correlation was found, between de clinical condition and hypotension. After 24 months an auto evaluation (15D and SF-36 surveys) was proposed to all patients.
Results:
The mean values of cholesterol in women´s group was HDLc-38 mg/dl, LDLc - 135.5 mg/dl and in men´s group was a HDLc - 33 mg/dl and LDLc-163 mg/dl
In 75 (39.68%) patients with ages comprises between between 35-55 years, augmented values of IMT were found during carotid vascular assessement (mean - 2.3 mm) without differentiation of sexes.
After 24 months 98% complying therapeutic proposed and changing lifestyle.
Subsequent biochemical evaluation of women´s group showed mean values of HDLc - 53 mg/dl and LDLc - 93 mg/dl, whereas the men´s group had a mean HDLc - 44 mg/dl and LDLc - 90.5 mg/dl.
In the group of 75 patients with ages comprised between 35-55 years, there was a significant decrease of the mean IMT - 1.75 mm.
The women´s group with ages between 20-30 years kept a hypotension profile.

03r. Pathophysiology & Disease Mechanisms: vasculature & neoangiogenesis

PERLECAN DOMAIN V IS DIFFERENTIALLY ALTERED IN AN EXPERIMENTAL MODEL OF COGNITIVE IMPAIRMENT AND DEMENTIA

A. Marcelo-McCabe[1], J. Roberts[1], H. Brothers[1], D. Wilcock[1], G. Bix[1]
[1]Sanders-Brown Center on Aging, University of Kentucky, Lexington, USA

Objectives: Although vascular contributions to cognitive impairment and dementia (VCID) are the second leading causes of dementia after Alzheimer's disease, they remain poorly understood due to their diverse etiology. The brain may attempt to compensate for vascular injury and resultant hypoperfusion via angiogenesis, the process of new blood vessel growth from pre-existing vasculature, and regulated by growth factors and the extracellular matrix (EM). We hypothesize that the bioactive domain V (DV) protein fragment of the EM component perlecan regulates angiogenesis in response to VCID pathology which is experimentally studied with the bilateral carotid artery stenosis (BCAS) model. Furthermore, we hypothesize that vascular injury and cognitive impairment is caused, in part, by gradual diminishment of DV levels.
Methods: Male C57/BL6 mice were subjected to BCAS by wrapping metal coils around the carotid arteries which remained in place for 30 days or 6 months. Brains were removed for qPCR, immunohistochemical, and Western analysis.
Results: qPCR analysis showed no change in perlecan gene expression in the thalamus of BCAS mice at 30 days or 6 months. However, there was a significant increase in gene expression in the cortex of BCAS mice at 30 days compared to sham. Immunohistochemistry also showed an increase in DV in the cortex after 30 days. Western blot analysis demonstrated a trend of decreased cortical DV protein expression in BCAS mice compared to sham mice after 6 months.
Conclusions: DV may play a role in regulating angiogenesis, and its gradual diminishment over time could contribute to VCID.

ADPD5-0644
COGNITIVE CORRELATES OF CEREBROVASCULAR REACTIVITY IN OLDER ADULTS

Y.S. Shim[1], K.Y. Eah[2], D.S. Shim[3]
[1]Neurology, The Catholic University of Korea College of Medicine, Bucheon, Korea
[2]Neurology, Dongguk University Kyungju Hospital, Kyungju, Korea
[3]Neurology, The Catholic University of Korea, Bucheon, Korea

Introduction: Cerebrovascular dysfunctions play a role also in the pathogenesis of Alzheimer's disease (AD), and Transcranial Doppler sonography (TCD) can be used for the cerebral hemodynamic measures. The aim of this study was to explore the contribution of cerebral hemodynamic changes to the cognitive impairment in patients with AD.
Methods: A total of 194 subjects representing 52 controls, 75 patients with mild cognitive impairment (MCI) and 67 patients with AD were included. By using TCD, cerebrovascular reactivity (CVR) was evaluated by the breath-holding, in addition to the mean blood flow velocity (MFV) and pulsatility index (PI) of the middle cerebral artery. Analyses were adjusted for age, education, severity of white matter hyperintensities, and vascular risk factors.
Results: AD patients were older and low-educated (all, $p<0.001$). After adjusting for covariates, MFV and PI did not differ among three groups. However, CVR was significantly reduced in AD group (45.33±11.49 cm/sec), compared with other groups ($p<0.001$). MMSE score was correlated with PI ($r=-0.192$, $p=0.004$) and CVR ($r=0.263$, $p<0.001$). Multiple regression also showed CVR was associated with mini-mantal state examination (MMSE) score. CVR value was different according to clinical dementia rating (CDR) score ($p<0.001$)
Conclusion: Our finding that CVR is reduced in AD may be suggestive of underlying microangiopathic mechanism. Furthermore, there was an association between impaired cerebrovascular reactivity and cognitive impairment in older adults. Further research is needed to fully establish whether altered cerebral hemodynamics may be considered an independent factor of cognitive decline or an effect of pathological processes involved in AD.

ADPD5-1520
EFFECTS OF WHITE MATTER DISEASE ON DEMENTIA

T. Chabrashvili[1], H. Lamonica[1], B. Sawaya[2]
[1]Neurology, Tufts Medical Center and Tufts University School of Medicine, Boston, USA
[2]Neurology, Temple University School of Medicine, Philadelphia, USA

White Matter Disease (WMD) is a reflection of multiple microinsults to the brain over a person's lifetime. We aim to study the burden of white matter disease in an elderly urban population diagnosed with dementia. We hypothesize that White Matter Hyperintensity (WMH) volume and region-specific distribution may be associated with an increased risk of developing dementia and may serve as an MRI marker of risk of dementia. METHODS: We retrospectively selected the MR images of patients with a diagnosis of dementia and quantitatively measured the volume and distribution of WMH on MR fluid attenuated inversion recovery images using an import DICOM (Digital Imaging and Communications in Medicine) image tool of Analyze 10.0 software (AnalyzeDirect). The locations specified were Subcortical, Deep White Matter (DWM) and Periventricular parenchyma. We compared them to age matched controls. RESULTS: 877 patients were diagnosed with Alzheimer's dementia from 2000 to 2010 in an urban hospital. There were 398 patients identified with both dementia and stroke; from the remaining 479 patients with dementia only, 105 had MR imaging available for review (age: 69.2+10.4 years). The dementia group had a significantly higher total ((1.38%+1.30% vs. 0.55%+0.66%, $p<0.02$), deep (0.36%+0.38% vs. 0.14%+0.15%, $p<0.01$) and periventricular (0.10%+0.09% vs. 0.03%+0.04%, $p<0.04$) WMD compared to the controls. CONCLUSION: Dementia patients have significantly more WMD burden than age matched controls in total, deep and subcortical white matter disease. Patients with extensive WMH should be identified and aggressively treated to slow the progression of vascular insults that may affect the progression of dementia.

ADPD5-1571

BRAINS FOR DEMENTIA RESEARCH: CONCORDANCE OF VASCULAR FACTORS DURING LIFE WITH VASCULAR PATHOLOGY POST MORTEM

G. Hayes[1], P. Francis[1]
[1]Wolfson Centre for Age Related Diseases, King's College London, London, United Kingdom

Background:
Brains for dementia Research (BDR) is a programme of planned brain donation with structured assessments of cognition behaviour and function during life. There are now approximately 3,000 participants of which over 250 have died. Participants may or may not have cognitive impairment when they join. This cohort provides the opportunity to examine concordance between vascular factors recorded during life (Hachinski Ischemia score, CAMDEX past history) and evidence of vascular pathology at post-mortem.
Methods
Hachinski Ischemia score and CAMDEX past history were used to provide evidence of vascular factors and the neuropathological examination where details of any vascular pathology was recorded using established methods by BDR neuropathologists.
Results.
Preliminary examination of data showed that 47 of the deceased had Hachinski score calculated during life with 7 scoring 5 or above. Surprisingly only 4 of these cases had clear evidence of vascular pathology. Of the remaining 41, with score 4 or below evidence of vascular pathology was noted in 13 cases (3 as principle diagnosis). Examination of CAMDEX past history is ongoing.
Conclusions
At face value and consistent with some previous reports there is limited concordance between assessments of vascular factors during life and post-mortem vascular pathology. It may be that some recording of vascular pathology may relate to vascular events after the last assessment or that specific risk factors provide a better indication of subsequent vascular pathology. The BDR cohort (data and tissue) is available to researchers to answer questions relevant to people with dementia.

04a. Therapeutic Targets & Mechanisms for Treatment: immunotherapy

ADPD5-0974

EFFECTS OF IMMUNOTHERAPY ON STROKE PATHOLOGY IN A MOUSE MODEL OF ALZHEIMER'S DISEASE AND VASCULAR DEMENTIA

T.L. Beckett[1], K. Kohler[1], D.P. Powell[2], D.M. Niedowicz[1], M.P. Murphy[1]
[1]Sanders-Brown Center on Aging, University of Kentucky, Lexington, USA
[2]MRISC, University of Kentucky, Lexington, USA

OBJECTIVES People with type 2 diabetes (T2DM) are at a higher risk for age-related dementias such as Alzheimer's disease (AD), and for vascular complications such as stroke and vascular de-mentia. We have created a novel mouse line which combines a diabetic phenotype with a model of amyloid deposition in order to study the confluence of T2DM and AD.

METHODS We crossed the leptin receptor deficient db/db mouse with the APP(ΔNL)/PS1(P264L) knock-in mouse to create a novel mouse line that displays vascular disturbances (stroke, microhemorrhage) and severe cognitive deficits – the db/AD mouse. To determine the effect of amyloid-beta (Aβ) on vascular pathology, we began active immunotherapy with fibrillar Aβ42 at ~2 months of age, with boosters at regular intervals for 10 months. Cognitive ability was then measured with Morris water maze and stroke pathology was measured via MRI.

RESULTS Preliminary results indicate a potentially small cognitive benefit due to active immunization independent of genotype, although the bulk of the study is still underway. However, the benefit was small, and unrelated to improving cerebrovascular pathology. In fact, as with other immunotherapy treatments, we have seen some increased severity of stroke pathology in a small number of animals.

CONCLUSIONS The results of this study imply that removal of Aβ alone will not necessarily be sufficient to treat AD with vascular comorbidity or vascular cognitive impairment. A secondary arm of this study will investigate the broader role of γ-secretase function in the development of pathology.

GLUTAMATE INDUCES NA+/H+ EXCHANGER-1 (NHE-1) ACTIVATION THROUGH SUSTAINED INTRACELLULAR ACIDOSIS, WHICH LEADS TO PHOSPHORYLATION OF NHE-1 THROUGH PKC-BETA PATHWAYS

B. Lee[1], *Y. Jung*[1]
[1]*College of Pharmacy, Ajou University, Suwon, Korea*

1. Objectives The Na^+/H^+ exchanger-1 (NHE-1) is a ubiquitously expressed pH-regulatory membrane protein that functions in the brain. It is increased by intracellular acidosis through the interaction of intracellular H^+ with an allosteric modifier site in the transport domain. In the previous study, we investigated that glutamate-induced NHE-1 phosphorylation mediated by activation of PKC-beta in cultured neuron cells via ERK/p90RSK pathways result in NHE-1 activation. However, whether glutamate stimulates NHE-1 activity solely by the allosteric mechanism remains elusive. **2. Methods** Cultured primary cortical neuronal cells were subjected to intracellular acidosis by exposure to 100 μM glutamate or 20 mM NH4Cl. After the desired duration of intracellular acidosis, the phosphorylation and activation of PKC-beta, ERK1/2 and p90RSK were determined by Western blotting. **3. Results** We investigated that duration of intracellular acidosis is controlled by glutamate exposure time. The NHE-1 activation increased while intracellular acidosis is sustained for > 3 min. To determine sustained intracellular acidosis induces NHE-1 phosphorylation, we examined the phosphorylation of NHE-1 induced by intracellular acidosis by transient exposure to NH_4Cl. Sustained intracellular acidosis activated and phosphorylated NHE-1. In addition, sustained intracellular acidosis also activated the PKC-beta, ERK1/2 and p90RSK in neuronal cells. **4. Conclusions** We conclude that glutamate stimulates NHE-1 activity through sustained intracellular acidosis which mediates NHE-1 phosphorylation regulated by PKC-beta/ERK1/2/p90RSK pathways in neuronal cells. This work was supported by the Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology [Grant 2012R1A1A2044497].

THERAPEUTIC POTENTIAL OF WITHANIA SOMNIFERA SUPPLEMENTATION: IMPLICATIONS IN EXPERIMENTAL FOCAL CEREBRAL ISCHEMIA

A. Sood[1], *R. Sandhir*[1]
[1]*Biochemistry, Panjab University Chandigarh, Chandigarh, India*

Objective:
To investigate the neuroprotective efficacy of *Withania somnifera (WS)* supplementation in preventing focal cerebral ischemia.

Methods:
Ischemic stroke was induced in male wistar rats using middle cerebral artery occlusion (MCAO) for 90 min, followed by reperfusion injury for 24 hrs. The progression of cerebral ischemia was assessed by single-photon emission computed tomography (SPECT) and the preventive effect of *WS* supplementation was analyzed via TTC staining including histopathological examination. Neurobehavioral tasks including, actophotom-eter, narrow beam walk, morris water maze and novel object recognition test were evaluated using Anymaze tracking software. Brain water content, blood-brain barrier integrity and matrix metalloproteinases (MMPs) levels were assessed.

Results:
MCAO rats showed increased neurobehavioral deficit score, significant motor impairments (assessed using narrow beam walk, actophotometer test) and cognitive deficits (assessed using Morris water maze test and novel object recognition test). A significant reduction in cerebral blood flow was observed in SPECT scanning of MCAO animals. MCAO animals also showed marked histopathological changes in terms of increased cerebral infarct volume, presence of pyknotic nuclei and astrogliosis in the cortex. Enhanced blood brain barrier leakage and brain edema were observed following ischemia reperfusion injury, as shown by increased Evan's blue staining, higher brain water content and increased MMPs levels. However, *WS* pre-treatment (300 mg/kg body weight) for 30 days to MCAO animals was able to efficiently improve behavioral functions, attenuate blood brain barrier alterations and reduced histological changes.

Conclusion:
The result suggests the propensity of *WS* supplementation in preventing ischemic stroke.

POSSIBILITY OF METABOLIC THERAPY IN TREATMENT OF VASCULAR COGNITIVE IMPAIRMENT.

L. Gimoyan[1], G. Silvanyan[2]
[1]Neurology, Yerevan State Medical University, Yerevan, Armenia
[2]Angioneurology, Yerevan State Medical University, Yerevan, Armenia

Objectives. Neuropathological studies in most cases of dementia and cognitive impairment reveal a large load of vascular ischemic brain lesions. Therefore we have explored effect of antioxidant drug mildronat (meldonium) and neuroprotective citicoline (ceraxon) use in patients with vascular cognitive impairment. This drugs have demonstrated neuroprotective effects in acute stroke and has been shown to improve cognition in patients with vascular cognitive impairment and even in some patients with Alzheimer disease but with no clear consensus.

Methods . 120 patients (72 female , 48 male, average age 71,6 years) with vascular cognitive impairment received mildronat 1000 mg i/v and ceraxon 1000 mg i/v for ten days and then continued treatment orally for 6 months. Main clinical manifestations were impaired attention and forgetfulness, psychomotor slowing, impaired executive and visuospatial skills, change in personality, and emotional disturbance. The patient closely followed clinically, with repeated neuropsychological assessment. Results compared with a control group (N=135).

Results

The benefits of treatment began to be apparent within the first monthes.46 patients showed stable improvement in cognitive performance measures and in daily life. 40 patients trend back to their baseline. 34 patients had no improvement after treatment. There was no case of worsening disease or bad drug bearing. Statistically significant reduction in cognitive impairment was seen in the treated group in the domains of memory, attention and executive functions.

Conclusion The use of mention drugs has proved to be a valid treatment in patients with a vascular cognitive impairment and appears to be a safe.

ADPD5-1632
COGNITIVE IMPAIRMENT AND HYPOTHYREOSIS
L. Gimoyan[1], S. Asatryan[2]
[1]Neurology, Yerevan State Medical University, Yerevan, Armenia
[2]Neurology, 2-nd medical hospital of Erevan, Yerevan, Armenia
Objectives. In the practice of neurology we often face to cognitive impairment due to is different couses. One of which is hypothyreosis; the last one is often unrecognised, becouse it proceeds under mask of other deasises. The timely recognition of patology promotes the benifits of treatment resalts.
Methods. We observed 70 patients with mild and moderate cognitive impairment, 51 female, 19 male, average 60±7,5. The patiens were observed in dynamic with clinical examination, neuropshichology tests, CT, MRI, labarator, inclusive hormonal tests. 43 patients detected clinical or subclinical hypothyreosis. 40 patents have accompanied anemia and bradycardia.
Results. 38 patients were get same improuvment after addition of hormonal therapy to neuroprotective treatment, benefits were seen in the domains of memory, attention, executive functions, bradycardia and anemia. 5 had no any improvement. There was no case of worsening disease or bad drug bearing.
Conclusion. Additional ivertigations should be done to understand in this cases the real couse of cognetive impairment (hypothyreosis, anemia, bradycardia). All patients with mild and moderate cognitive impairment should be screened for revealing hormonal disturbanses.

ADPD5-0285
NOOTROPIC TREATMENT OF COGNITIVE IMPAIRMENT IN EARLY REHABILITATION PERIOD OF ISCHEMIC STROKE

L. Pustokhanova[1], E. Morozova[1]
[1]Department Of Neurology, Perm State Medical Academy, Perm, Russia

Objectives. To determine cognitive status in poststroke patients and carry out pathogenetic therapy.
Methods. Ninety five poststroke patients (38–82 years, 61 males and 34 females) were randomly assigned to receive phenotropil (n=64) or placebo (n=31) in a double-blind study. Clinical and neuropsychological investigation was carried out at one and three months after the first hemispheric ischemic stroke with the use of NIHSS, Barthel index (BI), MMSE, FAB, Semantic and Phonetic Verbal Fluency test (SVFT and PVFT), attention test (AT), Clock Drawing Test (CDT). Background indices and their change during 2 months' treatment with phenotropil/placebo were evaluated. Control group consisted of 35 persons without stroke.
Results. The data differences between poststroke patients and control group were fixed in MMSE (p=0.0003), FAB (p=0.0000), SVFT (p=0.0001), PVFT (p=0.0033), AT (p=0.0001) one month after stroke. The decrease of neurological deficit and frontal dysfunction was found in both groups: phenotropil (p = 0.0031 and p = 0.0000) and placebo (p=0.0208 and p=0.0003). Only after treatment with phenotropil the indices MMSE (p = 0.0004) and CDT (p = 0.0064) were improved, differences with control group in MMSE, FAB and PVFT disappeared. The data differences between poststroke patients and control group in MMSE (p = 0.0043), FAB (p = 0.0094) and PVFT (p = 0.0383) remained after treatment with placebo.
Conclusion. The decrease of frontal functions, verbal fluency and attention is observed in poststroke patients. The use of phenotropil in rehabilitation period leads to normalization of existing disorders and regress of neurological deficiency.

GLYCEMIC REGULATION THROUGH KETOGENIC DIET OR METFORMIN TREATMENT IN A NOVEL MURINE MODEL OF TYPE 2 DIABETES AND ALZHEIMER'S DISEASE

K. Kohler[1], D.M. Niedowicz[1], D.K. Powell[2], T.L. Beckett[1], T.L. Platt[1], M.P. Murphy[1]
[1]Sanders-Brown Center on Aging, University of Kentucky, Lexington, USA
[2]MRISC, University of Kentucky, Lexington, USA

OBJECTIVES. Our mice combine two disease models, Type 2 Diabetes and Alzheimer's disease (AD). They are morbidly obese, diabetic, and show both severe vascular and beta-amyloid (Aβ) pathology in the brain with increasing age. In this study, we investigated the outcome of treatment with either the anti-diabetic drug metformin or a short-term ketogenic diet in regards to weight, cholesterol, insulin and glucose levels, and the effects on neuropathology in this mouse line.
METHODS. For our diet study, we placed 4-5 month old mice of varying genotypes on a ketogenic diet (~80% calories from fat) for three months and evaluated weight, glucose, Aβ, phospho-tau, insulin, leptin and cholesterol levels. Metformin (200 mg/kg/day) was used to treat middle-aged diabetic mice, which were then subjected to a cognitive evaluation via Morris water maze, and subsequently imaged by MRI.
RESULTS. Endpoint measures of the ketogenic diet showed that, although the diet had no effect on weight, it lowered both plasma glucose and insulin levels, while cholesterol levels remained unchanged. Leptin levels increased significantly, whereas the presence of both Aβ and phospho-tau were decreased. The mice were surprisingly resistant to metformin, which resulted in only modest benefits.
CONCLUSIONS. As vascular or mixed dementia is an important area for the development of therapies, further exploration of these and other interventions will be important in the db/AD mice. We are particularly interested in how environmental exposures interact with the natural course of the disease to influence the development of neuropathology. Funded by NIH (ES024158, AG045809, NS083692).

ADPD5-2008

EFFECT OF INTENSIVE GLYCAEMIC CONTROL ON COGNITIVE DECLINE IN PATIENTS WITH TYPE 2 DIABETES: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

R. Tuligenga[1]
[1]*CESP, INSERM 1018, Villejuif, France*

Abstract

Aim:

The aim of this meta-analysis was to compare the effect of intensive versus standard glycaemic control on cognitive decline in type 2 diabetic patients.

Methods:

A systematic search of PubMed and ALOIS was conducted from inception up to October 30, 2014. Randomized controlled trials (RCTs) of type 2 diabetic patients comparing the rate of change in cognitive function among participants assigned to intensive versus standard glycaemic control were included. An inverse-variance weighted random-effects model was used to calculate standardized mean differences (SMDs) and 95% confidence intervals.

Results:

A total of 24, 297 patients from five RCTs were included in the meta-analysis. Follow-up ranged from 3·3 to 6·2 years. The result from the pooled analysis showed that intensive glycaemic control was not associated with slower rate of cognitive decline in patients with type 2 diabetes, compared to standard glycaemic control. (SMD=0·02; 95% confidence interval = -0·03 to 0·08) although there was some heterogeneity across individual studies (I^2=68%, P for heterogeneity=0·01).

Conclusions:

There are few diabetes control trials including cognitive endpoints and a small number of trials comparing intensive and standard treatment strategies. Currently, intensive glycaemic control should not be recommended for prevention of cognitive decline in patients with type 2 diabetes because there is no evidence of its effectiveness. Moreover, the use of intensive diabetes treatment results in an increase of risk of hypoglycaemia, which is linked to greater risk of poor cognition.

EFFECT OF A SPECIFIC MULTI-NUTRIENT DIET ON SYSTOLIC BLOOD PRESSURE AND CEREBRAL HEMODYNAMICS IN AGING APOE4 AND APOE-KO MICE

M. Hellwich[1], M. Wiesmann[1], V. Zerbi[1], D. Jansen[1], L. Mellendijk[1], L.M. Broersen[2], A. Heerschap[3], J.A.H.R. Claassen[4], A.J. Kiliaan[1]
[1]Anatomy,
Radboud University Medical Centre Donders Institute for Brain Cognition and Behaviour, Nijmegen, Netherlands
[2]Nutricia Research, Nutricia Advanced Medical Nutrition, Utrecht, Netherlands
[3]Radiology, Radboud University Medical Centre, Nijmegen, Netherlands
[4]Geriatric Medicine, Radboud University Medical Centre, Nijmegen, Netherlands

Objectives
It is known that the cholesterol-transporter apolipoprotein ε (apoE) genotype is associated with the development of both cardiovascular and neurodegenerative diseases like Alzheimer's disease (AD).
We tested the effects of long-term consumption of a specific multi-nutrient diet on systolic blood pressure (SBP) and cerebral hemodynamics in two vascular risk models: the apolipoprotein ε4 (apoE4) and the apoE knockout (apoE-ko) mice.
Methods
We investigated the relationship between SBP monitored twice each month via tail cuff plethysmography, cerebral blood flow (CBF) measured with MR by FAIR-ASL, and a dietary intervention in 16-18 month old wild-type (WT) C57bl/6j controls, apoE-ko and apoE4-mice. At 2 months of age, the mice were put on the diets (Control + Experimental) for the remainder of the experiment.
Results
From 16-18 month of age, apoE-ko mice had an increased SBP compared to WT littermates, which was lowered by the Experimental diet. In addition, the Experimental diet increased also the cortical CBF in apoE-ko mice.
At 18 month of age, only Control fed apoE4 mice had a raised SBP compared to their WT littermates, being not visible in apoE4 mice fed the Experimental diet. The cortical and thalamic CBF was decreased at 18 month of age. All animals fed the Experimental diet had a higher CBF than Control fed animals.
Conclusions
We provide new evidence for a relationship between apoE and risk factors for AD. Our data suggest that this specific multi-nutrient diet has beneficial effects on early pathological consequences of hypercholesterolemia and vascular risk factors for AD.

ADPD5-0262

THE CORRELATION OF WMH AND COGNITION IN BINSWANGER TYPE VCIND AND VAD

J. Kwon[1], J. Yoon[2], K. Lee[3], S. Ahn[1], Y. Hong[1]
[1]Neurology, Fatima Hospital, Changwon-si, Korea
[2]Bio and Brain Engineering, Korea Advanced Institute of Science and Technology, Daejeon-si, Korea
[3]Neurology, Samsung medical center, Changwon-si, Korea

Objectives: To evaluate the correlation of white matter hyperintensities(WMH) and cognition in patients with Binswanger type vascular cognitive impairment without dementia(VCIND) and vascular dementia(VaD).

Backgrounds: Because of its heterogeneity, research of vascular dementia is very difficult to perform and design. Among them, Binswanger type subcortical abnormalities(i.e. white matter hyperintensities, WMH) is relatively happened homogenously to its pathophysiology and clinical features. Although we frequently notice WMH on advanced MRI, we don't yet understand the role of WMH on cognition.

Methods: Patients(N = 57) with Binswanger type VCIND(N=27, K-MMSE =22.67±3.85) and VaD(N=30, K-MMSE =14.53±5.99), according to neuroradiological working criteria, were selected. We excluded subjects with significant number of lacunes for more homogenous group. We evaluated the volume and location of WMH on MRI by visual rating. For detailed cognitive function assessment, all subjects were performed Seoul Neuropsychological Screening Battery-Dementia version (SNSB-D).

Results: The performance of general cognitive function is not correlated with total volume of WMH in Binswanger type VCIND and VaD. The performance of each cognitive subdomain is also not correlated with related area in MRI. The cognitive function is influenced by their educational level and sometimes age. After control the total volume of WMH, education and age factors, ratio of anterior to posterior WMH volume is correlated with general cognitive function.

Conclusions: The volume and location of WMH is not correlated with cognitive performance in Binswanger type VCIND and VaD. We suggest its possible role of WMH as auxiliary factor of cognitive reserve.

06a. Imaging & Biomarkers: structural MRI

ADPD5-0291

NEUROIMAGING CHARACTERISTICS OF BRAIN STRUCTURE CHANGES IN VASCULAR PATIENTS WITH MILD COGNITIVE IMPAIRMENT

L. Pustokhanova[1], I. Khokhryakova[2], E. Morozova[1]
[1]Department Of Neurology, Perm State Medical Academy, Perm, Russia
[2]Department of Radial Diagnosis, Perm State Medical Academy, Perm, Russia

The location and severity of brain changes are not included in neuroimaging of patients with mild cognitive impairment (MCI).

Objective. To evaluate brain structure changes in vascular patients with cognitive impairment. To determine of diagnostic capabilities of structural magnetic resonance imaging in evaluation of vascular cognitive impairment.

Methods. Forty two patients (16-males, 36-female) aged 40-81 with risk factors for cerebral vascular diseases. Clinical and neuropsychological testing (MMSE, FAB) were conducted. Neuroimaging data were evaluated according to presence of diffuse and focal changes and expansion of ventricular system.

Results. Twenty one patient had MCI. Eighteen of them had a history of cerebral stroke. Indicators of neuropsychological testing differ in groups with and without MCI (MMSE-26,35±0,85 and 28,70±0,82; p=0.0000; FAB-12,84±2,14 and 16,2±2,65; p=0.0000). Severity of atrophic process in patients with MCI was more defined than in patients without MCI (p <0.02). Periventricular and subcortical leukoaraiosis was observed more frequently in patients with MCI. Focal changes in the form of cystic glial ones and lacunar infarctions dominated in patients with post-stroke variants of MCI. No statistically significant differences of ventricular system expansion in groups were revealed.

Conclusion. Combination of periventricular and subcortical leukoaraiosis localized in frontal and parietal lobes with lacunas in underlying parts of grey and white substances and convexital atrophy is the most significant in cognitive deficiency. Leukoaraiosis and subcortical silent brain infarcts are the basis of vascular cognitive impairment. Relationship of cognitive deficiency with atrophic processes of cortical structures exists.

WHITE MATTER MICROSTURCTURAL CHANGES IN PURE ALZHEIMER'S DISEASE AND SUBCORTICAL VASCULAR DEMENTIA

Y. Kim[1], H. Kwon[2], J. Lee[2], H. Kim[1], N. Jung[1], J. Kim[1], S. Kim[3], K. Lee[4], D. Na[1], S. Seo[1]
[1]Neurology, Samsung Medical Center, Seoul, Korea
[2]Biomedical Engineering, Hanyang University, Seoul, Korea
[3]Radiology, Samsung Medical Center, Seoul, Korea
[4]Nuclear Medicine, Samsung Medical Center, Seoul, Korea

Background & Objective : After eliminate confounding effects mixed Alzheimer and vascular pathology, there are different patterns of neuropsychologic and cortical thickness analysis between AD and SVaD. Therefore, we investigate white matter microstructural changes of Alzheimer disease and subcortical vascular dementia.
Methods : We prospectively recruited patients who were clinically diagnosed with AD and SVaD at Samsung Medical Center between September 2008 and May 2011. And we recruited individuals who had subjective memory impairment (SMI) as a control group. We used tract-based spatial statistics of diffuse tensor imaging (DTI) to compare patterns of reduced fractional anisotropy (FA).
Result : Compared with SMI, AD patients showed reduced FA in frontal and parietal area, while SVaD patients showed reduced FA in the whole white matter tract. Comparing between AD and SVaD patients directly showed that SVaD patients had reduced FA across the entire white matter tract skeleton.
Conclusions : SVaD patients showed more reduced FA compared with AD patients. It suggest that microstructural change of white matter is more progressed in SVaD patients than AD patients. Further studies may be needed to clarify microstructural changes of both dementias.

06c. Imaging & Biomarkers: PET - amyloid

ADPD5-1694

INFLUENCE OF AMYLOID-BETA UPON COGNITIVE DECLINE IN VASCULAR COGNITIVE IMPAIRMENT – A 3-YEAR LONGITUDINAL STUDY

V. Mok[1], *W.Y. Liu*[1], *A. Wong*[1]
[1]*Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong China*

Background:
We hypothesized that amyloid-beta (Aβ) deposits drive progressive cognitive decline in vascular cognitive impairment (VCI). We investigated the influence of Aβ deposits upon long-term cognitive decline in subjects with stroke/transient ischemic attack (TIA).
Methods:
We recruited 76 subjects with varying severity levels of cognitive impairment after stroke/TIA to receive Pittsburgh compound B (PiB) positron emission tomography (PET). Subjects with known Alzheimer's dementia prior the index event were excluded. We performed mini-mental state examination (MMSE) upon subjects at 3 month (m, baseline), 15 m (year 1), 27 m (year 2) and 39m (year 3) after the index event. We arbitrary defined stage 1, 2, and 3 as the period from baseline to year 1, year 1 to year 2, and year 2 to year 3, respectively. Patients with global PiB retention standardized uptake value ratio (SUVR) > and ≤ 1.5 were classified as mixed and pure VCI, respectively. We compared rate of cognitive decline between subjects having mixed VCI (mVCI) and pure VCI (pVCI), with age and education adjusted.
Results:
Sixty subjects completed 3 years follow-up. For mVCI subjects (n=13), MMSE declined at a similar rate throughout all stages (stage 1, -0.6± 4.5; stage 2, -1.6± 2.3; stage 3, -2.7± 2.5, *p*= 0.272). Cognition of pVCI subjects (n=47) declined initially in stage 1 (-1.8±3.6, *p*=0.005) and remained static at stage 2 (0.3± 3.2) and 3 (-0.3±2.7, *p*=1).
Conclusion:
Cognition of subjects with VCI harbouring Aβ deposits continues to decline in the long-term.

IMPACT OF MILD COGNITIVE IMPAIRMENT ON THE CHANGES IN BIOELECTRICAL BRAIN ACTIVITY IN PATIENTS UNDERGOING ON-PUMP CORONARY ARTERY BYPASS GRAFTING

I. Tarasova[1], O. Maleva[2], A. Chernobay[1], O. Barbarash[3], L. Barbarash[4]
[1]Department of Cardiovascular Diagnostics,
Research Institute for Complex Issues of Cardiovascular Diseases Russian Academ, Kemerovo, Russia
[2]Department of Polyvascular Atherosclerosis,
Research Institute for Complex Issues of Cardiovascular Diseases Russian Academ, Kemerovo, Russia
[3]Director,
Research Institute for Complex Issues of Cardiovascular Diseases Russian Academ, Kemerovo, Russia
[4]Head Scientist,
Research Institute for Complex Issues of Cardiovascular Diseases Russian Academ, Kemerovo, Russia

Background: Neurological complications after on-pump cardiac surgery are one of the largest unsolved problems of modern cardiac surgery. The patients suffering from mild cognitive impairment (MCI) are regarded as a high-risk group for ischemic changes in the brain and the progression of cognitive impairment induced by cardio-pulmonary bypass. Non-invasive neuromonitoring (electroencephalography (EEG)) can provide information on subclinical symptoms and topography of cerebral ischemia.
Purpose: To study the topography of the spectral EEG power in coronary artery disease (CAD) patients with or without MCI before and after on-pump coronary artery bypass grafting (CABG).
Materials and Methods: A total of 53 male patients (age 47-68 years) were assigned to two groups: with MCI (n = 19, MMSE score – 26.3±0.95) and without MCI (MMSE score – 28.5±0.79, n=34). Monopolar EEGs were recorded on 3–5 days before and 7–10 days after surgery in 62 sites of 10-20 system. The EEG power was calculated in frequency ranges of 4-30 Hz.
Results: All patients have demonstrated theta1 and beta1 power increase 7–10 days after CABG compared to preoperative values. The topographic distribution of EEG changes was different in MCI and non-MCI groups: the patients with MCI had more prominent cortical dysfunction in the frontal and central regions.
Conclusions: The cortical dysfunction in the frontal brain areas can be associated with the progression of cognitive deficits, worsening social and household maladjustment in CAD patients with MCI.

ADPD5-0516
NEUROPHYSIOLOGICAL ASSESSMENT OF COGNITIVE IMPAIRMENT IN VASCULAR DEMENTIA.
A. Kostylev[1], N. Pizova[1], M. Danilova[1], M. Bykanova[1]
[1]Department of Neurology, Yaroslavl State Medical Academy, Yaroslavl, Russia
Background. Search neurophysiological markers of cognitive impairment in vascular dementia is still an unsolved problem.Cognitive evoked potentials (p300) used to assess cognitive impairment in various neurological diseases, including vascular dementia. However, it is interesting to study the level of short-term memory and the state of p300.
Material and methods. We studied 26 patients with a diagnosis of vascular dementia (17 female and 9 male, average age 63.7 y.). Average score of MOCA test was 21.5. To evaluate the short-term memory, we used the "Digit Span" scale. To study the auditory cognitive evoked potentials using the standard "10-20%" EEG montage and "odd-ball" paradigm. As a comparison group selected healthy of similar age and sex (n=18).
Results. When comparing groups of patients and healthy significant differences were observed in the test result memory ($p<0.01$) and index latency p300 ($p<0.05$).There was no physiological growth of p300 latency depending on the age of the patient. In addition, the level of p300 latency depended on the number of these numbers during the test for memory for patients.The more numbers were called, the less was the latency ($p<0.01$).
Conclusion. By our hypothesis, p300 indicator can be used to assess the state of short term memory in patients with vascular dementia. However, the study is limited by the small sample of patients and requires more subjects.

ADPD5-0813
ABSOLUTE NON-INVASIVE NIRS DETECTS DIET-INDUCED AND AGE-ASSOCIATED CHANGES IN BRAIN MICROVASCULAR CIRCULATION

A. Troen[1]
[1]*Biochemistry Food and Nutrition Science, Hebrew University of Jerusalem Israel, Rehovot, Israel*

Objectives: Commonly occurring senescent and pathological changes to cerebral microvascular circulation may play an important role in the early and potentially preventable stages of cognitive decline. We and others have found a loss of capillaries to correlate with cognitive decrements and precede neurodegeneration in animals.
Methods: To understand the functional impact of such microvascular loss, we developed an innovative non-invasive near infrared spectroscopy (NIRS) instrument, which is particularly sensitive to the microvasculature and which allows us to measure *absolute* brain hemoglobin concentration (reflecting microvascular volume) and oxygen saturation at rest and in response to physiologic challenges. We used it to evaluate cerebral blood volume and vascular reactivity in several animal models as a function of age, hypertension and dietary vascular risk (hyperhomocysteinemia and NAFLD).
Results: We detected substantial decrements in absolute hemoglobin concentrations between young and old hypertensive animals indicating substantial structural microvascular loss, even when the relative vascular reactivity did not differ between groups (i.e. percent change from resting conditions). In the model of dietary vascular-risk, young but not old animals showed a reversible diet-induced reduction in brain hemoglobin concentration, indicating that vascular plasticity might be limited in older animals. In some respects, these results are consistent with cross-sectional findings comparing absolute NIRS measures in young adult and old humans.
Conclusions: Non-invasive absolute NIRS may be useful as a biomarker for the early detection and monitoring of brain microvascular disease in pre-clinical research and in humans. The most informative diagnostic parameters and their interpretation remain to be established.

ADPD5-1536

CEREBROVACULAR RISK FACTORS AND THEIR DIFFERENT EFFECT ON NEURODEGENERATIVE AND VASCULAR BIOMARKERS

D. Bittner[1], M. Höhne[1], M. Görtler[1], H.J. Heinze[1], S. Schreiber[1]
[1]Neurology, Otto-von-Guericke University, Magdeburg, Germany

Introduction: It is well known that concomitant vascular pathology aggravates Alzheimer's dementia (AD). However vascular risk factors, particularly diabetes mellitus have shown to be related independently to hippocampal atrophy hence a marker of neurodegeneration. This retrospective analysis was dedicated to estimate the effect of the three most common cerebrovascular risk factors on vascular encephalopathy and AD biomarkers in a sample of subjects ranging from healthy controls to AD via mild cognitive impairment (MCI) in sense of a cross-sectional study for neurodegeneration and from AD to pure vascular dementia (VD) via mixed dementia in sense of different lots of vascular and AD pathology.

Material/Methods: A total of 120 subjects (28 controls, 22 MCI, 29 AD, 26 mixed dementia and 15 VD) were included. For the whole group of subjects an association of vascular risk factors (arterial hypertension, diabetes mellitus and hypercholesteraemia) and markers of vascular pathology (white matter hyperintensity, intima media thickness of the carotid artery) and neurodegeneration (cerebrospinal fluid markers, e.g. ptau, tau, Aβ42 and Aβ ratio and hippocampal atrophy), respectively, were investigated.

Results: Subjects with diabetes mellitus had smaller hippocampi (p=.05), reduced Abeta (p=.06) and elevated tau (p=.04) while there was no association to white matter hyperintensities. Arterial hypertension was related to white matter hyperintensities (p=.002) only and hypercholesterinaemia to a smaller hippocampus (p=.01).

Discussion: From these data evidence derives that different cerebrovascular risk factors have a different impact on vascular encephalopathy, respectively neurodegenerative markers.

NEUROPHYSIOLOGIC EVALUATION OF DEPRESSION AND DEMENTIA IN POST STROKE ELDERLY PATIENTS

D. Petrovska Cvetkovska[1], N. Dolnenec Baneva[1], A. Taravari[1], G. Novotni[1]
[1]Neurology, University clinic for neurology, Skopje, Macedonia

Objective: To evaluate the influence of brain lesion localization as a risk for depression and dementia in post stroke patients (PSP). Material and methods: The study was prospective, randomized, in duration of 1 year, and included post stroke patients diagnosed and treated at the Department for Cerebrovascular Diseases. The patients were evaluated by means of the NIH Stroke Scale, Mini-Mental State Examination, Barthel Index, modified Rankin Scale, and MOS-Short Form 36. The evaluation period was 1, 3, 6 and 12 months after stroke. Results: Sixty eighth stroke survivors were assessed (mean age: 61.2 years; 52.2% males). The m-RS score ≤2, had 51.2% of the PSP had an m-RS score ≤2. The prevalence of depression and vascular dementia was significantly higher in females than in males (24.6 vs. 14.4%; x^2, $p = 0.03$). Elderly patients had significant worst MMSE and Bartel changes. The evaluation period showed the biggest changing 6 months after stroke. Post stroke dementia and depression was significantly associated ($p < 0.0001$) with education level, lower social and cognitive functioning, dependence in the instrumental activities of daily living and presence of diabetes in the multivariable regression analysis (R adjusted = 0.34). The relative risk of depression after a left-hemisphere stroke, compared with a right-hemisphere stroke, was 0.94 (95% CI 0.73-1.11). Conclusions: Post stroke dementia and depression was highly prevalent in the chronic phase of stroke. Early detection and recognition of associated risk factors is important to treat and prevent depression and dementia, in a rehabilitation setting.

MODULATING NEUROLOGICAL OUTCOMES IN A MURINE MODEL OF MIXED DEMENTIA
D. Niedowicz[1], V. Reeves[1], T. Platt[1], T. Beckett[1], K. Kohler[1], D. Powell[2], L. Brewer[3], C. Latimer[3], N. Porter[3], M.P. Murphy[1]
[1]Center on Aging, University of Kentucky, Lexington, USA
[2]MRISC, University of Kentucky, Lexington, USA
[3]Molecular and Biomedical Pharmacology, University of Kentucky, Lexington, USA
OBJECTIVES. Obesity and type 2 diabetes mellitus (T2DM) confer an increased risk for neurological disorders, including Alzheimer's disease (AD), vascular dementia, and stroke, though the underlying mechanisms are currently unknown. To answer this question, we created a murine model that encapsulates features of these diseases.
METHODS. We crossed the obese, diabetic db/db mouse with the *APP*$^{deltaNL/deltaNL}$*/PS1*$^{P264L/P264L}$ knock-in model of AD. We characterized the resulting mice (*db/AD*) for metabolic dysfunction, cognitive impairment, and amyloid deposition. We also assessed vascular structure and health using various methods, including MRI, histology, and vascular corrosion casting.
RESULTS. The *db/AD* mice were morbidly obese, exhibited metabolic dysfunction, and showed severe cognitive deficits. These mice did not have increased parenchymal or vascular amyloid deposition compared with non-diabetic controls, though expression of PS1 was elevated. *db/AD* mice did have severe vascular abnormalities, including aneurysms and strokes, that are consistent with the pathology observed in human diabetics.
CONCLUSIONS. The presence of vascular dysfunction in the absence of excess amyloid deposition is a key feature of the *db/AD* mouse line making them a useful model in which to study the mixed dementia that typifies T2DM. We are currently using adeno-associated virus technology to investigate the molecular mechanisms of neurological dysfunction and the role of tau in these pathologies. Finally, we are now using the *db/AD* mice to investigate different potential therapies, including telmisartan, an angiotensin receptor antagonist with off-target effects on cerebrovascular function. Funded by CART Foundation, Alzheimer's Association (IIRG-10-172905), Bright Focus Foundation, NIH (ES024158, AG045809, NS083692), and AHA (13IRG14330016).

09a. Patient Care & Support: caregiver support

ADPD5-0426

FAMILY CAREGIVERS: A SUPPORT THAT NEEDS A SUPPORT (A STUDY WITH SOCIAL WORK INTERVENTION PERSPECTIVE)

S. Jolly[1]

[1]*The MS University of Vadodara, Gujarat, India*

Objectives:

1. To understand care giving activities and processes of care giving in the select families of Vadodara taluka having Pateint with Dementia (PWD).
2. To find out the stress associated domains of caregivers and its management
3. To suggest and prepare guidelines for a training module with focus on - Coping strategies for caregivers

Methods:

It was both exploratory and descriptive study .Both qualitative and quantitative approaches are used. A non- probability, purposive sampling method was used to study 103 dementia patients clinically diagnosed (and available)

The above sample is supported with substantial number of case studies and Interviews with Health care professionals

3. Results:

For the informal support, data reveals that 67.7% family caregivers get help from the spouse and 60.2% family caregivers receive support from other family members.

68.9% caregivers receive direct help in maintaining personal hygiene (cleaning if patients soils, comb hair, wear clothes, nails trim, brush shaving etc).

16.5% caregivers reported that family members had discontinued support and 6.8% caregivers have reported that friends, relatives and maids have stopped giving support.

4.Conclusion:

The study helped to gather insights into care giving support. Caregivers are not able to recognize early symptoms,they take it as a part of normal Aging. Recognition of illness happens only when psychiatric symptoms are evident in the patient.Caregivers are not able to make proper arrangements due to lack of proper training.Lack of information related to course of the disease impacts the care giving arrangements. Registration of cases is low in PHCs, Government and Private Hospitals.

EFFECTIVENESS OF TRAINING INFIRM ELDERLY PEOPLE USING A MACHINE WITH A COGNITIVE DYSFUNCTION IMPROVEMENT SYSTEM

R. Hirasawa[1], Y. Funaki[1], H. Hanaoka[2], F. Kaneko[2], H. Okamura[2]
[1]Hiroshima, Hiroshima International University, Higashi-hiroshima, Japan
[2]Hiroshima, Hiroshima University, Hiroshima, Japan

1. Objective: The decrease in balance control in the elderly is an important risk factor for falls and markedly influences their activities of daily living (ADL) and quality of life (QOL). In a previous study, we reported a correlation between balance control and mental function in the elderly.
In this study, we investigated the effectiveness of training using a machine with a cognitive dysfunction improvement system (mirgometer) for improving the physical and cognitive functions and mental state of infirm elderly individuals.
2. Methods : The subjects comprised infirm elderly individuals using elderly facilities. Mirgometer intervention was monitored for 6 months, and the subjects were evaluated for motor function (balance ability and flexibility), mental function (cognitive function and psychological state), ADL, and QOL.
Furthermore, the change of each function over time in the control group, which synchronized a condition, was compared with that in the intervention group.
3. Results: At 6 months, the mirgometer score and cognitive function were significantly improved. The meaningful drop of the balance function was recognized in the exercise function in the control group.
4. Conclusion: This intervention significantly improved cognitive and motor functions in the infirm elderly. Therefore, continual training could aid in improving and maintaining the physical and mental functions and QOL in infirm elderly people.

09f. Patient Care & Support: cognitive training

ADPD5-1725

COMPUTER COGNITIVE PROGRAMS AND ENTERTAINING COMPUTER GAMES: WHAT ARE DIFFERENCES?

A.F. Bezdenezhnykh[1], S.V. Prokopenko[1], E.Y. Mozheyko[1], T.V. Koryagina[1]
[1]Chair of Neurology and Medical Rehabilitation,
Krasnoyarsk State Medical University named after Professor V.F. Voyno-Yasenetsky, Krasnoyarsk, Russia

Objectives: Comparing an effectiveness of using neuropsychological computer programs for cognitive correction with effects of using entertaining computer games for rehabilitation of patients with post stroke cognitive impairments.
Methods: Patients after hemispheric stroke in recovery period (up to 1 year) with cognitive impairments (N=47, age 40-65) were randomized into three groups. All patients received physiotherapy. Patients in the intervention group had 10 everyday training sessions with neuropsychological computer programs of 40 min duration. Participants in the active control group played entertaining games keeping the identical regimen. The passive control group patients received standard treatment.
Results: In the intervention group after training course we observed significant improvements on every cognitive and functional scales. In the active control group changes on FAB, Moca, Shulte's test, MMSE were also statistically significant. We found no significant changes on cognitive scales in the Passive control group after treatment. Significant improvements were observed in the intervention group comparing with the passive control group (MoCA, CDT, FAB, Shulte's test). Differences between groups where patients played neuropsychological and entertaining games were statistically insignificant. At the same time there were no significant differences between the active control and the passive control groups.
Conclusions: Additional using of the complex of neuropsychological computer programs is an effective and simple method of the correction cognitive impairments in post stroke patients comparing with the standard rehabilitation without special cognitive training. It is still necessary to clarify whether there is a difference between effectiveness of neuropsychological computer training and entertaining computer games.

09g. Patient Care & Support: art, music & life style

ADPD5-1669

A CASE STUDY OF THE RESPONSES OF A PERSON WITH SEMANTIC DEMENTIA TO THE USE OF MUSIC WITH ACTIVE VIDEO

C. Le Navenec[1], J.O.N. Parr Vijinski[2]
[1]Nursing, University of Calgary, Calgary, Canada
[2]Gerontology, previously with Univ of Western Ontario, London Ontario, Canada

Objectives: The question of the use of music for persons with dementia is an area of intense investigation. However, there is limited literature available regarding their responses to engaging with music (e.g., singing or humming to the music, clapping or tapping feet to the beat) while at the same time viewing themselves on a video of the session on a computer. The aim of our case study is to provide insights about this type of situation, which we term Active Video Musical Interaction (AVMI).
Method: A total of 61 short video clips were made,using Skype video component on a lap top computer with a 85 year old relative of the 2nd author who has been experiencing Semantic Dementia since 2009. These videos were shown to the relative during each informal music listening session over a 6 month period. Only her favorite music during her adult years were selected.
Results: The salient findings of this case study revealed that the older relative was more attentive and enjoyed the sessions as indicated by increased eye contact with the laptop screen and her smiles.
Conclusion:: The AVMI technique is an easy to use method that family caregivers could use to enhance interaction with their relative and the quality of life for the family unit. A formal large scale study is planned in order to measure specific affective changes using the Affect Rating Scale.

ADPD5-0453
NEUROMONITORING IN PATIENTS WITH FOCAL BRAIN LESIONS DURING REHABILITATION

E. Melnikova[1], A. Razumov[1]
[1]Department for rehabilitation of patients with neurological diseases, Moscow Center for Research and Practice in Rehabilitation Restorative and Sports Medi cine, Moscow, Russia

Objectives. Neuromonitoring is important not only for checking the effectiveness of rehabilitation, but also for timely correction of the rehabilitation program to prevent the exhaustion of functional reserves. The aim is to search for the reliable criteria for determining the functional prognosis and monitoring the condition of patients during rehabilitation.
Methods. We examined 100 patients with stroke and traumatic brain injury, mean age 67.5 years. All patients underwent clinical neurological examination, extended neuropsychological testing, neurophysiological examination in the dynamics, which included the evoked potentials of the brain.
Results. In the study of contingent negative variation (CNV), we found that low amplitude and short duration of the positive part of the wave correlated with cognitive decline, low social activity, and preceded the decompensation of the disease and exacerbation of already existing symptoms. We found that the elongation of the latent period of P300 potential and the violation of the ratio of amplitudes of positive and negative parts of CNV were typical mainly for patients with mild cognitive impairment, who had unsteadiness when walking with high risk of falls. In these patients, the improvement of motor functions during rehabilitation was less clear compared with others. The improvement of the parameters of cognitive evoked potentials in dynamics during rehabilitation correlated with the improvement of motor functions of hand and leg.
Conclusions. The evoked potentials of the brain in conjunction with the results of the extended neuropsychological testing may be the objective indicators for monitoring the condition of patients during rehabilitation.

ADPD5-0817
CHANGES ON BLESSED-DEMENTIA-INFORMATION-MEMORY-CONCENTRATION-TEST AFTER STROKE

M. Valkova[1], B. Stamenov[1], D. Peychinska[1], E. Tzolova[2], A. Izmaylov[1], M. Ivanov[1]
[1]Neurology Clinic, UMHAT "Dr Georgi Stranski" Pleven Bulgaria, Pleven, Bulgaria
[2]Neurology Clinic, UMHAT "Aleksandrovska" Sofia Bulgaria, Sofia, Bulgaria

Objectives: Ischemic stroke is one of the leading causes for death and disabilities. Searching for clear and easier screening tests, suitable for everyday practice, remains an open question. One of them can be Blessed-dementia-information-memory-concentration test (BDIMCT). The aim of our study was to apply BDIMCT at subacute stroke stage and to find changes on it.
Methods: We examined 109 poststroke subjects (at 3rd month after stroke) on average age 66.67±9.03 years (67 males, 42 females) and 112 controls (aged 66.70± 9.13, 69 males, 43 females) with BDIMCT.
Results: Patients showed lower total points number than controls (23.80±5.87 vs 29.87±2.41, p=0.0001), lower 5-min recall results (1.98±1.46 vs 3.86±1.11, p=0.0001), lower information subscale results (11.51±2.66 vs 13.64±0.85), lower personal memory (6.50±1.01 vs 6.99±0.09, p=0.0001), lower nonpersonal memory (1.91±1.02 vs 2.81±0.65, p=0.0001) and lower concentration points (1.88±0.92 vs 2.64±0.58, p=0.0001). Patients with cortical strokes had better results on total BDIMCT points than those with subcortical strokes (27.61±3.26 vs 21.00±5.41, p=0.0001). Additional multifocal ischemic encephalopathy leaded to low total BDIMCT points (21.03±5.83 vs 27.13±3.89, p=0.0001). Severity of stroke (measured by NIHSS) was associated with decreasing of BDIMCT total points (r=-0.52, p=0.0001). Aging and low education level were also associated with lower test results. Some vascular risk factors (arterial hypertension, chronic ischemic heart disease and diabetes mellitus) were associated with lower BDIMCT results but only in control group.
Conclusions: On the basis of our results, we can conclude that BDIMCT may be a useful test for cognitive impairment after stroke in general practice.

ADPD5-1569

COMPARISON OF VERBAL AND NONVERBAL FLUENCY PERFORMANCE WITH MINI-MENTAL STATE EXAMINATION IN DETECTING COGNITIVE IMPAIRMENT IN DIFFUSE SUBCORTICAL WHITE MATTER DISEASE OF THE BRAIN

Z. Gomez[1], P. Noble[1], D. Dasig[1]
[1]Neurosciences, Makati Medical Center, Makati City, Philippines

Introduction: The use of Magnetic Resonance Imaging (MRI) recently have revealed changes in the cerebral white matter however, the clinical significance of these are incompletely understood. Leukoaraiosis was introduced to designate periventricular or subcortical areas of hyperintensity on MRI and could be the only finding in younger people with cognitive deficits secondary to stroke. Early identification of vascular dementia was emphasized in order to administer treatments earlier. Verbal fluency tests measures executive processes as it requires word retrieval, recall, self-monitoring, initiation, and inhibition of responses. The design fluency test measures the ability to generate series of novel abstract designs.

Objective: To compare the performance in verbal and nonverbal fluency test in detecting cognitive impairment in patients with diffuse subcortical white matter disease in a tertiary hospital.

Method: Subjects, atleast 30 years old underwent MRI of the brain from August 1 to September 30, 2013 were purposively recruited. Excluded were the patients with clinical stroke, Alzheimer's and Parkinson's Disease. MMSE, verbal and design fluency test were performed and scored.

Results: Sixty subjects were included in the study. T-test was used to compare two groups with numerical data and showed that there was a significant difference noted in phonemic (p=0.02), semantic (0.04), design fluency test (0.01) scores as proven by the p values all less than 0.05.

Conclusion: Patients with diffuse subcortical white matter disease has significantly lower performance on both the verbal and design fluency test with no significant difference on the MMSE.

10d. Other: diagnostics

ADPD5-1798

NEUROPSYCHOLOGICAL TESTS AND CSF BIOMARKERS PREDICT DEMENTIA AND DISTINGUISH BETWEEN VASCULAR DISORDERS AND AD AT THE MCI STAGE

A.I.K. Nordlund[1], *A. Wallin*[1]
[1]*Institute of Neuroscience and Physiology,*
Sahgrenska Academy at University of Gothenburg, Molndal, Sweden

Objective: The objective was to study which neuropsychological tests and cerebrospinal fluid biomarkers in a Mild Cognitive Impairment (MCI) population strongest predict conversion to dementia in general, Alzheimer's disease (AD), and mixed/vascular dementia (MD/VaD).
Method: Three hundred and fifteen MCI subjects were followed up after two years. The baseline neuropsychological battery consisted of tests assessing speed and attention, learning and episodic memory, visuospatial, language and executive functions. The biomarkers were T-Tau, P-Tau Aβ1-42 and NFL.
Results: At follow up 63 MCI subjects had progressed to dementia; 29 to AD, 16 to MD, 13 to VaD and 5 to other forms of dementia. After correction for age, education and multiple comparisons there were highly significant differences between stationary MCI and incipient dementia patients on 19 out of 20 neuropsychological tests. Also on T-Tau, P-Tau and Aβ1-42 there were significant differences. The variables that best predicted dementia in general were memory, speed/attention, executive tests and T-Tau. The variable profiles of incipient AD and MD/VaD differed quite clearly. T-Tau, P-Tau, memory and visuospatial tests predicted AD; speed/attention, executive and language tests predicted MD/VaD. The sensitivity and specificity figures were quite good for both dementia in general and the specific dementia diagnoses, with areas under the curve of 0.91 for dementia, 0.92 for AD and 0.87 for MD/VaD.
Conclusions: The test battery and the biomarkers predicted dementia with good sensitivity and specificity. The combination of neuropsychological tests and CSF biomarkers distinguished quite convincingly between AD and MD/VaD two years before diagnosis.

10d. Other: diagnostics

ADPD5-1935
ROLE OF COMORBID RISK FACTORS ON POST-STROKE COGNITIVE PERFORMANCE
M. Valkova[1], B. Stamenov[1], M. Danovska[1], D. Peychinska[1]
[1]Clinic of Neurology, UMHAT "Dr Georgi Stranski" Pleven Bulgaria, Pleven, Bulgaria
Aim: The aim of the present investigation was to evaluate the role of some comorbid risk factors on post-stroke cognitive performance.
Contingent and methods: In the study were included 109 patients with first ever clinically verified ischemic stroke (mean age 66.67±9.03, 61% males) and 112 controls (mean age 66.70±9.03). Cognitive functions were examined with a neuropsychological battery as follows: Mini Mental State Examination (MMSE), Blessed Dementia Information Memory Concentration Test, 10 word test for short-term verbal memory and delayed recall, Benton visual retention test, Isaack's Verbal Fluency test (VF), Clock drawing test, Hamilton Depression Scale.
Results: Arterial hypertension was found associated with cognitive impairment (CI) of the controls and the visual spatial ability of the post-stroke survivors 3 months after the onset. Ischemic heart disease (IHD) was associated with lower MMSE and VF scores and higher depression levels of ischemic stroke patients and with lower global cognitive performance, verbal and visual memory changes, VF score and higher depression levels of the age-matched controls. Arrhythmias lead to higher depression levels in the acute stage of stroke. Diabetes mellitus (DM) was not found associated with additional cognitive impairment of the ischemic stroke patients. Controls with DM showed global CI, memory and VF changes and higher depression levels. Patients with chronic obstructive pulmonary disease (COPD) also had VF and visual memory impairments.
Key words: comorbidity, poststroke cognitive impairment

ADPD5-0755
RENAL FUNCTION, MRI BRAIN CHANGES AND POST-STROKE COGNITIVE IMPAIRMENT

E. Auriel[1], E. Kliper[1], S. Shenhar-Tsarfaty[1], A. Mike[1], D. Ben Bashat[1], L. Shopin[1], A. Korczyn[2], N. Bornstein[1], E. Ben Assayag[1]
[1]Neurology, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel
[2]Neurology, Tel Aviv University, Tel-Aviv, Israel

Background and Purpose: Limited data exist regarding the relationship between chronic kidney disease and post-stroke cognitive impairment. We aimed to evaluate the relationship between impaired renal function and markers of cerebral small vessel disease, brain pathology and cognitive decline in a longitudinal post-stroke cohort.
Methods: The TABASCO study is a prospective cohort of mild-moderate ischemic stroke/TIA patients, who underwent a 3T MRI, and were assessed for their cognitive function at hospital admission, 6, 12 and 24 months later, using the Montreal Cognitive Assessment (MoCA) and a computerized cognitive testing battery. Renal function was estimated at admission using the Cockcroft Gault creatinine clearance (CCl) equation. The volume and integrity of preexisting white matter hyperintensity (WMH), ischemic lesions and brain atrophy on MRI were measured.
Results: Baseline data were available for 462 subjects (mean age 67.4 years, 60.4% males). Participants with a CCl <60 ml/min (n=182) performed significantly worse in all cognitive tests over time ($p<0.001$) than those with a CCl $\geq$60 ml/min (n=280), had enlarged WMH volume ($p<0.001$), cortical atrophy ($p=0.002$) and smaller hippocampi ($p<0.001$).
After the 2-years, 16% of the participants developed cognitive impairment.
Multiple logistic regression analysis controlling for traditional risk factors, including cardiovascular, showed a significant association of CCl <60 ml/min with development of cognitive impairment at the end of follow-up [odds ratio: 2.99 (95% confidence interval: 1.08–8.27), $p = 0.035$].
Conclusions: Decreased renal function is associated with increased cortical atrophy and is a predictor of cognitive decline 2 years after stroke/TIA, possibly reflecting small vessel disease.

ADPD5-1150
SMALL VESSEL DISEASE MARKERS CORRELATE WITH MOTOR DYSFUNCTION IN PATIENTS WITH SUBCORTICAL VASCULAR IMPAIRMENT
Y. Kim[1], H. Kim[1], N. Jung[1], J. Kim[1], S. Kim[2], Y. Kim[3], D. Na[1], S. Seo[1]
[1]Neurology, Samsung Medical Center, Seoul, Korea
[2]Radiology, Samsung Medical Center, Seoul, Korea
[3]Neurology, Ilsong Institute of Life Science, Seoul, Korea
Background & Objective: Specific effects of small vessel disease markers on motor dysfunction of subcortical vascular cognitive impairment are less reported than cognitive dysfunction. Pyramidal and extrapyramidal scale (PEPS) is a scale for the assessment of motor impairment in vascular cognitive impairment associated with small vessel disease. We aim to evaluate the relationships between each small vessel disease markers and motor function using the PEPS in SVCI patients.
Methods: We prospectively recruited 137 participants with SVCI at Samsung Medical Center between September 2008 and May 2011. Among 137 patients with SVCI, we performed PEPS to 129 subjects. The association of microbleeds with motor impairment was estimated using linear regression models. Adjustment was made for age, gender, education and vascular risk factor, other small vessel markers and amyloid burden.
Result: Of the 129 patients with SVCI, overall volumes of WMHs were 38.9 ± 18.5 mL. Prevalence of lacunes and MBs in these subjects were 116 (89.9%) and 85 (65.9%), respectively. Total WMH volumes were associated with total, gait, EPS and pyramidal PEPS. This trend is more prominent in the relationships between periventricular WMH volumes and PEPS. Total lacunes were associated with total, gait and pyramidal PEPS. This trend is more prominent in the relationships between lacunes located white matter area and PEPS. Lobar MBs are associated with pyramidal symptoms.
Conclusions: WMHs especially located on the periventricular area and lacunes especially located on the white matter area are associated with motor function. Cerebral MBs are not associated with motor symptoms except lobar MBs.

03g. Pathophysiology & Disease Mechanisms: mitochondrial dysfunction

ADPD5-0311

MITOCHONDRIAL AMYLOID BETA-BINDING ENZYME - THE BIOMARKER OF ALZHEIMER DISEASE OR MULTIPLE SCLEROSIS?

D. Ripova[1], A. Bartos[1], J. Ricny[1], Z. Kristofikova[1]
[1]AD Centre, Prague Psychiatric Centre, Prague, Czech Republic

Objectives:

Mitochondrial enzyme 17beta-hydroxysteroid dehydrogenase type 10 interacts with intracellular amyloid beta and is probably involved in the pathogenesis of Alzheimer disease via its overexpression. Our previous experiments revealed that enzyme levels in cerebrospinal fluid could be a prospective biomarker of Alzheimer disease (the changes start many years before the disease onset and the sensitivity is about 80%), unfortunately, the specificity is not very high (73% compared to controls, 53 – 59% compared to other types of dementia). Similar changes were observed in people with autoimmune neuroinflammatory multiple sclerosis, but this enzyme has not been evaluated as a biomarker.

Methods:

We estimated levels of enzyme (competitive ELISA) and of amyloid beta 1-42 (sandwich ELISA) in cerebrospinal fluid of 121 people (controls, people with clinically isolated syndrom due to multiple sclerosis and finally people with multiple sclerosis with 2 and more attacts).

Results:

We found the significant increase in enzyme levels (to 115%) only in people with multiple sclerosis with 2 and more attacts. The sensitivity was 64%, the specificity about 60% when compared to controls. No significant changes were observed in levels of amyloid beta 1-42.

Conclusions:

Levels of mitochondrial enzyme in cerebrospinal fluid seem to be the better biomarker of Alzheimer disease than of multiple sclerosis. Our results indicate that mitochondrial dysfunction plays an important role only in later stages of multiple sclerosis and that enzyme overexpression is not probably associated with effects of amyloid beta, in contrast to Alzheimer disease.

Supported by GACR P304/12/G069 and MHCR NT13890 projects.

03j. Pathophysiology & Disease Mechanisms: autoimmunity

ADPD5-1172

COGNITIVE IMPAIRMENTS PRECEDE MOTOR DYSFUNCTION DURING EXPERIMENTAL AUTOIMMUNE ENCEPHALOMYELITIS (EAE) MODEL: POTENTIAL THERAPEUTIC ROLE OF KALLIKREIN–KININ SYSTEM

E.L.G. Moreira[1], T.B. Alberti[2], R. Marcon[2], R.D. Prediger[2], J.B. Calixto[2], R.C. Dutra[3]
[1]Neuroscience Graduate Program Centre of Biological Sciences, Universidade Federal de Santa Catarina, Florianópolis, Brazil
[2]Department of Pharmacology Centre of Biological Sciences, Universidade Federal de Santa Catarina, Florianópolis, Brazil
[3]Laboratory of Autoimmunity and Immunopharmacology, Universidade Federal de Santa Catarina, Ararangua, Brazil

Multiple sclerosis (MS) is a progressive, demyelinating and inflammatory disease of the central nervous system that still without an effective therapy, which about 50–70% of MS patients experience important cognitive deficits, although the underlying pathogenic mechanisms remain unknown. Kallikrein–kinins (KKS) are polypeptides mediator key in inflammation and pain processes, and exert a critical role in regulating the early development of experimental autoimmune encephalomyelitis (EAE). **Objectives and Methods:** we sought to investigate whether KKS exert a role in modulating the development of cognitive impairments during the motor pre-symptomatic phase of EAE. **Results:** we provide evidence that spatial reference memory impairments occur before the pre-symptomatic phase of EAE, and these effects are directly associated with a decrease in ChAT expression and up-regulation of inflammatory cytokines in the brain areas (hippocampus and prefrontal cortex) involved in acetylcholine control of memory acquisition and maintenance. Relevantly, a marked increase of kinin receptors, mainly, B_1R expression occurred selectively in the hippocampus, whereas protein level was upregulated in both brain areas. In addition, genetic deletion of kinin B_1R prevented cognitive deficits and cholinergic dysfunction, as well as blocked expression of both Th17 and Th1 cytokines in the prefrontal cortex, lymph node and spleen of mice subjected to EAE. **Conclusion:** the discovery of cognitive deficits and upregulation of B_1R expression during pre-symptomatic phase of EAE could give rise to temporal markers of the disease as well as open up fresh perspectives in the development of therapeutic approaches for autoimmune disorders, such as MS.

04n. Therapeutic Targets & Mechanisms for Treatment: anti-inflammatory targets

ADPD5-1865

REMYELINIZATION AND OPC DIFFERENTIATION BY DUAL GSK-3/PDE7 INHIBITORS

A. Martinez[1], C. Gil[1], F. de Castro[2], A. Bribian[2], E.M. Medina-Rodriguez[2]
[1]CIB, CSIC, Madrid, Spain
[2]Hospital Paraplejicos, SESCAM, Toledo, Spain

1. Objectives. Demyelinating diseases, as multiple sclerosis (MS), are unmet pathologies without no effective treatment up to date. We have shown that GSK-3 inhibitors and PDE7 inhibitors are useful MS drug candidates as they are effective in EAE mice model. Moreover we have shown how PDE7 inhibitors are able to promote oligodendrocyte precursors cells differentiation [1]. Our goal is to test if dual GSK-3 /PDE7 inhibitor may be a valuable drug candidate
2. Methods. We use a couple of dual GSK-3/PDE7 inhibitors belonging to the iminothiadiazole family to test remyelinization after treatment in in vitro and ex vivo models. We use cerebellum mice slices treated with lysolecitine and OPCs from newborn mice.
3. Results. A clear increase in OPCs differentiation was observed after drug candidates treatment. Remyelinization in cerebellum slices is recovered after three days treatment with our two dual GSK-3 /PDE7 inhibitors named VP1.15 and VP3.15
4. Conclusions. These two compounds, VP1.5 and VP3.15, that simultaneously inhibit GSK-3 and PDE7, are good drug candidates for the disease-modify pharmacological treatment of multiple sclerosis. These new drugs will show their efficacy in future clinical trials.

04p. Therapeutic Targets & Mechanisms for Treatment: neurotrophic factors

ADPD5-1608
KLOTHO ENHANCES REMYELINATION FOLLOWING CUPRIZONE-INDUCED DEMYELINATION
C.R. Abraham[1], C.D. Chen[1], R. Avila[2], S. Medicetty[2], E. Zeldich[1]
[1]Biochemistry, Boston University School of Medicine, Boston, USA
[2]Neuroscience, Renovo Neural Inc., Cleveland, USA
Objectives: The current study examined whether overexpression of Klotho in transgenic mice can enhance remyelination following cuprizone-induced demyelination, and improves the clinical outcome in experimental autoimmune encephalomyelitis (EAE).
Methods: Demyelination was achieved by feeding transgenic mice overexpressing the transmembrane form of Klotho (KL-OE) and wild type (WT) littermates cuprizone-containing chow for 6 weeks. The animals were then allowed to remyelinate for 3 weeks. Paraphenylenediamine staining and PDGFRα and GSTpi immunohistochemistry were performed on corpus callosum (CC) sections for quantification of myelin, and progenitor and mature oligodendrocytes, respectively. The EAE model was induced with the MOG35-55 peptide. The animals were scored daily for clinical symptoms for 30 days.
Results: Following 6 weeks of demyelination, both KL-OE mice and WT littermates demonstrated almost complete and comparable demyelination of the CC. However, the level of spontaneous remyelination was increased approximately two-fold in KL-OE mice. Although there were no significant differences in the numbers of PDGFRα and GSTpi positive cells in KL-OE or WT, the increase in myelinated axons in the KL-OE could potentially be due to individual oligodendrocytes myelinating more axons. Following EAE induction, Klotho overexpression did not affect the clinical scores, likely due to the different roles Klotho plays in the brain and spinal cord.
Conclusions: This is the first *in vivo* description of the striking beneficial effect of Klotho as a regulator of remyelination in the CNS white matter and, thus, increasing Klotho expression should be considered as a therapy for enhancing remyelination in individuals with MS and other demyelinating diseases.

[4]Physiology and Pharmacology, Sackler School of Medicine Tel Aviv University, Tel Aviv, Israel

Cannabinoids exert potent immunoregulatory activities. Our previous studies showed that the non-psychoactive cannabinoid, cannabidiol (CBD, a component of *Sativex*), ameliorated clinical symptoms in murine Myelin Oligodendrocyte Glycoprotein (MOG)35-55-induced Experimental Autoimmune Encephalomyelitis model of Multiple Sclerosis. Moreover, CBD decreased MOG-specific T cell proliferation and cytokine secretion including of IL-17. The mechanisms of these activities are poorly understood. Herein, we describe gene networks and intracellular pathways that are mediating the suppressing effects of CBD in an activated MOG35-55-specific T cell lineage. Encephalitogenic MOG35-55-specific T cells were stimulated with MOG35-55 in the presence of spleen-derived APCs with or without CBD, then separated using magnetic-bead CD4+ selection and subjected to microarray analysis of mRNA levels. Ingenuity Pathway Analysis and Gene Ontology identified IL-17 polarization, IL-6 and IL-10-signalling as top canonical pathways affected by the CBD treatment. Main upstream regulators affected by CBD were recognized as EGR2, STAT5A and NRF1. The effects of CBD on activated encephalitogenic T cell were linked to the regulation of selective T cell activation molecules (BTLA, CD40, CD69, IFNGR1), intracellular modulators of MAPK (DUSP6, DUSP2), PKA (CREM) and Jak/STAT (SOCS3, STAT5) pathways. Gene targets within cell cycle regulation pathways (PTPN6, SLC3A2, VAV3, DDR1) and modulators of oxidative stress (MT1A, HMOX1, SLC30A1) were also significantly affected by the CBD treatment. The microarray results were confirmed using qPCR on selected gene targets. Immunoblotting demonstrated that CBD reduces IL-17 by decreasing STAT3 phosphorylation and increasing that of STAT5. Our observations increase our understanding of the mechanisms of the anti-inflammatory activities of CBD.

DEVELOPMENT OF SCREENING SYSTEM FOR BLOCKERS OF NMO-IGG BINDING TO AQUAPORIN-4

K. Park[1], E. Ju[1], S. Yeon[1], J. Choi[1], S. Kim[2], S. Kim[2]
[1]Center for Neuro-medicine, Korea Institute of Science and Technology, Seoul, Korea
[2]Department of Neurology College of Medicine, Seoul National University, Seoul, Korea

Neuromyelitis Optica (NMO) is an inflammatory demyelinating autoimmune disease of optic nerve and spinal cord caused by binding of NMO-specific Immunoglobulin-G autoantibodies (NMO-IgG) to astrocyte water channel aquaporin-4 (AQP4). We prepared human M23-AQP4-expressing U87MG stable cell lines and performed high-throughput small molecule inhibitor screening system by quantitative measurement of two immunofluorescence imaging on binding of NMO-IgG to AQP4 using high content screening (HCS). Furthermore, we set up a screening system for small molecule blockers against the binding of NMO-IgG to AQP4 measuring lactate dehydrogenase release for complement dependent cytotoxicity. Our development of screening system on small molecule blockers of NMO-IgG to AQP4 would lead to better understanding of further pathogenesis and therapeutic researches.

ALZHEIMER'S DISEASE RISKS IN AUTOIMMUNE DISORDERS PATIENTS

X. Li[1], J. Sundquist[1], K. Sundquist[1]
[1]Center for Primary Health Care Research, Lund University, Malmö, Sweden

OBJECTIVES: To investigate association between autoimmune disorders and hospitalization for Alzheimer's disease, and to study whether the risk is associated with follow-up time and age.
PATIENTS & METHODS: In this follow-up study, the nationwide database was used to identify 43 hospitalized conditions of autoimmune disorders in patients from the Hospital Discharge Register. Follow-up of 797 424 patients with autoimmune disorders was carried out from 1964 to 2010. This study includes separate follow-ups for shorter intervals. Standardized incidence ratios (SIRs) were calculated for depression in patients with autoimmune disorders by comparing them to subjects without autoimmune disorders.
RESULTS: Among total of 43 conditions of autoimmune disorders, 10040 Alzheimer's disease was identified with an SIR of 1.29 (95% CI 1.26-1.32). 17showed an increased risk. The remaining 14 conditions were still at risk when Alzheimer's disease diagnosed in the year of autoimmune disorders diagnosed was excluded. The risks depended on the age at hospitalization for Alzheimer's disease. The SIRs for Alzheimer's disease declined by age at hospitalization of patients with chronic rheumatic heart disease, Crohn disease, diabetes type 1, Grave disease, hashimoto thyroiditis, multiple sclerosis, pernicious anemia, Sjören syndrome, and system lupus erytematosus. The risk of Alzheimer's disease decreased with follow-up time. Chronic rheumatic heart disease, type 1 diabetes, Graves' disease, pernicious anemia, polymyalgia rheumatic, and Wegener granulomatosis showed significant risk of Alzheimer's disease after ten years follow-up of autoimmune disease.
CONCLUSIONS: This large study quantified the increased risks of Alzheimer's disease in patients with many types of autoimmune disorders.

[2]Department of Neurology,
Charles University 1st Faculty of Medicine and General University Hospital in Prague, Prague, Czech Republic
[3]International Clinical Research Center, St. Anne's University Hospital Brno, Brno, Czech Republic

Background: Multiple sclerosis (MS) is a chronic disease of young adults, where beside motor and visual deficits also cognitive impairment including memory and neuropsychiatric symptoms, especially depression and anxiety, are present. Recent studies indicated that cognitive impairment may be present also in patients who are at a high risk of MS, in patients with clinically isolated syndrome (CIS).
Objectives: To assess whether cognitive functions, especially memory, regardless of depression and anxiety are impaired in patients with CIS.
Methods: Patients with CIS on interferon-β (n=44; 8.1±9.5 months on medication; EDSS 1.6±0.7) underwent clinical examination, brain MRI, cerebrospinal fluid assessment and neuropsychological examination of all cognitive domains. Depression and anxiety were assessed with Beck Depression Inventory (BDI) and Beck Anxiety Inventory (BAI), respectively. Results were compared to age, gender and education matched healthy controls (n=32).
Results: Patients with CIS and controls did not differ in basic demographic characteristics. General linear model analysis with BDI and BAI scores as covariates revealed that patients with CIS were impaired on learning and memory recall (ps=.009) compared to controls. Patients with CIS were further impaired on tests of executive functions (ps≤.038) and attention and working memory (ps≤.038). There was no impairment of language and visuo-spatial functions.
Conclusions: Our results suggest that mild cognitive impairment with predominant amnestic syndrome is present regardless of depression and anxiety in patients at a high risk of MS.

ADPD5-0276
PLASMA INFLAMMATORY BIOMARKERS FOR HUNTINGTON'S DISEASE PATIENTS AND MOUSE MODEL
C. Chen[1], K. Chang[1], Y. Wu[1]
[1]Neurology, Chang Gung Memorial Hospital, Taipei, Taiwan
Huntington's disease (HD) is caused by expanded CAG repeats encoding a polyglutamine tract in the huntingtin (HTT) protein. Lines of evidence have observed neuroinflammation, particularly microglial activation, is involved in the pathogenesis of HD. By examining the expression levels of 13 microglia-derived inflammatory markers in the plasma of 5 PreHD carriers, 15 HD patients and 16 healthy controls, we found plasma levels of IL-6, MMP-9, VEGF and TGF-β1 were significantly increased in HD patients when compared with the controls, while plasma level of IL-18 were significantly reduced in HD patients compared with controls. Plasma level of IL-6 was reversely correlated with the UPDRS independence scale and functional capacity. The inflammatory markers were further measured in plasma from R6/2 mouse HD model. In rotarod test, R6/2 HD mice started to manifest HD phenotype at 7.5 weeks of age. Higher plasma VEGF levels of R6/2 mice than those of age-matched wild-type (WT) littermates were noted from 7 (presymptomatic stage) to 13 weeks of age (late symptomatic stage). The plasma IL-6 levels of R6/2 mice were higher than those of the WT littermates from 9 (early symptomatic stage) to 13 weeks of age. R6/2 mice demonstrated higher MMP-9 and TGF-β1 levels than their WT littermates from 11 (middle symptomatic stage) to 13 weeks of age. In contrast, the plasma IL-18 level was lower than those in WT littermates since 11 weeks of age. These altered expressions of inflammatory markers may serve as the potential biomarkers for HD onset and progression.

01k. Protein Misfolding & Aggregation: clearance of misfolded proteins

ADPD5-1827
NEUROPATHOLOGIC PHENOTYPE ASSOCIATED WITH A UBQLN2 P497L MUTATION IN 3 AFFECTED WOMEN FROM 3 GENERATIONS

K.L. Newell[1], J.R. Murrell[2], C.E. Seidman[3], D.H. Harter[4], B.F. Ghetti[2]
[1]Pathology and Laboratory Medicine, University of Kansas School of Medicine, Kansas City, USA
[2]Pathology and Laboratory Medicine, Indiana University School of Medicine, Indianapolis, USA
[3]Genetics, Harvard Medical School, Boston, USA
[4]Neurology, George Washington University School of Medicine and Health Sciences, Washington D.C., USA

Objectives: Ubiquilin 2, encoded by the *UBQLN2* gene on the X chromosome, delivers ubiquitinated proteins to the proteasome for degradation. *UBQLN2* mutations have been linked to amyotrophic lateral sclerosis (ALS)-frontotemporal dementia.
Methods: A 63 year-old (63y) woman with progressive weakness, dysarthria, and dysphagia was diagnosed with ALS. Her 20y daughter developed spastic paralysis, dysarthria, dysphagia, and dementia, and this woman's 20y daughter developed ALS. Duration of clinical symptoms ranged from 4-17 years. Deaths occurred at ages 67y, 37y, and 24y, respectively. Brain and spinal cord autopsies followed. Formalin-fixed, paraffin embedded sections of brain and spinal cord were stained with hematoxylin and eosin-Luxol fast blue and Thioflavin S. Immunohistochemical stains included β-amyloid, tau, α-synuclein, UBQLN2, and TDP-43. DNA was isolated from frozen brain tissue for genetic analysis.
Results: Upper and lower motor neuron loss was variable among the 3 subjects. The 37y brain showed frontal lobe atrophy with neuronal loss and gliosis in cortex and caudate nucleus. Substantia nigra degeneration ranged from mild (24y) to moderate (67y) to severe (37y). The 67y brain contained Lewy bodies, sparse-moderate beta-amyloid immunopositive diffuse plaques, and sparse phospho-tau. UBQLN2-cytoplasmic and neuropil aggregates were present in frontal and temporal cortex, hippocampus, and inferior olivary nucleus. TDP43-immunoreactive inclusions were present in spinal cord and hippocampus. Genetic analyses confirmed a c.1490C>T in the *UBQLN2* gene in the 67y and 24y brains.
Conclusions: Neuropathologic studies of this X-linked disorder, hypothesized to result in perturbed protein clearance, may lead to new insights into the pathogenesis of misfolded protein diseases.

ADPD5-1134

IN SILICO MODELING OF RECENTLY DISCOVERED KOREAN PSEN1 MUTATIONS

E. Bagyinszky[1], S.O. Bae[1], S.S.A. An[1], S. Kim[2]
[1]BioNano, Gachon University, Seongnam-si Gyounggi-do, Korea
[2]Department of Neurology, Seoul National University Bundang Hospital, Seongnam-si Gyounggi-do, Korea

Three genes can be involved in early onset Alzheimer's disease: APP, PSEN1 and PSEN2. Majority of mutations were described in PSEN1 (almost 200 due to the recent updates). A few mutations were studied in cell models to confirm their pathogenic nature, but the functional data was not available for all mutations. Since the transfection, *in vivo* cell line studies of mutations are expensive, time consuming, we performed *in silico* modeling on the PSEN1 mutations.

We performed PolyPhen2 prediction for the variants. In addition, we tried to model the 3D structure of proteins with RAPTOR-X software, and compared the 3D structure of normal and mutant PS1 proteins. This software might be a promising approach to predict the pathogenic nature of variants.

In our studies, we discovered four novel and known variants in Korean EOAD patients, which might be involved in disease onset: H163P (novel), T116I (known), L226F (known), L232P (novel). 3D structure of PS1 with T116I showed differences in the N-terminal region, because of the hydrophobic isoleucine. PS1 with H163P looked similar like the wild PS1, but the different properties of histidine and prolie might support the pathogenic nature of this mutation. PS1 with L226F looked also similar to the normal PS1, but since phenylalanie is the biggest amino acid, it might result structural changes in the TM region. In L232P mutation, the rigid proline might result torsion in the helix structure.

This *in silico* analysis could be promising approach to predict the pathogenic nature if mutations, especially the novel ones.

ADPD5-1308
HIPPOCAMPAL EXPRESSION OF GABAA RECEPTOR SUBUNITS IN NEURODEGENERATIVE DEMENTIAS
E. Berger-Sieczkowski[1], I. Milenkovic[2], E. Dassler[2], E. Auff[1], G.G. Kovacs[2]
[1]Medical University of Vienna, Department of Neurology, Vienna, Austria
[2]Medical University of Vienna, Institute of Neurology, Vienna, Austria
Objectives: The $GABA_A$ receptor family is a target for various clinically relevant drugs, including the benzodiazepines. They are pentameric chloride ion channels, which are composed of a total of 19 different subunits. The alpha5 subunit of the $GABA_A$ receptors has been implicated in cognition. Thus, our aim was to evaluate the presence of the alpha5 subunit and its most common assembling partner the gamma2 subunit in strategic regions involved in memory processing such as the dentate gyrus and the CA1 subregion of the hippocampus in various neurodegenerative dementing illnesses.
Methods: We included 46 cases with Alzheimer`s disease (AD)-related changes grouped according to Braak stages, 14 cases with AD-related changes and argyrophilic grain disease, 20 AD cases with limbic TDP-43 pathology, and 10 cases with dementia with Lewy bodies. We performed morphometric immunohistochemistry and compared the density of subunit expression with the amount of protein deposits (phospho-tau, phospho-TDP-43, a-synuclein) in the same subregions.
Results: $GABA_A$ receptor subunits are relatively preserved during the progression of AD-related changes. Moreover, this is not significantly influenced by concomitant neurodegenerative disorders. However, significant inter-individual variability of the expression of $GABA_A$ receptor subunits is associated with the load of protein deposition in the evaluated anatomical regions.
Conclusion: Our results suggest that $GABA_A$ receptor-based therapies in neurodegenerative dementias should be initiated on an individual basis rather than based on artificial disease categories.

ADPD5-0570

THE DEREGULATIONS OF GENE EXPRESSION IN LRRK2- ASSOCIATED PARKINSON'S

Y. Zhao[1], L. Ong[1], E. Tan[2]
[1]Clinical Research, Singapore General Hospital, Singapore, Singapore
[2]Neurology, National Neuroscience Institute, Singapore, Singapore

BACKGROUND Leucine rich repeat kinase 2 (LRRK2) is one of the most important causative gene in Parkinson's disease (PD). The pathophysiological role of LRRK2 is presently
unclear.
OBJECTIVES To identify the deregulations caused by LRRK2 gene mutations that is associated with pathogenesis of PD.
METHODS LRRK2 gene stable transfected DA neuronal cell lines were generated containing wild type or variant LRRK2 gene cDNA (G2019S/G2385R). Total RNA was isolated from the three stable transfected cell lines. The GeneChip Human Gene 1.0 ST array (Affymetrix) was used for identification of gene expression profiling. Real- time PCR and Weston blotting were used to further verify the genes that showed deregulation results in Gene Chips.
RESULTS The results of genome wide gene expression profiling showed the differences in multiple genes of LRRK2 mutational cell lines compared with the wild type. In particular the dopamine metabolizing genes Dopamine Bata-Hydroxylase (DBH) and DOPA Decarboxylase (DDC) were significantly decreased. DBH and DDC genes code for two enzymes in the dopamine metabolism pathway. The decreases of DDC and DBH have been further confirmed by Real-time PCR and Western Blotting.
CONCLUSIONS The disorder of Dopamine metabolism is a significant pathogenesis of PD, dysregulated dopamine metabolism contributes to the pathogenesis of PD have been confirmed. To identify the Dopamine deregulators caused by LRRK2 gene mutations may provide the evidence of pathogenesis in PD.

02l. Cell, Molecular & Systems Biology: huntingtin

ADPD5-0781

A HUNTINGTIN BASED PEPTIDE INHIBITOR OF CASPASE-6 PROVIDES PROTECTION FROM MUTANT HUNTINGTIN INDUCED MOTOR AND BEHAVIORAL DEFICITS

D. Offen[1], I. Aharony[1], D. Ehrnhoefer[2], A. Shruster[1], X. Qiu[2], S. Francios[2], M. Hayden[2]
[1]Felsenstein Medical Research Center, Tel Aviv University, Petach-Tikva, Israel
[2]Centre for Molecular Medicine and Therapeutics, University of British Columbia, Vancouver, Canada

Over the past decade, increasing evidence has implied a significant connection between
caspase-6 activity and the pathogenesis of Huntington's disease. Consequently, inhibiting caspase-6 activity was suggested as a promising therapeutic strategy to reduce mutant Huntingtin toxicity, and to provide protection from mutant Huntingtin induced motor and behavioral deficits. Here we describe a novel caspase-6 inhibitor peptide based on the huntingtin caspase-6 cleavage site, fused with a cell penetrating sequence. The peptide reduces mutant Huntingtin proteolysis by caspase-6, and protects cells from mutant huntingtin toxicity. The continuous sub-cutaneous administration of peptide protected pre-symptomatic BACHD mice from motor deficits and behavioral abnormalities. Moreover, administration of the peptide in an advanced disease state resulted in the partial recovery of motor performance, and an alleviation of depression related behavior and cognitive deficits.
Our findings reveal the potential of substrate-based caspase inhibition as a therapeutic strategy, and present a promising agent for the treatment of Huntington's disease.

ADPD5-1225

REVERSAL OF APOE4 INDUCED BRAIN PATHOLOGY BY LENTIVIRUS-DRIVEN VEGF EXPRESSION

S. Salomon-Zimri[1], I. Luz[1], O. Liraz[1], M. Glat[2], Y. Barhum[2], D. Offen[2], D.M. Michaelson[1]
[1]Neurobiology Sagol School of Neurosciences The George S. Wise Faculty of Life Sciences, Tel Aviv University, Tel-Aviv, Israel
[2]The Neuroscience Laboratory, The Felsenstein Medical Research Center, Tel-Aviv, Israel

Background: Alzheimer's disease (AD) is associated with neuronal and vascular dysfunction. Vascular endothelial growth factor (VEGF) has been shown to play an important role in both the neuronal and vascular systems. ApoE4, the main genetic risk factor for AD is associated with increased neurodegeneration and vascular impairments.
Objectives: To study the effects of apoE4 on brain VEGF levels and to examine the extent to which the brain and cognitive pathological effects of apoE4 can be reversed by over-expression of VEGF.
Methods: The levels of VEGF in hippocampus of naïve apoE3 and apoE4 young targeted replacement mice ware determined prior to and following injection of either VEGF nor GFP expressing lentivirus and the resulting effects on apoE4-driven brain and behavioral pathologies ware than measured.
Results: The levels of VEGF in the hippocampus of naïve apoE4 mice were lower than those of corresponding mice which express its AD benign isoform apoE3. Similar results were obtained with VEGF mRNA, suggesting that apoE4 down-regulates the expression of VEGF. These effects was associated with cognitive impairments; decreased levels of the pre-synaptic marker VGluT and of the ApoE receptor Apoer2 in hippocampal neurons; and corresponding accumulation of hyperphosphorylated tau and A-beta. Over-expression of VEGF utilazing lentivirus reversed cognitive improvement and reduced the isoform specific effects in various brain parameters between apoE4 and apoE3 mice.
Conclusions: VEGF play a role in mediating apoE4-driven cognitive and brain pathologies in TR-mice. This suggests that VEGF tailored treatment can be beneficial in AD and apoE4 carriers.

ADPD5-1237

VEGF MEDIATES APOE4-INDUCED NEOVASCULARIZATION AND SYNAPTIC PATHOLOGY IN THE CHOROID AND RETINA

S. Salomon-Zimri[1], R. Antes[1], S.C. Beck[2], M.G. Garrido[2], T. Livnat[3], I. Maharshak[1], T. Tamar Kadar[4], T. Seeliger[2], D. Weinberger[3], D.M. Michaelson[1]

Institute for Ophthalmic Research Centre for Ophthalmology, Tübingen, Germany

[3]Laboratory of Eye research,
Felsenstein Medical Research Center (FMRC) Rabin Medical Center, Petah Tikva, Israel

[4]Department of Pharmacology, Israel Institute for Biological Research, Ness Ziona, Israel

Background: Apolipoprotein E4 (apoE4), the most prevalent genetic risk factor for Alzheimer's disease (AD), is associated with neuronal and vascular impairments. Recent findings suggest that retina of apoE4 mice have synaptic and functional impairments.

Objectives: To investigate the extent to which the functional and synaptic effects of apoE4 in the retina are associated with parallel vascular effects. This was performed by studying the effects of apoE4 on the retinal and choroidal vascular systems in young targeted replacement mice under resting conditions and following laser-induced neovascularization (CNV).

Methods: Mice were subjected to laser-induced CNV and the extents to which this treatment effects the neuronal and vascular systems in the choroid and retina were measured prior to and following 3 and 14 days from treatment.

Results: There were no histological differences between the retinal and choroidal vasculatures of naïve apoE3 and apoE4 mice. In contrast, laser-driven choroidal injury induced higher levels of CNV in apoE4 than in apoE3 mice. VEGF levels of naïve apoE4 retina were lower than in apoE3 mice. In contrast, VEGF levels rose more pronouncedly in apoE4 than in apoE3 mice following laser injury. Similar effect was observed in apoE levels.

Conclusions: The findings obtained suggest that VEGF mediates the apoE4-induced neovascularization and synaptic pathology in the choroid and retina. These findings have important implications regarding the treatment of apoE4-related ophthalmologic pathologies (i.e. AMD), as well as of apoE4-related brain neuronal and vascular pathologies (i.e. AD) and suggest a novel therapeutic approach for treating these pathologies.

ADPD5-2295

APOLIPOPROTEIN E ISOFORM-SPECIFIC EFFECT ABOUT AUTOPHAGY AND SURVIVAL IN CAD CELLS

M. Ortiz[1], H. Arboleda[1], G. Arboleda[1]
[1]Medicine, Universidad Nacional de Colombia, Bogotá, Colombia

ApolipoproteinE (ApoE) carries cholesterol and other lipids, within both, the plasma, and the central nervous system. There are three ApoE alleles in humans (ApoE2, 3 y 4). Although ApoE4 has been defined as a risk factor in Alzheimer's diseases, the molecular effects associated to ApoE4 have not been fully described. The main purpose of the research is to study the differential effects of ApoE isoforms in the survival and autophagy pathways under a neurotoxic model context.

Methods: the differentiated cells were incubated with the ApoE 2, 3 and 4. After 1 hour of pre-treatment with ApoE, ceramide was added for incubation process during 24 hours. Mitochondrial metabolism was measured by MTT assay and cell survivor by LDH assay. Protein's expression was evaluated by Western blot's technique and immunofluorescences, so to finally detect, autophagosomes.

The ApoE4 and ceramide treatment causes a cellular viability decrease and the ApoE2 and 3, does not. It decreases in the phosphorylation level of AKT and AMPK, compared to ApoE2-ceramide and ApoE3-ceramide treatments. The presences of the phosphorylation of ERK protein does not show a significant variation in the treatments; phosphorylation of p38 variation is mainly revealed in ApoE2 and 3-ceramide treatments.

Finally, these results suggest that ApoE4-ceramide treatment raises metabolism, and cellular stress response associated to activation of the p38 pathway (maybe associated to an increase production of ROS). Inhibition of autophagy is associated to cellular death whereas ApoE3 and ApoE2-ceramide treatment protects cells from the neurotoxic effect through autophagy's activation.

LACTULOSE AND MELICIOSE AS AGGREGATION REDUCERS TARGETING AUTOPHAGE IN CELL MODELS OF SPINOCEREBELLAR ATAXIA 3

Y. Wu[1], C. Lin[1], W. Chen[1], C. Chao[1], T. Lin[2], C. Chen[1], J. Yang[3], G. Lee[2], H. Hsieh-Li[2], G. Lee-Chen[2]

[1]Neurology, Chang Gung Memorial Hospital, Taoyuan, Taiwan

[2]Life Science, National Taiwan Normal University, Taipei, Taiwan

[3]Institute of Bioinformatics and Systems Biology, National Chiao Tung University, Hsinchu, Taiwan

Trehalose, a chemical chaperone and mTOR-independent autophagy enhancer, has shown promise in models of huntington's disease, Parkinson's disaese and tauopathies. In this study, two trehalase-indigestible trehalose analogs, lactulose and melibiose, were examined for their potentials in spinocerebellar ataxia (SCA) treatment. Using ATXN3/Q_{75}-GFP 293 cells, a putative SCA3 cell model, we found the ATXN3/Q_{75} aggregation was significantly prohibited by lactulose and melibiose because of theirs abilities to influence ATXN3/Q_{75} protein folding and up-regulating of autophagy. Meanwhile, lactulose and melibiose reduced the production of reactive oxygen species (ROS) in ATXN3/Q75 cells. Both of them further inhibited the aggregation and promoted neurite outgrowth in neuronally differentiated SH-SY5Y ATXN3/Q_{75}-GFP cells. These findings suggest the therapeutic applications of trehalase-indigestible trehalose analogs in aggregation-associated neurodegenerative diseases.

[3]Research Center of Neurobiology D. Bovet, Dept. Biology and Biotechnologies Charles Darwin Sapienza University of Rome, Rome, Italy

Objectives: To evaluate whether inflammatory state in MS patients may be related to non-neuronal cholinergic system dys-function we have measured ACh levels, AChE and BuChE activity and expression and the production of pro-inflammatory cytokines in PBMC and serum of MS patients and in healthy donors (HD).

Methods: MS patients were, matched for sex and age to HD. ACh cytokine levels in serum were measured by commercial kit and AChE and BuChE by Ellman test. Real-Time PCR were performed to determinate AChE, BuChE and cytokines mRNA expression in PBMC.

Results: In MS patients expression of AChE and BuChE was higher than in HD. In PHA-stimulated PBMC of MS patients, the expression of IL-4, TNFα , IFNg, IL-6 and IL-17 was significantly higher, while, IL-10 and IL-18BP were significantly lower compared with HD.

When PBMC isolated from MS patients were co-treated with PHA and nicotine, the expression and production of TNF-α and IFNg were significantly reduced, IL-4 and IL-18BP were increased, while IL-17, IL-6 and IL-10 not appeared significantly modified. Interestingly, the serum levels of IL-17, as well as AChE and BuChE enzymatic activity were higher in MS than HD, while levels of ACh were lower.

Conclusions: Our results suggest that decreased levels of ACh in MS may be related to increased activity of its hydrolytic enzymes and to higher pro-inflammatory cytokine levels. Stimulation of nicotinic receptors contribute to reduce the levels of pro-inflammatory cytokines suggesting that the re-stablishment of cholinergic function may contribute to reduce the inflammatory state in MS

Gamma-frequency oscillatory activity plays an important role in information integration across brain areas. Disruption in gamma oscillations is implicated in cognitive impairments in psychiatric disorders, and 5-HT3 receptors (5-HT3Rs) are suggested as therapeutic targets for cognitive dysfunction in psychiatric disorders. Using a 5-HT3aR-EGFP transgenic mouse line and inducing gamma oscillations by carbachol in hippocampal slices, we show that activation of 5-HT3aRs, which are exclusively expressed in cholecystokinin (CCK)-containing interneurons, selectively suppressed and desynchronized firings in these interneurons by enhancing spike-frequency accommodation in a small conductance potassium (SK)-channel-dependent manner. Parvalbumin-positive interneurons therefore received diminished inhibitory input leading to increased but desynchronized firings of PV cells. As a consequence, the firing of pyramidal neurons was desynchronized and gamma oscillations was impaired. These effects were independent of 5-HT3aR-mediated CCK release. Our results therefore revealed an important role of 5-HT3aRs in gamma oscillations and identified a novel cross-talk among different types of interneurons for regulation of network oscillations. The functional link between 5-HT3aR and gamma oscillations may have implications for understanding the cognitive impairments in psychiatric disorders.

[2]Neurology, University of Miami Miller School of Medicine, Miami, USA

Objectives: Use RNASeq to characterize coding and non-coding RNA transcription in temporal pole tissues from Late-Onset Alzheimer's disease (LOAD) versus control and Dementia with Lewy Body (DLB).

Methods: RNA-Seq was performed on the HiSeq2000 using total RNA. Tissues were from matched temporal pole (BA 38) from 10 cases each of LOAD, DLB and controls. RNA was extracted using Qiagen's miRNeasy and libraries prepared using Epicentre's Script-Seq. GSNAP aligned ~75% of the reads to the genome.

Results: Each library generated 40-65 million reads. A total of 53,245 genes (19,207 protein-coding and 34,038 ncRNAs, based on ENCODEv15) having detectable levels of transcription were identified. 2,504 out of 53,245 genes had nominal differences in transcription ($p<0.05$) between the ten LOAD samples and ten normal controls. After correcting for multiple testing by False Discovery Rate (FDR<0.05), 16 (11 coding) of the 2,504 genes differed significantly between LOAD and normal controls. More ncRNA transcripts were observed than protein-coding transcripts, but the average read depths of ncRNAs were less than protein-coding genes. To study the processes disrupted in LOAD, we performed network analysis on the 2,504 genes that had nominal significance between LOAD and normal controls. Using Weighted Gene Co-transcription Network Analysis (*WGCNA*) on transcription values of the 2,504 genes revealed that these genes aggregated into seven GO networks, two of which, innate immune response and myelination were specific to LOAD, when compared to both normal and DLB transcription.

Conclusions: RNASeq demonstrates significant differences in transcription and affected networks between LOAD and DLB and controls.

PHASIC DOPAMINE RELEASE PLAYS A CRITICAL ROLE FOR SPIKE-TIMING DEPENDENT PLASTICITY OF EXCITATORY SYNAPSES ONTO STRIATAL MEDIUM SPINY NEURONS.

T. Shindou[1], *M. Ochi-Shindou*[1], *J. Wickens*[1]
[1]*Neurobiology Research Unit,*
Okinawa Institute of Science and Technology Graduate Univesity, Onna-son, Japan

[Objectives] The striatum is the principal input nucleus of the basal ganglia, receiving glutamatergic afferents from the cerebral cortex. It has been suggested that activity-dependent synaptic plasticity in the striatum is a cellular mechanism for reinforcement-based motor learning and phasic dopamine (DA) release is associated with positive reinforcement. However, there has been little evidence showing the role of phasic DA in the striatal STDP. In this study, we tested that the hypothesis that phasic DA release in the striatum is critical for the induction of corticostriatal synaptic plasticity.
[Methods] Whole cell recording in slice preparations obtained from adult BAC transgenic mice that selectively express GFP in D1R-expressing cells was performed in this study. The rapid application techniques by caged-dopamine photolysis was used to investigate effects of phasic DA on the striatal STDP.
[Results] We found that spike-timing dependent long-term potentiation (t-LTP) was induced by prepost protocols in D1R-expressing projection neurons in the striatum. The photolysis was applied at 300 ms prior to, 0 msec, 2 sec, or 4 seconds after the pairing protocols. Of these timing conditions, the photolysis at 2 sec after the pairing significantly blocked the t-LTP. We suggest that the timing of DA release could be an important factor to modulate the striatal STDP.
[Conclusion] We conclude that the phasically, timing-dependent DA release was a key determinant for induction of striatal STDP. These results suggest the timing of striatal dopaminergic regulation is implicated in motivational processes and motor function, and also a therapeutic relevance of Parkinson’s disease.

DOPAMINERGIC CELL LOSS AND STRIATAL NEUROCHEMISTRY IN 14-3-3GAMMA KNOCKOUT MICE TREATED WITH MPTP

P. Steinacker[1], P. Oeckl[1], B. Hengerer[2], A. Aitken[3], B. Ferger[2], M. Otto[1]
[1]Department of Neurology, University of Ulm, Ulm, Germany
[2]Department of CNS Diseases Research, Boehringer Ingelheim, Biberach, Germany
[3]School of Biomedical and Clinical Laboratory Sciences, University of Edinburgh, Edinburgh, United Kingdom

Objectives: Dysregulation of 14-3-3 proteins has been observed in Parkinson's disease (PD) and overexpression of specific 14-3-3 isoforms, including 14-3-3gamma, in dopaminergic cells was protective in different PD models. Here, we investigated the effect of 14-3-3gamma deletion in the acute MPTP model of PD *in vivo*.
Methods: 14-3-3gamma knockout mice and wildtype controls were treated with MPTP (1-methyl-4-phenyl-1,2,3,6,-tetrahydropyridine, 4x10 mg/kg, 2h interval). The striatal concentrations of dopamine (DA) and serotonin (5-HT) and their metabolites were measured by HPLC and sections of the substantia nigra pars compacta (SNpc) were examined for tyrosine hydroxylase (TH)-positive cells to quantify neurodegeneration.
Results: Untreated and MPTP treated 14-3-3gamma knockout mice had higher concentrations of DA, DOPAC, and 3-MT, compared with untreated and MPTP treated wildtype mice, respectively. The DA turnover was comparable in untreated 14-3-3gamma knockout mice and wildtype controls. However, the MPTP-induced increase in DA turnover was attenuated in 14-3-3gamma knockout mice compared to wildtype. The number of TH positve neurons was reduced in MPTP treated WT and 14-3-3gamma knockout mice to a similar extent by about 60%.
Conclusion: Since 14-3-3s activate TH it could have been expected that 14-3-3gamma knockout leads to decreased DA synthesis and increased rate of cell death, but we observed the opposite effects regarding dopamine and did not find an influence on neurodegeneration in the SNpc in the acute MPTP model. This points to different roles of 14-3-3 isoforms *in vivo* and a more complex regulation of DA levels and cell death compared to *in vitro* models.

STRUCTURAL INVESTIGATIONS ON DISEASE-RELATED AMYLOID FIBRILS BY SOLID-STATE NMR SPECTROSCOPY

H. Heise[1], C. Beumer[1], L. Gremer[2], W. Hoyer[2], E. Mirecka[2], H. Müller[1], T. Piechatzek[1], D. Schölzel[1], B. Uluca[1], F. Weirich[1]

[1]Solid-State NMR, Physikalische Biologie, Düsseldorf, Germany

[2]ICS-6 FZ Jülich, Physikalische Biologie, Düsseldorf, Germany

Objectives

Elucidation of structure and dynamics of amyloid fibrils and their implication in disease progression is still a challenge due to the non-crystalline, insoluble nature of aggregated proteins [1]. Recently, solid-state NMR-spectroscopy has emerged as a promising tool for structure elucidation in aggregated proteins.

Methods

We applied MAS NMR Solid-state NMR-spectroscopy with and without DNP enhancement to the study of fibrils from recombinantly expressed [2] human IAPP and ovine PrP [3].

Results

For hIAPP, we could obtain site-selective resonance assignments for most of the residues and define the location of the core region. Strongly reduced flexibility throughout the peptide was confirmed. Residues of the N-terminal loop gave rise to extremely well-resolved signals. For ovine PrP we could recently obtain NMR suitable fibrils by seeding with PrPSc particles. A comparison with spontaneously generated fibrils from recombinant PrP revealed higher homogeneity in the seeded fibrils, and location of beta-strands could be proposed.

Conclusions

The location of beta-strands of fibrillar hIAPP and the well-ordered state of the N-terminal loop confirms its important role in the aggregation process. For ovine PrPSc we could show the effect of seeding with infectious particles on a molecular level.

[2]Department of Neurology, National Hospital Organization Minami-Kyoto Hospital, Kyoto, Japan
[3]Biomedical MR Science Center, Shiga University of Medical Science, Shiga, Japan

Objectives:
New diagnostic criteria based on a guideline for iNPH was submitted. Although CSF tap test and MRI features are used for diagnosis, the utility of CSF biomarker has not been strictly evaluated for assistance of diagnosis. It was reported that the CSF concentration of Lipocalin-type prostaglandin D synthase (L-PGDS), secreted in the CSF as β-trace, was decreased in iNPH as compared to other diseases with dementia. In order to investigate whether the different expression of CSF biomarkers between iNPH and other diseases with dementia is useful for differential diagnosis, we determined the CSF levels of L-PGDS, p-tau (181), Aβ40 and Aβ42.
Methods:
CSF samples were obtained from 35 patients diagnosed with possible or probable iNPH and 26 patients, which included Alzheimer's disease (AD), other diseases showed dementia, autoimmune diseases and control subjects. Each patient provided informed consent. The CSF biomarkers were measured by enzyme-linked immunosorbent assay (ELISA).
Results:
L-PGDS was significantly decreased in iNPH (mean±SD: 6.57±4.20) compared to the other diseases group with dementia (13.37±3.35). Decrease of Aβ42 was more often observed in AD, but also found in a part of iNPH. There was no significant difference between AD and iNPH. A trend towards higher levels of p-tau (181) was observed in AD.
Conclusions:
The CSF L-PGDS level was significantly decreased in iNPH as compared with other demented patients. Recently iNPH is increased among the geriatric population, and often accompanied by AD. It may be useful for differential diagnosis to measure various CSF biomarkers correlated with dementia simultaneously.

[5]Medicine, Weill Cornell Medical College, New York, USA

Introduction: Contextual memory formation relies on induction of new genes in the hippocampus. A polymorphism in the promoter of the transcription factor XBP1 was identified as a risk factor for Alzheimer´s disease and bipolar disorders. Here we uncover a key role for XBP1 in higher cognitive function, unrelated to its function as a major regulator of the ER stress response.

Methods: We performed behavioral screening on *xbp1* conditional knockout mice. Additionally, we overexpressed XBP1s with a novel transgenic mouse and with localized adenoviral delivery into the hippocampus of wild-type animals. We evaluated LTP and gene expression related to memory formation.

Results: Mice lacking XBP1 in neurons showed ablated contextual memory formation and impaired LTP while overexpression of XBP1s improved performance in memory tasks. XBP1 regulates a cluster of genes involved in memory formation, including BDNF. The $XBP1^{Nes-/-}$ phenotype could be reversed by site-specific delivery of BDNF to the hippocampus.

Discussion: Our study reveals an unanticipated function of XBP1 in cognitive processes that operates via a bidirectional regulatory loop with BDNF. Strategies to enhance XBP1s activity in the brain may translate into beneficial effects for the treatment of memory disorders.

Whilst the cause of dopamine cell loss in Parkinson's disease (PD) is unknown, it is clear that the male-sex is a strong risk factor. The incidence and prevalence of PD is 2-fold higher and disease progression more rapid in males than females. Growing evidence suggests that sex-specific genes contribute to this male-bias in PD. We previously showed that the male-sex determining gene, SRY, co-localises with male dopamine neurons, where it regulates dopamine biosynthesis and motor function. Here, we investigated the regulation and function of nigral SRY in normal and 6-hydroxydopamine (6-OHDA) lesioned hemiparkinsonian rats. We assessed the effect of reducing nigral SRY levels, via repeated injection of SRY antisense oligonucleotide into the rat substantia nigra (SNc), on motor and dopaminergic function. In normal male rats, SRY antisense treatment significantly reduced motor function in the cylinder and rotarod tests, which was associated with a reduction in nigral TH mRNA and striatal dopamine content, compared to the sense-treated group. Conversely, SRY antisense treatment in female rats did not affect motor function. In 6-OHDA-lesioned male rats, nigral SRY mRNA was significantly up-regulated at 7 days following 6-OHDA injection. Remarkably, SRY antisense treatment significantly attenuated 6-OHDA-induced motor deficit and dopamine cell loss in male rats, compared to the sense-control, indicating a detrimental role for SRY in the injured male SNc. These data indicate a double-edged role for SRY in normal and injured dopamine neurons in the male SNc and that inhibition of SRY may be a novel therapeutic target for PD in males.

ER-A36, A NOVEL VARIANT OF ER-A, MEDIATES B-ESTRADIOL-DERIVED NEUROPROTECTION FROM MPP+-INDUCED DAMAGE IN PC12 CELLS

L. Huang[1], Q.I.Q.I. Zhang[1], Y.A.N.G. Liu[1], X.I.N. Guan[1], Y. Zhang[1], W. Zou[1]
[1]Liaoning Normal University, College of Life Science, Dalian, China

Accumulating experimental evidence indicates that estrogen exerts dose-dependent neuroprotection at usual physiological levels and can improve damage from cerebral ischemia at supraphysiological concentrations. Extranuclear estrogen receptors mediate this beneficial effect. ER-α36, a novel subtype of estrogen receptor, functions differently from classical ER-α in response to membrane-initiated estrogenic signaling and recent findings have demonstrated that physiological β-estradiol exhibits a protective effect on PC12 cells (ER-negative) undergoing oxygen-glucose deprivation *in vitro*. We have identified expression and the subcellular location of ER-α36 in ER-negative PC12 cells. To investigate the potential involvement of ER-α36 in the beneficial effects of β-estradiol, an *ER-α36* gene knockdown cell model was developed in PC12 cells. It was found that β-estradiol attenuated MPP^+-induced cellular damage. Experiments with PC12-36KD cells revealed that β-estradiol failed to protect against cellular damage following *ER-α36* gene knockdown, suggesting that ER-α36 mediates the beneficial effects of β-estradiol against MPP^+-induced cellular damage in PC12 cells. Further studies are underway to understand the more comprehensive function and molecular mechanism of estrogenic signaling within the nervous system.

Objective: Since the discovery of human induced pluripotent stem cells (iPSCs), much excitement and interest has been created around this technology as a platform for generating pluripotent stem cell lines from a range of specific genetic backgrounds, both normal and diseased. We have developed highly consistent and scalable differentiation protocol for making various types of human neurons, specifically midbrain dopaminergic neurons. This protocol provides a consistent platform to study various aspects of midbrain dopaminergic neuron biology, including Parkinson's disease.
Methods: Using an optimized episomally-derived human iPSC platform, we developed a scalable method for the generation of differentiated, cryopreserved human midbrain dopaminergic neurons (iCell(R) DopaNeurons). Gene expression was analyzed by target-focused PCR arrays. Electrophysiological properties were measured using whole-cell patch clamp and the network-level activity was evaluated on multi-electrode array (MEA).
Results: Here, we present data characterizing gene expression for these floor plate-derived midbrain dopaminergic neurons with proper regional and neural subtype specifications. These cells displayed characteristic neuronal electrophysiological properties, including ion channel activity, evoked and spontaneous action potentials and excitatory post-synaptic currents. In addition, results from the MEA showed characteristic excitatory phenotypes with responses to known pharmacological agents and enhanced population bursts in an astrocyte co-culture environment.
Conclusions: Robust and reproducible methods to generate functional iCell DopaNeurons at high purity will enable the successful downstream production of panels of disease-specific samples derived from donor iPS cells for the study of neurodegenerative disorders such as Parkinson's disease.

DEPRESSION ASSOCIATED TO ANIMAL MODELS OF PARKINSON'S DISEASE IS DIRECTLY CORRELATED WITH DEFICITS IN STRIATAL DOPAMINE AND HIPPOCAMPAL SEROTONIN

M. Vital[1], R. Andreatini[1], J. Barbieiro[1], S. Boschen[1], M.M.S. Lima[1], C. Da Cunha[1], R. Santiago[1]

[1]Pharmacology, Universidade Federal do Parana, Curitiba, Brazil

The neurotransmitter deficiency hypothesis of PD considers that low serotonin levels in the brain of patients is a risk factor for depression. We investigated if the infusion of 6-hydroxydopamine (6-OHDA) was able to induce depressive-like behavior. Rats were infused bilaterally in the substantia nigra with 6-OHDA. The animals were randomly divided into SHAM (n=8-9) and 6-OHDA (n=8-9). The open field was performed 1, 7, 14 and 21 days after the stereotaxic surgery. The forced swimming test was carried out 7, 14 and 21 after the surgery, although those groups were submitted to the sucrose preference consumption test on days 7, 14 and 21 after neurotoxin. The striatum and hippocampus structures were rapidly dissected after FST. In the open field the rats of 6-OHDA groups presented a decrease in locomotion and rearing frequencies 1 day after surgery. The results of forced swimming test indicated that 6-OHDA rats exhibited reduction in the time of swimming and increased in the immobility time regarding the groups control and SHAM in the days 7, 14, 21 after surgery. After the motor recovery, 6-OHDA was able to produce anhedonia and behavioral despair in the days 7 and 21 after surgery. These behavioral responses were accompanied by reductions of striatal DA. Additionally, decreases in hippocampal 5-HT content were detected in the 6-OHDA group. Notably, correlations were found between 5-HT and DA levels and swimming, immobility, and sucrose preference. Our results indicate that 6-OHDA produced depressive-like behavior accompanied by striatal DA and hippocampal 5-HT reductions.

A TARGETED PROTEOMICS APPROACH FOR THE IDENTIFICATION AND QUANTIFICATION OF LAMP2 IN CEREBROSPINAL FLUID, A CANDIDATE BIOMARKER FOR NEURODEGENERATIVE DISEASES

S. Sjödin[1], A. Öhrfelt[1], G. Brinkmalm[1], H. Zetterberg[1], K. Blennow[1], A. Brinkmalm[1]
[1]Psychiatry and Neurochemistry, Neuroscience and physiology, Gothenburg, Sweden

Objective
The objective was to identify candidate biomarkers in cerebrospinal fluid (CSF) to investigate the involvement of the endo- lysosomal system in neurodegenerative diseases, with focus on Alzheimer's disease. To achieve this, we developed a targeted proteomics method against Lysosome-associated membrane glycoprotein 2 (LAMP2), a protein which might reflect pathophysiological alterations in the endo- lysosomal system.
Methods
A targeted proteomics hybrid approach was used were immunoprecipitated LAMP2 protein was digested with trypsin and subjected to analysis with a nano liquid chromatography system coupled to a hybrid quadropole orbitrap mass analyzer. Western blotting was used for validation of the method. Using isotope labeled peptides a selected reaction monitoring (SRM) method was developed to monitor and quantify a set of identified endogenous peptides in CSF. The method was evaluated in a set of experiments exploring the variability.
Results
We have with confidence identified six proteotypic non-isoform specific LAMP2 peptides in CSF using mass spectrometry. By the combination of mass spectrometry and immunoprecipitation we have confirmed the presence of a LAMP2 fragment consisting of at least amino acids 46-351. Furthermore, we have developed an SRM method with the ability to quantitate the level of LAMP2 in CSF.
Conclusions
For the first time we have detected LAMP2 in human CSF using mass spectrometry. The SRM method, which has been developed for the quantitation of LAMP2 in CSF, is presently being used to explore the protein as a potential CSF biomarker for neurodegenerative diseases in a number of case-control cohorts.

PROBING MOLECULAR MECHANISMS UNDERLYING LYSOSOMAL CALCIUM DEFECTS IN ALZHEIMER'S DISEASE AND DYSTONIA

R. van der Kant[1], R. Chaves[1], G. Woodruff[1], L. Goldstein[1]
[1]Sanford Consortium for Regenerative Medicine, University California San Diego, San Diego, USA

In addition to the endoplasmic reticulum (ER) the lysosome is a major storage organelle for intracellular calcium ions. Calcium homeostasis in the lysosome is not well understood, and it is unclear how lysosomes acquire calcium. Interesting for Alzheimer's disease pathology, lysosomal calcium levels are significantly lowered in presenilin-1 deficient cells. As presenilin seems to be required for lysosomal calcium loading, it is likely that familiar Alzheimer's disease patients have altered lysosomal calcium levels. Using induced-pluripotent stem cell (IPSC) techniques we demonstrate that lysosomal calcium levels are indeed altered in fibroblast and IPSC derived neurons of presenilin mutant familiar Alzheimer's disease patients. Furthermore we find that lysosomes are "overloaded" with calcium in a newly identified dystonia type. Our data indicates that regulation of lysosomal calcium levels at the cellular levels is important for neuronal function.In addition, we have set up a candidate based genetic screen in patient and control fibroblasts and IPSC derived neurons to identify genes involved in lysosomal calcium loading. Identifications of such genes will increase our insight into the regulation of lysosomal calcium and possibly offer new (drugable) targets to tackle diseases in which lysosomal calcium homeostasis is affected.

[2]Medical Toxicology Centre, Institute of Neuroscience, Newcastle upon Tyne, United Kingdom

[3]Campus for Ageing and Vitality, Institute of Neuroscience, Newcastle upon Tyne, United Kingdom

OBJECTIVES: Imbalance of iron homeostasis has been implicated in neurodegenerative disorders such as Alzheimer's disease (AD). It is unclear however whether the accumulation of iron in the brain is caused by nerve cell loss or whether it is involved in nerve cell death. Neuroferritinopathy (NFR), a rare adult onset movement disorder caused by mutations in the ferritin light chain (FTL), provides a direct link between iron dysmetabolism and neurodegeneration. Mutant FTL has a dominant negative effect on the function of ferritin, the major iron storage molecule. The aim of this study was to investigate the possible pathomechanisms related to brain iron accumulation.

METHODS: Post-mortem Frontal Cortex from 4 AD, 3 NFR and 5 age-matched controls was subjected to analysis using routine molecular biology techniques.

RESULTS: The levels of FTL were significantly higher in NFR compared to controls and the ratio of ferritin light/heavy chain was altered. A similar trend was observed in AD. A tendency towards abnormalities in lysosomal markers LAMP1 and LAMP2 in relation to FTL was characteristic for NFR and AD. Cathepsin D was significantly reduced in NFR compared to controls. Ongoing investigation will determine lysosomal activities in these cases. A trend towards downregulation of the transcription factor EB, which induces lysosomal biogenesis and regulates mitochondrial quality control, was observed in AD, with no changes in NFR. Mitochondrial protein levels were severely reduced in AD, however no significant abnormalities were observed in NFR.

CONCLUSIONS: Defect in iron homeostasis may lead to lysosomal pathology. Further research is warranted.

IMPLICATIONS OF DISRUPTED AUTOPHAGY ON CHOLESTEROL TRAFFICKING, NEURONAL SURVIVAL AND STRATEGIES FOR DRUG DEVELOPMENT IN NIEMANN PICK TYPE C1

P. Ordonez[1], *L.S.B. Goldstein*[2]
[1]*Pediatrics, University of California San Diego/Rady Children's Hospital San Diego, San Diego, USA*
[2]*Cellular and Molecular Medicine, University of California San Diego/Rady Children's Hospital San Diego, San Diego, USA*

Successful development of therapeutic interventions for Alzheimer's Disease (AD) and related neurodegenerative disorders will require a deeper understanding of mechanisms of disease initiation and progression. Niemann-Pick type C1 (NPC1) is a fatal pediatric dementia characterized by the accumulation of cholesterol in the lysosomal compartment. The disease shares intriguing clinical and histological similarities with AD, suggesting a common mechanism of onset and progression. We used reprogramming technology to develop sets of NPC1 and control human induced pluripotent stem cell (hIPSC) lines, and we generated patient-specific pure neuronal cultures using a standard differentiation protocol. We found that NPC1 neurons have disrupted mitochondrial turnover by autophagy that leads to mitochondrial depolarization and increased production of reactive oxygen species, all of which are likely to contribute to neuronal failure. Our data also raise the important and new possibility that NPC1 neurons initially survive cholesterol accumulation because they activate autophagy. We have evidence that in NPC1 mutant neurons, autophagy may function as a backup pathway that releases trapped cholesterol, albeit at lower efficiency, but sufficient to protect neuronal viability until birth and perhaps for a few additional years. Further mechanistic studies lead us to identify a potential new transporter that mediates autophagy-dependent cholesterol efflux from the lysosomal compartment. Our data highlight the central role that autophagy disruption plays in the selective neuronal failure observed in NPC1. Additionally, our approach establishes a cell-based platform for the high-throughput screening of therapeutic compounds that can revert mitochondrial dysfunction while preserving bulk autophagy in NPC1 and related neurodegenerative diseases.

UBIQUITIN/NGF INTERACTIONS ARE REGULATED BY METAL IONS

D. Milardi[1], A. Travaglia[2], V. Lanza[1], V. Zito[1], G. Malgieri[3], C. Isernia[3], R. Fattorusso[3], G. Arena[4], E. Rizzarelli[1]

[1]Institute of Biostructures and Bioimages, National Research Council (CNR), Catania, Italy

[2]Center for Neural Science, New York University, New York, USA

[3]Department of Environmental Biological and Pharmaceutical Sciences and Technology, Second University of Naples, Napoli, Italy

[4]Department of Chemical Sciences, University of Catania, Catania, Italy

Objectives. Ubiquitin-proteasome system (UPS), Nerve Growth Factor (NGF) trafficking, and metal homeostasis are crucial factors in neuronal survival. UPS is known to regulate the NGF sorting machinery; in addition metal ions bind NGF and Ub. However, only a coarse description of the molecular events lying at the root of these biological events is available. In this work we investigate the physical association between Ub and NGF and the role played by metal ions in regulating this interaction.

Methods. WB assays have been employed to investigate Ub-NGF association in the absence and in the presence of Cu(II) and Zn(II) metal ions. Next, we have also studied NGF(1-14), a peptide fragment encompassing the metal binding N-terminal domain of human NGF, to model NGF-Ub interactions by means of NMR, CD and ITC.

Results. Ubiquitin weakly associates with NGF. In particular, the flexible, metal binding N-terminal part of NGF (NGF1-14) interacts with residues 1-20, 52-61, 66-76 of Ub and undergoes a random-coil to Polyproline II conformational transition upon Ub binding. Metal ions, Cu(II) in particular, may turn off Ub-NGF association.

Conclusions. Altogether these evidences support a causative relationship between the age-related increase in the metal-ion levels, UPS malfunction, NGF signaling and neurodegeneration. Hopefully, these evidences will pave the way to studies addressing the role played by metal ions in driving Ub-mediated NGF signaling in vivo.

IMPROVED MITOCHONDRIAL LIPID PROFILE AND COGNITIVE FUNCTIONS IN EXPERIMENTAL MODEL OF HUNTINGTON'S DISEASE: PROTECTION USING MITOCHONDRIA TARGETED THERAPY

M. Arpit[1], *R. Sandhir*[1]
[1]*Biochemistry, Panjab University, Chandigarh, India*

Objectives:
The study was designed to investigate the neuroprotective effect of mitochondrial modulators; alpha-lipoic acid (ALA) and acetyl-L-carnitine (ALCAR) in 3-NP induced alterations in mitochondrial lipid composition, mitochondrial structural appearance and memory functions.
Methods:
Experimental model of HD was developed by administering 3-NP at sub-chronic doses, twice daily for 17 days. The 3-NP treated animals were supplemented with combination of ALA+ALCAR for 21 days and their therapeutic effect was evaluated in terms of improving mitochondrial lipid composition and cognitive functions by using automated video tracking software (Anymaze^{TM}).
Results:
The levels of conjugated dienes, cholesterol and glycolipids were found to be significantly increased, whereas the levels of phospholipids (phophoethanolamine, phosphocholine, phosphoserine) including cardiolipin were found to be significantly decreased in the mitochondria isolated from the striatum of 3-NP treated animals. 3-NP induced increase in cholesterol to phospholipid ratio reflected decreased mitochondrial membrane fluidity. Mitochondrial membrane fluidity assessed using DPH and pyrene probes showed increased values for fluorescence polarization, anisotropy, anisotropy parameter, order parameter, microviscosity, annular fluidity, bulk fluidity and excimer/monomer ratio. The 3-NP administration also resulted in mitochondrial ultra-structural changes assessed using electron microscopy and spatial memory impairments (in elevated plus maze test). Combined supplementation with ALA+ALCAR to 3-NP treated animals for 21 days restored mitochondrial lipid composition, improved structural appearance and ameliorated memory impairments.
Conclusion:
The results suggest an imperative role of these two modulators in improving mitochondrial lipid profile and cognitive functions if given together and thus could be engaged in managing HD.

AUTOPHAGY AS A SCAVENGER OF REACTIVE SPECIES DAMAGE AND PROTECTOR AGAINST NEURODEGENERATION

J. Zhang[1], *V. Darley-Usmar*[1]
[1]*Pathology, University of Alabama at Birmingham, Birmingham, USA*

Objectives: Reactive damage contributes to age-dependent accumulation of dysfunctional mitochondria and protein aggregates, and are associated with neurodegeneration. Supplementation of reactive species scavengers to suppress the initiation of oxidative stress with molecules such as alpha-tocopherol, ascorbate and coenzyme Q has limited success in clinical trials. This may due to: 1) reactive species scavengers cannot reverse established damage to proteins and organelles; 2) reactive species scavengers are limited in action to specific radicals, and can only be effective if neurodegeneration specifically involves the reactive species to which they are targeted and 3) suppression of endogenous reactive species may perturb cell signaling, induce reductive stress and be deleterious. Alternative approaches that can circumvent these limitations are needed. We proposed that autophagy, while not previously considered a reactive species scavenging system, may serve this essential function by removing damaged or dysfunctional proteins and organelles particularly mitochondria which can generate reactive species. **Methods:** We tested this hypothesis using primary neurons exposed to lipid peroxidation product 4-hydroxynonenal (HNE), rotenone and nitric oxide. **Results:** We found that neurons exhibited concentration dependent bioenergetic dysfunction and cell death in response to HNE and rotenone in normoxia, and $NO^{\cdot}$ in hypoxia-reoxygenation conditions. Inhibition of autophagy exacerbated cell death observed in response to HNE, rotenone or $NO^{\cdot}$. Furthermore, cell metabolism plays an important role in regulating autophagy and survival. **Conclusions:** These studies provide new insight and a novel mechanism regarding the role of autophagy in scavenging reactive species damage and protecting against neurodegeneration.

P62/SQSTM1 DEFICIENCY IS ASSOCIATED TO MITOCHONDRIAL DISTURBANCES

F. Bartolome[1], E. Carro[1], J. Hardy[2], H. Plun-Favreau[2], A.Y. Abramov[2]
[1]Neurosciences, Instituto de Investigacion Hospital 12 de Octubre, Madrid, Spain
[2]Molecular Neuroscience, UCL- Institute of Neurology, London, United Kingdom

BACKGROUND: A growing body of published experimental evidences is showing abnormal mitochondrial function related to patients with frontotemporal dementia and amyotrophic lateral sclerosis (FTD/ALS). Mutations in the same disease-causing genes in both disorders have been reported and they support the idea of a FTD-ALS continuum. Interestingly, *VCP* and *p62*/*SQSTM1* mutations which have been found causing FTD/ALS are also identified causing Paget's Disease of the Bone. We have recently demonstrated that VCP (Valosin Containing Protein) deficiency is associated with profound mitochondrial uncoupling, resulting a significant reduction of cellular ATP production. Decreased ATP levels in VCP deficient cells lower their energy capacity, making them more vulnerable to high energy demanding processes.
OBJECTIVES: To study the mitochondrial pathophysiology associated to p62/SQSTM1 (p62) deficiency.
METHODS: Dynamic live-cell imaging techniques to explore the mitochondrial pathophysiology in a p62-knock-down (p62 KD) human dopaminergic neuroblastoma cell line (SH-SY5Y) and fibroblasts from patients carrying two independent pathogenic mutations in the *p62/SQSTM1* gene.
RESULTS: We confirm that p62 deficiency is associated to inhibition in the cell respiration inducing decreased mitochondrial membrane potential. This inhibition resulted in higher ROS production, compelling the cells to switch from glycolysis to the pentose phosphate pathway as reflects the elevated NADPH and GSH levels.
CONCLUSIONS: These findings highlight the pathophysiological events that may occur in FTD/ALS associated with p62 deficiency.

[1]Department of Pharamcology University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India
[2]Department of Pharamcology University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India
[3]Department of Biochemistry, Panjab University, Chandigarh, India

Objectives: Oxidative stress and mitochondrial dysfunction has been suggested to play key role in the development and maintenance of the neuropathic pain. The present study was designed to explore the role of oxidative stress in the spinal nerve ligation (SNL) induced neuropathic pain with the help of various behavioral, biochemical, mitochondrial and cellular alterations in rats.
Methods: In the present study, unilateral lumbar L5 and L6 spinal nerves were ligated to induce neuropathic pain in rats. Behavioral parameters were assessed on the day before ligation and successively on day 7th, 14th, 21st and 28th post ligation. Oxidative stress parameters and mitochondrial enzyme functions were assessed on day 28 after behavioral observations.
Results: SNL resulted in significant increase in mechanical allodynia, mechanical hyperalgesia, cold allodynia and heat hyperalgesia, transfer latency as assessed by Vonfrey, Randall Selitto, Acetone drop, Hot plate and elevated plus maze tests respectively. SNL also resulted in significant increase in oxidative stress parameters (increased lipid peroxidation, nitrite, reduced superoxide dismutase, catalase and glutathione) in lumbar spinal cord and brain. Mitochondrial enzyme complexes activities were significantly inhibited by SNL. Pioglitazone (a PPAR gamma agonist) treatment (10 and 20 mg/kg, i.p.) for 28 days significantly reversed the various behavioral, biochemical and mitochondrial alterations in SNL treated animals.
Conclusions: Results of the present study show that ameliorative potential of pioglitazone in SNL induced behavioral and mitochondrial alterations which may be further attributed to inhibition of oxidative stress and mitochondrial dysfunction in rats.

THIOREDOXIN 80, A NOVEL PLAYER IN INSULIN SIGNALING: IMPLICATIONS FOR ALZHEIMER´S DISEASE

T. Persson[1], P. Rodriguez-Rodriguez[1], J. Calvo-Garrido[1], L. Galán-Acosta[1], A. Cedazo-Minguez[1]

[1]NVS, Karolinska Institutet, Stockholm, Sweden

Objectives

Despite being widely investigated, the mechanisms behind Alzheimer´s disease (AD) are not completely understood but increasing evidence suggests the implication of metabolic alterations related to glucose metabolism and insulin resistance in its development. Insulin is related with tau protein phosphorylation and autophagic clearance of Aβ, thus participating in the regulation of two major hallmarks in AD. We have previously demonstrated that Thioredoxin 80 (Trx80), which is dramatically decreased in AD brains, has an anti-amyloidogenic effect on Aβ and prevents its toxicity. Insulin has been described to form amyloid aggregates that lead to a loss of function. We believe that Trx80 could prevent insulin aggregation, and thus act as a key player in regulating insulin signaling in brain. For this reason, understanding Trx80 role in brain and its effects over metabolic regulation and insulin signaling could be essential for understanding the molecular mechanisms underlying AD.

Methods

Western Blot, MTT assay, Glucose uptake measurement, ThT assay, qPCR.

Results

We show that Trx80 prevents insulin aggregation *in vitro* and that aggregated insulin fails to activate the most common insulin pathways. Cell viability studies clearly demonstrate that aggregated insulin lacks its mitogenic effect. Interestingly, in all cases the lack of function of aggregated insulin is rescued when insulin is co-incubated with Trx80.

Conclusions

The results suggest a key role for Trx80 in regulating insulin signaling and glucose metabolism as well as Aβ clearance in brain, although the molecular mechanisms and the possible coordination between these two processes remain to be investigated.

[3]Psychiatry Institute,
Center for Interdisciplinary Research on Applied Neurosciences (NAPNA) University of S ão Paulo, São Paulo, Brazil

Inflammatory activity has been investigated as potential biological mechanism associated to neurodegenerative cascade affecting Alzheimer's disease (AD) and may be related to mild cognitive impairment (MCI) due this pathology. Apolipoprotein E e4 allele has been established as a potential risk factor to neurodegenerative condition linked to AD. Regular physical exercises can contribute to reduce pro-inflammatory cytokines. Therefore, the objective of this study was to analyze the effects of 16-week of physical exercises program on peripheral levels of tumor necrosis-alpha (TNF-a) and interleukin-6 (IL-6) in elderly with mild cognitive impairment (MCI). Participants were genotyped for APOE polymorphism. Sixty-seven participants were assigned into control (CG) and trained (TG) groups. The TG was composed by 35 participants, and 10 were genotyped as e4 allele carriers. All subjects included in the TG participated in a physical training for a 16-week period and attended at least 75% of the sessions. Considering the control group, for the APOE genotype, from 32 participants, 8 were identified as e4 allele carriers Results showed a significant between-subjects interaction ($p<0.05$) indicating the beneficial contribution of training on reductions of TNF-α and IL-6 levels, independently of the APOE genotype. Physical exercises may reduce low-grade chronic inflammation even under neurodegenerative conditions and APOE genotype seems not modulate these effects.

ADPD5-2132

EFFECTS OF CO-ADMINISTRATION OF GHRELIN AGONIST (GHRP-2) AND GH ON TNF-A, IL-6 AND INOS GENE EXPRESSION INDUCED BY LPS IN THE BRAIN

M. zendehdel[1]

[1]*Basic Sciences, tehran university veterinary faculty, Tehran, Iran*

The aim of this study was to examine the anti-inflammatory effects of co-administration of growth hormone-releasing peptide-2 (GHRP-2) and growth hormone (GH) on tumor necrosis factor-α (TNF-α), interleukin-6 (IL-6) and inducible nitric oxide synthase (iNOS) gene expression induced by LPS in the mouse brain. Thirty-five male NMRI mice (25±5 g) were injected through the mouse tail vein with saline, GHRP-2 (100 µg/kg), GH (25 µg/kg) or GHRP-2 + GH, 30 min before the intraperitoneal injection of LPS (5 mg/kg). Then, inflammation was induced by the intraperitoneal injection of LPS. The control animals received sterile saline in the first and second injections. Changes in the expression level of TNF-α, IL-6 and iNOS genes were studied in the mouse brain by a semi quantitative RT-PCR method. The results of this study showed that GHRP-2 or GH significantly decreased the expression of TNF-α and IL-6 genes in brain 2 h after the injection of LPS. Co-administration of GHRP-2 and GH markedly reduced the expression of TNF-α and IL-6 genes. LPS had no effect on the expression of iNOS gene in brain. The data suggest that co-administration of GHRP-2 and GH has a protective effect in brain inflammation induced by LPS through inhibition of TNF-α and IL-6.

Facultad de Ciencias Biológicas. Pontificia Universidad Católica de Chile, Santiago, Chile
[3]Psiquiatría, Facultad de Medicina. Pontificia Universidad Católica de Chile, Santiago, Chile
[4]Salud Pública, Facultad de Medicina. Pontificia Universidad Católica de Chile, Santiago, Chile

Objectives: The role of antibodies in neuropsychiatric disorders remains little understood. Cognitive impairment is frequently observed in systemic lupus erythematosus (SLE), the prototypic autoimmune disease. Here we studied the pathogenic potential of autoantibodies against ribosomal phosphorylated proteins (anti-P), which cross-react with a neuronal surface P antigen (NSPA) protein and have long been considered a risk factor in diffuse brain dysfunctions.
Methods: Anti-P from SLE patients were analyzed in: 1) Passive transfer experiments and electrophysiology assays, assessing memory related hippocampal functions in mice; 2) Intracellular calcium variations (Fura 2-AM) and apoptosis (caspase-3 activation and Tunel); 3) Cognitive function in SLE patients using *Cambridge Neuropsychological Test Automated Battery* (CANTAB) and ANCOVA models.
Results: Anti-P directly injected by stereotaxis into the hippocampus or added to primary cultures induced neuronal apoptosis, likely due to calcium influx. However, intravenously injected anti-P impaired memory (water maze assays) without detectable signs of apoptosis in hippocampus. Anti-P enhanced excitatory post-synaptic transmission involving over-activation of both AMPA and NMDA receptors and leading to abrogation of long-term potentiation in hippocampal CA1. Cognitive deficit in SLE patients associated with anti-P in fronto-parietal cortex dysfunctions such as attention and spatial planning abilities.
Conclusions: Anti-P have the potential to perturb neuronal function in the brain inducing apoptosis and altering glutamatergic synaptic transmission and plasticity, which depending on the region can lead to memory impairment. Anti-P might contribute to the frequently observed cognitive impairment in SLE. (Financed by Conicyt Basal Project PFB12/2007).

GOLGI APPARATUS FRAGMENTATION AND ACTIVATION OF ATF6 SIGNALING IN THE UNFOLDED PROTEIN RESPONSE IN HEREDITARY SPASTIC PARAPLEGIA TYPE 54

K. Mongeon[1], *F. Abadía-Molina*[2], *A. MacKenzie*[1]
[1]*Cellular and Molecular Medicine, University of Ottawa, Ottawa, Canada*
[2]*Departamento de Biología Celular CIBM, Universidad de Granada, Granada, Spain*

Objectives: Hereditary Spastic Paraplegias (HSPs) are a group of genetic disorders characterized by limb spasticity and weakness, psychomotor delay and intellectual disability. Recently, DDHD domain-containing protein 2 (DDHD2) was identified as the causative gene for autosomal recessive HSP54. DDHD2 is an intracellular phospholipase A1 (iPLA1) implicated in organelle biogenesis and membrane trafficking. Here we examine a role for DDHD2 in endoplasmic reticulum (ER) and Golgi vesicle trafficking to determine if irregular protein accumulation and activation of the unfolded protein response (UPR) contributes to the pathogenesis of HSP54.
Methods: Human fibroblasts derived from an HSP54 patient with a compound DDHD2 heterozygous frameshift mutation [c.1386dupC (p.Ile463-Hisfs*6)] and a missense mutation [c.1978G>C (p.Asp660His)] were characterized via Western Blot Analysis, real-time PCR, and Immunofluorescence staining.
Results: We identified abnormalities in the UPR of HSP54 fibroblasts: BiP was induced, PERK was downregulated, XBP-1 splicing remained unchanged, and ATF6 protein levels were increased leading to induction of its proteolytic cleavage. These alterations resulted in induction of the UPR downstream effector CHOP. Fragmentation and dispersion of the Golgi apparatus was also observed. Finally, it was found that HSP54 patient cells have an increase in DDHD1, another iPLA1 protein with similar activity as DDHD2.
Conclusions: Our results clearly indicate that HSP54 patient cells have defects in protein processing in the ER, which triggers activation of the ATF6 branch of the UPR, and perhaps a compensatory increase in DDHD1 expression. These results indicate that the UPR likely plays a role in HSP54 pathogenesis and may serve as a therapeutic target.

INCREASED TAU PHOSPHORYLATION CORRELATES WITH PKA AND AKT ACTIVATION AFTER TRAUMATIC BRAIN INJURY IN 3XTG-AD MICE

A. Noel[1], I. Poitras[1], C.N. Winston[2], M.P. Burns[2], E. Planel[1]
[1]neurosciences, CHU de Québec - Pavillon CHUL, Quebec City, Canada
[2]neurosciences,
Laboratory for Brain Injury and Dementia Georgetown University Medical Center, Washington, USA

Traumatic brain injury (TBI) is a major environmental risk factor for Alzheimer's disease (AD). Tau pathology can be found in post-mortem brain many years after a single severe or repetitive mild TBI. Since Tau hyperphosphorylation is suggested to play a major role in AD pathogenesis, its induction after injury may play a role TBI pathology. There are reports of acute phospho-Tau accumulation after experimental TBI using a controlled cortical impact (CCI) model. Here, we examined Tau and phospho-Tau accumulation in the 3xTg-AD mouse model 2 and 4 weeks post-CCI to determine if these acute changes can persist chronically after injury in the mouse.

An increase in Tau phosphorylation was observed in the ipsilateral striatum of injured mice and persisted 4 weeks post-injury. In this side, a sustained PKA activation was observed concomitantly with an increase of the activated form of Akt at 4 weeks. In the contralateral striatum, TBI induced a transient increase in Tau phosphorylation. This Tau hyperphosphorylation was associated with a temporary activation of Akt 2 weeks after CCI. The injured mice did not show any changes in either Tau phosphatase levels or APP cleavage, as compared with sham mice. Our data suggest that the hyperphosphorylation of Tau found in the ipsilateral striatum could be linked to sustained PKA activation, while transient Tau hyperphosphorylation observed in the contralateral side could be related to Akt activation. Moreover, these results provide further evidence for the independent relationship between Tau hyperphosphorylation and APP processing in the TBI context

GSK3BETA HAS A ROLE IN BIDIRECTIONAL SYNAPTIC PLASTICITY: GENETIC AND PHARMACOLOGICAL EVIDENCE.

T. Ahmed[1], V. Sabanov[1], A. Latif-Hernandez[1], M. Bovet Carmona[1], A. Schreurs[1], F. Van Leuven[2], D. Balschun[1]

[1]Lab Biological Psychology, KU Leuven, Leuven, Belgium

[2]Experimental Genetics Group LEGTEGG Department of Human Genetics, KU Leuven, Leuven, Belgium

Objectives: GSK3β, a proline-directed serine-threonine kinase, has multiple roles in neuronal energy homeostasis, protein translation, synaptogenesis, synaptic plasticity and cognition. Dysfunction of this enzyme has been proposed in neuropsychological and neurodegenerative disorders such as schizophrenia, bipolar depression, autism and Alzheimer's disease (AD). A common trait of these disorders is defective synaptic functioning, which manifests as perturbed synaptic plasticity. Current hypotheses position GSK3ß in a central role in long-term depression (LTD) but not in long-term potentiation (LTP).

LTD and LTP are thought to underlie different forms of memory at the cellular level.

Methods: Using long-term field recordings in the hippocampal CA1-region of mice, we re-evaluated the function of GSK3ß in protein-synthesis dependent late forms of LTD and LTP (<3 h, L-LTD and L-LTP) by using specific pharmacological inhibitors and neuron-specific GSK3ß KO mice (*Gsk3b$^{n-/-}$*).

Results: We found an impairment of L-LTD upon bath-application of the specific GSK3ß inhibitors SB216763 and indirubin-3-oxime thereby corroborating previous reports. Strikingly, the same compounds caused a severe deficit in L-LTP. These findings were confirmed by recordings in the intact brain from freely-moving rats. Furthermore, an independent genetic analysis of *Gsk3b$^{n-/-}$* mice revealed severely deteriorated L-LTD and L-LTP. In addition, we provide pharmacological evidence that upstream regulators of GSK3β (CDK5, AKT-PI3K pathways) are differentially involved in L-LTD and L-LTP.

Conclusions: The role of GSK3β in long-term synaptic plasticity has to be re-defined, which has major implications for its normal functions - and for its dysfunction in neurodegenerative disorders.

ADPD5-0462

GHRELIN ENHANCES NIGRAL DOPAMINERGIC NEURONAL EXCITABILITY BY INHIBITION OF IM AND IA

H. Jiang[1], *L. Shi*[1], *J. Xie*[1]

[1]*Physiology, Medical College of Qingdao University, Qingdao, China*

Objectives: The gut-derived orexigenic peptide hormone ghrelin enhances neuronal firing in substantia nigra pars compacta (SNc) where excitability of dopaminergic neurons determines the function of nigrostriatal system for motor coordination. However, how ghrelin regulates the excitability of dopaminergic neurons remains largely unknown. Therefore, we sought to understand the molecular mechanism and signaling pathway of the excitatory effects of ghrelin on nigral dopaminergic neurons.Methods: Whole-cell and nystatin-perforated patch clamp recordings were used to record the neuronal firing and potassium current on rat brain slices. Dopamine release and turnover in the rat striatum were measured using HPLC-ECD and fast cyclic voltammetry (FCV). Postural and bar test were used to detect the effects of ghrelin on haloperidol-induced catalepsy.Results: Ghrelin (0.1-1000 nmol/L) directly stimulated the firing rate of dopaminergic neurons does-dependently, as it was not antagonized by excitatory and inhibitory synaptic inhibitors. In addition, ghrelin (100 nmol/L) reversibly and significantly decreased the amplitude of both Kv7/KCNQ/M-current (I_M) and transient potassium current (I_A) to 50% and 53% of control, respectively. This effect was abolished by selective inhibitors of GHS-R1a, PLC, and PKC. XE991 and 4-AP, the specific I_M and I_A inhibitors, abolished ghrelin-induced hyperexcitability. *In vivo*, intracerebroventricular ghrelin administration causes increased dopamine release and turnover in the striatum. Microinjection of ghrelin into SNc results in contralateral dystonic posturing, and attenuates the catalepsy elicited by haloperidol. Conclusions: Our findings reveal that ghrelin exerts its function by inhibiting I_M and I_A via GHS-R1a-PLC-PKC pathway, resulting in enhanced excitability of nigral dopaminergic neurons for improvement of motor impairment.

NANOTECHNOLOGY APPLICATIONS FOR ALZHEIMER'S DISEASE

J. Leszek[1], K. Kazimierz Gasiorowski[2], J.I.N. Zhang[3]
[1]Psychiatry, Wroclaw Medical University, Wroclaw, Poland
[2]Pharmacy, Wroclaw Medical University, Wroclaw, Poland
[3]Dpt of Chemical and Biochemical Engineering, University of Western Ontario, Ontario, Canada

Objectives: Dementia of Alzheimer's type(AD) affects memory,thinking and behavior.Scientists believe that changes in the brain may begin 10-20 years before symptoms appear and AD is diagnosed.The need to diagnose and treat the devastating disease at an early stage is critical to manage and treat AD.Unfortunately,the lack of valided biomarkers limits the possibility of the earlier stages of Alzheimer's disease. The advance of nanotechnology could offer huge opportunities in early-stage diagnosis and well-treatment of AD.
Methods: This presentation discusses the challenges of current treatment and diagnosis of AD and the development on biocompatible nanoparticles, and provide the rational and potentials of using nanoparticles for both drug carrier and imaging contrast agent for diagnosis and treatment of AD.
Results: Biocompatible nanoparticles with diameter in the range of 1-100nm could be used as targetes delivery system for drugs(e.g. Rivastigmine) to overcome the blood-brain barrier(BBB), and to minimize the side effects caused by over-dosage.In addition, biocompatible nanomaterials with enhanced optical and magnetic properties, may allow them being excellent alternative contrast agents for early-stage diagnosis.
Conclusion: With more studies using nanomaterials and nanotechnology in complex biochemical environment of the central nervous system, it is most likely that nanomaterials and nanotechnology can be give significant impact on the early-stage diagnosis and treatment of AD

GENERATION OF PATIENT-SPECIFC HUMAN NEURAL STEM CELLS WITH THE ABILITY TO PRODUCE MATURE NEURONS AND ASTROCYTES FOR DISEASE-MODELLING

S. Bolognin[1], T. Palm[2], J.C. Schwamborn[1]
[1]Developmental and Cellular Biology, Luxembourg Centre for Systems Biomedicine, Esch-Sur-Alzette, Luxembourg
[2]Stem Cell Biology and Regeneration, Institute of Cell Biology, Munster, Germany

Objectives

To develop a novel hiPSCs-based protocol which allows the generation of expandable hNSCs that can be either maintained under self-renewing conditions over high passages or differentiated into various neuronal sub-types.

Methods

hNSC were first generated from iPSCs by the chronological administration of media with defined compositions. After generating a stable hNSC culture, transition to either neurons or astrocytes was achieved after 2 and 8 weeks respectively. Cell identity was confirmed by immunofluorescence and quantitative real time PCR investigations.

Results

The generation and maintenance of hNSCs was robustly achieved. hNSCs maintained both self-renewing features as well as the potential of indefinite proliferation over numerous passages as demonstrated by the expression of marker as Nestin, SOX1, SOX2 and of the proliferation marker Ki67. Under neuronal differentiation media, hNSC differentiated into functional neurons expressing MAP2, GABA, vGlut1 and TH. hNSC were also differentiated into astrocytes expressing GFAP, S100ß and Vimentin. We were able to obtain a population of mature astrocytes both in a quiescent state with a protoplasmic morphology (not positive for GFAP) as well as in a reactive phenotype characterized by GFAP expression. The expression of glutamate transporter and water channel in all the cells strongly support the acquisition of mature functions.

Conclusions

The easy execution of the differentiating steps allows the generation of functional neurons and long expandable astrocyte cultures, which can be used for modeling disease-specific pathological traits. Moreover, human iPSCs bear the advantage of being derivable in a patient-specific manner. This makes them suitable for autologous engraftments.

PHYSICAL ACTIVITY INCREASES ADULT HIPPOCAMPAL NEUROGENESIS AND SPATIAL LEARNING ABILITIES IN A MOUSE MODEL OF PARKINSON'S DISEASE

C. Klein[1], J. Rasinska[1], L. Empl[1], M. Sparenberg[1], A. Poshtiban[1], D. Iggena[1], Y. Winter[2], M. Rivalan[2], A. Flöel[3], B. Steiner[1]

[1]Neurology, Charite University Medicine Berlin, Berlin, Germany

[2]Neurocure Excellence Cluster, Humboldt University, Berlin, Germany

[3]Neurocure Excellence Cluster, Charite University Medicine Berlin, Berlin, Germany

Objectives

Modulation of adult neurogenesis in neurodegenerative disorders has been investigated in animal models of Parkinson's disease (PD). PD is associated with continuous loss of dopaminergic neurons in the substantia nigra leading to dopamine depletion. In the clinic, physical exercise improved motor and cognitive functions in PD patients. Animal experiments have demonstrated the involvement of endogenous neural precursors correlating with better clinical outcome.

Methods

Here, we investigated the impact of different durations of voluntary physical exercise on hippocampal neurogenesis in the MPTP mouse model. Additionally, we measured dopamine levels in the striatum and hippocampus and determined the expression of genes that might link dopamine to neurogenesis. We also studied the association of neurogenesis with spatial learning and memory in the Morris Water Maze (MWM).

Results

MPTP transiently altered the differentiation process of newly generated neural precursor cells. Physical exercise accelerated the differentiation process and increased net neurogenesis. Exercise did not reversed the MPTP-induced dopamine depletion but increased the upregulation of dopamine receptor D1 (drD1) expression in the hippocampus. MPTP impaired spatial learning, whereas short-term exercise increased spatial learning in the MWM.

Conclusions

The results indicate that dopamine via its receptor drD1 modulates neurogenesis in the hippocampus and associated spatial learning and memory abilities. Physical exercise reversed the effects of dopamine depletion on neurogenesis and cognition probably through a mechanism that is independent of the dopamine level in the hippocampus. Hence, physical exercise might serve as a potential therapeutic for neurodegenerative disorders in humans by positively regulating adult neurogenesis and cognition.

ADPD5-1689

MICROGLIA-SPECIFIC PROGRANULIN LOSS IN FRONTOTEMPORAL DEMENTIA

K.R. Miller[1], A. Glas[2], S. Jacob[1], F.L. Heppner[1]

[1]Neuropathology, Charite University Medicine Berlin, Berlin, Germany

[2]Department of Biosciences, Radboud University Nijmegen, Nijmegen, Netherlands

Frontotemporal dementia (FTD) represents a clinically and pathologically heterogeneous group of neurodegenerative disorders that form the second-most prevalent cause of early-onset dementia. Mutations in the granulin gene (*GRN)* leading to progranulin (PGRN) haploinsufficiency account for 5-10% of all FTD cases and nearly 25% of familial FTD cases, but the mechanism through which progranulin deficiency leads to neurodegeneration is unknown. Progranulin, a pleiotropic growth factor, is expressed by both neurons and microglia cells in the brain. By depleting and exchanging the endogenous $PGRN^{+/+}$ (wild-type) microglia pool with PGRN-deficient myeloid cells in otherwise wild-type ($PGRN^{+/+}$) mice, we assessed the microglia-specific contribution of PGRN deficiency to FTD-like neuropathology in aged animals, while sparing neuronal PGRN expression. Histological, biochemical and cognitive analyses of FTD-related pathology in mice lacking PGRN exclusively in microglia or in all CNS resident cells allowed for the identification of the specific cellular source accountable for FTD-like changes. These data broaden our understanding about PGRN actions and pinpoint specific targets for future therapeutic approaches.

A SPECTRUM OF CHRONIC TRAUMATIC ENCEPHALOPATHY PATHOLOGY IN THE BRAINS OF BOXERS

M. Dhillon[1], A. Liu[1], P. Cole[2], J. Carvalho[2], S. Gentleman[1]
[1]Medicine, IMPERIAL COLLEGE LONDON, London, United Kingdom
[2]Corsellis collection, West London Mental Health Trust, London, United Kingdom

Chronic traumatic encephalopathy (CTE) is a progressive neurodegenerative condition associated with a history of repetitive mild traumatic brain injury as can be experienced in some contact sports. In recent years the clinical presentation of deficits in cognition, behaviour, mood and motor function associated with this condition have been linked to the presence of extensive glial and neuronal tau pathology in the post mortem brain. Although initially described in boxers as 'dementia pugilistica', the term CTE is now used to cover other sporting and non-sporting activities associated with repetitive brain injury. The aim of this study was to determine the extent and distribution of pathology in a seminal series of dementia pugilistica cases which first reported in the 1970s (Corsellis et al. Psychol Med 1973; 3: 270-303). Tissue sections from the brains of 25 boxers (amateur and professional) and 4 age-matched non-boxing controls from the Corsellis archive were immunostained for tau, A-beta and alpha-synuclein. Twelve of the seventeen professional boxers (70%) and, interestingly, one of the non-boxing controls displayed tau pathology consistent with CTE. Neurofibrillary tangles, neuropil threads and astrocytic tangles were seen located focally in the depths of the sulci, and in perivascular (see figure), subpial and periventricular locations. Two of the amateur boxers also showed some minor tau pathology but even within the professional boxer group there was a wide variation in the extent of the CTE pathology. Further work is underway to determine what factors may have determined the severity of the pathology in this cohort.

DISEASE-DRIVEN CHANGES IN A DISCRETE POPULATION FROM THE CEREBELLAR CORTEX

V. Sottile[1], L. Chakrabarti[2], S. Salih[1]
[1]Wolfson STEM Centre School of Medicine, The University of Nottingham, Nottingham, United Kingdom
[2]School of Veterinary Medicine and Science, The University of Nottingham, Nottingham, United Kingdom

In mammals, adult neurogenesis is thought to be restricted to two regions in the brain, the lateral ventricle and the hippocampus. Recently, cells exhibiting some stem cell characteristics have been identified in the Purkinje cell layer (PCL) of the adult cerebellum. These cells identified in adult mouse as the Bergmann glia have also been reported in human cerebellum. Bergmann glia cells are characterised by long radial glia processes, and share co-expression of markers such as Sox1/2/9 with neural stem cells (NSCs) typically found in the subventricular and subgranular zones. When isolated in culture, these cells exhibit marker expression, proliferation and differentiation characteristics comparable to NSCs.

To further investigate the possible role of these cells in adult cerebellum, a disease model presenting gradual cerebellar degeneration was analysed and compared to tissue from asymptomatic controls. Immunohistochemical analysis confirmed the persistence of the Sox1/2/9^{+} cell population in the Purkinje cell layer even at stages where Purkinje cells had partially or totally disappeared. Tissue analysed at different time-points provided insight into the cellular processes associated with the ataxic phenotype, and the cellular features of the Bergmann glia evaluated across the different stages. The present study reveals the differential changes occurring in the 2 intercalated cell populations present in the PCL during cerebellum degeneration, which have implications for approaches to cerebellar pathologies.

PREFERENTIAL HEME OXYGENASE-1 ACTIVATION IN STRIATAL ASTROCYTES ANTAGONIZED DOPAMINERGIC NEURONS DEGENERATION IN MPTP-INTOXICATED MICE

J. Xie[1], N. Song[1], X. Xu[1], X. Yu[1]
[1]Physiology, Medical College of Qingdao University, Qingdao, China

Objective: PD is characterized by the loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc) with accompanying evidence of increased oxidative damage. Heme oxygenase-1 (HO-1) is crucial to the response to oxidative stress via the catabolism of heme into carbon monoxide, biliverdin and iron. The present study aims to investigate neuroprotective effects of HO-1 activation induced by cobalt protoporphyrin IX (CoPPIX) in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) intoxicated mice. Methods: Double immunefluorescence staining and western blots were used to measure HO-1 levels in vivo and in vitro. High performance liquid chromatography was used to analyze the striatal dopamine levels. Flow cytometry was used to indicate the mitochondria function. Results: MPTP triggered a robust HO-1 activation in the astrocytes of striatum after 1d treatment, and then dropped dramatically. Intraventricular administration of CoppIX for 8 days could preferentially activate HO-1 in astrocytes in striatum rather than SNpc. The loss of dopaminergic neurons was blocked and striatal dopamine content were restored in the subacute MPTP models with CoPPIX administration. We then analyzed HO-1 response in primary cultured ventral mesencephalic astrocytes and neurons treated by 1-methyl-4-phenyl-pyridinium (MPP^+). The results showed HO-1 up-regulation in astrocytes appeared much earlier than that in neurons. Although HO-1 activation induced by CoppIX might be double-edged in neurons, it always showed cytoprotective effects in astrocytes. Conclusion: These results indicated that preferential HO-1 activation in striatal astrocytes might convey neuroprotective effects on dopaminergic neurons in PD. This also provided evidence for targeting HO-1 in striatal astrocytes for PD therapeutics.

PAK4 CONFER NEUROPROTECTION IN PD THROUGH CRTC1

S. Won[1], M. Park[1], S. You[1], K. Lee[2], H. Kim[3], E. Shin[1], E. Kim[1]
[1]Department of Biochemistry College of Medicine, Chungbuk National University, Cheongju, Korea
[2]Department of Marine Life Science, Chosun University College of Natural Sciences, Gwangju, Korea
[3]Department of Medicine and Microbiology College of Medicine, Chungbuk National University, Cheongju, Korea

PD is an aging-related neurodegenerative disease caused by dopaminergic (DA) neuron loss in the substantia nigra (SN) in which decreased dopamine lead to motor dysfunctions. p21-activated kinase 4 (PAK4) plays a key role in cell survival and neuronal development. We therefore investigated a possible neuroprotective role of PAK4 in PD. We found that $pPAK4^{S474}$ levels, an index of PAK4 activation, were markedly decreased in DA neurons in human PD brain and a 6-hydroxydopamine (6-OHDA) Parkinson animal model. Intriguingly, the remaining pPAK4-positive DA neurons in PD brain were immunolabelled with anti-B-cell lymphoma 2 (Bcl-2) but not by terminal deoxynucleotidyl transferase-mediated dUTP nick end-labelling (TUNEL). Knocking down PAK4 expression sensitised rats to 6-OHDA-induced PD development, including behavioural dysfunction. Conversely, constitutively active PAK4 (caPAK4) expression protected DA neurons from 6-OHDA insult, thereby preserving motor function. This neuroprotective effect of caPAK4 was mediated by phosphorylation of CREB-regulated transcription coactivator (CRTC1) at serine 215. $CRTC1^{S215A}$, a nonphosphorylated isoform, compromised the ability of caPAK4 to induce the expression of the neuroprotective CREB target genes Bcl-2, brain-derived neurotrophic factor (BDNF) and peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC1-α). Our results support a neuroprotective role for PAK4 in PD and elucidate a downstream mechanism. These results identify this PAK4 pathway as a potential target for PD management.

MYOCARDIAL INFARCTION IN RAT INDUCES BRAIN ISCHEMIA UPREGULATING PS2 AND PS1 PROMOTING NEURONAL DEGENERATION DURING AGING

J. Kesavan Swaminathan[1], K. Arul Salomee[1]
[1]Department of Bioinformatics, Bharathidasaan University, Tiruchirappalli, India

Objective: Presenilin (PS) expression is regulated by several cellular factors with age. PS1 & PS2 is regulated by ischemic conditions increasing their expression levels promoting apoptosis during Myocardial Ischemia (MI). Therefore age associated MI may cause brain ischemia (BI) and thereby expected to influence PS overexpression in the brain. Present study thus aims at investigating MI as a possible cause for BI and neurodegeneration during aging.
Methodology: Young and aged male wistar rats induced with MI and BI through LAD ligation and MCAO respectively was utilized for present study, where young and aged rats treated as –ve control and BI rats treated as +ve control. To understand age associated neurodegeneration mediated by MI, PS1 & PS2 levels, Inflammatory and apoptotic markers were studied using Immunoblotting. Histopathology was done to confirm neurodegeneration.
Results: Aged rat heart ischemia had significantly raised brain ischemic pattern that was evident through elevated HIF-1α levels. Further, PS2 & PS1 levels were significantly upregulated rising inflammatory and apoptotic markers in aged rat brain induced with MI. Pathological observation further confirmed neurodegenerative pattern in aged rat brain induced with MI when compared to young and aged control rats. Interestingly, MI induced aged rats displayed similar observation as that of BI induced aged rats providing major link between heart ischemia and neurodegeneration.
Conclusion: Upregulation of AD determinants (PS2 & PS1) along with inflammatory and apoptotic markers provided a valuable information on age associated MI that can induce BI initiating neurodegeneration, and may thus shed light on age associated SAD.

[5]DES, Research Unit Analytical BioGeoChemistry - Helmholtz Center Munich, Munich-Neuherberg, Germany

Chronic Manganese exposure leads to degeneration of dopaminergic neurons inducing a Parkinson-like complaint called Manganism. Deciphering the ongoing neurodegenerative mechanisms in the affected brains is still a major task for understanding the complex modes of action.
We analyzed and identified relevant Mn-carriers being responsible for a widely uncontrolled transport across neural barriers (NB): Mn speciation in paired serum/cerebrospinal fluid (CSF) samples was performed two-dimensionally by SEC-ICP-DRC-MS and CZE-ICP-DRC-MS. The most important Mn-carrier, Mn-citrate, was identified by ESI-FT-ICR-MS. Elevated Mn-citrate concentration in serum were shown to act as marker for increased Mn concentration in CSF (and brain), the latter elevating the risk of Mn-dependent neurological disorders.
To clarify molecular mechanisms of Mn-neurotoxicity we applied ESI-FT-ICR-MS and IC-ICP-OES to rat brain extracts after low-dose Mn-feeding, simulating chronic Mn-exposure. ESI-FT-ICR-MS-analysis of brain extracts revealed an increase in oxidative stress markers like glutathione-disulfide (GSSG), prostaglandins, and 15(S)-HETE, a marker for lipid peroxidation. Acetylcholinesterase activity and glutamate concentrations were also increased in brain samples of Mn-supplemented rats, indicating oxidative stress in brain, too. Furthermore, a shift in neuronal Fe(III) to Fe(II) was observed, promoting Fenton reaction and formation of chemical radicals. For the first time altered Fe-species distribution could be related to Mn-induced neuroinflammation, enlarging knowledge of this complex neurodegenerative condition. The combination of various speciation- and different mass spectrometry techniques provided information how Mn enters the brain without efficient control at NB and provided substantial evidence that Mn-induced neuroinflammation leads to oxidative stress triggered by multifactorial pathophysiological processes.

LACTOFERRIN SYNTHESIZED BY MICROGLIA ANTAGONIZES MPP+-INDUCED NEUROTOXICITY TO THE DOPAMINERGIC NEURONS

J. Wang[1], M. Bi[1], N. Song[1], J. Xie[1]
[1]Physiology, Medical College of Qingdao University, Qingdao, China

Objectives: Lactoferrin (Lf) can bind to lactoferrin receptor (LfR), leading to iron transport through the plasma membrane. Lf also has a wide variety of biological functions, for example, antioxidant, anti-carcinogenic and anti-inflammatory properties. In the brain, Lf is only synthesized and released by activated microglia, and LfR is mainly expressed in neurons. Lf mRNA levels and LfR expression were increased in Parkinson's disease (PD) patients and animal models which indicate a relevance of Lf/LfR and PD. The aim of the study was to investigate how iron influenced Lf release by microglia, as well as to clarify if Lf tended to transport iron to dopaminergic neurons leading to cell death or protect dopaminergic neuron from neurotoxin. Methods: enzyme-linked immunoabsorbent assay, real-time PCR, flow cytometry, western blots, laser confocal scanning microscopy and other methods were used in this experiment. Results: activated microglia could synthesize and release abundant Lf. This process was further enhanced by iron load. In ventral mesencephalon neurons, both forms of Lf: iron-free (apo-Lf) and iron-saturated (holo-Lf) exerted neuroprotective effects against MPP+-induced neurotoxicity by a mechanism, believed to enhance the mitochondrial transmembrane potential, improve the activity of SOD, increasing the expression of anti-apoptotic protein Bcl-2. Although apo-Lf but not holo-Lf chelated cellular iron, there were no difference between the two types of Lf for the protective effects. Conclusions: iron overload can increase the activated microglia releasing Lf. Both apo-Lf and holo-Lf play protective role on ventral mesencephalon neurons against MPP^+, which is independent on iron chelating ability.

RC DEFECT-ALTERED CARDIOLIPIN REMODELING IN ASSOCIATION WITH MITOCHONDRIAL DYNAMICS IN NARP CYBRIDS AND ITS PARENTAL 143B AND P0 CELLS

M. Jou[1]

[1]*pharmacology, Chang Gung University, Taoyuan, Taiwan*

Mitochondrial (m) respiratory complexes (RC) are vital for electron transport and ATP generation. RC defects result in significant mitochondrial stress for an enhanced apoptosis. This study investigated RC defect-altered remodeling of cardiolipin (CL), a signature phospholipid in the mitochondrial inner membrane crucial for RC stability and ATP generation, in association with mitochondrial dynamics of mROS formation, mCa2+ overload, delta si depolarization in 143B osteosarcoma cells, NARP cybrids and its parental 143B and mtDNA less p0. We demonstrate that NARP cybrids, in contrast to 143B and p0 cells which are more sensitive to oxidative stress, are more vulnerable to Ca^{2+} stress possibly due to complex V inhibition-induced enhanced delta si, the main driving force for mCa2+ uptake. Confocal imaging also revealed that all RC inhibitions and cell stresses resulted in various degrees of mCa2+ overload, mROS formation, delta si depolarization and CL depletion. Compared to complexes I or II, inhibition of complex III, IV, or V enhanced more NARP toxicity due to more mROS dependent CL depletion. Interestingly, among these stresses, overloaded mCa2+ and inhibition of complex IV and V demonstrated clear CL-dependent threshold effects on cell viability particular in NARP cybrids. These results conclude a RC defect-altered CL remodeling associated with NARP toxicity.

INSIGHTS INTO THE PATHOPHYSIOLOGY OF NEURODEGENERATIVE FXTAS BY GENOMIC APPROACH

S. Zongaro[1], R. Hukema[2], P. Barbry[1], R. Willemsen[2], B. Mari[1], B. Bardoni[1]
[1]IPMC, CNRS UMR 7275, Valbonne, France
[2]DEPARTMENT OF CLINICAL GENETICS, ERASMUS MC, Rotterdam, Netherlands

Objectives: Fragile X-associated Tremor Ataxia Syndrome (FXTAS) is an adult-onset neurodegenerative disorder leading to a combination of tremor, gait imbalance, Parkinsonism and cognitive decline. It is due to the elevated level of *FMR1* mRNA (2-8 fold), whose absence causes the Fragile X Syndrome. At the cellular level, FXTAS is characterized by the presence of age-dependent nuclear inclusions, containing *FMR1* mRNA, which are considered the cause of neurodegeneration. Mouse models exist recapitulating the disorder. Interestingly, young people and mice not yet displaying FXTAS symptoms and/or nuclear inclusions, may suffer of neurological and psychiatric problems (e.g. poor memory, autism, bipolar disorders), probably because of the elevated *FMR1* mRNA.
Methods: We combined genomic and neuronal morphology approaches.
Results: We performed whole-genome analysis on mRNA obtained from total brain and synaptosomes from young (15 weeks old) and aged (72 weeks old) FXTAS mice. The synaptosomal analyses display alterations in pathways involved in learning and memory, synaptic plasticity, as well as neurodegeneration (increased SNCA) also in young animals. Abnormal gene expression in total brain is only relevant in old mice and the classes of genes that are altered are consistent with the neurodegenerative character of FXTAS. However, in these mice, also pathways involved in neuronal maturation and morphology have been highlighted by our analysis.
Conclusions: Our results strongly suggest a double nature of FXTAS: neurodegenerative and neurodevelopmental. For this reason we started a morphological analysis (dendritic arborization and spine morphology) of mouse FXTAS cultured cortical neurons (not showing nuclear inclusions) and will present recent results.

ADPD5-1404

HUMAN IPSC-DERIVED NEURONAL NETWORKS GROWING ON MICRO-ELECTRODE ARRAYS USED IN NOVEL PHENOTYPIC FUNCTIONAL IN VITRO SCREENING ASSAYS FOR PARKINSON'S AND ALZHEIMER'S DRUGS

B. Bader[1], A. Pielka[1], A. Voss[1], O. Schroeder[1]
[1]Stem cells, NeuroProof, Rostock, Germany

Phenotypic screening has led to the majority (6/7) of successfully launched CNS drugs in the last decade.

Objectives: our aim was to apply human iPSC-derived neuronal networks growing on multiwell micro electrode arrays (MEAs) for functional phenotypic in vitro screening of Alzheimer's (AD) and Parkinson's (PD) relevant compounds.

Methods: we cultured different commercially available cortex-like and dopaminergic neurons derived from human iPSCs and optimized culture conditions to obtain spontaneous activity showing network communication patterns. These networks were treated with low-concentrated Abeta42 and MPP+, respectively, to induce a functional pathophysiology but no systemic neurotoxicity and tested known neuroprotective substances and drugs to rescue and/or prevent the functional impairment. Using multi-parametric data analysis of spike trains we calculated a readout able to capture, both, compound-induced impairment and rescue.

Results: we show that the used commercial human neuronal cultures produce robust spontaneous activity within 2 weeks in vitro, that both, Abeta42 and MPP+ induce significant functional effects on network activity and plasticity/communication on cortex-like and dopaminergic cultures, respectively, which can be prevented and rescued by neuroprotective substances. We compare the results with those of our available assays using primary mouse neurons.

Conclusion: functional phenotypic in vitro screening using human iPSC-derived neuronal networks growing on multiwell MEAs provides a scalable platform to test novel leads or advanced drugs (repurposing) for future AD and PD therapies.

LATERAL HABENULA AS A LINK BETWEEN DOPAMINERGIC AND SEROTONERGIC SYSTEMS CONTRIBUTES TO DEPRESSIVE SYMPTOMS WITH PARKINSON'S DISEASE

X.F. Luo[1], B.L. Zhang[1], J.C. Li[1], Y.Y. Yang[1], Y.F. Sun[1], H. Zhao[1]
[1]Department of Physiology Key Laboratory of Pathobiology Ministry of Education, College of Basic Medical Sciences Jilin University, Changchun, China

Objectives: Degeneration of substantia nigra dopaminergic neurons is a key pathological change of Parkinson's disease (PD), and its motor consequences have been widely recognized. Recently, mood disorders associated with PD have begun to attract a great deal of interest, however, their pathogenesis remains unclear. The lateral habenula (LHb) is closely related to the substantia nigra and raphe nuclei, which are associated with the pathogenesis of depression. In this study, we investigated the effect and its mechanism of the LHb lesions on depressive-like behavior in PD rats.
Methods: We screened rats with depressive-like behaviors from PD model animals by using forced swim test; the cytochrome coxidase (CCO) activity in the LHb of PD rats with depressive-like behaviors (PDD rats) was measured; The changes of depressive-like behaviors and 5-HT level in the raphe nuclei of PDD rats was observed after the LHb lesions respectively.
Results: We found that CCO activity in the LHb of PDD rats was twice that seen in the control rats. In the forced swim test, LHb lesions caused a decrease in depressive-like behavior of PDD rats as indexed by decreased immobility times and increased climbing times. LHb lesions also caused an enhance in 5-HT levels of the raphe nuclei.
Conclusions: It suggested that LHb lesions may improve depressive-like behavior in PD rats by increasing 5-HT levels in the raphe nuclei. Thus, LHb contributes to the depressive-like behavior in PD rats via mediating the effects of dopaminergic neurons in the substantia nigra on serotonergic neurons in the raphe nuclei.

CURCUMIN SUPRESSESS EXPRESSION OF COX-2 AND FORMATION OF MITOCHONDRIA MEDIATED FREE RADICALS IN D-GALACTOSE INDUCED AGEING IN RATS

D. Banji[1], O. Banji[1], C. Kalpana[1], C. Kranthi Kumar[2]
[1]Pharmacology, Nalanda College of Pharmacy, Nalgonda Telangana, India
[2]Pharmacology, Wright State University, Ohio, USA

Objectives: Aging alters the configuration of neurons often leading to neurodegenerative disorders. During aging, antioxidant defenses are compromised producing mitochondrial damage and apoptosis of neurons. Neuroinflammation and accumulation of abnormal proteins also promote neuron damage. The aim was to delineate the role of curcumin in minimizing neuron damage induced by D-Galactose; by inhibiting the expression of inflammatory & apoptotic proteins and evaluating its impact on memory in rats. **Methods:** Rats were categorized into naïve control group, D-galactose (150 mg/kg; s.c; 56 days) exposed groups, and curcumin (50 & 100 mg/kg; orally; 63 days) treated groups. Cognitive studies were undertaken. Mitochondrial complexes, oxidation of lipids & proteins and antioxidant enzymes were determined in the brain mitochondrial fraction. Western blot was performed to detect COX-2 protein and cleaved caspase-3. Histological assessment of the CA2 region of hippocampus was done. Behavioral studies were analyzed by Repeated Measures ANOVA and other parameters by one way ANOVA followed by Post Hoc Dunnett test using SPSS version 16.0 at $p<0.05$ level of significance**. Results:** D-galactose induced significant cognitive deficits owing to mitochondrial dysfunction, neuroinflammation and apoptosis. Treatment with curcumin down regulated the expression of COX-2 protein, reduced apoptosis, increased the activity of complex-I & III and improved antioxidant defense compared with D-galactose treated group ($p<0.05$). Curcumin protected the CA2 region of the hippocampus from the deleterious impact of D-gal. **Conclusion:** By abating the over-expression of COX-2 and cleaved caspase-3, curcumin exerted significant protection of neurons and improved memory thereby serving as a prospective neuroprotective agent.

MICE DEFICIENT IN COLLAPSIN RESPONSE MEDIATOR PROTEIN-1 EXHIBIT AGE-RELATED COGNITIVE DECLINE

Y. Tsai[1], S. Huang[2], S. Lin[3], T. Chin[3]
[1]Graduate Institute of Life Science, National Defense Medical Center, Taipei, Taiwan
[2]Department of Biochemistry, National Defense Medical Center, Taipei, Taiwan
[3]Department of Bioscience Technology, Chung Yuan Christian University, Chung Li, Taiwan

Background: Collapsin response mediator protein-1 (CRMP-1) was initially identified as a molecule that mediates the extracellular signals from semaphorin 3A and involved in neuronal development. However, the impact of CRMP-1 in cognitive deficits with aging remained unknown. *Objective*: We aimed to study whether the absence of CRMP-1 accelerated aging-related cognitive impairment. *Methods*: The study examined behavioral performance in Morris water maze (MWM) of wild-type (WT) and age-matched *crmp1* knock-out (KO) mice at different ages: adult (9-10-month-old), middle-aged (14-15-month-old) and aged (19-20-month-old). Then, the level of phosphorylated tau in cortex and hippocampus was compared to WT and age-matched *crmp1* KO mice in different ages after sacrificed. *Results*: In MWM, the *crmp1* KO mice had longer mean daily escape latencies than WT mice. We also analyzed search strategies using MWM. *crmp1* KO mice used less spatial strategies and more nonspatial systematic strategies, whereas WT mice used more spatial strategies. Both in escape latencies and search strategies, the elder mice had the worse performance than younger mice, especially in *crmp1* KO mice. Moreover, deletion of CRMP-1 in hippocampus resulted in the increase of phosphorylated tau level at serine202 in middle-aged mice and at serine202 and serine396 in aged mice when compared to age-matched WT mice. These data were consistent with previous studies that tau is hyperphosphorylated in its pathological forms. *Conclusions*: Our results implied CRMP-1 deficits was associated with poor escape latencies and search strategies, and led to the hyperphosphorylation of tau at serine202 and serine396 with aging.

CHANGES OF PROTEOMIC PROFILES IN THE AGING HIPPOCAMPUS FROM POSTMORTEM HUMAN BRAINS

B. Xu[1], W. Qiu[1], Y. Gao[2], W. Liu[1], N. Wang[1], D. Zhang[1], W. Ge[2], C. Ma[1]
[1]Human Anatomy Histology and Embryology Neuroscience Center,
Institute of Basic Medical Sciences Chinese Academy of Medical Sciences, Beijing, China
[2]Immunology,
Institute of Basic Medical Sciences Chinese Academy of Medical Sciences, Beijing, China

Neurodegenerative diseases such as Alzheimer's Disease (AD) are highly correlated with aging. With the newly founded human brain bank in the Neuroscience Center, Chinese Academy of Medical Sciences & Peking Union Medical College, we performed a proteomic study in the hippocampus of postmortem human brains. The ages of death ranged from 22-98, and were grouped into 4 aging groups: 20-50, 50-70, 70-90, and over 90 (n=4 each). None of the donors was diagnosed with neurodegenerative diseases according to their medical history. Our studies identified 4582 proteins, among which 99 were upregulated and 43 were downregulated. Three of these changed proteins, glial fibrillary acidic protein (GFAP), Vimentin and annexin A1 were used to verify the proteomics results by western blot. Combined bioinformatics analysis shows that some proteins (such as tau and APOE) seriously associated with the AD pathogenesis showed no change in aged group compare with the younger groups, but a number of proteins involved in the electron transport chain were downregulated, which was also found in previous studies of AD. Therefore the regulatory process involved in people with normal aging process is different with the AD patients. The results demonstrated the feasibility of brain tissue research on the basis of standardized Chinese human brain bank, and suggested a series of changes in proteomic profile in human hippocampus that may relate to aging and age-related neurodegenerative disorders.

Supported by: CAMS Neuroscience Center Fund #2014C01 (CM), PUMC&CAMS/IBMS Dean's Fund #2011RC01 (CM); and the Chinese Human Brain Banking Consortium.

THE STUDY OF VASOREACTIVITY OF CEREBRAL VESSELS IN PATIENTS WITH PARKINSON DISEASE

D. Alsalmawy[1], *M. Hamdy*[1]
[1]*Neurology, Faculty of medicine Alexandria University, Alexandria, Egypt*

Background: The frequent orthostatic intolerance in PD could be the consequences of cardiovascular-autonomic failure and/or damaged cerebral auto regulation **Objective**: The purpose of this study is to evaluate cerebral vasoreactivity in patients with Parkinson disease and 15 healthy controls were included in the study. Methods: Transcranial Doppler study was done to measure the mean velocities of the middle cerebral artery on either side at rest and after breath-holding to see the effect of hypercapnia on the blood velocities. This is done twice (once after the intake of antiparkinsonian drug and the other time 12 hours after the last dose) [group 2 and 1 respectively). **Results:** There was statistical significant difference between the patients (whether in group 1 or 2) and the control group regarding the breath holding index(P=0.003 and 0.022respectively).while the difference between the two patient groups was not statistically significant (p=0.477).Conclusion patients with Parkinson disease have poor vasoreactivity of cerebral blood vessels that may share in pathogenesis of some symptoms. This is independent on drug therapy.

Asan Medical Center University of Ulsan College of Medicine, Seoul, Korea
[8]Department of Neurology, Bundang Jesaeng Hospital, Seongnam-si Gyeonggi-do, Korea

Background: A progressive reduction in the speed and amplitude of repetitive action is an essential component of bradykinesia, which is called sequence effect (SE). Because SE is specific to Parkinson's disease (PD) and is suggested to be associated with motor arrest, its features are of great interest. The aim of this study is to find the neural correlates of SE and to demonstrate whether dopaminergic deficit is correlated with SE, which has never been studied.

Methods: We enrolled 12 patients with de novo PD in an academic tertiary referral hospital. Correlations between SE severity and alterations in gray and white matter were studied. The association between severity of the SE and striatal dopaminergic deficits was also analyzed.

Results: The volumetric changes of the anterior cingulate cortex (ACC) and the inferior semilunar lobule of the cerebellum were significantly negatively correlated with the degree of SE. The long association fibers connecting the frontal lobes to the temporal, parietal, and occipital lobes were significantly associated with SE. There was a significant correlation between SE in the more affected hand and the caudate dopamine transporter binding in the more affected hemisphere.

Conclusions: Our results suggest that the ACC and the cerebellum (inferior semilunar lobule) are associated with the severity of SE. Taken together with DTI findings, the present study proposes that ACC may have an important role. Our data show that the caudate dopaminergic activity may be related to SE.

DYSFUNCTION OF THE VEGETATIVE NERVOUS SYSTEM AS A FACTOR OF FORMATION OF COGNITIVE IMPAIRMENT

E. Yakupov[1], S. Perminova[1]

[1]of neurology neurosurgery and medical genetics, Kazan State Medical University, Kazan, Russia

Objective. To identify the presence and the factors contributing to the emergence of cognitive impairment in patients with dysfunction of the vegetative nervous system.
Methods. We examined 24 patients with dysfunction of the vegetative nervous system, including 4 men and 20 women age 39,0±13,5. All patients underwent examination neurological of status, MOCA, verbal descriptive scale of pain scores, the questionnaire of neurotic disorders, the Hamilton depression rating scale, the scale of Taylor, the questionnaire against non-adaptable traits, MRT of the brain.
Results. All patients had complaints about headaches, poor memory and attention. The presence of white demographism in an atypical plase was revealed in 7 patients, the presence of simpathicotonia after the test Asner Dannii in 19 patients. MRT of the brain pathology was not revealed. The presence of cognitive impairment confirmed by MOCA totaled 25,0±0,4 in 83,3%. Verbal descriptive scale of pain scores showed a level 2,5±1,6, that corresponded to weak pain. The questionnaire of neurotic disorders revealed in all patients the presence of neurotic disorders. The Hamilton depression rating scale revealed the presence of a mild depressive episode in 18 patients. The scale of Taylor showed average level of anxiety (17,9±2,6). The questionnaire against non-adaptable traits revealed a tendency to frequent mood swings (56,0±4,1).
Conclusions. Patients with dysfunction of the vegetative nervous system with predominance of simpaticotonia have cognitive impairment in the presence of weak pain, the neurotic, the average level of anxiety in the presence of against non-adaptable traits that may be considered when prescribing therapy.

ADPD5-0540
CARPAL TUNNEL SYNDROME IN TREMOR DOMINENT PD
J. Baik[1]
[1]*Neurology, Sanggye Paik Hospital Inje University, Seoul, Korea*
Unilateral hand tremor is one of cardinal symptoms in Parkinson's disease. Also, mechanical traumatic hand movement is one of risk factors in carpal tunnel syndrome. Our objectives were to examine the hypothesis that repetitive mechanical movement may be related to the development of carpal tunnel syndrome in Parkinson's disease with unilateral hand tremor by using neurophysiological study. Study participants comprised 33 de novo Parkinson's disease patients with unilateral hand tremor, and compared between tremor hand and no tremor hand in the same patients. Seven patients (21.2%) of 33 patients had carpal tunnel syndrome. All CTS patients showed neurophysiological abnormalities in hand without tremor, instead of the hand without tremor. In addition, in patients with no carpal tunnel syndrome, sensory nerve action potential was lower in the hand without tremor than the hand without tremor, although there were no significant differences statistically. We concluded that hand tremor in de novo Parkinson's disease patients was not related to the development of carpal tunnel syndrome directly. In contrast, more frequent use of the normal hand may induce mechanical loading and may be associated with CTS in hand without tremor. Early diagnosis of Parkinson's disease and the proper education of hand use may be essential for the prevention of carpal tunnel syndrome in Parkinson's disease tremor patients.

REPRODUCTIVE EXPERIENCE IMPACTS ON PARENTAL BEHAVIOR AND BRAIN DEVELOPMENT IN MICE.

O.L. Lopatina[1], Y.K. Komleva[1], Y.V. Gorina[1], N.V. Kuvacheva[1], A.B. Salmina[1]
[1]Department of Biochemistry Medical Pharmaceutical and Toxicological Chemistry, Krasnoyarsk State Medical University named after Prof. V.F. Voino-Yasenetsky, Krasnoyarsk, Russia

For all species of mammals motherhood is associated with as significant changes at the behavioral and cellular levels in combination with the accumulated experience of social interactions that attracting more and more attention of scientists to study the molecular mechanisms of parental behavior in different contexts by using animal models. Reproduction, with its attendant natural endocrine and postpartum sensory experiences, may facilitate lifelong learning and memory, and may mitigate markers of neural aging, in the rat. Combining natural hormonal exposure with subsequent substantial experience with stimuli from the offspring may preserve the aged parous female brain relative to that of null females. For a small number of mammals, including humans, fatherhood and paternal behavior play an equally important role in the nurturing offspring. Much less is known about the neural and hormonal mechanisms of paternal behavior, but emerging knowledge in this area indicate that the processes of paternal behavior formation involve similar hormones and neuromodulators, and similar regions of the brain as is established in maternal brain. Critical effects of parental behavior may be considered as a consequence of structural and functional changes in the male and female brain associated with parental behavior from rodents to humans. Searching for new molecular and cellular markers for the development of targeted control of neuroplasticity induced by reproductive experiences and parental behavior open up a new opportunity for the diagnosis, prevention and treatment of neurological dysfunction associated with neurodegeneration.

[3]Cardiovascular surgery, Clinica Cardio VID / Bolivariana University, Medellin, Colombia
[4]Neumology, Hospital Pablo Tobón Uribe / Bolivariana University, Medellin, Colombia

Objective: To present a patient with pulmonary thromboembolism who underwent surgical thrombectomy and presented a catatonia-like syndrome secundary to hypoxic ishemic bilateral basal ganglia lesion.

Methods: 28 yom history of idiopathic pulmonary thromboembolism ans pulmonary hypertension admitted for pulmonary thrombectomy (Figure 1). Cardiopulmonary bypass and several controlled cardiorespiratory arrest with hypothermia were done. After patient began to decrease verbal fluency, fixed gaze, decreased blink rate and movements, altered mental state, sadness and crying. At postsurgical day 3 mutism and not voluntarily movement, IC Neurology suspecting CVD. He was alert, poor eye contact and marked decrease in verbal fluency with insistence emitted words; opposed to evaluation and crying episodes, tendency to keep fixed posture and mild bilateral cogwheel rigidity. A catatonia-like syndrome diagnsois was done, paraclinical to rule out organic etiology. In NCCT no lesions (Figure 2), normal EEG, CPK, no elevation in acute phase reactants. AngioMR ruled out vessel lesion, hyperintense bilateral lesions in the basal ganglia suggestive of hypoxic ischemic encephalopathy were seen (Figure 3).

Results: Dramatic improvement with Lorazepam 2 mg tid, increased verbal fluency, voluntary movements an ambulation. He began to be anxious, difficulties to articulate. Psychiatric evaluation: abnormality in abstraction, concrete thinking, impaired phonological semantic verbal fluency, difficulty in tracking sequences TMT-A. No sensoperception disturbances, delusions, depressive symptoms; anxiety in relation to pulmonary pathology He continued to evolve successfully on Escitalopram for anxiety disorder but was stopped because maniac symptoms.

Conclusion: Patient had secondary catatonia-like síndrome due to hypoxic ischemic encephalopathy with bilateral basal ganglia lesions.

[2]Laboratory of Neurodegenerative Diseases Department of Anatomy & Department of Psychiatry, The University of Hong Kong, Hong Kong, Hong Kong China

[3]Department of Psychiatry, The University of Hong Kong, Hong Kong, Hong Kong China

Objectives: Among different risk factors, it has been implicated that depression can be a risk factor for developing Alzheimer's disease (AD). Cytoskeleton plays important role in stabilize both axonal transport and even the spines. It has been reported for the perturbation of cytoskeleton in AD and different psychiatric disorders. Therefore, we aim to evaluate cytoskeletal protein microtubules, phosphorylation of tau and actin in experimental models of depression and AD.

Methods: We have used corticosterone as a model agent for depression and oligomeric ß-amyloid (Aß) peptide as a toxin agent for AD. We employed cultured hippocampal neurons for as our experimental model. We used live-cell imaging, Western-blot analysis and immunofluorescent staining to evaluate the stability of microtubules, phosphorylation of tau and even the abundant of postsynaptic density protein PSD-95.

Results: After exposure to Aß or corticosterone, aggregation of microtubules was found in neurons expressing GFP-tubulin. The level of acetylated tubulin was reduced, suggesting instable microtubules. On the other hand, increased phosphorylation of tau occurred. The effect was not limited to microtubule. By expressing mCherry-actin in cultured hippocampal neurons, Aß or corticosterone also induced actin rod formation and reduction of PSD95 protein. To maintain the stability of microtubules by taxol, all the above pathological changes could be attenuated.

Conclusion: Our results have proved that corticosterone in depression induces similar pathological changes of microtubules and actin as if Aß in AD, which may explain why depression can be a risk factor for promoting cognitive impairment in AD.

STIMULATION-INDUCED THETA OSCILLATIONS IN GPI OF PATIENTS WITH PD

S. Ellis[1], A. Lopez Rios[2], S. Kalia[3], M. Hodaie[3], A. Lozano[3], W. Hutchison[1]
[1]Physiology, University of Toronto, Toronto, Canada
[2]Neurosurgery, Universitario Hospital San Vincente, Medellin, Colombia
[3]Surgery, Toronto Western Hospital, Toronto, Canada

Tremor is a common symptom of movement disorders including PD (PD). Current theories tend to focus on central movement control circuits, such as the basal ganglia and the cerebello-thalamic-cortical loop as being key components in PD tremor. Until recently, the globus pallidus internus (GPi) was thought to be a passive relay nucleus in a tremor-generating circuit. However, we have discovered neurons in the GPi during microelectrode mapping which can be induced into a theta oscillation following stimulation.

Objectives: The purpose of this study was to characterize the firing patterns of these neurons.

Methods: Electrical stimulation trains were delivered through a microelectrode recording neuronal activity with the following parameters: 1 sec duration; 3, 5, and 7.5 uA intensity; 200 Hz frequency.

Results: Preliminary data was collected from 37 neurons across 7 patients with either PD or dystonia. This data was analyzed for firing rate and pattern using a burst index prior to, and following stimulation. Firing frequency decreased following stimulation: 3uA baseline - 73.6Hz, decreased by 13.7Hz; 5uA baseline- 71Hz, decreased by 4.6Hz; 7.5uA baseline- 68.7 Hz, decreased by 16.9 Hz. Stimulation at 3uA increased the burst index by 0.34 and converted three cells to a bursty rhythm; at 5ua, the burst increased by 0.16 and changed the firing pattern of one neuron from random to bursty; and at 7.5uA, stimulation increased the burst index by 0.25 but no cells were converted to a bursty rhythm.

Conclusions: These results could implicate the GPi as an important component of tremorgenesis.

DECIPHERING THE ROLE OF GLUTAMATERGIC RECEPTORS AND ASSOCIATED SIGNALING IN ARSENIC INDUCED NEUROTOXICITY AND PROTECTIVE EFFICACY OF CURCUMIN IN RAT HIPPOCAMPUS

P. Srivastava[1], V. Kumar[1], R. Shukla[1], Y. Dhuriya[1], A.B. Pant[1], V.K. Khanna[1]
[1]Developmental Toxicology Division, CSIR-Indian Institute of Toxicology Research, Lucknow, India

Background: Involvement of cholinergic dysfunctions in arsenic induced neurotoxicity and protective effect of curcumin has been demonstrated recently by us. **Purpose:** Studies have been carried out to investigate involvement of NMDA receptors and post synaptic signalling proteins in arsenic induced neurotoxicity and protective efficacy of curcumin. **Methods:** Rats were exposed to arsenic (20 mg/kg b.w, p.o) or curcumin (100 mg/kg b.w, p.o) or simultaneously with arsenic and curcumin for 28 days. Assay of NMDA receptors by radioligand receptor binding and expression of NMDA receptor subunit (NR2A, NR2B, and NR1) and post synaptic signalling proteins (CAMKIIα, PSD-95, SynGAp, ERK ½) was carried out by Western blotting. mRNA expression of NMDAR1, NR2B and NR2A was studied by RT- PCR. TEM was utilized to count the number of synapse in hippocampus. **Results:** Arsenic exposure caused significant decrease in learning and memory associated with marked decrease in NMDA receptors, reduced NR2A mRNA levels, decreased expression of NR2A, p-CaMKIIα, PSD-95, increased expression of SynGAP in hippocampus, compared to control rats. Arsenic exposure also resulted to reduce number of synapses in hippocampus Simultaneous treatment with arsenic and curcumin was found to improve learning and memory and protect arsenic induced changes in post synaptic signalling proteins. Increased number of synapse in hippocampus was also observed in rats simultaneously treated with arsenic and curcumin. **Conclusion:** The results exhibit involvement of NMDA receptors and post synaptic signalling proteins in arsenic induced neurotoxicity and suggest that such changes could be protected curcumin.

UNDERSTANDING THE RELEVANCE OF THE BODY MASS INDEX IN ALZHEIMER'S DISEASE

A. Ciobica[1], L. Sandu[1], L. Oprica[1], E. Anton[2], D. Timofte[2]
[1]Biology, Alexandru Ioan Cuza University Iasi, Iasi, Romania
[2]Medicine, "Gr.T.Popa" University, Iasi, Romania

Background
The occurrence of obesity, commonly estimated using body mass index (BMI), and the most common late-onset dementia, Alzheimer disease (AD), are increasing globally.
Methods
Thus, in the present report we will describe the fundamental importance of this topic in public health, given the global epidemic of high adiposity and its consequences.
Results
In this way, both low and high BMI has been associated with cognitive impairment and dementia risk, including AD. Moreover, studies investigating the association between midlife BMI and risk for dementia demonstrated in generally an increased risk among overweight and obese adults. Also, a high BMI in middle-age or a decrease in BMI at late-age has been considered a predictor for the development of AD. Still, very few aspects are known about the BMI changes close to or after AD onset.
Conclusions
Thus, the possibility that high adiposity increases Alzheimer's disease risk is alarming given global trends of overweight and obesity in the general population. However, prevention and manipulation of adiposity may also provide away to prevent Alzheimer disease. In this way, further research evaluating BMI and dementia is required.

[3]Medicine, "Gr.T.Popa" University, Iasi, Romania

Background:
Autism is a complex disorder characterized by repetitive behavior and impaired social communication. Still, apart from these main manifestations, a significant number of cases display impaired emotional learning and memory functions.
Methods:
We tried to better understand the memory functions in an environmentally induced rat animal model of autism, based on the administration of valproic acid (VPA) during gestation (500 mg/kg or saline on day 12.5 of gestation) and examined the resultant progeny on specific memory tests, such as the Y maze task and the 8-arms radial maze.
Results:
Our data indicated that animals perinatally exposed to VPA are showing, besides specific social interaction deficiencies, significant behavioral alterations in Y maze task, as expressed in decreased spontaneous alternations percentage, suggesting affected immediate working memory and in the radial arm maze, as expressed to an increased number of both reference and working memory errors.
Conclusions:
In conclusion, we showed significant memory deficits in a VPA-induced rat model of autism, demonstrating also the relevance of the memory processes in autism, apart from the social deficiencies.

STUDYING THE MEMORY DEFICITS IN A KETAMINE-INDUCED RAT MODEL OF SCHIZOPHRENIA

A. Ciobica[1], M. Paulet[2], L. Hritcu[1], R. Lefter[2], M. Luca[2], E. Anton[3], Z. Olteanu[1], D. Timofte[3]

[1]Biology, Alexandru Ioan Cuza University Iasi, Iasi, Romania

[2]SOP HRD/159/1.5/S/133675 Project, Romanian Academy, Iasi, Romania

[3]Medicine, "Gr.T.Popa" University, Iasi, Romania

Background

Significant cognitive impairment is common in schizophrenia, affecting up to 75% of patients. In this way, it seems that a wide range of cognitive functions are affected, and particularly memory. Moreover, it seems that the cognitive impairment often pre-dates the illness onset.

Also, it is now generally accepted that a subchronic administration of 30 mg/kg ketamine induces reliable changes in behaviour of rat and parameters of dopaminergic, glutamatergic, and serotonergic neurotransmissions, which could resemble to schizophrenia manifestations.

Methods:

In this way, in the present experiment, we want it to test if there are any memory deficits in a ketamine-induced rat model of schizophrenia, as tested in the Y maze and radial arm maze tasks. To test this, rats were injected with 30 mg/kg ip ketamine or saline daily for seven consecutive days, while the behavioral experiments were performed 2 weeks after ketamine treatment.

Results:

Our data suggested significant memory deficits in this ketamine-induced rat model of schizophrenia in rat, as demonstrated by an increased number of reference memory errors in 8-radial arm maze. Also, the time necessary to finish this test was increased in the ketamine group, as compared to saline. Moreover, the spontaneous alternation percentage was significantly decreased, suggesting deficiencies in the immediate working memory.

Conclusions:

Our results presented here suggest that subchronic treatment with subanaesthetic doses of ketamine are inducing significant memory deficits, as tested in the Y maze and radial arm maze tasks.

FUNCTIONALITY OF ENERGY AND CALCIUM REGULATION IN ASTROCYTES AND MITOCHONDRIA IN BRAIN FROM ADRENOLEUKODYSTROPHY (X-ALD) MODEL ANIMALS

G. Reiser[1], N. Kruska[1], P. Schoenfeld[2], A. Pujol[3]
[1]Institut fuer Neurobiochemie, Otto-von-Guericke-Universitaet, Magdeburg, Germany
[2]Institut fuer Biochemie und Zellbiologie, Otto-von-Guericke-Universitaet, Magdeburg, Germany
[3]Hospitalet de Llobregat, IDIBELL, Barcelona, Spain

1-Objectives

Malfunctions of peroxisomal ABCD1 transporter proteins are responsible for clinical symptoms in the severe neurodegenerative disease X-ALD (X-linked adrenoleukodystrophy). ABCD1 mediates uptake of free very-long-chain fatty acids (VLCFA) and their CoA-esters into peroxisomes. ABCD1 dysfunctions result in VLCFA accumulation in body tissues of X-ALD patients. We aim to understand the still largely elusive underlying molecular mechanism of X-ALD pathogenesis.

2-Methods

Abcd1-knockout mouse, contributed by Aurora Pujol, displays biochemical abnormalities, like reduced VLCFA ß-oxidation and accumulation of VLCFA, as seen in X-ALD patients.

3-Results

We exposed astrocytes from wild-type and *Abcd1*$^{-/-}$ mice to supraphysiological VLCFA concentrations (C22:0, C24:0 and C26:0). Important for elucidating the X-ALD pathogenic mechanism is the severely diminished capability to revert oxidized pyridine nucleotides to NAD(P)H in *Abcd1*$^{-/-}$ astrocytes. Long-term exposure to VLCFA induces enhanced ROS generation, cellular *in situ* depolarization of mitochondria. The VLCFA-induced intracellular Ca^{2+} response is diminished in Abcd1$^{-/-}$ astrocytes. In isolated brain mitochondria from *Abcd1*$^{-/-}$ and wild-type mice, VLCFA similarly cause increased ROS generation, impaired oxidative ATP synthesis and diminished Ca^{2+} uptake capacity. VLCFA exacerbate cell death in astrocytes.

4-Conclusions

We found multiple impairments of energy metabolism. The differences in responses of mitochondria and astrocytes, observed for the hydrocarbon chain length of VLCFA suggest that detrimental activities of VLCFA in astrocytes involve defective cellular functions besides mitochondria. Astrocytes from *Abcd1*$^{-/-}$ mice respond more sensitively to VLCFA than those derived from wild-type mice. VLCFA increase the vulnerability of *Abcd1*$^{-/-}$ astrocytes, and finally, we suggest that their antioxidative defense is diminished in *Abcd1*$^{-/-}$ conditions.

7-MEOTA-DONEPEZIL LIKE COMPOUNDS – NOVEL AGENTS TO COMBAT ALZHEIMER'S DISEASE

J. Korabecny[1], P. Cabelova[2], R. Dolezal[2], E. Nepovimova[1], K. Babkova[1], K. Spilovska[1], M. Andrs[1], K. Musilek[1], O. Soukup[2], K. Kuca[2]
[1]Department of Toxicology and Military Pharmacy, University of Defence, Hradec Králové, Czech Republic
[2]Biomedical Research Centre, University Hospital, Hradec Králové, Czech Republic

Alzheimer's disease (AD) is a multifactorial progressive neurodegenerative disorder that manifests as memory loss, spatial disorientation, and gradual deterioration of intellectual capacity. Nowadays, there are no effective preventative measures or curative therapy for AD, its precise etiology remains unknown as well. To date, the pharmacotherapy of AD has relied on acetylcholinesterase (AChE) inhibitors – tacrine, donepezil, rivastigmine and galantamine – and, more recently, on an NMDA receptor antagonist – memantine. Multi-target-directed ligands (MTDLs) have a great potential for treating complex diseases such as neurodegenerative disorders because they interact with multiple targets. Since one of the two currently approved drug-groups in AD therapy are cholinesterase inhibitors, they are one of the most used starting compounds in MTDLs design strategy. In our contribution we will introduce 7-MEOTA-donepezil like compounds as MTDLs combining 7-MEOTA unit, representing less toxic tacrine (THA) derivative, with analogues of *N*-benzylpiperazine moieties mimicking *N*-benzylpiperidine fragment of donepezil. 7-MEOTA-donepezil like compounds exerted mostly non-selective profile in inhibiting cholinesetrases of different origin with IC_{50} values ranging from micromolar to sub-micromolar concentration scale. Kinetic analysis revealed mixed-type mode of inhibition presuming that these inhibitors are capable to simultaneously bind peripheral anionic site (PAS) as well as catalytic anionic site (CAS) of AChE. Molecular modeling studies and QSAR studies were performed to rationalize *in vitro* studies.

Supported by the Post-doctoral project (No. CZ.1.07/2.3.00/30.0044), Long Term Development Plan – 1011 and by the Grant Agency of the Czech Republic (No. P303/11/1907)

ADPD5-0452

LOW DOSE CHOLINESTERASE INHIBITOR AND SEROTONIN 5HT2A ANTAGONISM REDUCE COGNITIVE DEFICITS DUE TO 6-HYDROXYDOPAMINE LESION IN RATS

D.T. Hubbard[1], R.K. Shaheen[1], U. Hacksell[1], K. McFarland[1]
[1]In-Vivo Pharmacology, ACADIA Pharmaceuticals Inc., San Diego, USA

Objective: While Parkinson's disease (PD) is primarily associated with motor impairment, non-motor symptoms, including behavioral and cognitive disturbances, are prevalent and greatly impact daily functioning and quality of life. Current treatments for PD dementia include administration of cholinesterase inhibitors which can be accompanied by undesirable side effects. Lowering the required dose of cholinesterase inhibitor could reduce the prevalence or severity of these side effects. The current work examined the potential of using low-dose cholinesterase inhibitors in conjunction with a $5HT_{2A}$ antagonist to improve cognition in an animal model of PD.
Methods: Sprague Dawley rats received bilateral sham or 6-hydroxydopamine (6-OHDA) lesions of the substantia nigra (SN). Following recovery, rats were administered the $5HT_{2A}$ antagonist (M100,907), a cholinesterase inhibitor (donepezil or rivastigmine), or a combination of the two prior to assessment of novel object recognition (NOR) or working memory performance in the Morris water maze (MWM).
Results: Rats with a 6-OHDA lesion had impaired performance in the NOR and MWM compared with sham controls. Treatment with a cholinesterase inhibitor attenuated cognitive deficits of 6-OHDA lesioned rats. In addition, combined low and ineffective doses of M100,907 and a cholinesterase inhibitor also reversed deficits in both of these tests.
Conclusions: The current work suggests that rats with 6-OHDA lesion of the SN display cogntitive deficits. Further, combined administration of low dose cholinesterase inhibitors and low dose $5HT_{2A}$ antagonists, while ineffective alone, could be efficacious in treating cognitive deficits associated with dopaminergic cell death, potentially reducing the incidence of side effects.

STRUCTURAL ANALYSIS OF RGS4 INHIBITION: IMPLICATIONS FOR THERAPEUTIC DEVELOPMENT FOR PD

C. Higgins[1], D. Roman[1]

[1]Pharmaceutical Sciences and Experimental Therapeutics, University of Iowa, Iowa City, USA

Regulator of G protein signaling (RGS) proteins modulate G-protein-coupled receptors, whose proper regulation is essential for diverse physiologic processes. Recent findings support a critical role of RGS4 in the etiology of Parkinson's disease (PD). Pathological RGS4 over-expression brought on by decreased dopaminergic signaling in the striatum causes motor deficits by blunting cortico-striatial synaptic plasticity. RGS4 knockout mice are free from motor impediments in a mouse model (6-OHDA lesion) of PD, positioning RGS4 as a therapeutic target downstream of dopamine loss such that RGS4-targeted therapeutics would retain efficacy long after patients become refractory to L-DOPA therapy. Small molecule screens for RGS4 inhibitors have yielded a few hit compounds, and we have investigated their mechanisms using biophysical approaches in order to develop a framework to enable the rational design of small molecule RGS4 inhibitors for the treatment of PD. Our findings show that current RGS4-specific allosteric inhibitors exploit unique intrinsic protein dynamics of RGS4 to drive selectivity over homologs, e.g. RGS8. Our ongoing efforts seek to quantitatively measure RGS4 dynamics over broad timescales (ps-ms) to guide *in silico* molecular dynamics modeling of the inhibited conformational states of RGS4 for virtual docking.

[3]Research, FORUM Pharmaceuticals, Watertown, USA
[4]Laboratory of Translational Neuropharmacology, Yale University, New Haven, USA
[5]Biology, FORUM Pharmaceuticals, Watertown, USA

Pharmacological activation of nicotinic alpha7 receptors (nAChRs) may improve cognition in schizophrenia and Alzheimer's disease. The present study describes effects of FRM-0017874, an analogue of encenicline, on alpha7 receptors in vitro, and in behavioral and neurophysiological assays of cognitive function. FRM-0017874 demonstrated high affinity binding to rat brain alpha7 nAChRs, displacing [^{125}I]-alpha7-bungarotoxin (K_i = 18.1 ± 7.8 nM). In *Xenopus* oocytes expressing human alpha7 nAChRs, FRM-0017874 acted as a partial agonist, evoking inward currents with an EC_{50} of 0.42 µM. Lower concentrations of FRM-0017874 (0.04-1 nM) elicited no detectable current, but primed receptors to respond to sub-maximal concentrations of acetylcholine, potentiating these currents up to 1.9-fold. Higher concentrations induced receptor desensitization. FRM-0017874 improved novel object recognition in rats, and enhanced memory acquisition and reversal learning in mice in a water T-maze assay. Modulation of hippocampal theta oscillation is considered a neurophysiological correlate of the cognitive effects of drug treatment. FRM-0017874 showed a dose-dependent facilitation of the power of stimulation-induced hippocampal theta oscillation in both mice and rats. The brain unbound drug concentration-response relationship for increased theta synchrony was similar in both species, exhibited a biphasic pattern peaking around 3 nM, and overlapped with active doses and exposures observed in cognition assays. In summary, behavioral and electrophysiological assays indicate an "inverted-U"-shaped effective concentration range, underscoring the critical importance of clinical dose selection and pharmacokinetics for alpha7 nAChRs agonists.

[3]-, HiQScreen, Vésenaz-Geneva, Switzerland

[4]Pôle Expertise Recherche et Biopharmacie, Institut de Recherches SERVIER, Suresnes, France

S47445 is a novel positive allosteric modulator of glutamate AMPA-type receptors which possesses neuroprotective, antidepressant and cognitive enhancing properties in the absence of side effects in rodents after acute administration (see abstract on in vivo properties). The aim of the present study was to characterize its mechanism of action and effects on neuronal plasticity.

S47445 did not present affinity towards orthosteric binding sites of AMPA receptors but increased AMPA-mediated depolarization measured by fluorescent membrane potential dyes on rat primary cell cultures. Similarly, on oocytes injected with either rat cortex or human hippocampal mRNA, S47445 increased AMPA-evoked current and did not affect NMDA and kainate-evoked currents. Differential sensitivity of S47445 was examined at the human AMPA receptors subtypes.

On rat hippocampal slices, S47445 alone did not induced presynaptic noradrenaline release but enhanced AMPA-mediated release.

No toxicity was observed even at high concentrations (30-100µM) on rat cortical neurons.

S47445 both increased the expression of Brain Derived Neurotrophic Factor (BDNF) protein alone and was able to stimulate AMPA-induced BDNF expression on rat primary cortical cell cultures.

In vivo, S47445 (10-30 mg/kg ip) increased both the induction and the maintenance of the Long-Term Potentiation induced by 4 bursts tetanus in the dentate gyrus of the hippocampus in anaesthetized Wistar rats.

Taken together, these results indicate that S47445 via a selective positive allosteric modulation of AMPA receptors enhances neuronal and synaptic plasticity (LTP, BDNF expression), phenomenon that could be of interest for the treatment of various neurodegenerative diseases and mood disorders.

[6]Pôle Expertise Recherche et Biopharmacie, Institut de Recherches SERVIER, Suresnes, France

S47445 is a novel positive allosteric modulator of glutamate AMPA-type receptors, with a high permeability of the Blood-Brain-Barrier. It was shown to possess neurotrophic and antidepressant properties and to enhance synaptic plasticity. The present study describes S47445 in vivo pharmacological properties in rodents.

S47445 showed robust pro-cognitive effects in various models of episodic and spatial working memory in rodents at low doses (0.3-3 mg/kg p.o.). S47445 improved episodic-like memory in a novel object recognition test and partially counteracted scopolamine-induced amnesia. In mice, S47445 improved object recognition performance and counteracted alprazolam-induced memory deficits in delayed spatial discrimination task. Furthermore, S47445 was able to reverse age-induced deficits in contextual memory performances in mice. S47445 improved spatial working memory assessed by spontaneous alternation behavior on a T-maze in young mice and on Y-maze in old mice.

Besides its potent procognitive and neurotrophic action, S47445 also displayed neuroprotective activity in a model of hippocampal vulnerability in rats (30 mg/kg i.p.). S47445 did not induce wake-promoting effect as assessed by cortical EEG recordings in freely moving rats nor modify pentobarbital induced sleep duration in rats (30 mg/kg i.p.). No effect on general behaviour, body temperature, motor coordination and spontaneous locomotor activity nor occurrence of epileptic seizures were noticed after acute administration in mice (10-100 mg/kg p.o.) and rats (10-1000 mg/kg p.o.). All these results indicate that S47445 displays cognitive-enhancing properties without detectable CNS side-effects in the tested dose ranges and could have promising therapeutic potential for the treatment of cognitive disorders in Alzheimer's disease.

POTENTIAL NEUROPROTECTIVE EFFECTS ASSESSMENT OF THE ALPHA-7 NICOTINIC RECEPTOR AGONIST PHA 543613 IN A MODEL OF EXCITOTOXIC LESION IN RATS

L. Foucault[1], C. Tronel[1], A. Domene[1], S. Bodard[1], Z. Gulhan[1], G. Page[2], D. Antier[1], S. Chalon[1]

[2]Université de Poitiers, EA3808, Poitiers, France

Objectives:

New compounds targeting the neuroinflammation through the alpha7 nicotinic acetylcholine receptors generate major interest. We aimed to evaluate the effects of an agonist of these receptors, PHA 543613, in an *in vivo* model of excitotoxicity induced by intrastriatal injection of quinolinic acid (QA).

Methods:

Two groups of 6 rats each were exposed to surgery (150 nM QA in the right striatum). They received either four i.p. injections of PHA 543613 (6mg/kg 2h before QA lesion and at 2, 4 and 6 days post-lesion, dpl) or vehicle (control group). At 7 dpl, several neuronal and neuroinflammatory markers were evaluated, i.e. NeuN and GFAP by western blotting and the translocator protein 18 kDa (TSPO) by autoradiography. These parameters were also studied by immunofluorescence staining.

Results:

In the cortex and striatum, we observed an upward trend of NeuN expression in the lesioned side of PHA vs control group. In the striatum, the percentage increase of GFAP expression between ipsi- and controlateral sides was lower in PHA than in control group (59% vs 158%). Moreover, the increased accumulation of the TSPO ligand [^{3}H]PK-11195 was significantly smaller in the PHA than in control group (361% vs 450%, $p<0.05$). The positive impact of PHA 543613 treatment on inflammation was supported by the morphologic cells observation showing delayed microglial activation with mainly branched microglia in PHA-treated rats.

Conclusions:

In our experimental model of excitotoxicity, we showed that the administration of PHA 543613 lead to decrease neuroinflammation. Current studies are aimed at studying the consequences on neurodegeneration.

ADPD5-0257

ANTIOXIDANT EFFECTS OF LOW MOLECULAR WEIGHT FRACTION OF THE VENOM OF BOTHROPOIDES JARARACA AGAINST H2O2-INDUCED APPOPTOSIS IN HIPPOCAMPAL CELLS

S.M. Querobino[1], *A.S.A. Oliveira*[1], *D.C. Carrettiero*[1], *C. Alberto-Silva*[1]
[1]*Center of Human and Natural Science, Federal University of ABC, Santo Andre, Brazil*

Objective: The present study rated the neuroprotective property of low molecular weight fraction (LMWF) of the venom of *Bothropoides jararaca (Bj)* in cultured hippocampal cells

Materials and methods: Crude venom (CV) of *Bj* was filtered through a 10 kDa MW cutoff membrane (Amicon®) to obtain the LMWF. To confirm the absence of proteolytic enzymes and other proteins (>10kDa), the LMWF was analyzed by electrophoresis in SDS-PAGE and mass spectrometry. The primary hippocampal culture was obtained of Wistar neonate rats. The culture was characterized by immunocytochemistry assays. Cell stress was promoted using 50 µM of H_2O_2 for 20 hours. Neuroprotection was evaluated by concomitant treatment with LMWF (0.1µg/mL) and H_2O_2 (50 µM). Cell viability was determined using an assay based on MTT reduction. The expression of cleaved caspase-3 enzyme was performed by western blot. Quantitative values were analyzed by one-way ANOVA (Tukey´s post-test, respectively; $p<0.05$).

Results: The results indicate that the LMWF filtrate contained no high-molecular weight contaminants. After the treatment with 100 µM of H_2O_2 we could observe a decrease of cell viability of 32,84± 8,06% ($p <0,001$), while the previous treatment in culture cells with 0,1 µg/mL LMWF following by 100 µM of H_2O_2, it was observed 77,46 ± 5,35% ($p<0,05$) of cell viability. Evidence has shown that cells treated with LMWF 0.1 µg/mL and then with H_2O_2 (50µM) show lower expression of cleaved caspase-3 cells than the cells treated just with H_2O_2.

Conclusion: The results suggest that LMWF has cytoprotective activity against oxidative stress caused by H_2O_2.

EFFECT OF VITAMIN E ON PASSIVE AVOIDANCE LEARNING IN ANIMAL MODEL OF ALZHEIMER'S DISEASE

G. Mahmoodi[1]

[1]*Department of Exoerimental science, Islamic Azad UniversityKermanshah Branch, Kermanshah, Iran*

Objective :Free radicals and the oxidative agent are important in aging and age-related neurodegenerative disease such as Alzheimer. Vitamin E is an antioxidant compound that play a beneficial role in maintaining neural integrity and preventing cell death. In this research the effect of intracerebroventricular (ICV)administration of vitamin E on inhibitory avoidance(IA) memory in rats with Alzheimer's disease(AD)was investigated.
Material and method: 42 aged Wistar male rats (350-400 g,18-20 months old)were divided into 6 groups : n-L+Veh group: non-lesioned rats with vehicle treatment; L group: NBM-lesioned rats; L+Veh group: NBM-lesioned rats with vehicle injection and L+vit.E groups(10 or 25 or 50µg/rat): NBM-lesioned rats with vitamin E injection.
A guide cannula was implanted stereotaxically in the right lateral ventricle for injection of vitamin E, AD-like cognitive deficiency was induced by injection of ibotenic acid into Nucleus Basalis of Meynert (NBM) bilaterally (5µg/µl in each side). A step-through inhibitory avoidance task was used for memory assessment.
Result :Our results showed that vitamin E(25 and50µg/rat) caused a significant increase in consolidation and memory retention in AD.
Conclusion: These results suggest that vitamin E could improve memory retention in aged rats with dementia type of AD (with NBM lesioned).
Key words: Alzheimer's disease , Nucleus Basalis of Meynert (NBM),vitamin E, passive avoidance learning, rat.

ORIENTIN PROTECTS NEURONAL CELL LINE FROM HYDROGEN PEROXIDE INDUCED OXIDATIVE DAMAGE VIA UP-REGULATING NRF2/KEAP1 REDOX SIGNALLING PATHWAYS

A.P.K. Ling[1], K.Y. Lam[2], R.Y. Koh[3], Y.P. Wong[1]
[1]Medical Biotechnology Dept of Human Biology, International Medical University, Kuala Lumpur, Malaysia
[2]School of Postgraduate Studies and Research, International Medical University, Kuala Lumpur, Malaysia
[3]Biomedical Science Dept of Human Biology, International Medical University, Kuala Lumpur, Malaysia

Introduction: Orientin is a water-soluble flavonoid C-glycoside which is isolable from *Ocimum sanctum*. It has been suggested to have antioxidant, antiviral, vasodilatation, cardioprotective, radiation protective effect, neuroprotective effect and to be able to cross blood-brain-barrier. Thus, it is a potential treatment or prevention of neurodegenerative diseases (ND). Furthermore, oxidative stress has been highly implicated in the progression of ND, hence, this leads to the study on Nrf2/Keap1 redox signalling pathway for the targeted effective therapies of ND in the future.
Objectives: To determine the effects of orientin on nitric oxide levels, intracellular calcium levels and the mechanism by which orientin protects SH-SY5Y neuroblastoma cells from H_2O_2-induced oxidative damage.
Methods: Orientin at pre-determined maximum non-toxic dose (MNTD), 20 µM and half MNTD (1/2 MNTD), 10µM were subjected to SH-SY5Y cells for 24 h, followed by 150 µM of H_2O_2 oxidative induction for 24 h at 37ºC. The Griess assay and Fluo-4 NW calcium assay were then performed to measure the NO levels and intracellular Ca^{2+} levels by a microplate reader respectively. The regulation of Nrf2/Keap1 redox signalling pathway was analysed by Western blotting.
Results: MNTD and 1/2 MNTD significantly reduced NO levels and significantly reduced intracellular Ca^{2+} levels by 33.49% and 28.20% when compare to H_2O_2 treatment alone. The regulation of Nrf2/Keap1 redox signalling pathway was confirmed by Western blotting.
Conclusions: Orientin protects SH-SY5Y cells from H_2O_2-induced oxidative damage by reducing NO levels and intracellular Ca^{2+} levels while up-regulating Nrf2/Keap1 redox signalling pathway.

[3]School of Postgraduate Studies and Research, International Medical University, kuala lumpur, Malaysia
[4]Biomedical Science Dept of Human Biology, International Medical University, kuala lumpur, Malaysia

Introduction: Neurodegenerative disorders are incurable disorder associated with the functional defect on the neuronal cells evoked by various machineries. Among these, oxidative stress is one of the main pathogenic machineries causing neuronal cell impairment and lead to neurodegenerative disorders such as Parkinson's and Alzheimer's diseases. It occurred due to the imbalance of reactive oxygen species or reactive nitrative species (ROS/ RNS) and antioxidant in the neuronal cells. Nrf2/KEAP1 is the antioxidative pathway which is triggered by oxidative stress, leads to the expression of antioxidative enzymes for neuroprotection.
Objectives: Our preliminary studies suggested that methanol extracts of *Ocimum santum* (OcSME) potentially protect the human neuroblastoma cells from hydrogen peroxide-induced neurodegeneration. Thus, this study aims to investigate the mechanism action of neuroprotective effects of OcSME on hydrogen peroxide (H_2O_2)-induced SH-SY5Y cells.
Methods: The effects of OcSME on nitrate oxide level was determined by Griess reagent assay. Intracellular calcium level, mitochondria membrane potential (MMP) activities and western-blot analysis in H_2O_2-induced SHSH5Y cells were evaluated.
Results: Studies demonstrated that maximum non-toxic dose (MNTD) of OcSME could reduce the nitric oxide level while the intracellular calcium level was not significantly decrease upon H_2O_2 exposure. Meanwhile, exposure of SHSY5Y cells on 150 µM H_2O_2 showed the effects on the MMP. The potential of OcSME on Nrf2/KEAP1 signalling pathway regulation was further confirmed by western blot.
Conclusions: OcSME suggested to possess the potential to protect SH-SY5Y cells from H_2O_2 induced oxidative stress. This present study suggested the mechanism action of OcSME in Nrf2/Keap1 signalling pathway regulation.

ORIENTIN PROTECTS NEURONAL CELL LINE FROM HYDROGEN PEROXIDE INDUCED OXIDATIVE DAMAGE VIA UP-REGULATING PI3K/AKT SURVIVAL WHILE DOWN-REGULATING MAPK/ERK APOPTOSIS PATHWAY

K.Y. Lam[1], A.P.K. Ling[2], R.Y. Koh[3], Y.P. Wong[2]
[1]School of Postgraduate Studies and Research, International Medical University, Kuala Lumpur, Malaysia
[2]Medical Biotechnology Dept of Human Biology, International Medical University, Kuala Lumpur, Malaysia
[3]Biomedical Science Dept of Human Biology, International Medical University, Kuala Lumpur, Malaysia

Introduction: The current prescribed medications for neurodegenerative diseases (ND) only treat the symptom rather than the cause while possess various adverse effects to the patients. Therefore, natural products or plants derivatives might be a better alternative to prevent or to treat ND. This study targets on one of the flavonoid compounds, orientin, in which it has been reported to show anti-apoptotic effect on SH-SY5Y neuroblastoma cells. Nevertheless, the basic mechanisms underlying are yet to be elucidated.

Objectives: To study the mechanism by which orientin protects SH-SY5Y neuroblastoma cells from H_2O_2-induced oxidative damage.

Methods: The cells were treated with 20µM and 10µM of orientin, which are the pre-determined maximum non-toxic dose (MNTD) and half MNTD (1/2 MNTD) for 24 h at 37ºC and subsequently with 150µM of H_2O_2 oxidative induction. Cells were then subjected to the measurement of mitochondrial membrane potential (MMP) and Annexin V/propidium iodide apoptosis assay by flow cytometry whereas the regulation of PI3K/Akt survival pathway and MAPK/ERK apoptosis pathway was analysed by Western blotting.

Results: Studies showed that MNTD and 1/2 MNTD of orientin restored the loss of MMP by 30.66% and 34.21% and reduced 27.85% and 43.98% of early apoptotic cells when compared to H_2O_2 treatment alone. The regulation of PI3K/AKT survival and MAPK/ERK apoptosis pathways was further confirmed through Western blot.

Conclusions: Orientin protects SH-SY5Y cells from H_2O_2-induced oxidative damage by restoring the loss of MMP, preventing early apoptosis of cells and up-regulating PI3K/Akt survival pathway while down-regulating MAPK/Erk apoptosis pathway.

CHRYSIN SUPPLEMENTATION IMPROVES ACQUISITION AND RETENTION BEHAVIOR IN ANIMAL MODEL OF MEMORY IMPAIRMENT

N. Bansal[1], *H. Kaur*[1]

[1]*Pharmacology, ASBASJSM College of Pharmacy, Ropar, India*

Chrysin (5,7-dihydroxyflavone) is a naturally occurring flavone, obtained from passion flower *Passiflora incarnata* Linn. (Passifloraceae). The present study aimed to explore the putative role of Chrysin in the modulation of memory processes in mice. Swiss albino mice (either sex; 6-8 weeks; 20-30 g) were used in this study. The experimental protocol was approved by Institutional Animal Ethics Committee (IAEC). Chrysin was administered in two doses (30 and 60 mg/kg; *p.o.*) to mice daily for 28 successive days. Memory impairment was induced by two methods- Lipopolysaccharide (LPS; 1 mg/kg; *i.p.*) induced amnesia and Alprazolam (0.5 mg/kg; *i.p.*) induced amnesia. Morris water maze (MWM) and Elevated plus maze (EPM) served as exteroceptive behavioral models to evaluate the memory. After behavioral studies, the brain ACHE) activity, TBARS, GSH, nitrite, SOD and catalase levels were measured. Administration of chrysin (60 mg/kg; *p.o.*) for 28 days to mice not only prevented the LPS- as well as alprazolam-induced enhancement of transfer latency of mice in EPM test but reduced the escape latency time on 4th day and increased the time spent in target quadrant on 5th day in MWM test as compared to control group. Further, Chrysin treatment caused the reduction in brain ACHE activity and also reversed the enhancement of brain TBARS and nitrite levels. Furthermore, GSH, SOD & Catalase activity also raised in chrysin treated group. Thus, Chrysin may prove to be useful remedy for the management of memory owing to its possible neuroprotective and its antioxidant properties.

ANTI-OXIDATIVE PROPERTY OF EDIBLE BIRD NEST AND ITS POTENTIAL IN ATTENUATING INTRANEURONAL REACTIVE OXYGEN SPECIES FORMATION INDUCED BY NEUROTOXIN

R.Y. Koh[1], M.Y. Yew[2], S.M. Chye[1], K.Y. Ng[2]
[1]Human Biology, International Medical University, Kuala Lumpur, Malaysia
[2]Jefferey Cheah School of Medicine and Health Sciences, Monash University Malaysia, Bandar Sunway, Malaysia

Objectives: This study aims to investigate the anti-oxidant activities of edible bird nest (EBN) and evaluate its potential in reducing neurotoxin-induced oxidative stress in neuronal cells.
Methods: EBN was cleaned and oven-dried. Part of the EBN was ground into powder and digested with pancreatin (sample S1). The remaining EBN was boiled with water. Filtrate of the extract was freeze-dried followed with pancreatin digestion (sample S2). DPPH (1-diphenyl-2-picryl hydrazyl) radical scavenging, ferric ion reducing antioxidant power (FRAP) and metal chelating assays were carried out for the determination of EBN's anti-oxidant activities. For evaluation of EBN's effect in reducing oxidative stress, SH-SY5Y cells were cultured and pre-treated with EBN. The cells were then challenged with 6-hydroxydopamine hydrochloride (6-OHDA) and intracellular reactive oxygen species (ROS) level was assessed with the dichlorofluorescein-diacetate (DCFH-DA) assay.
Results: S1 displayed higher DPPH radical scavenging activity than S2. S1 recorded highest activity of 16.70% at 0.0625 mg/ml whilst S2 achieved comparable results (12.21%) at 4 mg/ml. At 4 mg/ml, S1 showed ferric ion reducing antioxidant power of 32.93% whereas S2 showed slightly lower activity of 26.25%. Generally, S1 displayed higher reducing power than S2. As for metal chelating ability, S2 displayed better effect compared to S1. S1 showed 23.69% of activity whereas S2's activity was 46.47% at 4 mg/ml. Results from the DCFH-DA assay showed that S2 reduced 6-OHDA-induced ROS formation while S1 showed no significant reductive effect.
Conclusions: S1 and S2 displayed moderate antioxidant activity and S2 was able to inhibit ROS formation in neuronal cells.

04o. Therapeutic Targets & Mechanisms for Treatment: anti-oxidants

ADPD5-1424

THE TRANSCRIPTION FACTOR NRF2 AS A POTENTIAL TARGET FOR NEUROPROTECTION AND REDUCTION LEVODOPA-INDUCED TOXICITY IN PD

A. Tarozzi[1], M. D'Amico[1], F. Morroni[2], G. Sita[2], S. Baggiato[3], L. Ferraro[3], P. Hrelia[2]
[1]Department for Life Quality Studies, University of Bologna, Rimini, Italy
[2]Department of Pharmacy and Biotechnology, University of Bologna, Bologna, Italy
[3]Department of Life Sciences and Biotechnology, University of Ferrara, Ferrara, Italy

Levodopa, an precursor of dopamine, is a drug for relieving the symptoms of PD. The progressive decrease in drug response and occurrence of motor complications are frequent problems in the management of patients with PD. Moreover, the levodopa fails to prevent the progression of the degenerative processes. Various studies show that oxidant formation, following levodopa metabolism, could cause dopaminergic neuronal death. Recent studies demonstrate the ability of Nrf2 inducers to reduce the neuronal death occurring in neurodenegerative diseases. The Nrf2 regulates the expression of a wide array of redox status, cytoprotective and anti-inflammatory genes. Among Nrf2 inducers, we studied the ability of sulforaphane (SF) isothiocyanate to prevent and/or counteract the redox status impairment and cell death induced by a high concentration of levodopa in *in vitro* model of dopaminergic neurons. We found that the pre-treatment of neurons with SF showed inhibitory effects of levodopa-induced neuronal death through the translocation of Nrf2 into the nucleus and subsequent antioxidant endogenous molecule induction, such as glutathione. The ability of SF to exert neuroprotective effects was also recorded during or after the treatment with levodopa, suggesting that Nrf2-controlled target genes are involved in neuronal survival. Moreover, SF reduced levodopa-induced dyskinesia in a rat model of PD. Synergistic neuroprotective effects are also very interesting, especially for the combination of low concentrations of levodopa and SF. Taken together, these findings suggest that Nrf2 pathway inducers may be a promising class of drug to ameliorate the ratio risk/benefit associated with levodopa therapy.

ASSOCİATİON OF SERUM URİC ACİD LEVELS WİTH THE L-DOPA TREATMENT AND DİSEASE PROGRESSİON İN PARKİNSON'S DİSEASE

E. VİERU[1], A. KOKSAL[1]
[1]norology,
Bakirkoy Training and Research Hospital for Psychiatry Neurology & Neurosurgery, Istanbul, Turkey

Background: This study aimed to evaluate whether the serum UA level was associated with the disease progression and L-Dopa treatment of Parkinson' Disease.
Methods: 80 İdiopatic Parkinson's Disease patients age and sexually similar 80 healthy people Serum Uric Acid levels were measured. Parkinson's Disease group was divided into 2 subgroups according to L Dopa treatment. 1st group was İdiopatic Parkinson's disease Patients who did not use as pharmaceutical treatment L-Dopa and 2nd group Parkinson's disease Patients who used L-Dopa.The disease progression was scored by Hoehn and Yahr (H&Y) scales and disease durations; PD group was divided into 2 subgroups according to H&Y scales. 1st group was considered as the early stage of İdiopatic Parkinson's Disease and it included 1st stage patients. 2nd group included İdiopatic Parkinson's Disease Patients in other upper stages.
Results: İdiopatic Parkinson's Disease patients were found to have significantly lower levels of serum Uric Acid than controls. Differences between İdiopatic Parkinson's disease groups according to pharmaceutical treatment, the serum UA levels were gradually reduced in group which used L-Dopa treatment.As the disease progression, the serum UA levels were gradually reduced. There was significantly inverse correlation of UA levels with H&Y scales.
Conclusion: Association of serum Uric Acid levels and İdiopatic Parkinson's disease progression was found. Serum Uric Acid levels may lead to endogen antioxidantcapacity which could decrease the oxidative stress in patogenesis of Parkinson Disease. As the result, Uric acid could play a neuro-protective role in Parkinson's Disease.

[3]Translational medicine and neurogenetics,
Institute of Genetics and Molecular and Cellular Biology, Strasbourg, France
[4]Cytogenetics, Banaras Hindu University, Varanasi, India

O-GlcNAcylation is an important post-translational modification of proteins and is known to regulate a number of pathways involved in cellular homeostasis. This involves dynamic and reversible modification of serine/threonine residues of different cellular proteins catalyzed by O-linked N-acetylglucosaminyltransferase and O-linked N-acetylglucosaminidase in an antagonistic manner. We present here our findings that decreasing O-GlcNAcylation enhances the viability of neuronal cells expressing polyglutamine-expanded huntingtin exon 1 protein fragment (mHtt). We also show that O-GlcNAcylation regulates the basal autophagic process and that suppression of O-GlcNAcylation significantly increases autophagic flux by enhancing the fusion of autophagosome with lysosome. This regulation considerably reduces toxic mHtt aggregates in eye imaginal discs and partially restores rhabdomere morphology and vision in a fly model for Huntington disease. This study is significant in unraveling O-GlcNAcylation-dependent regulation of an autophagic process in mediating mHtt toxicity. We would discuss our attempts to target the autophagic process through the suppression of O-GlcNAcylation as a therapeutic approach in treating Huntington disease.

FLAVONES AS INHIBITORS OF AMYLOID-LIKE FIBRIL FORMATION
V. Smirnovas[1], T. Sneideris[1], R. Malisauskas[1], L. Baranauskiene[1], I. Kunigelyte[1], K. Michailova[1], A. Botyriute[1], D. Darguzis[1], R. Rutkiene[1]
[1]Department of Biothermodynamics and Drug Design,
Vilnius University Institute of Biotechnology, Vilnius, Lithuania
Several natural and synthetic flavone derivatives have been reported to inhibit formation of amyloid fibrils or to remodel existing fibrils. In many studies the primary method for determining the effectiveness of inhibition is measuring Thioflavin T (ThT) fluorescence. This method demonstrably results in a number of false positives for inhibition. First we studied the effects of 265 commercially available flavone derivatives on insulin fibril formation. We enhanced the effectiveness of ThT fluorescence measurements by fitting kinetic curves to obtain halftime of aggregation. We showed that without a change in an assay, but just by observing complete kinetic curves it is possible to eliminate numbers of false positive and sometimes even false negative results. Five flavones proved to be outstanding inhibitors of insulin amyloid-like aggregation.
To check if these five derivatives could be universal inhibitors of amyloid-like fibril formation we tested their effect on lysozyme, amyloid-beta, alpha-synuclein, and prion protein aggregation. All of the tested flavones decrease ThT fluorescence intensities in case of all tested polypeptides; however the picture is different when halftimes of aggregation are compared. Preliminary results suggest all five flavones to inhibit alpha-synuclein fibrillation, at least one to work on lysozyme and prion protein and none in case of amyloid-beta.

GENE THERAPY WITH NEUROTROPHIC FACTORS IMPROVED RECOVERY AFTER SCIATIC NERVE INJURY IN MICE

D. Offen[1], M. Glat[1], F. Benninger[2], T. Ben-Zur[1], Y. Barhum[1], I. Steiner[2], D. Yaffe[3]
[1]Felsenstein Medical Research Center, Tel Aviv University, Petach-Tikva, Israel
[2]Neurology, Rabin Medical Centerl, Petach-Tikva, Israel
[3]Molecular Cell Biology, Weizmann Institute of Science, Rehovot, Israel

Background: Damage to the sciatic nerve (Sciatica) is a common medical condition causing great morbidity. The usual causes include direct trauma, prolonged external pressure on the nerve, and pressure from disk herniation. Possible complications include loss of sensation in the leg and loss of motor control. In mild cases, conservative treatment is feasible but following a severe injury to the nerve, recovery may not be possible. Previously we have shown that transplantation of bone marrow derived stem cells or muscle progenitor cells that ectopically secrete neurotrophic factors improve and accelerate recovery of sciatic nerve damage. The aim of our current study was to evaluate the effect of neurotrophic factors in a sciatic nerve crush injury mouse model facilitated via viral vectors.

Results: Mice injured at the sciatic nerve showed motor deficits and reduction in compound muscle action potential (cMAP) amplitude as well as reduced nerve conduction velocity. Recovery was monitored up to 40 days after injury and a significantly faster recovery was demonstrated in animals injected with viral vectors containing BDNF, GDNF, IGF-1, and VEGF genes as well with a mixture of these genes, compared to those injected with GFP gene or saline as controls.

Conclusion: Our preliminary results indicate an enhaced recovery after sciatic nerve injury in mice transfected with one or all four neurotrophic factor genes. This indicate for further investigations and possible future clinical studies using direct transfection of neurotrophic factor genes to enhance recovery after nerve injury and prevent long term disability.

ROLE OF VASCULAR TROPHIC FACTORS IN NEURAL STEM CELL NICHE

Y. Kim[1], H. Kwon[2], Y. Kwon[1]
[1]Biology School of Sciences, KyungHee University, Seoul, Korea
[2]Bioscience and Biotechnology, Hankuk University of Foreign Studies, Yongin, Korea

Micro-environment of neurogenic region contains specialized cells such as micro-vascular endothelium in addition to neural precursor cells (NPCs) and astrocytes. We found ErbB4, a receptor for heregulin, was expressed in the early NPCs (type1) and the proliferating NPCs (type2a) which express Sox2 and GFAP, but not in the mature NPCs. Heregulin isoforms were, however, produced by brain vascular cells of endothelium and pericytes in neurogenic niche of the sgz of the adult rat brain. Ki-67 positive proliferating NPCs were mainly found nearby vascular ECs labeled with CD31 and pericytes expressing NG2 and α-SMA, where micro-vessels branch out. When co-cultured with EC or pericytes, the Ki-67 positive proliferating NPCs prepared from E16 rat hippocampus were markedly increased. When we knocked down the expression of ErbB4 by siRNA injection into the adult mice hippocampus, proliferating NPCs were significantly decreased. We next investigated the factors released from brain vascular cells by RNA sequencing method and protein array. We found that many genes including heregulin isoforms were up- or down-regulated when NSCs were co-cultured with vascular cells. This result proposes that factors released from brain ECs and pericytes mediate the interaction between NPCs and niche cells and the neurogenesis is largely influenced by these factors in the NPC niche of the adult hippocampus.

This study was supported by a grant from Korea Science and Engineering Research Foundation (KOSEF; Stem cell research project, 2011-0019354) and a grant (2012M3A9C6049937) funded by the Ministry of Education, Science and Technology, the Republic of Korea.

PROBE PIN DEVICE EMBEDDING WIRELESS POWER TRANSMISSION TECHNOLOGY FOR ADAPTIVE DEEP BRAIN STIMULATION

U. Lee[1], S. Choi[2], Y. Park[2], H. Yoon[3]
[1]Neurosurgery, Gachon Gil Hospital, Incheon, Korea
[2]Langley Research Center, NASA, Hampton VA, USA
[3]Department of Engineering, Norfolk University, Norfolk VA, USA

Current DBS technology is limited to provide autonomic parameter adjustment depending on patient's symptoms with Parkinson's disease. Various adaptive DBS technologies are proposed and under development to continuously and precisely respond to clinical conditions using a closed loop feedback system and enhance therapeutic effectiveness. In this research, we present a Probe Pin Device (PPD) for integrative neural sensing which is based on optical sensing technology and continuously and selectively measure neurotransmitter levels in targeted brain area along with temperature and pressure sensing. Furthermore, in this research, a wireless power transmission technology is integrated with the pin probe device for long term operation without the need of post-surgical operation for battery change.

In this research, a proto-typed PPD which encompasses optical neurochemical sensing and wireless power transfer technologies has been developed. It is clearly demonstrated that intraoperative and post-operative neurochemical monitoring in real time and long term operation is possible by the miniaturized PPD. The novel PPD sensing system we developed will allow autonomous feedback control of DBS and significantly enhance the treatment efficacy for Parkinson's patients.

SYNERGETIC EFFECT OF INTRATHECAL BACLOFEN AND DEEP BRAIN STIMULATION IN TREATING DYSTONIA

Y. Awaad[1], T. Rizk[2], R. Tamer[2]
[1]Pediatric Neurology, University of Michigan Medical School, MI, USA
[2]Pediatric Neurology, Al-Takhassusi, Riyadh, Saudi Arabia

Abstract
Dystonia is a syndrome of sustained muscular contractions of opposing muscles with various etiologies. The currently available symptomatic treatment strategies are quite effective for some of various types of dystonia. They help in decreasing involuntary movements, correcting abnormal posture, preventing contractures, reducing pain, and improving function and quality of life. Intrathecal Baclofen and Deep Brain Stimulation were proved to be fairly effective in controlling dystonia when used separately. We are reporting a synergetic effect of ITB and DBS when used simultaneously in two cases of primary generalized dystonia with excellent control of dystonia.
Key Words: Dystonia, Intrathecal Baclofen, Deep Brain Stimulation.

ROLE OF PREOPTIC AREA THERMO TRANSIENT RECEPTOR POTENTIAL VANILLOID TYPE I (TRPV1) AND TYPE IV (TRPV4) CHANNEL IN SLEEP & THERMOREGULATION IN RATS

R. Yadav[1], *H. Mallick*[1], *A. Jaryal*[1]
[1]*Physiology, All India Institute of Medical Science, Delhi, India*

Method: The study was conducted in 12 male Wistar rats. Under thiopentone sodium anesthesia (40 mg/kg BW) a bilateral guide cannula (24G) with indwelling styli was implanted with their tips aimed at 2 mm above the preoptic area (POA) as per De Groot's atlas. A radio transmitter TA10TAF-40 (Data Science International, USA) for the telemetric recording of body temperature (Tb) was implanted in the abdomen. A K- type thermocouple wire was inserted near the hypothalamus to measure the brain temperature (Tbr). The study was conducted into two groups. In first group (n=6) TRPV1 agonist, capsaicin (0.2µg/0.2µl) injection was given. While in second group (n=6) TRPV4 agonist, GSK1016790A injection was given. The site of injection was confirmed histologically.

Result:TRPV1 agonist and TRPV4 agonist decrease body and brain temperature at different time interval from twelve PM to four PM after microinjection and increase REM sleep.

Conclusion: The TRPV1 channel agonist and the TRPV4 agonist injection in the preoptic area (POA) brings about fall in body and brain temperature and increasing REM sleep.

PISA SYNDROME, BONSAI SYNDROME AND DROPPED HEAD SYNDROME IN PD: TREATMENT WITH BOTULINUM TOXIN INJECTION.

M. Horiuchi[1]
[1]*Neurology, Kawasaki Municipal Tama Hospital, Kawasaki, Japan*

Objectives: Lateral axial dystonia (LAD) has been described in patients with Parkinson's disease (PD) as Pisa syndrome (PS). In patients with PS, the trunk is pulled by the paraspinous muscles to the lateralized side. In these cases, botulinum toxin (BTX) should be injected into the paraspinous muscles of the lateralized side. However, in some cases of LAD, the enlarged paraspinous muscles push contralaterally. When this happens, BTX should be injected into the paraspinous muscles opposite the lateralized side. The leaning tower of Pisa is pulled by gravity, but Bonsai trees are tightened by wires. Similarly, in Bonsai syndrome (BS), LAD is a result of tension created by enlarged contralateral paraspinous muscles. In cases with dropped head syndrome (DHS), BTX should be injected into the sternocleidomastoid muscles or scalene muscles.
Methods: We experienced three cases of PS, two cases of BS and four cases of DHS. BTX was injected into the paraspinous muscles of the lateralized side in PS, opposite of the lateralized side in BS and into the sternocleidomastoid muscles or scalene muscles in DHS.
Results: All cases were improved.
Conclusions: Treatment with BTX is useful for PS, BS and DHS in PD. When treating LAD in PD, PS or BS should first be identified.

EFFECT OF PIOGLITAZONE AGAINST STREPTOZOTOCIN INDUCED MEMORY DYSFUNCTION: POSSIBLE ROLE OF NITRIC OXIDE MODULATORY MECHANISM

A. KUMAR[1], A. Prakash[1]
[1]NEUROPHARMACOLOGY DIVISION UIPS, Panjab University Chandigarh, Chandigarh, India

Objective of the study- The present study was carried out to elucidate the neuroprotective effect of pioglitazone against the intracerebroventricular infusion of streptozotocin (ICV STZ) induced cognitive impairment and mito-oxidative damage in rats.

Materials and Methods- Male adult Wistar rats were injected with intracerebroventricular streptozotocin (ICV-STZ) bilaterally (3 mg/kg) in first day and 3 days later. Pioglitazone was administrated for three weeks in post surgery. The rats were sacrificed on the 21nd day following the last behavioral test, followed by biochemical estimations (oxidative stress parameter, mitochondrial enzymes).

Results- ICV STZ resulted in poor retention of memory in Morris water maze task and caused marked mito-oxidative damage as compared to sham group. It also caused a significant increase in the oxidative damage, alteration of mitochondrial enzyme complex activity (I to IV), increased acetylcholinesterase enzyme activity in hippocampus and cortex as compared to sham animals. Chronic treatment pioglitazone (15, 30 mg/kg) treatment significantly improved memory retention and attenuated mito-oxidative damage parameters, restored mitochondrial enzyme complex activity and acetylcholinesterase activity in streptozotocin treated rats. L-arginine (50 mg/kg) pretreatment significantly reversed the protective effect of pioglitazone in ICV treated animals. Further, L-NAME (5 mg/kg) pretreatment with pioglitazone (15 mg/kg) significantly potentiated their protective effect which was significant as compared to their effect per se.

Conclusion- The study results demonstrate the nitric oxide modulatory mechanism could be involved in the neuroprotective effect of pioglitazone in preventing the cognitive impairment as well as the mito-oxidative stress caused by ICV STZ in rats.

EFFECTS OF THE PAIN RECOGNITION AND TREATMENT PROTOCOL ON REDUCING EXPRESSION OF PAIN AMONG INSTITUTIONALIZED RESIDENTS WITH DEMENTIA

Y.H. Chen[1], L. Lin[2]
[1]Department of Nursing, Mackay Medical College, New Taipei City, Taiwan
[2]School of Nursing, Yang-Ming University, Taipei City, Taiwan

Background: Many strategies were used to improve pain management in institutionalized residents with dementia, but the effects of these methods are controversial.
Objectives: The study purpose was to compare the effect of PRT protocol coupled with basic pain education (Experimental group) versus the effect of basic pain education alone (Control group) in improving pain management performance of registered nurses (RNs) and reducing pain related expressions of residents with dementia at post-intervention and 3-month follow-up.
Design: A double-blind cluster randomized controlled trial was conducted in 4 dementia special care units with 195 residents.
Methods: The RNs' weekly pain management performance (eg, use of pharmacologic and non-pharmacologic strategies, use of referral) was recorded by a structure sheet, and the Verbal Descriptor Scale (VDS), Mobilisation-Observation-Behaviour-Intensity-Dementia Pain Scale (MOBID) and the Cohen-Mansfield Agitation Inventory (CMAI) were used to assess residents' pain-related expressions.
Results: The generalized linear mixed model (GLMM) analysis showed that after intervention, the experimental group's number of weekly non-pharmacologic pain relief strategies and number of weekly referral for pain management were significantly increased than the control group. And residents' verbal and behavioral expressions of pain in the experimental group were significantly decreased than those in the control group. However, no significant differences between groups were found in the use of prescribed pain medications and the agitated behaviors expressed by residents.
Conclusions: The study findings support the effectiveness of performance of the PRT protocol and it is recommended for routine use in residents with dementia to improve the quality of pain care.

TRANSFECTING CELLS WITH LASER LIGHT.
F. Gunn-Moore[1], K. Dholakia[2]
[1]Biology, University Of St Andrews, St Andrews, United Kingdom
[2]Physics, University Of St Andrews, St Andrews, United Kingdom
Objectives
To be able to transfect cells in the mammalian nervous system neurons has always relied on a variety of different methods for example microinjection, electroporation, lipophilic chemicals, or the production of viral constructs. All of these techniques have their advantages but none of them can provide fast cell specific or a sub-cellular manipulation. Here we have developed this ability by utilising laser light in adapted commercially available optical set-ups.
Methods
We are able to shape and control exactly laser light, as such we have developed, and are continuing to develop, a series of different optical setups which provide the capability of using laser light to introduce biological material into cells including mammalian neurons. Our work is with the end-user in mind and so we have developed this ability using continuous wave blue diode lasers through to the use of femtosecond pulsed titanium-sapphire lasers, and have ported these through either standard optical microscopes, optical fibers and have also developed a touch-screen interface.
Results
We describe some of the optical set ups we have developed. Specifically we show our touch-screen interface system for the selective transfection of primary neurons with optogenetics based constructs. These light induced proteins allowed us to show that the transfected neurons are electrophysiologically normal.

Conclusions
We have developed a suite of optical based tools that can be adapted to transfect cells of the nervous system either in 2D or 3D cultures but also hold the potential of transfecting cells in situ potentially within a living brain.

PAIN IS UNDERESTIMATED IN THE MANAGEMENT OF CASES WITH SEVERE DEMENTIA.

E. Granvik[1], K. Nägga[1], S. Mayer[1]
[1]Skåne University Hospital, Clinical Memory Research Unit Memory Clinic, Malmö, Sweden

Objectives

Many older people experience pain, usually related to medical conditions such as arthrtis, cancer, vascular diseases or wounds. However, the rate of analgesic use in cases with dementia is far lower than cognitively healthy elderly, indicating a high likelihood of untreated pain in dementia. Pain may remain unrecognized and untreated due to dementia specific manifestations such as limited language skills, impaired memory or altered ability for reflection.

Pain can manifest in other presentations in dementia where behavioral and psychological symtoms in dementia, BPSD, are common. Different examples are resistance of aid in ADL, aggression, anxiety etc. There is even a risk of overtreatment with psychotropic drugs instead of appropriate pain management.

The Swedish BPSD-registry has a mandatory question about pain and recommends the Abbey Pain Scale for assessment.

Method

Extracted data from the BPSD-registry including information on presence of pain and prescription of analgesic drugs.

Results

In November 2011, 50 % (n=502) of the registred persons with dementia had **no** pain manifestations. In September 2014 there was an increase to 70 % (n= 18 858) of the registred persons. During the same time period the use of analgesics was also increasing.

Conclusions

Through the Swedish BPSD-registry we show that management of pain is underestimated in persons with dementia. By the use of of a mandatory question, pain management can be improved.

THE BENEFICIAL EFFECTS OF COMBINING NOVEL IRON CHELATING/MAO INHIBITORY COMPOUND WITH FORTIFIED HIGH CALORIE/ENERGY DIET IN SOD1-G93A TRANSGENIC ALS MICE

S. Golko-Perez[1], O. Weinreb[1], S. Mandel[1], T. Amit[1], M. B.H. Youdim[1]
[1]faculty of medicine, Technion-Israel Institute of Technology, Haifa, Israel

Objectives: Based on a novel therapy approach that consider a simultaneous manipulation of multiple targets in Amyotrophic Lateral Sclerosis (ALS) treatment, we demonstrated that the multi-target, brain permeable, iron chelator-monoamine oxidase (MAO) inhibitory compounds, M30 series conferred a significant improvement in survival time and motor performance of SOD1-G93A transgenic ALS (mSOD1) mice. The current study examined the prospect of strengthening the basal energy status of mSOD1 mice, by combined treatment of another multifunctional-iron chelator member of this series, VAR with high calorie-energy supplemented diet (CED).
Methods: mSOD1 mice treated with VAR (0.5 and 2.5 mg/kg, p.o. 3 times weekly) +CED cocktail treatment, starting at disease symptomatic stage of 88 days after birth and continuing until time of death. Total neurological deficits were assessed during the experiment and histological, enzymatic and biochemical analyses were determined at the symptomatic stage of 121 days old in all treated-mice.
Results: We demonstrated that VAR+CED treatment, significantly delayed the onset of motor dysfunction and showed superiority in extending the lifespan of mSOD1 mice, compared to the effects of each individual components. In addition, VAR+CED treatment significantly up-regulated the mitochondrial master regulator biogenesis pathway, PPARγ/PGC-1α, increased the mitochondrial respiratory chain enzymes, NADH and succinate dehydrogenases and attenuated neuromuscular junction denervation and motoneuron loss, compared to the individual treatments, in mSOD1 mice.
Conclusions: Our findings provide significant evidence that our multifunctional iron chelating drug VAR may improve mitochondrial function and bioenergetic deficits and thus, can be suggested as novel effective ALS therapeutic approach.

[2]chemistry, McGill University, Montreal, Canada

[3]neuroscience, Douglas mental health university institute, Montreal, Canada

Farnesyl pyrophosphate (FPP) and geranylgeranyl pyrophosphate (GGPP) are precursor to numerous human metabolites and responsible for the post-translational prenylation of approximately 2% of the total mammalian proteome. Nitrogen-containing bisphosphonate (*N*-BP) inhibitors are currently used in the treatment of osteoporosis, osteolytic metastases from breast, prostate cancer and multiple myeloma. The drugs risedronate and zoledronate typify the molecular architectures of current *N*-BP drugs. However, the very poor cell-membrane permeability and tissue distribution of these compounds, as well as their modest selectivity for hFPPS *versus* other related enzymes of the mevalonate pathway, renders these compounds unsuitable for investigating CNS disorders.. Recently, we found that specific genetic polymorphisms in the hFPPS and hGGPPS genes correlate significantly with aberrant accumulation of Tau and phospho-Tau in human autopsy-confirmed AD brains, but not with AB42 concentrations.

Our efforts towards the design of molecules that have an optimized size, shape and electrostatic surface complimentarily with the active site cavities of hFPPS and hGGPPS, and exhibit lower affinity for bone and higher cell-membrane permeability, will be described. Our medicinal chemistry efforts are guided by compound profiling *in vitro* using the recombinant hFPP and hGGPP synthases, the latter being the gateway enzyme to the prenylation of the small GTPase protein RhoA-cdc42, associated with the accumulation of phospho-Tau protein in the brain. We believe that this specific pathway is implicated either in the response to neuronal damage or, as part of the neurodegenerative process that characterises progression in Alzheimer’s disease and related tauopathies.

Center for Neuroscience and Cell Biology University of Coimbra, Coimbra Portugal, Portugal

[4]Laboratory of Physiology University of Coimbra,
Center for Neuroscience and Cell Biology University of Coimbra, Coimbra Portugal, Portugal

1. Objectives: The neuroprotection exerted by the anti-type 2 diabetes (T2D) drug exendin-4 (Ex-4) suggests that it may prevent and/or attenuate T2D-associated neuronal/cognitive deficits and ultimately neurodegenerative diseases. We hypothesized that chronic peripheral Ex-4 administration is neuroprotective and decreases AD-like neuropathology in middle-aged T2D male rats.
2. Methods: 8-month-old male Goto-Kakizaki (GK) and Wistar control rats were given Ex-4 (5 ug/kg/day, 2.5 ul/h, 28 days) or saline subcutaneously. Spatial memory was evaluated by Morris water maze (MWM) test. GLP-1 receptor (GLP-1R) signaling, autophagy, synaptic integrity, amyloid-beta (Abeta) and phosphorylated tau (P-Tau) protein were given by immunoblotting and ELISA in blood and brain homogenates.
3. Results: Peripheral Ex-4 decreased fasting blood glucose levels, glycated hemoglobin (HbA1C) and insulin resistance (HOMA-IR) in GK rats. Accordingly, Ex-4 also lowered brain glucose levels and stimulated GLP-1R-mediated signaling (as given by cAMP, Akt and PI3K levels and PKA activity). Consequently, Ex-4 was able to stimulate autophagy in GK rat brains (as given by mTor, LC3, p62, Beclin, Atg7, Parkin, LAMP-1). Strikingly, the Ex-4-induced decrement in brain Abeta1-42 levels and P-Tau (Thr181 residue) was accompanied by improved synapse function/integrity (synapthopysin and PSD-95) and spatial memory in T2D rats.
4. Conclusion: Ex-4 therapy may enhance GLP-1R-mediated signaling, thereby improving glucose homeostasis, insulin sensitivity and 'protective' autophagy, preventing the development of AD-like hallmarks and ultimately restoring synaptic and cognitive function.

Supported by FEDER (Programa Operacional Factores de Competitividade – COMPETE) and Portuguese funds via FCT (projects: PTDC/SAU-TOX/117481/2010; Pest/SAU/LA0001/2011; fellowships: SFRH/BD/90036/2012, PTDC/SAU-TOX/117481/2010 and SFRH/BPD/84473/2012).

[5]Autors, contributed equally to this work., Bogotá, Colombia

Introduction: Changes in DNA methylation were recently described to play a role in the progression of Alzheimer's disease (AD). Nuclear receptors, in particular LXRs, have been shown to improve cognitive function in murine models of AD and to regulate epigenetic modifications of DNA inducing transcriptional de-repression.

Objectives: To evaluate the effect of a short-term treatment (ST) of GW3965 (LXR agonist) in cognitive function and DNA methylation pattern in the hippocampus of 3xTg-AD and WT mice.

Methods: 24 months-old 3xtg-AD mice were treated with GW3965 (50mg/kg/day – 6days). Cognitive performance was evaluated by Morris Water Maze; Aβ-burden by thioflavin-S; methylation pattern of DNA from hippocampus was evaluated via modified bisulfite conversion and subsequent hybridization on Infinium Methylation BeadChip 450K.

Results: GW3965 improves cognition without a significant change on Aβ burden. These changes were associated to restoration of the DNA methylation pattern in promoter regions of *LMOD3, DLGAP3,* and *TUBB2A* genes, similar to WT mice. *LMOD3* is highly expressed in the murine brain during development and is associated with smooth muscle cells, which are reduced in AD; *DLGAP3* is a postsynaptic scaffolding protein that is highly expressed in glutamatergic synapses, and is downregulated in AD patients; *TUBB2A* is a tubulin protein critical for neuronal development proliferation and migration.

Conclusion: GW3965 treatment improves cognition in the 3xtg-AD associated with recovery of methylation pattern of genes that may be important for improvement of synaptic and cognitive function.

Acknowledgements: We thank Dr. Jon Collins (GSK, Stevenage, UK) for providing the GW683965A.

Keywords: Alzheimer, LXR, LMOD3, DLGAP3, TUBB2A.

COGNITIVE EFFECTS OF BENZODIAZEPINE-USE IN SUBJECTS WITH MILD TO SEVERE ALZHEIMER'S DISEASE AND RELATED DEMENTIA

A. Khan Rhodes[1], M. Farrell[2], B. Rothman[2]
[1]Research & Training, Nathan Kline Institute for Psychiatric Research, New York, USA
[2]Research & Training, ProPhase LLC, New York, USA

BACKGROUND:
Long-term benzodiazepine (BDZ) use affect cognition adversely and may be partly irreparable. The degree of cognitive retrieval after withdrawal, if any, that is preserved is also unclear. Psychiatrists use benzodiazepines to treat anxiety, sleep disorders, and acute agitation associated with AD. The aim of the study was to investigate the link in core cognitive functions for subjects who are treated with BDZ.

METHODS:
A naturalistic longitudinal dataset of 2859 subjects (134 on BZD) followed for over 30 years was examined. Categorical analysis was completed for BZD and non- BZD subjects. Transformations were computed to correct for normality and group imbalances.

RESULTS:
Subjects' scores in the BDZ group on most tests remained at the lower percentiles of normative scores. The following cognitive items showed significant differences at the $p \leq 0.001$ level indicating more impairment in BZD group: Finding way around the house (Chi-Square=9.564), around neighborhood (Chi Square=14.302), remembering things (Chi-Square=11.483), MMSE What city are we in (Chi-Square=11.743), MMSE What borough? (Chi-Square=44.678), MMSE Name 3 objects (Chi-Square=44.056) and MMSE Naming (Chi-Square 55.524). Long-term benzodiazepine users were consistently more impaired than non-BDZ across cognitive categories, with effect sizes ranging in magnitude from –1.07 to –0.40. Mean weighted effect size –0.66 (SD±0.21).

CONCLUSIONS:
The observation that BDZ use has several implications for the informed decision to include subjects on BDZ or subjects with long term use. Emerging evidence may suggest that some medications might be a safe and efficacious treatment of long-term BDZ use should be considered for subjects with AD.

ADPD5-1993

A NEW TREATMENT FOR CLINICAL STABILIZATION IN PARKINSON´S DISEASE.

E. de Font-Réaulx R[1]

[1]*Neurological Center, ABC Medical Center-Methodist International Network, Mexico City, Mexico*

It is mandatory to have a safe and effective treatment to stop Parkinson´s disease (PD) progression. Previous clinical trials designed to stop PD´s progression have failed to demonstrate significant clinical stabilization. We administrated to PD patients a new oral treatment designed to stop the disease progression called Cervô. It contains four substances that have a synergic effect in controlling the most important known mechanism of disease progression as: aberrant apoptosis, oxidative damage, mitochondrial degeneration, caspases activation, Mitogen-Activated Protein-Kinases (MAPK) activation. We previously demonstrated that it is safe to use Cervô in humans and that has no collateral effects. **Results**: In the Cervô clinical stabilization clinical trial, we included 42 patients with Parkinson´s disease. Age: 42 to 89 years old (mean 66.12 years), 23 female (54.8%), 19 male (54.2%). Initial United Parkinson´s Disease Rating Scale subscale 3 (UPDRS) score: 1-15 (mean 5). Maximum follow-up period: 72 months, mean 29.6 (+/- 22.28 SD). We included only patients with more than 6 months of follow-up for the clinical stabilization analysis (n=37). No disease progression (no increase in the UPDRS score) in 34 (91.8%) patients, and 31 (83.78%) patients improved their basal UPDRS score. There were 2 clinical remissions (5.4 %) and the disease progressed in 1 (2.7 %). **Conclusions:** Until today, there is no medication that had proven to be effective in controlling PD´s progression. Cervô is a new and promising compound that may stop PD´s progression.

ADPD5-0213

THERAPEUTIC POTENCY OF ESMIRTAZAPINE IN MPTP INDUCED PARKINSON'S DISEASE MODEL

B. Aryal[1]

[1]*Department of Clinical Pharmacology, Chitwan Medical College, Chitwan, Nepal*

Objective: 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP)-is reported neurotoxin to develop Parkinson's disease (PD) Model. Esmirtazapine, a noradrenergic and specific serotonergic antidepressant (NaSSA) was also reported to increase dopamine release in the cortical neurons with 5-HT dependent manner. Hence, this study investigates the therapeutic potency of Esmirtazapine in MPTP-treated rat model of PD.

Methods: SD rats, 8 weeks of age, were used in this study. Rats were subjected to MPTP treatment (20mg/kg, intraperitoneal) to establish a PD model. Esmirtazapine (4mg/kg, 8mg/kg or 61mg/kg, intraperitoneal) was administered once a day for 3 days after MPTP treatment. Beam-walking and rota rod tests were used for behavior assessment. Dopamine (DA) and its metabolites activity were quantified by validated LC-MS/MS methods and Western blot analysis.

Results: MPTP-induced motor dysfunction, assessed by beam-walking and rota-rod tests, was significantly improved by administration of esmirtazapine . Biochemical examinations by LC-MS/MS and western blot analysis suggested esmirtazapine facilitated utilization of dopamine by increasing turnover and protein expression of transporters, without affecting on neurodegenerative process by MPTP. These therapeutic effects of esmirtazapine were reduced by administration of clonidine, a selective agonist for α2-NAR, or of prazosin, an inhibitor for α1-NAR, respectively.

Conclusion: These results showed esmirtazapine had a therapeutic potency against PD in a rat model. Because PD patients sometimes show depression together, it will be a useful drug for a future PD treatment.

EFFECTS OF COFFEE ON BDNF ACTIVITY IN HUMAN NEUROBLASTOMA SH-SY5Y CELLS.

S. Kakio[1], K. Takahashi[1], M. Tago[1], H. Tamura[1]
[1]Pharmaceutical Science, Graduate School of Pharmacy Keio University, Tokyo, Japan

Objectives

Coffee is one of the most world widely consumed beverage on a daily basis. Recent epidemiological studies have suggested that daily coffee consumption reduces the risk of several neurodegenerative diseases. However, the precise molecular mechanisms of the effects of coffee are yet uncertain. Neurotrophins, such as BDNF, have effects on various neurodegenerative diseases in development of symptoms and prolongation of life. In this study, we analyzed the effects of coffee on BDNF activity in human neuroblastoma cells SH-SY5Y.

Methods

SH-SY5Y cells were induced to differentiate by *all-trans* retinoic acid treatment for 6 days. On day 6, cells were exposed to coffee (cf.) or decaffeinated coffee (dcf.) at 0, 2.5% (v/v) for two hours followed by BDNF treatment. After 0-120 minutes, whole cell lysates were isolated and phosphorylation of TrkB, ERK, and Akt was measured by immunoblots. Total RNA was isolated from the cells treated with BDNF plus cf. or dcf. for 4 hours and real-time PCR was performed to measure BDNF-induced gene expression.

Results

Cf. and dcf. inhibited BDNF activity by inhibiting TrkB and Akt phosphorylation. Furthermore, cf. and dcf. abolished the induction of BDNF gene expression mediated by TrkB signaling. Major components of coffee including caffeine did not show any effect on TrkB signaling.

Conclusion

Coffee inhibited BDNF-mediated TrkB signaling by interfering phosphorylation of TrkB and Akt. The active component of coffee is not major constituents. Further study to elucidate the mechanism of the effect of coffee on BDNF function in neuronal cells should be carried out.

CXXC PEPTIDE MOTIF FROM MESENCEPHALIC ASTROCYTE-DERIVED NEUROTROPHIC FACTOR (MANF) ANTAGONIZES APOPTOTIC AND NECROPTOTIC DEATH AND HAS ANTI-OXIDANT ACTIVITY

V. Bozok[1], J. Palgi[1], U. Arumäe[1]
[1]Gene Technology, Tallinn University of Technology, Tallinn, Estonia

Objective: To study the cytoprotective effect of MANF-derived CXXC motif containing peptide CKGC against different types of programmed cell death (PCD).
Background: Novel factors MANF and CDNF are good candidates for a drug against neurodegeneration. However, they raise the problem of their administration to the brain of a patient, as they cannot penetrate the blood-brain barrier. Small molecules that could substitute neurotrophic factors would help to overcome this difficulty. One such molecule could be CKGC, a MANF-derived neuroprotective peptide.
Methods: Human T lymphocyte-derived Jurkat cells were exposed to the conditions inducing intrinsic apoptosis, extrinsic apoptosis or necroptosis. CKGC peptide at different concentrations was added to growth medium to reveal the cytoprotective capacity of the peptide against different types of PCD. SKGS control peptide with cysteines substituted to serines was used to reveal the importance of cysteine residues in the function of the peptide. The ability of CKGC to decrease reactive oxygen species (ROS) and preserve mitochondrial membrane potential, as well as its cell membrane permeability were measured.
Results: CKGC peptide protects Jurkat cells against all three PCD types, although high concentrations are needed. It effectively decreases ROS and maintains the integrity of mitochondria, which explains its anti-apoptotic effect. The peptide passively penetrates plasma membrane, although not very effectively.
Conclusions: MANF-derived peptide with CXXC motif could theoretically be an alternative for MANF protein as a drug against neurodegenerative diseases, as it can counteract different modes of programmed cell death, although some improvements in efficiency and cell permeability are still needed.

SULFURETIN PREVENTS INFLAMMATORY RESPONSES AND NEURONAL CELL DEATH BY BLOCKING THE NF-κB SIGNALING PATHWAYS IN NEURONAL CELLS

S. Ma[1], S. Hong[1], Y. Jung[1], J. Hwang[1], J. Kim[1], J. Seo[1], J. Lee[1], Y. Ko[1], S. Lee[1], C. Jang[1]

[1]School of Pharmacy, Sungkyunkwan University, Suwon 440-746, Korea

We investigated the mechanisms of sulfuretin protection of neuronal cells from apoptotic cell death induced by the Parkinson's disease (PD)-related neurotoxin, 6-hydroxydopamine (6-OHDA). We examined whether sulfuretin acts as an anti-oxidant to reduce oxidative stress and mitochondrial-mediated apoptotic cascade events in 6-OHDA-induced neurotoxicity in SH-SY5Y cells. We also investigated whether sulfuretin specifically acts by inhibiting phosphorylation of mitogen-activated protein kinase (MAPK), phosphatidylinositol 3-kinase (PI3K)/Akt, and glycogen synthase kinase-3beta (GSK-3β) as well as activation of the nuclear factor-kappa B (NF-κB) pathway. Sulfuretin significantly inhibited neuronal cell death, neurotoxicity, apoptosis, and reactive oxygen species (ROS) production. Sulfuretin also strikingly attenuated 6-OHDA-induced mitochondrial dysfunction. Moreover, sulfuretin significantly attenuated 6-OHDA-induced phosphorylation of c-Jun N-terminal kinase (JNK), p38, extracellular signal-regulated kinase 1/2 (ERK 1/2) MAPKs, PI3K/Akt, and GSK-3β. Eventually, sulfuretin inhibited 6-OHDA-induced NF-κB translocation to the nucleus induced by 6-OHDA. The results of the current study provide the first evidence that sulfuretin protects SH-SY5Y cells against 6-OHDA-induced neuronal cell death, possibly through inhibition of phosphorylation of MAPK, PI3K/Akt, and GSK-3β, which leads to mitochondrial protection, NF-κB modulations and subsequent suppression of apoptosis via ROS-dependent pathways. Thus, we conclude that sulfuretin may have a potential role for neuroprotection and, therefore, may be used as a therapeutic agent for PD.

[3]Chemistry, Federal Institute of Piaui, Teresina, Brazil
[4]Chemistry, Federal University of Bahia, Salvador, Brazil
[5]Pharmacy, Federal University of Bahia, Salvador, Brazil

Objectives: Evaluate acetylcholinesterase (AChE) activity of an isolated compound of ethanolic extract of flowers of *Bellis perennis* L. **Methods:** Flowers were collected in Pacoti, Ceará and deposited at herbarium Graziella Barroso of Federal University of Piauí, with register number 27,276. *In vitro* activity of AChE was evaluated by Ellman and colleagues method (1961). All the *ex vivo* experiments performed in this study got approved by the Animal Experimentation Ethics Committee of the Federal University of Piaui (# 077/10). **Results:** The analysis of IR and NMR spectrums allowed to conclude that the isolated fraction is isorhamnetin 3-O-β-D-(6''-acetyl)-galactopyranoside. There was an inhibition in AChE activity *in vitro* of 83.85 and 17.22 when rivastigmine was used (positive control) at the concentrations of 0.2 e 0.0125%, respectively. Isolated fraction at concentrations 0.0125; 0.00652; 0.003125 and 0.001563% produced an inhibition of 64.30; 55.83; 43.87 and 38.13% in AChE activity, respectively. In the *ex vivo* studies, we verified a decrease of 91% in the AChE activity among mice treated with 10 mg/kg (0.89 ± 0.21) of fraction when compared with negative control (10.03 ± 0.16; $p<0.05$). In comparison with the group treated with rivastigmine (5.69 ± 1.20), we verified a decrease of 84.4% in AChE activity among mice treated with at dose 10 mg/kg (0.89 ± 0.21; $p<0.05$) of isolated compound. **Conclusion:** The isolated compound is able to more effectively increase cholinergic stimulation, suggesting its possible use in treatment of neurodegenerative diseases such as Alzheimer's disease.

ADPD5-1974

MONOAMINE OXIDASE INHIBITORS ISOLATED FROM CRATAEGUS PINNATIFIDA BGE. VAR. MAJOR FRUITS

K. Hwang[1], *Y. Choi*[1]
[1]*Plant Resources Research Institute, Duksung Women's University, Seoul, Korea*

OBJECTIVES - In previous experiments, it was found that the fruits extract of *Crataegus pinnatifida* Bge. inhibit monoamine oxidase (MAO) activity. This study addresses the isolation of well known-but not previously reported in this plant-organic acid methylesters that show inhibitory activity against MAO from methanol extract of fruits.

METHODS - MAO activities was determined according to the method previously reported by Ryu *et al*.(A) and Han *et al*.(B). The powered sample of the fruits was extracted with MeOH at room temperature for one month. Repeated chromatography on silica gel and reverse phase silica gel afforded compound 1 and 2 from ethyl acetate fraction.

RESULTS – The ethyl acetate extract of the hawthorn fruits showed higher inhibition and on both of MAO-A and MAO-B. Compound 1 and 2 were not positive Liebermann-Buchard reaction, ninhydrin test or Pauly reaction. IC_{50} values Compound1 against MAO-A and MAO-B were determined 0.12 mM and 0.068mM, respectively. IC_{50} values of compound2 against MAO-A and MAO-B were determined 0.01 mM and 0.025mM. Spectral data indicated that Compound 1 was citric acid dimethylester and Compound 2 was citric acid monomethylester.

CONCLUSION - Two citric acid methylesters were major components in MAO activities found in the fruit of *Crataegus pinnatifida* . These compounds have been reported in other plants but have not been reported in *Crataegus pinnatifida* Bge. var. major. The present study indicates that these molecules including ursolic acid and quercetin have MAO inhibitory activities and other biological activities or industrial usages of these molecules may be found through futher investigation.

ADAMANTYL-GROUP CONTAINING 1,4-DIHYDROPYRIDINE DERIVATIVE PROTECTS AGAINST STRESS-INDUCED CHANGES IN BRAIN PROTEIN EXPRESSION IN RATS

U. Beitnere[1], Z. Dzirkale[1], S. Isajevs[2], B. Jansone[1], V. Klusa[1]
[1]Pharmacology, University of Latvia Faculty of Medicine, Riga, Latvia
[2]Pathology, University of Latvia Faculty of Medicine, Riga, Latvia

Objectives: Neurotrophins, adhesion molecules and enzymes related to cholinergic and glutamatergic systems are considered critical molecules that maintain synaptic plasticity and memory formation. Stress is a significant factor that can alter brain cell properties leading to impairments in synaptic plasticity and further to neurodegeneration. We assessed the ability of adamantyl-containing 1,4-dihydropyridine (DHP) derivative (compound AV-6-93) to protect against stress-induced alterations in synaptic plasticity proteins in the striatum and the hippocampus in rats. Previously adamantane molecule has been used in the design of neuroprotective drugs (Kornhuber et al., 1991), while DHP ring serves as the carrier moiety.
Methods: Male Wistar rats (8-10 per group) were treated ip for two weeks with AV-6-93 at the dose 1 mg/kg or saline (control). One hour after the last drug administration, rats were exposed to 2 h immobilization stress. The expression of the hippocampal and striatal BDNF, AChE, GAD67 and NCAM were analysed by Western blot and immunohistochemically.
Results: Our data showed that 2h immobilization stress caused a considerable (about 2-fold) induction of striatal and hippocampal BDNF and striatal AChE, NCAM, but did not influence GAD67 expression. The compound AV-6-93 normalized the expression of BDNF, AChE and NCAM in the striatum and hippocampus close to control levels, while did not influence GAD67 expression.
Conclusion: The data obtained indicate that the compound AV-6-93 regulates the stress-induced overexpression of brain synaptic plasticity proteins, such as BDNF, AChE and NCAM. We suggest that adamantyl- and DHP moieties can be useful for the design of neuroprotective drugs.

GREEN TEA: A NEW DAWN IN THE ERA OF NEURODEGENERATIVE

R. Sharma[1], *S. Vyas*[1]

[1]*Pharmacy, DR. HARISINGH GOUR CENTRAL UNIVERSITY, SAGAR, India*

A few cups of tea in a day keep doctor away. This proverb is proving its magical impact in the in the era of neurological disorders. Neurodegeneration in Parkinson's, Alzheimer's, or other neurodegenerative diseases emerges due to various reasons, due to composite set of toxic reactions, counting oxidative stress (OS), inflammation, and amassing of protein aggregates, results in the failure of neurons. Green Tea Flavonoides (catechins), poly phenols, and their antioxidants screening promising antioxidant, anti-inflammatory and divalent metal chelating actions, to infiltrate the brain barrier and to shield neuronal death in a broad display of neurological bugs. By this study we endeavour the new dawn on the multi-pharmacological neuro-protective activities of green tea with exceptional accent on brain-permeable, biodegradable ,patient compliance, transitional metal (iron and copper)-cheatable/radical forager nontoxic possessions.

THE PROTECTIVE EFFECT OF CURCUMIN ON TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN BOTH SUBSTANTIA NIGRA AND THE VENTRAL TEGMENTAL AREA, AFTER ACUTE ALUMINUM INTOXICATION.

W. LAABBAR[1], A. ELGOT[1], H. GAMRANI[1]
[1]Neurosciences, Cad Ayad university, Marrakech, Morocco

Aluminum (Al) is a potent neurotoxic metal wich has been associated to several neurodegenerative diseases, it has no known function in human; however, this metal is accumulated in substantia nigra, and considered by some authors as a risk factor for developing Parkinson's Diseases. Moreover, some few studies demonstrated that Al can include changes in many neurotransmitter levels including the dopaminergic system. Among several medicinal plants having a beneficial effect on health; curcumin is extracted from *Curcuma longa* rhizomes, and well known as a multi-functional drug with antioxidative activities. Using the immunohistochemistry procedure, with tyrosine hydroxylase antibody (TH: the key enzyme of dopamine synthesis), the present study evaluates the possible protective effect of curcumin on Al intoxicated rats (animals receiving Al acute treatment). Thus, experiments were carried out on male wistar rats intoxicated acutely with an intraperitoneal injection of Al (25mg/Kg B.W.), and (100mg/Kg B.W.), the two Al intoxicated groups (25mg/Kg B.W.) and (100mg/Kg B.W.) received concomitantly Curcumin by oral gavage (30mg/kg B.W.). Our results showed, a significant and gradual increase of TH immureactivity in both the substantia nigra (SN) and the ventral tegmental area (VTA) in acute Al intoxicated rats, this enhanced immunolabelling concerns both somata and their related fibers. This increased TH immunoreactivity has been remedied with daily curcumin administration in all Al intoxicated groups. We suggested that Al causes alterations on dopamine neurotransmission, this inconvenience might be treated by curcumin exhibiting a potential protective effect.

ANTICHOLINESTERASE AND ANTIOXIDANT ACTIVITIES OF APIGENIN-7-O-GLUCOPYRANOSIDE ISOLATED OF BELLIS PERENNIS L.

J. Costa Júnior[1], T. Costa Marques[1], R. Freitas[2], R. Carvalho[3], C. Feitosa[3], L. Lima[4], J. David[5], J. David[4]
[1]Chemistry, Federal of Piauí, Teresina, Brazil
[2]Pharmacy, Federal University of Piaui, Teresina, Brazil
[3]Chemistry, Federal University of Piaui, Teresina, Brazil
[4]Chemistry, Federal University of Bahia, Salvador, Brazil
[5]Pharmacy, Federal University of Bahia, Salvador, Brazil

Objectives: This study describes the isolation and identi?cation of apigenin-7-O-glucopyranoside (ApG), a ?avonoid isolated from ?owers of *Bellis perennis* L. (Asteraceae). The *in vitro* antioxidant activity and the inhibition against enzyme acetylcholinesterase (AChE) were evaluated. **Methods:** The chemical structure of the substance isolated was de?ned based on the analysis of ^{1}H NMR and ultraviolet spectroscopic data, and comparison of data obtained with those reported in literature. Quantitative activity AChE was evaluated by Ellman and colleagues spectrophotometric method adapted (1961) and Moyo and colleagues (2010). Evaluation of antioxidant activity *in vitro* for formation of hydroxyl radical (OH•) from the Fenton reaction and TBARS and nitric oxide (NO). **Results:** The flavonoid showed strong *in vitro* antioxidant potential, because of the capacity of removal of hydroxyl radicals and nitric oxide, and also prevented the formation of thiobarbituric acid-reactive substances. These parameters were inhibited at the highest concentration of ApG at rates of 77.7%, 72% and 73.4%, respectively, in addition to inhibiting acetylcholinesterase, suggesting potential use in the treatment of neurodegenerative diseases. In vitro studies indicated that there was 92.02% inhibition of AChE activity when Neostigmine (Exelon®) was used as positive control at a concentration of 0.1%. The 50% inhibitory concentration (IC_{50}) was also determined, which corresponded to 1.91 µmol/l, with 95% con?dence intervals of 0.53 and 3.42 µmol/l (r^2 = 0.8332). **Conclusion:** If these e?ects are established, it is possible to justify the use of this ?avonoid in preclinical and pharmacological models that simulate neurodegenerative diseases.

FOLIC ACID IS NEUROPROTECTIVE IN A PARKIN KNOCKDOWN DROSOPHILA MODEL OF PD

S. Srivastav[1], S. Singh[1], A. Yadav[1], S. Srikrishna[1]
[1]Biochemistry Faculty of Science, Banaras Hindu University, Varanasi, India

Objectives: Loss-of-function mutation(s) in *parkin* is commonly associated with familial Autosomal recessive juvenile Parkinsonism (AR-JP). Mutations in *the Drosophila parkin* (a human *parkin* ortholog) have deciphered important insights to AR-JP etiopathology. In this context, the therapeutic potential of folic acid (FA) in the alleviation of parkin loss of function in dopaminergic (DA) neuron associated discrepancies in *Drosophila* transgenic model of AR-JP was explored.
Methods: *parkin* knockdown in dopaminergic neuron was carried out using UAS *parkin*^{RNAi}-DA GAL4 genetic approach. Mortality, climbing assay, ATP levels, and oxidative stress were used to assess the effect of FA supplementation to UAS *parkin*^{RNAi}-DA GAL4 flies. qRT-PCR for relative analysis of mitochondrial biogenesis and mitophagy was carried to study any possible FA potential in regulating mitochondrial functioning.
Results: *parkin* knockdown in DA neurons leads to high mortality rate, reduced climbing ability, elevated oxidative stress, low ATP level and altered mitochondrial functioning. Folic acid supplementation reverses high mortality, significantly improves motor ability and reduces oxidative stress. ATP levels improve in FA supplemented flies with *parkin* knockdown background. qRT-PCR analysis depicted improved mitochondrial biogenesis.
Conclusions: Folate is an essential cofactor known for its importance in neurogenesis, and its deficiency is linked with Alzheimer's and Parkinson's. In this context, we looked for the effect of FA supplementation in flies with a specific parkin knockdown background in DA neurons. Our result shows that FA improves behaviour response, reduces stress, and improves the ATP level, suggesting FA therapeutic potential in context to discrepancies linked with *parkin* associated AR-JP in Drosophila model.

IMPACT OF NANOTECHNOLOGY BASED DRUG DELIVERY SYSTEM IN THE ARENA OF NEURODEGENERATIVE DISORDERS

P. Sahu[1], V. Mishra[1], S. Kashaw[1]
[1]Department of Pharmaceutical sciences,
Department of Pharmaceutical sciences Dr. H S Gour University, SAGAR, India

Nanotechnology in 21st centaury unlock new-fangled eon in the meadow of medicine and healthcare. The impact of Nanotechnology is incredibly profound in the treatment of many ailments especially in cancer, Neurodegenerative disorders, Skin diseases etc. Nanotechnology based drug delivery like liposomes, Nanoparticles, Nanogels, Niosome, Phytosome etc create a novel avenue for the management of world most exaggerated neurodegenerative disorders like Alzheimer etc. Nanotechnology in simple term implies the engineering, mechanization and the manufacturing of materials and substances at the atomic and the molecular level that provides an aid for combating of Neurogenerative disorders. Herein, we discuss the important aspects of Nanotechnology based drug delivery and tissue engineering, revealing the supremacy and the challenges we are currently facing, in dealing with variety of diseases especially Neurogenerative disorders.

A NOVEL IN VIVO ACTIVE ANTI-AMYOTROPHIC LATERAL SCLEROSIS (ALS) CHEMICAL CHAPERON BASED DRUG CANDIDATE

T. Getter[1], I. Zaks[1], Y. Barhum[2], T. Ben-Zur[2], S. Petri[3], D. Offen[2], A. Gruzman[1]
[1]Chemistry, Bar Ilan University, Ramat Gan, Israel
[2]Medical Research Center, Tel Aviv University, Tel Aviv, Israel
[3]ALS Centre, Medical School Hannover, Hannover, Germany

Amyotrophic Lateral Sclerosis (ALS) also known as Lou Gehrig's disease is a fatal neurodegenerative disease, characterized by the selective degeneration of motor neurons in the brain and spinal cord, which leads to progressive paralysis and death. The majority of ALS is acquired spontaneously (sALS), with inherited disease accounting for only 10-15% of all cases. Recent studies provide compelling evidence that aggregates of mutated or misfolded proteins underlies both types of ALS.
Chemical chaperones that include polyols, trimethyl N-oxid (TMAO), phenylbutiric acid and different amino acid derivatives, have been shown to reverse the mislocalization and aggregation of proteins associated with many human diseases. However, using chemical chaperones as drugs is limited by their very high active concentration (mM range). We propose to overcome this obstacle by coupling known chemical chaperons to organelle targeting moieties in order to increase their concentrations at specific sites, in particular in cellular organelles where aggregation takes place (lysosomes, ER, Golgi, mitochondria). Refolding by chemical chaperons enabled proteolytic enzymes and proteasome system to cleave the misfolded proteins properly.
We have synthesized several ester and amide based chemical chaperon prodrugs. The lead compound, GZ-23, in the micromolar concentration range, has shown both neuronal and astrocyte protective effects *in vitro* and in daily doses of 10 mg/kg has dramatically improved the neurological functions and delayed body weight loss in ALS mice. Thus, this novel class of chemical chaperones is a strong candidate for developing new anti-ALS drugs.

[3]Institute of Biomedical Sciences, Univ. of São Paulo, São Paulo, Brazil
[4]Psychiatric Institute, Univ. Federal do Rio de Janeiro, Rio de Janeiro, Brazil
[5]Center of Mathematics Computing and Cognition, Univ.Federal of ABC, Santo André, Brazil

Objective: To investigate the effects of aerobic training on BDNF plasma levels and aerobic capacity of older adults with AD. Also, there were verified possible relations between BDNF plasma levels, metabolic variables, and cognitive functions. Method: Twenty-nine older adults with AD participated in the study, which was a nonrandomized, controlled, blind trial. Sample of were assigned to a training group (n = 16 - Moderate aerobic training on the treadmill, three times a week, for twelve weeks) and a control group (n = 13 - without systematic physical activity). We determined aerobic capacity at incremental test, using VO_2, treadmill grade, treadmill time and maximum lactate. Blood collection to obtain BDNF plasma levels, metabolic variables and lactate levels. Cognitive function was evaluated using Frontal Assessment Battery, Clock Drawing Test, Verbal Fluency and Symbol Search. Results: Training group and control group showed a significant increase on BDNF levels ($p = 0,02$; $F= 6,07$), however, the effect size was moderate for the training group (0,42) and small for the control group (0,14). Training group improve aerobic capacity, VO2 ($p < 0,001$), treadmill time ($p < 0,001$), and treadmill grade ($p < 0,001$) and decrease levels of LDL cholesterol ($p= 0,04$; $F= 4,28$) when compared to the control group. Conclusion: The moderate aerobic training was also effective for increased BDNF levels, improving aerobic capacity and reduced LDL cholesterol of older adults with AD.

IS THERE THE PREVENTIVE EFFECT OF COMT-INHIBITOR ON PARKINSON'S DISEASE ASSOCIATED WITH DEMENTIA?

I. Song[1], J. Kim[1], K. Lee[1], Y. Kim[2]
[1]Neurology, The catholic University of Korea, Seoul, Korea
[2]Neurology, College of Medicine Konyang University, Daejeon, Korea

Background: Elevated homocysteine (hcy) levels are associated with dementia, which is a frequent non-motor symptom of Parkinson's disease (PD). High levels of hcy in PD patients treated with levodopa are thought to result from increased synthesis during the metabolism of levodopa by COMT, and that use of a COMT-inhibitor may reduce hcy levels. In this study, we sought to clarify the effects of COMT-inhibitors on dementia in PD patients.
Methods: Thirty-eight PD patients without dementia (PDwoD), 35 PD patients with dementia (PDD), and 48 controls were enrolled in this study. All subjects underwent neuropsychological testing and a neurological examination. The hcy levels were measured in all subjects, and the relationship between hcy levels and dementia was evaluated in two PD groups (those that underwent treatment with levodopa-alone versus treatment with levodopa plus a COMT-inhibitor).
Results: Patients in the PDD group showed higher hcy levels than patients in the PDwoD group, though there was no significant difference in the hcy level between PDwoD patients and healthy controls. Regarding the effects of a COMT-inhibitor, there was no correlation between hcy levels in the 2 PD subgroups, indicating that there were no significant effects of the COMT-inhibitor on PDD. In addition, the odds ratio for PDD with the use of a COMT-inhibitor was 0.864 (95% CI=0.342-2.180).
Conclusions: These results are in agreement with previous studies in that levodopa treatment in PD patients leads to elevated hcy concentrations. COMT-inhibitors, on the other hand, had no preventive effect on cognitive impairment in PD patients.

ADPD5-1075

EFFICACY AND SAFETY OF OPICAPONE, A NEW COMT-INHIBITOR, IN PD PATIENTS WITH MOTOR-FLUCTUATIONS: PHASE-III, RANDOMIZED, DOUBLE-BLIND, ACTIVE- AND PLACEBO-CONTROLLED, PARALLEL-GROUP STUDY (BIPARK I)

J. Ferreira[1], A. Lees[2], J. Rocha[3], A. Santos[3], N. Lopes[3], T. Nunes[3], P. Soares-da-Silva[3]
[1]Neurological Clinical Research Unit, Instituto de Medicina Molecular, Lisbon, Portugal
[2]Neurology and Neurosurgery, National Hospital for Neurology and Neurosurgery, London, United Kingdom
[3]R&D, BIAL - Portela & Co. S.A., S. Mamede Coronado, Portugal

Aims: Investigate the efficacy, safety and tolerability of 3 different doses (5, 25 and 50mg) of opicapone (OPC) administered once-daily, compared with 200mg entacapone (ENT) and placebo, in patients with PD on levodopa treatment and with motor fluctuations.
Methods: Multinational, multicentre, double-blind (DB), placebo- and active-controlled, parallel-group study. Subjects were randomized for the DB period to placebo (n=121), 5mg-OPC (n=122), 25mg-OPC (n=119), 50mg-OPC (n=116) or 200mg-ENT (n=122). Treatment duration was of 14-15 weeks, where subjects were instructed to keep ON/OFF diaries. The primary efficacy variable was the change from baseline in absolute OFF-time by an analysis of covariance (ANCOVA). Key secondary endpoints were the proportion of responders. Other secondary endpoints include Investigators'/Subjects' Global Assessment of Change (IGAC/SGAC), UPDRS, quality-of-life (PDQ-39, NMSS, PDSS, UPDRS), tolerability and safety (including mMIDI, C-SSRS and clinical laboratory tests) assessments.
Results: The 50mg-OPC group was significantly better than placebo (p=0.0005). The 200mg-ENT group also achieved statistical significance versus placebo (p=0.0141). Significantly more patients receiving either 25 or 50mg-OPC achieved the OFF-time responder endpoint (60.3% [p=0.0464] and 69.6% [p=0.0011], respectively), with both 5mg-OPC and 200mg-ENT not reaching statistical significance compared to placebo. Only patients receiving either 25 or 50-mg OPC reported significant improvements in IGAC and SGAC compared to placebo. The 50mg-OPC tended to be the most efficacious treatment tested, followed by all other active treatments.
Conclusion: Opicapone was safe, well tolerated, and effective in reducing the OFF-time in patients with PD on levodopa treatment and with motor fluctuations.

PHOSPHOLIPIDS AND PD: NEW OPPORTUNITIES FOR THERAPY.

S. Turuspekova[1], A. Seydanova[2], K. Musahmetova[3], A. Muratalieva[4]
[1]of internship and residency in neurology, Kazakh National Medical University, Almaty, Kazakhstan
[2]of neurorehabilitation, City Clinical Hospital #1, Almaty, Kazakhstan
[3]physiotherapy, City Clinical Hospital #1, Almaty, Kazakhstan
[4]physiotherapy, City Clinical Hospital #1, Almaty, Kazakhstan

Objective: to evaluate the effectiveness of treatments of ion-reflex fonoforeza phospholipids hypothalamus in correcting motor and cognitive impairments in patients with PD.
Materials and Methods: 39 patients studied: 25 men and 14 women; age: 63 to 69; disease duration: 8,1±2,2 years; Hoehn and Yahr scale points - 2,4±0,4. In determining motor impairment degree Tinetti scale was used; cognitive disorders – mini-mental state examination (MMSE), scales of Wechsler (WMS, WAIS) and Matisse; life quality - measured by McDowell index. Patients received an intramuscular injection of phospholipids hypothalamus, then after 1.5-2 hours sessions held ion-reflex fonoforeza phospholipids hypothalamus using techniques longitudinal fronto-occipital head galvanization.15 patients treated by protocol composed control group.Results: Motor activity's improvements and decrease in rigidity, tremor and hypokinesia were noted in patients receiving sessions of ion-reflex fonoforeza phospholipids hypothalamus. Patients'static and dynamic balance abilities (the Tinetti test) improved significantly by 25%. McDowell's disability index fell to 36. Neurodynamic and operational functions improved firmly. MMSE cognitive impairment degree showed positive trend with 23,3±1,5 reaching 27,1±1,5; Matisse scale indexes increased to 7,1% ($p < 0.01$). Logical, visual memory, account and thinking tests' results improved. Conclusions: research's dynamic demonstrates the sessions ion-reflex fonoforeza phospholipids hypothalamus using techniques longitudinal fronto-occipital head galvanization is positive impact on motor and cognitive function in patients with Parkinson's disease.

IMPACT OF CURRENT ANTIPSYCHOTIC MEDICATIONS ON COMPARATIVE MORTALITY AND ADVERSE EVENTS IN PEOPLE WITH PD PSYCHOSIS (PDP)

C. Ballard[1], S. Isaacson[2], O. Rascol[3], R. Mills[4], H. Williams[4], B. Coate[4], A. Corbett[1], D. Burn[5]

[1]Wolfson Centre for Age-Related Disorders, King's College, London, United Kingdom
[2]PD and Movement Disorders Center of Boca Raton, Boca Raton FL, USA
[3]Departments of Clinical Pharmacology and Neurosciences, Toulouse University, Toulouse, France
[4], ACADIA Pharmaceuticals Inc., San Diego CA, USA
[5]Institute of Neuroscience, Newcastle University, Newcastle upon Tyne, United Kingdom

Over 50% of people with PD will develop psychosis during the course of their disease. The symptoms of hallucinations and delusions are distressing and challenging for the individuals and their caregivers. PDP is commonly linked to institutionalization and increased risk of mortality. Atypical antipsychotics are frequently prescribed to address PDP despite limited evidence to support their efficacy and concerns about their safety in this generally elderly population. Limitations in the scope and design of published trials prevent a clear interpretation of mortality risk and adverse events, particularly for treatment periods exceeding 6 weeks. A post-hoc analysis was performed on data from 423 participants with PDP in an ongoing multicenter, open-label extension study of pimavanserin. Safety assessments were conducted at two weeks, one, three, six, nine and twelve months, and every six months thereafter, including comprehensive recording of adverse events and mortality. Data were analyzed according to whether participants received a concurrent antipsychotic drug (APD) versus those receiving pimavanserin alone. Participants who received a concurrent APD were significantly more likely to experience SAEs, including cognitive decline and infection. Increases in sedation, cardiovascular and stroke-related events, and thromboembolic events were also observed. In addition, there was a significant increase in mortality with concurrent APD use. These results highlight safety concerns with the use of current antipsychotics in PD, which appear similar to those reported previously in people with AD, and underscore the importance of identifying safer therapies for PDP that provide an effective alternative to current antipsychotic medications.

ADPD5-0265
PARKINSONISM-DEMENTIA
D. Ndoja[1], M. Rakacolli[1]
[1]Service of Neurology, UHC Mother Teresa, Tirana, Albania

28 patients (18 M,10 F) cared for Parkinsonism who presented memory decline evaluated by MMSE (mean 15) and respectively confirmed brain atrophy, aged from 24-76 (mean 58,57) years, were selected.
At age distribution were observed 2 picks of occurrence with 43% (50-60), 39% (60-70), succeed in elderly with 8% (>70 years), and youngest < 30 years of 10%. At social occupation; 36% retired, 10% professionals, 54% workers or unemployed.
Geographically they come from; center 43%, capital 29% and 28% from north and south of Albania equally dispersed.
Their isolated or combined ATCD; 21% vascular, cranial trauma or SRLS 8%, 10% smoking or alcoholics, 4% hepatitis, 43% nothing. Only 14% against 86% showed a familiar history. Disease duration was in 54% about 5 years, 25% of one year, 21% > 10 years. Parkinsonism was 54% hypertonic/akinetic and 46% of tremor form.
Among all 29% showed also spasticitet or 18% psychosis.
At MRI; in 82% brain atrophy in 14% of which,bi-Temporal DA-like atrophy was observed. As to diagnosis; idiopathic or vascular parkinsonism (25%, 21%), DA-like and MSA equally stated with 14%, Levy body disease 11%, CBD, neuroacantocitosis, MELAS and FTD with 4% respectively.
After treatment the half one had unchanged clinical state while others experienced clinical improvement.
Conclusion; parkinsonism patients with clinic of dementia as well were aged mostly between 50-70 years old, and presented more the akinetic/hypertonic form followed by the tremor form. The common diagnosis was the idiopathic and vascular parkinsonism, succeed less by MSA and other neurodegenerative diseases.

MILD COGNITIVE IMPAIRMENT – CORRELATIONS OF IMAGISTIC AND CLINICAL DATA

D. Podea[1], L. Piros[1], G. Ciobanu[1]
[1]Psychiatry, Vasile Goldis Western University of Arad, Arad, Romania

BACKGROUND: Mild cognitive impairment(MCI) is the clinical state between normal cognition and dementia in elderly people which does not interfere notably with activities of daily life; subjects perform more poorly on a variety of cognitive, functional and behavioral measures than normal persons of the same age.

MATERIAL AND METHOD: The study comprises 141 subjects between 60 and 92 years, diagnosed with MCI with Mini Mental State Evaluation (MMSE), clock drawing test (CDT) and computer tomography (CT).

MMSE score between 28-21 points is considered mild cognitive impairment.

RESULTS: The CT imaging showed specific types of cortical and subcortical atrophies. CT multislides was performed with 2.5 mm axial sections of brain and axial and coronary reconstruction with sections at 1mm, presenting accurate diagnosis criteria, highlighting the group studied the following:

-53.1% (75 patients) specific lesions to vascular dementia : moderate atrophy of the temporal lobe, hippocampus atrophy, frontal diffuse ischemia and subcortical hipodense ischemic lesions ;

-12.1% specific changes to Alzheimer's disease, as: obvious atrophy of hippocampus, ipsilaterale enhancement of temporal cone of lateral ventricle, temporal lobes atrophy, diffuse cerebral atrophy (lateral ventricles less extended), widening perimezencefalics cisterns;

-specific pathological changes due to age (34.8%): widening external and internal fluid spaces (lateral ventricles, ventricle III) enlargement of fronto-temporal fluid space, heterodense millimeter images on basal nuclei.

CONCLUSIONS: The study emphasizes the importance of imagistic examination to increase the accuracy of clinical diagnosis allowing early diagnosis of Alzheimer and vascular dementia, in order to recommend specific therapy from the early stages of cognitive dysfunctions.

DIFFUSION TENSOR IMAGING OF IDIOPATHIC NORMAL-PRESSURE HYDROCEPHALUS AND THE CEREBROSPINAL FLUID TAP TEST

K. Kang[1], H. Lee[1], U. Yoon[2]
[1]Dept. of Neurology, Kyungpook National Univsersity School of Medicine, Daegu, Korea
[2]Dept. of Biomedical Engineering,
Catholic University of Daegu College of Health and Medical Science, Daegu, Korea

Objectives: Damaged neural tracts contribute to the symptomatology of idiopathic normal-pressure hydrocephalus (INPH). Diffusion tensor imaging (DTI) is sensitive to microstructural changes in white matter not always detectable with ordinary MRI. We evaluated relationships between DTI parameters and clinical profiles in INPH patients, along with differences in these DTI measures between CSF tap test (CSFTT) responders and non-responders.
Methods: Fifty-four INPH patients (26 CSFTT responders and 28 CSFTT non-responders) constituted the final group for analysis. Fractional anisotropy (FA) and mean diffusivity (MD) were assessed using atlas-based tract mapping methods for 12 different fiber tracts.
Results: CSFTT non-responders, when compared to responders, showed lower FA values in the left anterior thalamic radiation (ATR) and left cingulum–hippocampus (CgH). The associations between clinical symptoms of INPH and DTI measures were most commonly found in the CgH. Higher MD in the CgH correlated with poorer cognitive performance. Higher MD in the right CgH also correlated with gait or motor dysfunction. Lower FA in the right CgH was correlated with urinary disturbance and cognitive impairment. Lower FA values in the corticospinal tract (CST) and right ATR significantly correlated with poorer cognitive performance, and correlated with gait dysfunction. Higher MD in left CST correlated with cognitive impairment.
Conclusions: Our findings may suggest a possibility for considering microstructural changes in white matter in ventriculomegaly patients as potential imaging markers for the prediction of CSFTT responders. We suppose that DTI parameters may help to assess cognitive dysfunction, gait, and motor deterioration in INPH, along with urinary disturbance.

SHAPE CHANGES OF HIPPOCAMPUS IN FRONTOTEMPORAL DEMENTIA AND ALZHEIMER'S DISEASE

J.H. Roh[1], C. Kim[1], E.J. Kim[2], D.L. Na[3], J. Lee[1]
[1]Neurology, Asan Medical Center, Seoul, Korea
[2]Neurology, Pusan National University Hospital, Pusan, Korea
[3]Neurology, Samsung Medical Center, Seoul, Korea

Objectives: To investigated hippocampus shape and cortical thickness patterns in subjects with behavioral variant frontotemporal dementia (bvFTD), progressive non-fluent aphasia (PNFA), and semantic dementia (SD) to understand the clinical implication of hippocampal shape changes.
Methods: From the Clinical Research Center for Dementia of South Korea–FTD Registry, 64 patients who fulfilled the diagnostic criteria by Knopman were recruited. All the participants completed thorough neuropsychological tests and 3-tesla brain MRI. Finally, MR data from 29 bvFTD, 11 PNFA, 24 SD, 17 subjects with normal cognition (NC), and 48 Alzheimer's disease (AD) were analyzed. The analyses were performed using methods previously described by authors. Institutional review board of the Asan Medical Center approved the study protocol.
Results: The hippocampal atrophy patterns were observed in the left hippocampal head (HH) and both hippocampal bodies (HB) in bvFTD, right HH and HB in PNFA, and almost all hippocampi in SD. Compared to bvFTD subjects, SD patients showed significant atrophy in the left HH and HB, which was more prominent than AD patients. Cortical thinning was observed in both frontal and temporal gyri in bvFTD, bilateral superior and middle frontal gyri and left inferior frontal gyrus in PNFA, and bilateral anterior temporal lobes in SD.
Conclusions: In conclusion, shape changes in the hippocampus possibly serve as additional biomarkers to differentiate the FTD subtypes. A relationship between the cortical thickness and the hippocampal shape will further denote the implication of hippocampal shape changes in patients with FTD.

[4]Department of Neurology, Otto-von-Guericke-University Magdeburg, Magdeburg, Germany
[5]Institute of Cognitive Neurology and Dementia Research (IKND),
German Center for Neurodegenerative Diseases (DZNE), Magdeburg, Germany

Objectives
Substantia nigra hyperechogenicity (SN^+) has been proposed as a risk marker for PD, Berg 2006). However, it currently remains unclear how SN^+ relates to dopaminergic function particularly with respect to learning and memory. Recent findings have supported a role for dopamine in human episodic long-term memory consolidation (Chowdhury et al., 2012). Here we investigated whether individuals with SN^+ demonstrate impaired long-term memory for novel events with respect to age-matched controls.

Methods
Eight healthy young (20-25), elderly (SN^-, 65-75) and SN^+ individuals (all groups M:F, 7:1) performed an incidental encoding task using emotional negative and neutral stimuli in which subjects were asked to discriminate between indoor/outdoor stimuli. Ten min and 6 hours after encoding subjects were asked to rate their recognition memory for the stimuli on a 5-point confidence scale.

Results
Healthy young individuals demonstrated a significant improvement in recollection of emotionally negative compared to neutral stimuli at 6 hours post encoding (corrected hit-rate emo vs neu 87.2% ± 2.4% vs 66.9% ± 8.5%, p = 0.03). This bias was not observed in SN^- individuals (emo vs neu 70.6% ± 8.0% vs 60.6% ± 6.1%) owing to a reduction in recollection of emotionally negative stimuli. SN^+ individuals demonstrated comparable recollection of emotionally negative stimuli with age-matched controls yet a significant decline in recollection of neutral stimuli (emo vs neu 72.2% ± 7.8% vs 51.6% ± 9.1%, p = 0.003).

Conclusions
Our preliminary findings suggest that preclinical SN pathology is associated with impaired long-term memory.

DISRUPTED WHITE MATTER INTEGRITY IN PARKINSON'S DISEASE WITH VISUAL HALLUCINATIONS

N. Yao[1], C. Cheung[1], S. Pang[2], R. Chang[2], K. Lau[2], K. Yu[1], H. Mak[3], G. McAlonan[4], S. Ho[2], S. Chua[1]

[1]psychiatry, The University of Hong Kong, Hong Kong, Hong Kong China
[2]Medicine, The University of Hong Kong, Hong Kong, Hong Kong China
[3]Radiology, The University of Hong Kong, Hong Kong, Hong Kong China
[4]IOP, King's College London, London, United Kingdom

Visual hallucinations carry poor prognosis in Parkinson's disease (PD). The integrity of structural connections in this condition has not been examined.

Magnetic resonance imaging was used to evaluate 12 PD patients with visual hallucinations (PDVH), 15 with PD without hallucinations (PDnonVH), and 14 healthy controls (HC). Diffusion tensor imaging (DTI) was used to calculate mean diffusivity (MD) and fractional anisotropy (FA) with tract-based spatial statistics (TBSS).

The PDVH had lower FA in regions coinciding with the left cortico-spinal tract, left superior longitudinal tract, right forceps major and right posterior inferior fronto-occipital fasciculus relative to PDnonVH and HC groups. FA in the right medial inferior fronto-occipital fasciculus and posterior inferior longitudinal fasciculus was however greater in PDVH than other groups. PDVH had lower FA in the right anterior thalamic radiation and right uncinate fasciculus, but higher FA in left uncinate fasciculus, bilateral posterior corpus callosum and bilateral medial inferior fronto-occipital fasciculus compared to HC. PDnonVH and HC had no difference in white matter indices.

In conclusion, PDVH had widespread abnormalities in the microstructure of visual pathways. Alongside degeneration reflected by lowered FA, there might be a potentially aberrant compensatory response signaled by higher FA, and these collectively contribute to visual hallucinations in PD.

[3]Neurology, Policlinico di Monza, Monza (MI), Italy
[4]Neurology, National Neurological Institute C. Mondino, Pavia, Italy
***Objectives**:* We show brain MRI and clinical features (video) of a peculiar and unilateral parkinsonism due to a giant aneurysm with good outcome after neurosurgery, widening the spectrum of conditions causing symptomatic parkinsonism. ***Case report**:* a 40-year-old man came to our attention with a 6-months history of tremor limited to his right arm. The tremor (4 Hz, middle amplitude) was present at rest during emotional activation or during drinking, shaving and writing. Neurological examination disclosed mild rigidity of the right arm and impairment of fine movements. Swing of the right arm was reduced during walking. Brain MRI revealed a left middle cerebral artery bifurcation giant aneurysm with almost complete thrombosis. The lesion resembled a space occupying process with compression on the left basal ganglia (F1). The patient underwent a complete aneurysm excision (F2). After surgery, the patient showed an almost complete clinical recovery indicating a still reversible impairment of nigro-striatal functions. ***Conclusions**:* A pure and strictly unilateral extra-pyramidal syndrome characterized this case suggesting a focal lesion in basal ganglia rather than an idiopathic Parkinson's disease. MRI disclosed an extremely rare cause of symptomatic hemiparkinsonism and allowed an effective treatment.

[6]Department of Cognitive Science, Budapest University of Technology and Economics, Budapest, Hungary

Objectives
Hippocampal dysfunction and alteration of hippocampal anatomy have been reported in several neuropsychiatric diseases. The hippocampus consists of anatomically distinct subfields. There are several data available that describe neuropsychiatric symptoms, focusing on cognitive impairments in systemic lupus erythematosus (SLE). We investigated whether in vivo volumes of hippocampal subfields differ between SLE patients and healthy control volunteers.

Methods
We recruited 18 SLE patients who meet the criteria of American College of Rheumatology 1997 (ACR 1997). Clinical examination and magnetic resonance imaging were performed in patients with SLE (n=18; mean age: 49.4 years (SD=12.0); 100% female) and in an age, gender, and education-matched healthy control group (n=20). We used FreeSurfer and manual segmentation techniques for labeling hippocampal subfields and cortical/subcortical regions in a high-resolution MRI setting at 3T (T1-weighted images with 1.0x1.0x1.0 mm resolution).

Results
SLE was associated with 15.6 % (SD=1.8) (P = 0.01) smaller mean Cornu Ammonis 1 and 3 (CA1/CA3) subfield volumes, whereas other subfields were spared. We found no evidence for smaller caudate nucleus, thalamus, or reduced neocortical volume in patients with SLE as compared with the control individuals. Cortical and subcortical volumes did not correlate with age and education.

Conclusions
Hippocampal subfield volume reductions were found in patients with SLE relative to matched healthy controls. The magnitude of reduction was significant only in CA1/CA3, which may be related to impaired cognition or affective disturbances. Further studies are warranted to elucidate the clinical correlates and pathophysiological mechanism of hippocampal subregion loss in SLE.

MRI IN THE RHINELAND STUDY: A PROTOCOL FOR MAPPING BRAIN STRUCTURE AND FUNCTION IN A PROSPECTIVE COHORT OF 30.000 ADULTS

W. Huijbers[1], E. Pracht[2], D. Brenner[2], R. Stirnberg[2], M. Boland[2], T. Stöcker[2], M. Breteler[1]
[1]Population Health Sciences, German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany
[2]MR Physics, German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany

Introduction: The Rhineland Study is a prospective population study among 30,000 participants aged ≥30 years and investigates the aging human brain and related neurological disorders. This longitudinal study will include quantification of brain structure and function over the adult lifespan, using magnetic resonance imaging (MRI). Therefore, we are developing an advanced MRI protocol that enables state-of-the-art data collection at high-throughput (150-200 adults weekly)**.**

Methods: MRI data will be acquired on 3T Prisma scanners (Siemens, Erlangen), with high performance gradient system and 64 channel head-neck coils. We generally utilize whole-brain 3D sequences with 2D parallel imaging and elliptical k-space coverage. The MRI protocol (>1 hour scan time) is shown in Table 1. The Free Protocol will allow specific data acquisition in subsets of the Rhineland cohort.

Results: Preliminary results indicate that accelerated sequences provide excellent image quality for further analysis. For instance, the MP-RAGE at 0.8 mm yields accurate cortical surface reconstruction, whereas the 3D-FLAIR and 3D-ME-GRE provide detail for white-matter lesions and microbleed detection. The MB-DWI and 3D-EPI provide excellent data to quantify the connectome. Figure 1 depicts a representative single-subject dataset.

Conclusion: It is feasible to obtain high-quality MRI data in limited acquisition time. In-house development of MRI sequences guarantees long-term support. The versatile MRI protocol provides a multitude of quantitative biophysical information of brain tissue. The Rhineland study also includes clinical, lifestyle and neuropsychological exams and collection of biomaterials, which together with this MRI protocol will enable discovery and validation of novel biomarkers for neurodegeneration

Figure	Protocol	Sequence	Res. [mm^3]	Time	Modality / Purpose

METABOLIC PECULIARITIES AND DYSFUNCTION OF THE RESTING STATE NETWORK IN PATIENTS WITH PARKINSON'S DISEASE AND DIFFERENT LEVEL OF COGNITIVE IMPAIRMENT: MRS AND FMRI STUDY

Z. Rozhkova[1], I. Karaban'[2], N. Karasevich[2]
[1]Radiology, Medical Clinic BORIS, Kiev, Ukraine
[2]Extrapyramid Disorders,
Institute of Gerontology of the Academy of Medical Sciences of Ukraine, Kiev, Ukraine

Purpose: We study integrity of RS DMN connectivity and local metabolic state in patients with PD and different level of CI.
Methods: Three groups of PD-patients (57-73y) are studied with 1.5T SIGNA EXCITE (GE). The 1st group (DPDG)-13 PD-patients with dementia. The 2nd group (CIPDG)-15 PD-patients with mild CI. The 3rd group (NPDG)-12 PD-patients with normal cognitive function. EPI BOLD scans were acquired using pulse sequence:TR/TE=3000/71ms. ICA analysis was used to identify 20 networks of RS-activity. Spectra are in anterior (APCG) and in posterior portion of cingulate gyrus (PPCG):TR/TE=1500/144ms.
Results: The analysis of the DMN revealed a gradual reduction in functional connectivity for the patients of DPDG in the cuneus, precuneus and PPCG, which correlate with severity of CI. RSNs involving areas of the cerebellum and frontal lobe, that could be interpreted as a potential compensatory mechanism to functional disorders caused by the CI. In NPDG connections between the APCG and PPCG, and inferior parietal gyrus bilaterally were found, activation of APCG decreased, but connectivity patterns persisted. In CIPDG activated clusters were found precuneally, and in PPCG, however no connection to the parietal lobe or APCG. In APCG the NAA/Cr in DPDG, CIPDG, NPDG:(1.68+-0.02),(2.04+-0.03),(2.32+-0.05), Cho/Cr:(0.84+-0.02),(0.81+-0.05),(0.53+-0.03). In PPCG NAA/Cr in DPDG, CIPDG, NPDG:(1.14+-0.12),(1.81+-0.02),(1.98+-0.04), Cho/Cr:(0.96+-0.02),(0.77+-0.03),(0.68+-0.03).Progressive decreasing NAA/Cr in PPCG and increasing of Cho/Cr for the patient of NPDG, CIPDG, DPDG were found.
Conclusions:Metabolic alterations in PPCG are indicators of neuronal loss and dysfunction, and may be marker of CI in PD-patients. fMRI, MRS give new approach for understanding pathophysiological changes in PD-patients associated with CI.

HIPPOCAMPAL RESTING-STATE CONNECTIVITY CHANGES IN EARLY ONSET VERSUS LATE ONSET ALZHEIMER'S DISEASE

K.H. Park[1], K.W. Park[2], Y. Noh[3], E.J. Choi[4], Y.D. Son[4]
[1]Neurology, Gachon University Gil Medical center, Incheon, Korea
[2]Neurology, Dong-a University Collage of Medicine, Busan, Korea
[3]Neurology, Gachon University Gil Medical Center, Incheon, Korea
[4]Neuroscience Research Institite, Gachon University, Incheon, Korea

Objectives
Different clinical manifestations have been reported according to early onset Alzheimer's disease (EOAD) and late onset Alzheimer's disease (LOAD). Furthermore, the hippocampal atrophy is frequently not seen in mild cases of EOAD. In this study, we investigated the changes in functional connectivity of the hippocampus using resting state functional MRI (fMRI) between EOAD and LOAD to estimate the clinical usefulness of hippocampal connectivity in EOAD with relatively sparing hippocampal structure.
Methods
Total 30 mild AD patients (≤ CDR 1) and 31 age matched control subjects were recruited. According to age onset, patients were further categorized by EOAD (<65 years old) and LOAD (>70 years old). For the resting fMRI, 2D echo planar images were acquired from 3.0T MRI and Data Processing Assistant for Resting-State fMRI (DPARSF, V2.3) was used for analysis.
Results
The left inferior parietal cortex of LOAD was significantly ($p<0.001$) reduced in the functional connectivity with the hippocampus compared to the EOAD. Bilateral middle orbitofrontal, inferior orbitofrontal, and right superior temporal cortex as well as left inferior parietal cortex showed relatively reduced connectivity. On the contrary, left hippocampus in EOAD showed more reduced connectivity with left middle frontal, right superior parietal, left inferior frontal cortex, and bilateral middle cingulate gyrus than LOAD.
Conclusions
EOAD revealed more connectivity reduction of hippocampus with frontal and parietal areas compared with LOAD. This result is consistent with differences of clinical symptoms of previous reports. Therefore, hippocampal connectivity may consider one of early diagnostic markers in EOAD with relatively mild hippocampal atrophy.

COMBINED USE OF VOXEL-BASED MORPHOMETRY AND FUNCTIONAL MRI IN PATIENTS WITH MEMORY IMPAIRMENT AFTER TRAUMATIC BRAIN INJURY.

A. Sokolov[1], S. Vorobyev[2], A. Efimtcev[1], V. Lobzin[2], V. Fokin[1]
[1]Radiology, Military Medical Academy, Saint-Petersburg, Russia
[2]Neurology, Military Medical Academy, Saint-Petersburg, Russia

Objectives. The purpose of this study was to evaluate brain activation by visual memory task in patients with posttraumatic memory impairment and to determine correlation between memory impairment and atrophy of memory specific brain regions.
Methods. To investigate the organization of memory and localize cortical areas activated by visual memory task we used functional MRI and to evaluate brain atrophy we used voxel-based morphometry (VBM). We studied 25 patients (age 29,6±8,9 years), 22 matched by age volunteers as a control group. For test stimuli we used series of 12 not related images for "baseline" and 12 images with for "active". 6 images in “active” period have been already presented in “baseline”. Stimuli were presented 3 times with reduction of repeated images to 4 and 2. For VBM and functional data post-processing we used SPM8.
Results. FMRI showed less activation in hippocampal formation and parahippocampal gyri comparing to controls group. The study also showed reduced activation in posterior cingulate gyrus. VBM showed general atrophy of grey matter, especially of both temporal lobes (fusiform and parahippocampal gyri), frontal lobes (superior frontal gyri), parietal lobes and cingulate gyrus. The most significant changes were found in mediobasal temporal lobe (up to 3.6 cm^3 at $p<0,01$) and thalamuses (up to 4.5 cm^3 at $p=0,01$).
Conclusions. Combined application of fMRI and VBM allows to assess brain atrophy along with functional component of memory impairment and can help to detect effects of traumatic brain injury before they may be revealed by means of conventional MRI study.

EMOTIONAL PROCESSING DYSFUNCTIONS IN MILD COGNITIVE IMPAIRMENT ARE THE RESULT OF LACKING NEURONAL INHIBITION

L. Michels[1], S. Kollias[2], A. Gietl[1], F. Riese[1], C. Hock[1]
[1]Division of Psychiatry Research and Psychogeriatric Medicine, University of Zurich, Zurich, Switzerland
[2]Institute of Neuroradiology, University Hospital Zurich, Zurich, Switzerland

Objectives
The recognition of emotional stimuli depends on the neuronal interplay of brain regions involved in memory- and emotional processing. Individuals with mild cognitive impairment (MCI) have problems to judge about the emotional content of images. We examined whether this is the result of functional impairments in the memory- or emotional system.
Methods
In 21 participants (10 MCI), we applied functional magnetic resonance imaging (fMRI) during a sustained emotional attention task. Participants should rate the valence of images (i.e. neutral or negative). We also recorded GABA-sensitive MR spectroscopy in the posterior cingulate cortex. Significant fMRI group differences are reported at $p < 0.001$ (uncorrected). Interactions between fMRI and GABA will be assessed by Spearman's correlations ($p < 0.01$).
Results
Accuracy was comparable between groups ($p > 0.1$). In participants with MCI, the contrast "negative - neutral stimuli" revealed lower fMRI signal responses in the hippocampus but larger responses posterior cingulate cortex relative to controls. In this region, GABA negatively correlated with the fMRI signal strength for negative stimuli ($p < 0.01$, $r^2 = 0.75$).
Conclusions
Our results suggest: First, participants with MCI need to engage a brain region (the posterior cingulate cortex) classically associated with resting-state activity. Second, the lack of hippocampal activity indicates a disturbed memory processing in MCI. Third, the observed coupling between lower levels of GABA and higher fMRI signal responses indicates that the control of (negative) emotional stimuli depends on local inhibitory control.

BRAIN PERFUSION SPECTCAN DIFFERENTIATE CLINICAL SUBTYPES OF PD

Y. Chung[1], I. Song[2], K. Lee[2], Y. Kim[3], J. Park[2]
[1]Nuclear medicine, The catholic University of Korea, Seoul, Korea
[2]Neurology, The catholic University of Korea, Seoul, Korea
[3]Neurology, College of Medicine Konyang University, Daejeon, Korea

Backgrounds: The clinical heterogeneity of Parkinson's disease (PD) is well recognized. It is possible to distinguish two main clinical subgroups, a tremor dominant PD (TP) and non-tremor dominant PD (NTP). However studies compared the regional cerebral blood flow between subtypes of PD had rarely been performed yet. Therefore, we conducted this study to investigate difference of perfusion SPECT in clinical subtypes of PD (TP and NTP) using SPM program. **Methods**: We recruited 43 patients with PD (21 TP and 22 NTP). All patients with PD underwent brain perfusion SPECT and evaluated motor severity by using the Hoehn and Yahr stage and Part III of the Unified Parkinson's Disease Rating Scale (UPDRS). We also compared tremor and non-tremor symptoms with motor phenotype scores between two subtypes of PD. **Results**: Brain perfusion SPECT showed significant hypoperfusion in TP compared with NTP in the left occipital lobe and middle occipital gyrus, left frontal lobe and superior frontal gyrus, cerebellar hemisphere, left lentiform nucleus. On the other hand, brain perfusion SPECT of NTP compared with TP showed hypoperfusion in right parietal lobe and precuneus, left temporal lobe and inferior temporal gyrus, both frontal lobe and inferior frontal gyrus. **Conclusion**: The present study indicates that pathophysiology of TP compared to NTP has more closely association with neuronal circuits including cerebellar pathway, such as CTC circuit. Therefore, we cautiously assert that neuronal systems other than the nigrostriatal dopaminergic system are likely involved in the generation of tremor in PD.

[6]Neurology, Skåne University Hospital, Lund, Sweden

Objectives
To identify disease-specific changes of the thalamus, the basal ganglia, pons and midbrain in progressive supranuclear palsy (PSP) using diffusion tensor imaging, resting state fMRI (rs-fMRI) and volumetric analysis.
Material and methods
Two cohorts were used. In cohort A, MRI diffusion and volumetric data were acquired in controls (n=21), PSP (n=27), Parkinson's disease (PD) and multiple-system atrophy (MSA-P) (n=11). In cohort B, comprising 30 controls and 8 patients with PSP, rs-fMRI data and clinical measures of motor performance and balance were available in addition to MRI diffusion and volumetric data. ROI-based analysis and tractography of diffusion data and seed-based analysis of rs-fMRI data were performed.
Results
In cohort A, we observed changes in mean diffusivity (MD) in the thalamus, red nucleus, superior cerebellar peduncle and midbrain in patients with PSP; most of these, including thalamic abnormalities, were not found in patients with PD or MSA-P. These changes were validated in cohort B. Further, MD of the dentatorubrothalamic tract was increased in PSP patients from both cohorts. Increased MD in the thalamus and along the dentatorubrothalamic tract correlated with impaired motor function or balance in patients with PSP. Volumetric analysis showed reduced thalamic volumes in PSP. The connectivity between the thalamus and anterior cingulate gyrus, caudate nucleus as well as frontal regions was reduced in PSP compared to controls.
Conclusions
Patients with PSP, but not PD or MSA-P, exhibit signs of structural and functional abnormalities in thalamus and in the dentatorubrothalamic tract. These changes might be associated with impaired balance.

QUANTITATIVE EEG AND MEDIAL TEMPORAL LOBE ATROPHY IN ALZHEIMER'S DEMENTIA

J. Ahn[1], J. Heo[1], H. Kim[2]
[1]Neurology, Seoul Medical Center, Seoul, Korea
[2]Neurology, Hanyang University Hospital, Seoul, Korea

The electroencephalogram (EEG) abnormalities in Alzheimer's disease (AD) have been widely reported and medial temporal lobe atrophy (MTLA) is one of the hallmarks in early stage of AD. We aimed to assess the relationship between EEG abnormalities and MTLA, and its clinical validity. A total of 18 patients with AD were recruited (the mean age: 77.83 years). Baseline EEGs were analyzed with quantitative spectral analysis. MTLA was assessed by a T1-axial visual rating scale. In relative power spectrum analysis according to the right MTLA severity, the power of theta waves in C4, T4, F4, F8, and T5 increased significantly and the power of beta waves in T6, C4, T4, F8, T5, P3, T3, F7 decreased significantly in severe atrophy group. In relative power spectrum analysis according to the left MTLA severity, the power of theta waves in T3 increased significantly and that of beta waves in P4, T6, C4, F4, F8, T5, P3, C3, T3, F3, F7 decreased significantly in severe atrophy group. The severe MTLA group, regardless of laterality, showed more severe quantitative EEG alterations. These results suggest that quantitative EEG abnormalities are correlated with the MTLA, which may play a important role in AD process.

ADPD5-1782
VALIDATION OF GAIT ANALYSIS USING THE SINGLE-POINT TRIAXIAL ACCELEROMETRY.

K. Kim[1], S.J. Byun[2]
[1]Neuropsychiatry Department, Seoul Naitonal University Bundang Hospital, Seongnam, Korea
[2]Neuropsychiatry Department, Seoul Naitonal University Hospital, Seoul, Korea

Objectives
We investigate the validity of the single-point triaxial accelerometry in gait analysis.
Methods
82 healthy elderly (48 men and 34 women, age : 68.9 ± 6.5) participants were recruited. The triaxial accelerometer was attached on L3 spine level as they walked. Subjects were given instructions to stand up from a chair, walk 20m at their comfortable speeds, turn around, walk back and sit down. *GAITRite*™ walkway was placed on the middle of walking distance. This protocol was carried out 3 times including one practice trial. MATLAB R2014a was used for signal processing and gait parameters estimating. Gait analysis was done using acceleration scores of each axis (mediolateral,vertical,anteroposterior) independently. The level of agreement with *GAITRite*™ was determined using intraclass correlation coefficients [ICC(3,1)] via SPSS 19.
Results
Table 1. The level of agreement between triaxial accelerometer and GAITRite™ (n=82). $\mu \pm \sigma$ = mean ± standard deviation.

Parameter	GAITRite® (μ±σ)	Intraclass Correlation (3,1)			Accelerometor (μ±σ)		
		Mediolateral	Vertical	Anteroposterior	Mediolateral	Vertical	Anteroposterior
Cadence (steps/min)	120.21±8.05	0.96 [0.93,0.97]	0.94 [0.90,0.96]	0.95 [0.93,0.97]	119.22±8.40	119.27±7.73	119.35±8.41
Velocity (m/s)	1.27±0.14		0.91 [0.86,0.94]			1.29±0.16	
Step time (s)	0.50±0.03	0.96 [9.32,0.97]	0.94 [0.91,0.96]	0.96 [0.94,0.97]	0.51±0.04	0.51±0.03	0.51±0.04
Stride time(s)	1.00±0.07	0.95 [0.92,0.97]	0.96 [0.94,0.97]	0.95 [0.93,0.97]	1.01±0.07	1.01±0.07	1.01±0.07
Step length (cm)	63.23±5.29	0.91 [0.86,0.94]	0.88 [0.82,0.92]	0.92 [0.88,0.95]	64.88±5.98	63.77±5.43	64.81±5.92
Stride length (cm)	126.64±10.59	0.90 [0.85,0.94]	0.91 [0.87,0.94]	0.91 [0.87,0.94]	129.97±12.00	129.51±11.90	129.74±11.88

Acceleration-based gait analysis showed excellent agreement with GAITRite™ over three axes; Cadence (ICC=0.94~0.96), Velocity (ICC=0.91), Step time (ICC=0.94~0.96), Step length (ICC=0.88~0.92), Stride time (ICC=0.95~0.96), Stride length (ICC=0.90~0.91). Right-left foot discrimination could be done from mediolateral acceleration data. Gait analysis using mediolateral and anteroposterior acceleration data showed higher agreement in step time and step length than vertical one.
Conclusions
Triaxial accelerometer based gait analysis gave accurate measurements over each of the three axes in healthy elderly subjects. Using tri-directional acceleration data simultaneously would be more powerful for analyzing gait.

ADPD5-1853
IMPACTS OF AGE AND GENDER ON GAIT IN THE ELDERLY.
S.J. Byun[1], K.W. Kim[2]
[1]Neuropsychiatry Department, Seoul national university hospital, Seoul, Korea
[2]Neuropsychiatry Department, Seoul national university Bundang hospital, Seongnam, Korea

Objectives
To explore the impact of age and gender on gait parameters derived from triaxial accelerometer in healthy seniors.
Methods
82 healthy elderly participants were recruited. The triaxial accelerometer was attached on L3 spine level. Subjects underwent three trials of 40m walking. MATLAB R2014a was used for signal processing and gait parameters estimating. Within-subject ensemble-average patterns were generated from at least 40 strides for each subject. Position of specific gait events and magnitude of acceleration at those events were determined from the pattern.
Results
There was no difference in the average ages of the women and men. Height, leg length and weight were bigger in men while those were not different by age. Step length, proportion of swing phase and single support phase was larger in men. (after correction of height, leg length and age). Walking speed and step length were smaller in older group. That decrease of walking speed was contributed by shorter step length, while the cadence was maintained. Subjects among younger age group had bigger acceleration scores at several gait events. Mediolateral acceleration showed definite difference by sex.

Conclusions
Age was related to changes in velocity and step length. Gender affected the proportion of gait phases. Gender impact on acceleration was observed most dramatically on mediolateral axis while age impact was biggest on vertical and anteroposterior axis.

VALIDATION OF GAIT ANALYSIS USING THE SINGLE-POINT TRIAXIAL ACCELEROMETRY.
K.W. Kim[1], S.J. Byun[2]
[1]Neuropsychiatry Department, Seoul Naitonal University Bundang Hospital, Seongnam, Korea
[2]Neuropsychiatry Department, Seoul Naitonal University Hospital, Seoul, Korea
Objectives
We investigated the validity of the single-point triaxial accelerometry in gait analysis.
Methods
82 healthy elderly (48 men and 34 women, age : 68.9 ± 6.5) participants were recruited. The triaxial accelerometer was attached on L3 spine level as they walked. Subjects were given instructions to stand up from a chair, walk 20m at their comfortable speeds, turn around, walk back and sit down. *GAITRite*™ walkway, which was employed as a gold standard, was placed on the middle of walking distance. This protocol was carried out 3 times including one practice trial. MATLAB R2014a was used for signal processing and gait parameters estimating. Gait analysis was done using acceleration scores of each axis (mediolateral,vertical,anteroposterior) independently. The level of agreement with *GAITRite*™ was determined using intraclass correlation coefficients [ICC(3,1)] via SPSS 19.
Results

Acceleration-based gait analysis showed excellent agreement with GAITRite™ over three axes; cadence (ICC=0.94~0.96), velocity (ICC=0.91), step time (ICC=0.94~0.96), step length (ICC=0.88~0.92), stride time (ICC=0.95~0.96), and stride length (ICC=0.90~0.91). Right-left foot discrimination could be done from mediolateral acceleration data. Gait analysis using mediolateral and anteroposterior acceleration data showed higher agreement in step time and step length than vertical one.
Conclusions
Triaxial accelerometer may be a cost-effective and convenient alternative in gait analysis to the gait analyzers using pressure or video sensors.

Table 1. The level of agreement between triaxial accelerometer and GAITRite™ (n=82). $\mu \pm \varepsilon$ = mean ± standard deviation.

ADPD5-1912
EVALUATION OF BIOMARKERS TROPONIN-I AND CK-MB IN SERUM OF MYOCARDIAL INFARCTION PATIENTS

M. Tazeem[1]
[1]*Biochemistry, institute of agriculture sciences, Lahore, Pakistan*

Abstract—Myocardial infarction (MI), commonly known as a heart attack, results from the interruption of blood supply to a part of the heart, causing heart cells to die. The most often used blood markers for myocardial infarction are the creatine kinase-MB (CK-MB) fraction and the troponin levels. Troponin is a highly sensitive and specific marker of myocardial Infarction. Complete study was designed by drew sample of 30 patients and compare them with 30 normal individuals age and gender wise respectively.
Results of complete study shows that significantly increased levels of cardiac biomarkers were found in age of 30-60 & 60-80 in cardiac patients as compare to normal one of same age group. The results of this study also show that levels of these biomarkers also indicate variation gender wise. The level of both biomarkers increases in female patients as compared to male patients.

Table I:

		Cardiac patients			Normal individuals			P values
Biomarkers	Age (years)	Mean ±SD	Median	Range	Mean± SD	Median	Range	
CK- MB	30-60	39.28±16.81	34.5	53	10.30±4.43	10	14	0.011
	60-80	44.13±29.75	31	114	14.85±5.97	13	17	0.024
Troponin – I	30-60	8.24±11.99	3.52	37.91	0.13±0.10	0.11	0.29	0.000
	60-80	9.34±14.89	2.39	49.59	0.18±0.11	0.18	0.34	0.001

Table II:

		Cardiac patients			Normal individuals			P values
Biomarkers	Gender	Mean ±SD	Median	Range	Mean ± SD	Median	Range	
CK- MB	Male	36.24±13	31	43	13.07±5.50	11	17	0.031
	Female	47.92±32.38	35	114	11.47±5.68	10	19	0.023
Troponin – I	Male	5.70±9.27	2.36	34.5	0.12±0.10	0.08	0.31	0.041
	Female	12.27±16.69	4.01	49.58	0.18±0.10	0.19	0.33	0.030

ADPD5-2055

DOES THE RIGHT INFERIOR PARIETAL LOBULE CORRELATE WITH TASK-UNRELATED THOUGHTS? : A TRANSCRANIAL DIRECT CURRENT STIMULATION STUDY

M. Nomura[1], *S. Kajimura*[1]
[1]*Graduate School of Education, Kyoto University, Kyoto, Japan*

Background: Task-unrelated thought (TUT) is associated with various impairments and excessive TUTs or rumination are reported in both normal and pathological conditions such as attention deficit/hyperactivity disorder (ADHD), alzheimer's desease, and mild cognitive impairment. Although TUTs have been associated with activity in the right inferior parietal lobule (IPL), which is a core region of the default mode network (DMN), the causal relationship remains unclear.
Methods: We investigated the relationship between the right IPL and TUT by applying transcranial direct current stimulation (tDCS), which efficacy was proved in psychiatric diseases such as depression, to the right IPL/left supraorbital forehead prior to a perceptually demanding flanker task, and TUTs during the task were compared among different tDCS conditions.
Results: Compared to the sham condition, the TUT index was increased and decreased by cathodal and anodal tDCS, respectively. The observed correlation of the TUT index with task performance supported the validity of the index. Moreover, anodal and cathodal stimulation induced the flanker effect (i.e., response delay caused by peripheral conflicting stimuli) in a more perceptually demanding condition, confirming the stimulation effect, and reduced it in a less perceptually demanding condition. These results support our hypothesis that tDCS to the right IPL modulates TUT frequency in a following attention-demanding flanker task, indicating that the right IPL plays causal role in regulating TUTs.
Conclusions: Our findings contribute to understanding the neural underpinnings of TUT and demonstrate that tDCS is a non-invasive way to modulate TUT occurrence that could be an efficient intervention in MCI and alzheimer's desease.

[6], Austin Health, Heidelberg, Australia
[7]Psychology, Macquarie University, Sydney, Australia
[8]Psychology, University of Melbourne, Melbourne, Australia

Objectives: Typical aging is usually accompanied by memory and executive function declines. Previous research has identified a group of 'super-agers" (SA) that retain cognitive abilities comparable to peers 20-30 years younger. In SAs, greater whole-brain cortical thickness and volume have been reported compared with typical-agers (TA). However, longitudinal data is lacking. This study evaluated baseline and longitudinal brain morphology trajectories in these groups.
Methods: Cognitively healthy (based on Clinical Dementia Rating/MMSE) participants (mean age = 71.08, SD= 6.28) were identified from the Australian Imaging Biomarker and Lifestyle (AIBL) study. Cognitive testing and brain Magnetic Resonance Imaging were completed every 18 months for six years. SAs (n=15) scored at/above normative mean memory and executive scores for individuals aged 30-44. Conversely, TAs (n=14) scored in the average range for same-aged peers. Groups were similar in age, education, gender, and *APOE* status (*p*s > 0.30).
Results: A mixed-model 2 (Group) x 5 (time) ANOVA revealed a group x time interaction for overall cortical thickness ($p < 0.05$), whereby groups did not differ at the first three time points, but SAs had greater cortical thickness at 54 and 72 months (*p*s < 0.05) compared to TAs. No differences in volume were found.
Conclusions: SAs and TAs displayed similar cortical thickness at baseline, but differing trajectories. The attenuated cortical thinning seen in SA could be a morphological effect of compensatory cognitive activity. This may involve preferential allocation of cognitive resources to monitoring and control, with subsequent implications for differential thickness in related neural regions.

[5]Department of Radiology, The Royal Melbourne Hospital, Melbourne, Australia
[6]Ageing, The Australian Healthy Ageing Organisation, Melbourne, Australia
[7]Womens Health, Womens Healthy Ageing Project, Melbourne, Australia

Background: It is estimated that targeting modifiable risk factors has the potential to prevent millions of cases of dementia worldwide [1] but this analysis assumes causation. To date no consensus exists on what the modifiable risk factors are for Alzheimer's Disease or when to target [2]. Few studies have longitudinal data stretching over multiple decades which assess all of these risks to determine the optimum targets and timing for intervention to improve cognition in ageing. In this paper we examine the timing and exposure to predictive factors on verbal memory performance in late life.
Methods: 389 participants had complete neuropsychiatric assessment and clinical information, physical measures and biomarkers collected over at least 2 time-points in the Women's Healthy Ageing Project. Mixed Linear models were conducted to assess the significance of main and interaction effects of risk factors on later life verbal memory. We explore the influence of latent, contemporaneous and cumulative exposures.
Results: Age and education were associated with baseline memory testing. Over the 20 years of study follow-up cumulative mid to late life physical activity had the strongest effect on later life memory, with cumulative hypertension and suboptimal HDL being the next most likely contributors to poor memory in later life.
Conclusion: Earlier modification appears ideal for disease prevention, with intervention after 65 missing two decades of significant cumulative risk. Further work will determine if irreversible neuropathological changes are associated with this risk exposure.

REVERSIBLE METABOLIC ENCEPHALOPATHY ASSOCIATED WITH FOLATE DEFICIENCY AFTER SELF STARVATION FOR DIET
W.T. Yoon[1]
[1]*Neurology, Kangbuk Samsung Hospital Sungkyunkwan University School of Medicine, Seoul, Korea*

Background: Folate is essential for the formation of biogenic amines and pterins in the central nervous system. Folate deficiency may lead to various neurological symptoms and disorders, including cognitive impairment, dementia, depression and movement disorders. Low folate and raised homocysteine levels are risk factors for cardiovascular disease and dementia. But, reversible metabolic encephalopathy associated with folate deficiency was rarely reported and folate deficiency after self starvation was not reported.
Case : A 43-year-old female presented with dizziness and tilting tendency. She was poor oral intake and had fasted intermittently for diet. Her neurological examinations revealed not only abulic symptoms diminished the number of words, but also recently aggravated memory impairment. Brain MRI demonstrated asymmetric and bilateral hyperintense lesions in the both corona radiata, lentiform nuclei, thalamus, midbrain and pons on T2, FLAIR and DWI. Laboratory blood test showed normal range of thyroid function, thiamine (95.9nmol/L), vitamine B12 (682.31pg/mL) except Folic acid (2.82ng/mL). Further evaluation revealed increased homocysteine (10.3umol/L) and abnormal activity of methylenetetrahydrofolate reductase (MTHFR) (60% of normal activity). Her neurological symptoms and the abnormalities in the brain MRI showed rapid improvement after administration of folic acid.
Conclusions: To our knowledge, this is the first case report of reversible metabolic encephalopathy associated with folate deficiency after self starvation for diet. As like this case, if there are neurological symptoms with folate deficiency after self starvation or diet, it should be considered diagnosis of metabolic encephalopathy.

BILATERAL STRIATAL NECROSIS IN A CHINESE FAMILY, A NEW TYPE?

H. Bi[1]

[1]*neurology department, Beijing Friendship Hospital, Beijing, China*

Objective

To report the clinical characteristics, gene mutation of bilateral striatal necrosis in a Chinese family.

Material and Methods

A family with BSN in the remote northwest mountain areas was collected. The proband was a 20 year old woman with dystonia, the elder and younger sister had the similar symptoms(Figure 1). The head MRI was performed for two patients and CT for one patient, what's more, muscle biopsy was performed for the proband. The NUP62,SLC19A3,SLC25A19,PANK2 gene and mitochondrial gene were examined.

Results

Three patients manifested generalized dystonia and the MRI or CT image showed bilateral striatal necrosis(Figure 2). There were no evident pathologic findings in the skeletal muscle. In the NUP62 gene, we found a cDNA337G-A heterozygous mutation(pG113S mutation). The same mutation was found in the other two patients, the normal sister, the father and the grandmother. The other genes(PANK2,SLC25A19,SLC19A3 and mitochondrial gene) were normal.

Conclusion

The clinical features of BSN in this family were summarized. The correlation between BSN and some known genes was ruled out. We deduce that the disease may be a new type and further study need to be done.

HMGCR IS A GENETIC MODIFIER FOR RISK, AGE OF ONSET AND MCI CONVERSION TO ALZHEIMER'S DISEASE IN A THREE COHORTS STUDY.

D. Dea[1], V. Leduc[1], L. De Beaumont[1], L. Theroux[1], P. Aisen[2], R.C. Petersen[3], R. Dufour[1], J. Poirier[1]
[1]Neuroscience, Douglas Mental Health University institute, Montreal, Canada
[2]Department of Neurosciences, University of California San Diego, San Diego, USA
[3]Alzheimer's Disease Research Center, Mayo Clinic College of Medicine, Rochester, USA

Several retrospective epidemiological studies report that utilization of 3-hydroxy-3-methylglutaryl-CoA reductase (HMGCR) inhibitors called statins at mid-life can reduce the risk of developing sporadic Alzheimer's disease (AD) by as much as 70%. Conversely, administration of these inhibitors in clinically diagnosed subjects with AD confers little or no benefits over time. Here, we investigated the association between AD and *HMGCR* rs3846662, a polymorphism known to be involved in regulation of *HMGCR* exon 13 skipping, in a founder population and in two distinct mixed North American populations of converting mild cognitively impaired (MCI) subjects [ADCS and ADNI cohorts]. Targeting more specifically women, the G allele negative (G-) AD subjects exhibit delayed age of onset of AD [***P* = 0.017**] and significantly reduced risk of AD [**O.R.: 0.521; *P* = 0.0028**], matching the effect size reported by the *APOE2* variant. Stratification for *APOE4* in a large sample of MCI patients from the ADCS cohort revealed a significant protective effect of G negative carriers on AD conversion three years after MCI diagnosis [**O.R.: 0.554; *P* = 0.041**]. Conversion rate among *APOE4* carriers with the *HMGCR*'s G negative allele was markedly reduced [**from 76% to 26.97%**] to levels similar to *APOE4* non-carriers [27.14%], which strongly indicate protection. Conversion data from the independent ADNI cohort also showed significantly reduced MCI or AD conversion among *APOE4* carriers with the protective A allele [***P* = 0.005**]. In conclusion, *HMGCR* rs3846662 act as potent genetic modifier for AD risk, age of onset and conversion.

[2]QUANTITATIVE AND FUNCTIONAL NEURORADIOLOGY RESEARCH UNIT DEPAR TMENT OF EXPERIMENTAL AND CLINICAL BIOMEDICAL SCIENCES, University of Florence, Florence, Italy
[3]DEPARTMENT OF MOLECULAR GENETICS, VIB, ANTWERP, Belgiu

Objectives: A genotype-phenotype correlation in a patient with late-onset Amyotrophic lateral sclerosis (ALS) with dementia carrying the *C9orf72* repeat expansion and the exon 1 (c. 47C>T, p. A16V) mutation in the sequestosome 1 (*SQSTM1)* gene [1].

Methods: DNA alteration was sequenced by ABI PRISM 310 sequencer. Genetic testing for repeats expansions in *C9orf72* gene was performed with microsatellite analysis on ABI 3730 DNA Analyzer

Results: Initially, the patient showed a progressive cognitive and behavioral impairment at 71 years. Memory difficulties, language disturbances and severe anxiety and agitation were described. After one year, he became aware of weakness of two fingers of the right hand. A first Electromyography (EMG) examination directed towards a possible carpal tunnel syndrome, but a second EMG revealed signs of motoneuron disease and he was diagnosed as ALS with spinal onset.

Brain magnetic resonance images showed moderate atrophy of the temporal structures (temporal lobes, hippocampus) suggesting Alzheimer's disease (AD) features.

The patient died of head injury from an accidental fall at age 74.

Conclusion: Combining clinical and genetic data, our findings suggest that the co-existence of *C9orf72* and SQSTM1 mutations may be implicated in the pathogenesis of AD/ALS unusual phenotype.

TARGETED EXOME CAPTURE AND SEQUENCING IDENTIFIES NOVEL SPG 11 MUTATION IN HEREDITARY SPASTIC PARAPLEGIA WITH THIN CORPUS CALLOSUM IN A CHINESE FAMILY

X. Tian[1], M. Wang[1], K. Zhang[2], X. Zhang[1]
[1]Department of Neurology, Xuan Wu Hospital Capital Medical University, Beijing, China
[2]Department of Radiology, Xuan Wu Hospital Capital Medical University, Beijing, China

Introduction: Hereditary spastic paraplegia (HSP) is a neurodegenerative disease characterized by progressive weakness and spasticity of the lower extremities, in complicated forms with additional neurological signs.

Material and methods: Nine subjects from the family were examined through detailed clinical evaluations, physical examinations and genetic tests. Targeted exome capture technology was utilized in identifying gene mutation.

Results: A novel compound heterozygous mutations in the *SPG11* gene were identified in this family, consisting of c.4001_4002insATAAC and c.4057C>G.

Conclusion: Our findings broaden the spectrum of *SPG11* mutations causing HSP and the phenotypic spectrum of the disease in Chinese patients. The targeted exome capture technology is an efficient method for molecular diagnosis in HSP patients.

EVALUATION THE RELATIONSHIP OF EDUCATION LEVEL AND COGNITIVE IMPAIRMENT WITH MOCA TEST

E. Yancar Demir[1], T. Özcan[2]
[1]Psychiatry, Ordu University School of Medicine, Ordu, Turkey
[2]Neurology, Ordu University School of Medicine, Ordu, Turkey

Objective:Mild cognitive impairment (MCI) is defined as “A cognitive decline greater than that expected for an individual’s age and education level but that does not interfere notably with activities of daily life.The Montreal Cognitive Assessment is a screening test for MCI.
Methods:We investigated the performance of MoCA in detecting MCI among elderly persons, a majority of whom have low level of education. Educational level was divided into three categories: group 1: Less than primary (<5 years) group 2: Primary (5 years), group 3: More than primary (more than 5 years). We evaluated effect of education in theMoCA scores and compared their test performance among group 1, 2 and 3.
Results:A total of 50 patients with a MCI (mean age 70.74±7.87, men) met the inclusion criteria.There was no differences by education in the total scores and the subscores for visuospatial/executive function, naming, attention, abstraction, delayed recall. Language was the only domain that showed significant differences between groups. In post hoc anlaysis, differences were found between group 1 and 3, and group 1 and 2. Group 1 had significantly lower scores for language.Repeat subscore of language was significantly lower in group 1 than group 2. In fluency, there were significant differences between group 2 and 3, and group 1 and 3.
Conclusion: Our results emphasized the need to adapt this test in only language section, thus it can be easily used in population with low education.

DECLINE IN COGNITIVE FUNCTION AND ELDER MISTREATMENT: FINDINGS FROM THE CHICAGO HEALTH AND AGING PROJECT

X. Dong[1], M. Simon[2]
[1]Rush University, RUsh Institute for healthy agin, chicago, USA
[2]NorthwesternUniversity, Department of OB GYN, chicago, USA

Background: This study aimed to examine the longitudinal association between decline in cognitive function and elder mistreatment (EM).
Method: Longitudinal study of a geographically-defined community in Chicago. Chicago Health and Aging Project (CHAP) is an epidemiological study conducted in a geographically-defined community (N=6,159). We identified 143 CHAP participants who had longitudinal cognitive data and EM reported to social services agency. The primary predictor was cognitive function, which was assessed using the Mini-Mental State Examination (MMSE), the Symbol Digit Modalities Test (Perceptual Speed), and both immediate and delayed recall of the East Boston Memory Test (Episodic Memory). An index of global cognitive function scores was derived by averaging z-scores of all tests. Logistic regression models were used to assess the association of cognitive function domains and risk for EM.
Results: After adjusting for potential confounders, every 1 point decline in global cognitive function (OR, 1.57(1.21-2.03)), MMSE (OR, 1.07(1.03-1.10)), episodic memory (OR, 1.46(1.14-1.86) and perceptual speed (OR, 1.05(1.02-1.07)) scores were associated with increased risk for EM. Lowest tertiles in global cognitive function (OR, 2.71 (1.49-4.88), MMSE (OR, 2.02 (1.07-3.80)), episodic memory (OR, 2.70(1.41-5.16)) and perceptual speed (OR, 4.41 (2.22 -8.76)) scores were associated with increased risk for EM.
Conclusion: Decline in global cognitive function, MMSE, and perceptual speed scores were associated with increased risk for EM.

ADPD5-0497

RELIABILITY AND VALIDITY OF A NEW BEHAVIORAL SCALE TO MEASURE BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS IN DEMENTIAS (BPSD): LUTHRA'S BEHAVIORAL ASSESSMENT AND INTERVENTION RESPONSE (LUBAIR) SCALE

A. Luthra[1]

[1]*Program for Older Adults, Homewood Health, Guelph, Canada*

OBJECTIVES: Establish reliability and validity of LuBAIR Scale. It is hypothesized LuBAIR will be less labour intensive, more comprehensive and improve categorization of behaviors into clinically meaningful categories.

METHODS Seven Long Term Care Facilities in Ontario, Canada, were selected for the study. 120 residents with a dementia diagnosis were recruited. Sixty residents exhibiting BPSDs were included in the study group and sixty participants not displaying BPSDs in the control group. Pittsburg Agitation Scale was used to screen for presence of BPSDs. Two registered nurses (RN) completed LuBAIR scale, BEHAVE-AD, and Cohen-Mansfield Agitation Inventory (CMAI) for each study group participant. This was done to establish inter-rater, Construct and Criteria Validity. Fourteen days later, the same RN completed LuBAIR Scale again for each participant for intra-rater reliability. A Clinical Utility Survey (CUS) was developed to evaluate nurse viewpoints on the usefulness of LuBAIR on three variables: less labor intensive, more comprehensive and better categorization of behaviors in clinical meaningful categories.

RESULTS: Intra-rater reliability was established for 8 of the 12 behavioral categories. Inter-rater reliability was established for 10 of the 12 behavioral categories. LuBAIR scale had comparable Construct and Criteria Validity. CUS findings showed 23% of nurses found LuBAIR to be less labor intensive, 77% found LuBAIR to be more comprehensive and an overwhelming majority, 98%, agreed LuBAIR helps understand behaviors in a clinically meaningful way.

CONCLUSIONS: LuBAIR has acceptable inter- and intra-rater reliability and Construct and Criteria Validity. It is more comprehensive and better at categorizing behaviors in clinically meaningful categories.

ADPD5-0542
PRESENILE DEMENTIA IN A COMMUNITY BASED DEMENTIA CLINIC
H. Kong[1]
[1]*neurology, Seoul Metropolitan Seobuk Hospital, Seoul, Korea*
Objective: Dementia most commonly occurs in late life, but a small percentage of patients begins in an early age. The most frequent diagnosis in early onset dementia is Alzheimer's disease, vascular dementia and frontotemporal dementia. There are a few studies in characterizing presenile dementia compared to an older onset dementia. The purpose of this study is to review and analyse the characterization of presenile dementia patients in our community based dementia clinic.
Methods: We reviewed presenile dementia patients, whose clinical onset of dementia has begun before 65 years of age, consecutively seen in our clinic, from January to November, 2013. We excluded vascular dementia and traumatic brain injury.
Results: The number of presenile dementia patients were 15. Among them, thirteen patients were AD and 2 were frontotemporal dementia. The mean age of patients was 64.7years and the mean onset age was 58.3 years old. The mean score of initial K-MMSE was 18.3±6.2 and the mean score of follow up K-MMSE in 2013 was 4.2±6.1, which showed statistically significant difference. The mean duration of first evaluation from onset of cognitive impairment was 27.8 months.
Conclusion: Our results showed that Alzheimer's disease is the major cause of presenile dementia. Even though presenile demenita patients were relatively uncommon and were a minority, we should pay attention to this diagnosis , especially to young people with cognitive complaints.

SCREENING FOR THE PRESENCE OF FMR1 PREMUTATION ALLELES IN PATIENTS WITH VARIOUS MOVEMENT DISORDERS IN TAIWAN

H.C. Chang[1], C.S. Lu[1], Y.H. Wu-Chou[2], Y.H. Weng[3], C.C. Chen[3], T.H. Yeh[3], S.C. Lai[3], C.L. Huang[4], R.S. Chen[3], Y.Z. Huang[3], J. Hung[3], W.Y. Lin[3]
[1]Neuroscience Research Center, Chang Gung Memorial Hospital, Taoyuan, Taiwan
[2]Human Molecular Genetics Laboratory Department of Medicine Research, Chang Gung Memorial Hospital, Taoyuan, Taiwan
[3]Department of Neurology, Chang Gung Memorial Hospital, Taoyuan, Taiwan
[4]Department of Neurology, Saint Paul's Hospital, Taoyuan, Taiwan

Objective: To investigate the presence of *FMR1* premutation alleles in patients with various movement disorders.
Background: Fragile X-associated tremor/ataxia syndrome is a neurodegenerative disorder characterized by cerebellar ataxia, intention tremor and less common Parkinsonism, polyneuropathy, executive function deficits and cognitive impairment. It might be caused by premutation CGG repeat expansion (range: 55~200) in the fragile X mental retardation 1 (*FMR1)* gene.
Methods: We enrolled 771 patients with various movement disorders including 649 Parkinsonism; 63 progressive supranuclear palsy (PSP), 105 multiple system atrophy (MSA), 30 corticobasal syndrome (CBS), and 417 atypical Parkinsonism (aPM), 15 chorea excluding Huntington's disease, 107 spinocerebellar ataxia (SCA) without known genetic causes. The control group included 1,407 women (mean age at test: 34.0±0.1 years) who had received prenatal tests from Ko’s obstetrics and gynecology clinic. Genotyping of CGG repeated length in *FMR1* was performed with a recently developed highly sensitive PCR method.
Results: The mean age at onset was 63.8±8.3, 57.0±20.3, and 43.8±18.2 years in respective parkinsonism, chorea and SCA groups. Three premutation carriers of 80, 55, 92 CGGs were detected in respective MSA, SCA and aPM patients. Seven premutation carriers were detected in 1407 controls. Gray-zone alleles (range: 45-54 CGG repeats) was found in 5 patients (1 PSP, 1 MSA, 2 aPM, and 1 SCA) and 16 controls. There was no difference in frequency of premutation carriers between patient (0.4%) and control groups (0.5%) (p=0.503).
Conclusions: *FMR1* premutation alleles were not correlated with various movement disorders in Taiwan.

ADPD5-1872
PSP AND MSA BOTH IN THE SAME FAMILY
S. Delibas Kati[1]
[1]*Neurology, Can Government Hospital, Canakkale, Turkey*
INTRODUCTION: Different neurodegenerative diseases can be seen in the same family,Regular follw ups are important to diagnose those patients and their relatives.
CASE 1: 69 year old male patient came to our hospital suffering from falls. He also had a slowdown in movements,mild tremor,postural instability,rough voice and limited eye movements.His routine laboratuary findings and brain tomography showed no specific sign.He had no response to increased levodopa doses..He was then hospitalized his inspiratuary stridor, REM sleep disorder and spontan falls were observed. With these symptoms he was referred to a university with the diganose of possible supranuclear palsy. The diagnosis was confirmed at the university.
CASE 2: 61 year old male patient came to our hospital with vertigo, amnesia and sudden hypotension symptoms. His brother was diagnosed as progressive supranuclear palsy 1 year ago and he was afraid that he would be like him in the end. In his examination orthostathic hypotension, mild postural instability and tremor was found. His cranial MRi and routine laboratuary finding seemed to be normal except low vitamin B12 level (196 pg/ml).He was treated for B12 deficiency but the symptoms still remained. He was referred to the university where he was diagnosed as possible multysystem atrofy.
CONCLUSION: Neurodegenerative disorders are common especially in older patients. Rarely different neurodegenerative diseases can be seen in the same family. Sometimes at the small hospitals the diagnosis for neurodegenerative disorders can be skipped. More attention and regular follow ups will be helpful for both the patient and the doctor.

COGNITIVE FUNCTION IN SUBJECTS WITH PHYSICAL FRAILTY BUT WITHOUT DEMENTIA OR COGNITIVE COMPLAINTS: RESULTS FROM THE I-LAN LONGITUDINAL AGING STUDY

P.N. Wang[1], Y.H. Wu[1], L.K. Chen[1], L.K. Liu[1]
[1]Neurology, Taipei Veterans General Hospital, Taipei, Taiwan

Background
Previous evidence has shown frailty may associate or predict dementia. However, the impact of frailty on different cognitive domains in subjects with physical frailty but without dementia or cognitive complaints have not been well investigated
Methods
Community residents aged 50 years and older in the I-Lan Longitudinal Aging Study were evaluated. All participants received frail status and cognitive function assessments. Frail status was diagnosed by the Cardiovascular Health Study criteria. Cognitive function was examined by a standard battery of neuropsychological tests, including the Mini-Mental State Examination (MMSE), memory, language, visuospatial and executive function tests. The effects of frailty on different cognitive domains were examined.
Results
Totally 1686 persons aged 50-92.2 years (mean 63.4±8.9) were enrolled. There were 678 persons (40.2%) recognized as pre-frail and 82 persons (4.9%) as frail. The pre-frail and frail persons had significant poorer performance in the MMSE and all cognitive domains. Slowness, weakness and exhaustion were the most significant frailty components associated with cognitive impairment. Frail subjects had greater risk for ≥1 cognitive domain impairments than prefrail subjects (OR 1.31 in pre-frail subjects versus OR 2.24 in frail subjects). Non-memory domain was first affected in pre-frail state and memory domain was significantly affected in becoming frail.
Conclusion
Cognitive impairment is presented in frail subjects without dementia and even in subjects without subjective cognitive complaint. The incremental impact of frailty on cognition and the susceptibility of non-memory domain may provide a new view in evaluating the pathogenesis of both frailty and cognitive impairment.

CORTICAL STRUCTURE ALTERATIONS IN NF-KAPPAB P50 SUBUNIT LACKING MICE

S. Bonini[1], A. Mastinu[1], G. Maccarinelli[1], L. La Rosa[1], M. Premoli[1], G. Ferrari-Toninelli[1], M. Memo[1]

[1]Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy

Objectives: Structural remodelling of cortical neurites is a dynamic process underlying neuronal network formation and functional brain plasticity, both in development and in adulthood. We previously demonstrated that NF-kappaB and Notch pathways cross-talk acts as neurites structural plasticity modulator. Considering the key role of Notch and NF-kappaB pathways during neurodevelopment, we investigated if $p50^{-/-}$ mice cortex present structural and neurochemical abnormalities.

Methods: NF-kappaB p50 subunit-deficient ($p50^{-/-}$) and wild type mice were analyzed in terms of cortical neuron morphology, cortical structure and behavioural abnormalities.

Results: We observed altered distribution of Notch1 immunoreactivity in the cortex of $p50^{-/-}$ mice compared to wild type littermates at first postnatal day 1 (P1). We found that P2 $p50^{-/-}$ mice present an increase in radial glial cells, Reelin levels and abnormalities in cortical layers. In adult $p50^{-/-}$ mice, we observed an abnormal columnar organization and a disorganization of brain connectivity network in the cortical somato-sensory area. Concerning neurotransmission, we found an imbalance in glutamate/GABA signallings. Finally, $p50^{-/-}$ mice reported a significant reduction in social interaction compared to the wild-type mice.

Conclusions: The structural plasticity alterations previously observed in the brain of $p50^{-/-}$ mice are followed by cortex cytoarchitecture, neurotransmission and behavioural defects. A better understanding of the molecular events participating in neurite remodelling and neuron connectivity may provide relevant information for innovative therapeutic approaches in a variety of neurological disorders, including Alzheimer's disease, depression, autism, and schizophrenia, which have been associated with dysregulated neuroplasticity.

ADPD5-2115
DELETION OF RCN2 CAUSES EARLY-ONSET DYSTONIA IN MICE
W. Shi[1]
[1]*Radiology, University of Virginia Health Systems, Charlottesville, USA*
Primary dystonia is a common but poorly understood movement disorder characterized by involuntary muscle contractions leading to abnormal movements and postures. Here, we report that deletion of mouse *Rcn2* results in abnormal movements and postures typical of early-onset **dystonia**. A fraction of *Rcn2* knockout mice manifested curly tails, twisting movements and abnormal postures. Abnormalities started from the tail and hind legs and progressed gradually to involve the front legs and trunk. Symptoms became more evident with increased or prolonged activity. Dystonic mice also manifested increased anxiety-like behaviors and markedly reduced body weight. Their lifespans varied from 7 months to over a year. Subtle histological changes, including a reduction in neuronal cells and an increase in apoptosis, were observed in the brain of 2-month-old dystonic mice, but apparent cell loss and formation of gliosis were observed in the cerebrum, basal ganglia, and cerebellum of 5-month-old dystonic mice. Thus, we have provided the first direct evidence that loss of *Rcn2* expression causes early-onset dystonia in mice partially due to increased neuron death.

ADPD5-0759

PROTECTIVE EFFICACY OF FERULIC ACID AGAINST PB-INDUCED OXIDATIVE DYSFUNCTIONS AND NEUROTOXICITY IN DROSOPHILA MELANOGASTER

L.K. Venkareddy[1], M. Muralidhara[1]
[1]BIOCHEMISTRY AND NUTRITION, CSIR-CENTRAL FOOD TECHNOLOGICAL RESEARCH INSTITUTE, Mysore, India

Objective: Lead (Pb) toxicity is a persistent public health problem throughout the world. Epidemiological studies have shown that Pb exposure is associated with significant deficits in cognitive functions among children. Approaches such as chelation, antioxidants and their combination can alleviate Pb-associated neurotoxicity. We examined whether ferulic acid (FA), enrichment can attenuate Pb-induced phenotype, oxidative stress and neurotoxic effects employing *Drosophila melanogaster* as the model.

Methods: Employing a co-exposure paradigm, we determined the lethality response and locomotor phenotype (speed) among two age groups (young/ adult) of flies exposed (7d) to Pb acetate (5-20mM, 7 d) in the medium. Subsequently, we studied the propensity of FA (25-50µM) - enrichment to offset Pb-induced (5mM) - oxidative dysfunctions and neurotoxicity in young flies.

Results: A concentration -dependent mortality ensued with Pb exposure, while young flies were more susceptible. Hyperactivity was discernible among both age groups. Pb exposure caused a robust global oxidative stress (as evidenced by elevated ROS/protein carbonyl levels in head/body regions, perturbations in antioxidant enzyme activities) and significant increase in the activities of complex I-III, despite elevated levels of total thiols/ GSH. Further, flies exhibited elevated activity of acetylcholinesterase and dopamine levels in head region. Interestingly, FA enrichment although had no significant effect on Pb-induced hyperactivity, offered marked protection against Pb-induced oxidative impairments and restored the activity levels of AChE and dopamine levels.

Conclusions: Employing this model, we are investigating the interactive effects of low levels of Pb exposure and neurotoxins (eg. rotenone and Paraquat) and the protective effects of selected phytoconstituents.

08d. Animal Models: drosophila

ADPD5-0772
PROTECTIVE EFFICACY OF CREATINE IN DROSOPHILA MODEL OF NEUROTOXICITY: RELEVANCE TO PD

S. Venkata Rao[1], *G. M*[1], *M. M*[1]
[1]*Biochemistry and Nutrition, Central Food Technological Research Institute, Mysore, India*

Objectives: To elucidate the efficacy of Creatine (Cr) to abrogate locomotor deficits, lethality and oxidative stress in *Drosophila melanogaster* induced by model neurotoxins such as Acrylamide (ACR) and 1-methyl-4-phenylpyridine (MPP^+).
Methods: The status of endogenous levels of oxidative stress markers, activities of antioxidant enzymes and acetylcholinesterase (AChE) were determined in adult flies maintained in Creatine (5-10mM) -enriched medium for 7d. Further, employing a co-exposure paradigm, the efficacy of Cr to abrogate ACR-induced locomotor phenotype, lethality, oxidative dysfunctions and neurotoxicity were investigated in adult flies. In another experiment, flies provided with Cr prophylaxis (for 10 d) were challenged with MPP^+ for 48 h in order to determine the resistance rendered against toxin insult.
Results: *D. melanogaster* exposed to Cr-enriched diet for 7 days exhibited significant diminution in the levels of reactive oxygen species (ROS), hydroperoxides (HP), nitric oxide with concomitant elevation in the levels total thiols, GSH and reduced AChE activity. At the higher concentration, Cr (10mM) significantly offset the incidence of ACR -induced mortality and improved the locomotor phenotype. Further, Cr-enrichment alleviated ACR-induced oxidative stress, (restoration of ROS, HP, NO levels and activity levels of antioxidant enzymes) and cholinergic deficit. Interestingly, Cr prophylaxis offered robust protection (29-57%) against MPP^+ exposure as evidenced by the incidence of lethality and improvement in locomotor phenotype.
Conclusion: Our experimental findings suggest the neuroprotective efficacy of Cr against neurotoxin exposure and its propensity to modulate oxidative dysfunctions in the Drosophila system.

ADPD5-1278

COGNITIVE AND MOTOR IMPAIRMENTS INDUCED BY A BILATERAL 6-OHDA LESION INTO THE STRIATUM OF THE RAT

E. Esneault[1], A.M. Hernier[1], E. Nail[1], V. Castagne[1]
[1]Pharmacology, PORSOLT, Le Genest Saint Isle, France

A number of non-motor symptoms such as depression, anxiety, and cognitive decline are observed at an early stage of Parkinson's disease (PD). The present study investigated the effects of a bilateral 6-hydroxydopamine (6-OHDA) lesion into the striatum on motor and cognitive end-points in the rat.
Animals were bilaterally lesioned with 6-OHDA at 4 µg/µL (two infusions per striatum). Three weeks after lesion, motor coordination was evaluated in the accelerating rotarod test. Animals were then tested in the operant delayed alternation (DA) and Morris water maze (MWM) tests.
In bilateral 6-OHDA lesioned rats, the drop-off time was significantly decreased in the accelerating rotarod test, as compared with sham-operated animals ($p < 0.05$). In the DA test, 6-OHDA-lesioned rats showed a clear increase in the number of sessions required to reach the criteria of 90% correct responses during the acquisition period. In the MWM test, the escape latency and the distance swum were significantly increased on Day 1 ($p < 0.001$ and $p < 0.01$, respectively) and on Day 3 ($p < 0.05$, for both parameters).
These results suggest that a bilateral 6-OHDA lesion into the rat striatum induced modest deficits on motor coordination in the accelerating rotarod test. Learning and working memory impairments were also observed on the acquisition of a DA task.
The bilateral 6-OHDA lesion into the striatum in the rat represents a partial lesion model of the nigro-striatal pathway with quantifiable motor and cognitive deficits mimicking an early stage of PD.

ADPD5-1610

OLFACTORY IMPAIRMENT IS MODULATED BY BULBAR DOPAMINERGIC D2 ACTIVITY IN THE ROTENONE MODEL OF PD AFTER REM SLEEP DEPRIVATION.

L. Rodrigues[1], A. Targa[1], A. Noseda[1], M. Aurich[1], P. Dos Santos[1], M. Lima[1]

[1]Physiology, Federal University of Paraná, Curitiba, Brazil

Objectives: We have led to the hypothesis that a modulation of the dopaminergic D2 receptors in the olfactory bulb could provide a more comprehensive understanding of the olfactory deficits in PD and after a short period of rapid eye movement (REM) sleep deprivation (REMSD).

Methods: We decided to investigate the olfactory, neurochemical and histological alterations generated by the administration of piribedil (a selective D2 agonist) or raclopride (a selective D2 antagonist), within the glomerular layer of the olfactory bulb, in rats submitted to intranigral rotenone and REMSD.

Results: Our findings provided an evidence of the occurrence of a negative correlation (r = - 0.52, P = 0.04) between the number of periglomerular TH-ir neurons and the bulbar levels of dopamine (DA) in the rotenone, but not sham groups. A significant positive correlation (r = 0.34, P = 0.03) was observed between nigral DA and olfactory discrimination index (DI), for the sham groups, indicating that increased DA levels in the substantia nigra pars compacta (SNpc) are associated to enhanced olfactory discrimination performance.

REMSD supposedly generates supersensitivity of D2, promoting a restorative effect to DA in different investigated areas.

Conclusion: The present evidence reinforce the idea that DA produced by periglomerular neurons, particularly the bulbar dopaminergic D2 receptors, is an essential participant in olfactory discrimination processes, the SNpc, and the striatum.

ADPD5-1653

STRIATAL MT2 MELATONIN RECEPTORS: REGULATION OF ANXIETY AND DEPRESSIVE-LIKE BEHAVIORS IN THE ROTENONE MODEL OF PARKINSON'S DISEASE

A. Noseda[1], L. Rodrigues[1], A. Targa[1], M. Aurich[1], P. Dos Santos[1], M. Lima[1]
[1]Physiology, Federal University of Paraná, Curitiba, Brazil

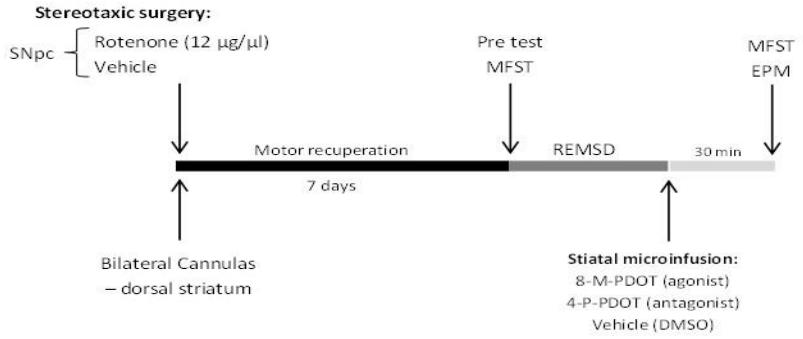
Objectives: The present study investigated the potential role of striatum MT2 melatonin receptor on anxiety and depressive-like behaviors after REM sleep deprivation (REMSD), in the rotenone model of Parkinson`s disease.

Methods

Results: We observed substantial anxiolytic-like effects promoted by activation of striatal MT2 receptors (P<0.01). The 4-P-PDOT group did not show an anxiogenic-like behavior, however, after 24h of REMSD rats spend more time on open arms (P<0.05). An anxiolytic-like behavior was observed in rotenone REMSD group, treated with MT2 agonist (P<0.01), antagonist (P<0.05) or vehicle (P<0.01).

The swimming, immobility and climbing parameters evidenced that 4-P-PDOT promoted antidepressant-like effects that were observed even in the rotenone REMSD 4-P-PDOT group (P<0.01).

Conclusions: These results indicated that striatal MT2 melatonin receptors exhibited important roles in anxiety and depressive-like behaviors in the rotenone PD model. Additionally, REMSD modulated these effects even after rotenone-induced lesion. Furthermore, we observed substantial antidepressant-like effect promoted by the blockade of striatal MT2 receptors.



Legend: Elevated plus maze (EPM); Modified forced swimming test (MFST); Substantia nigra pars compacta (SNpc);

PEDUNCULOPONTINE TEGMENTAL NUCLEUS AND DOPAMINERGIC SYSTEM: POSSIBLE ASSOCIATION BETWEEN REM SLEEP REGULATION AND MEMORY CONSOLIDATION

A. Targa[1], L. Rodrigues[1], A. Noseda[1], M. Aurich[1], P. Dos Santos[1], M. Andersen[1], M. Lima[1]

[1]Physiology, Federal University of Paraná, Curitiba, Brazil

Objective: The aim of this study was to investigate a possible association between the pedunculopontine tegmental nucleus (PPT) and the nigrostriatal dopaminergic system in REM sleep regulation and, consequently, in memory consolidation.

Methods: Rats underwent stereotaxic surgery for direct infusion of ibotenic acid (24 µg/µL) within the PPT. After seven days, the animals were exposed to REM sleep deprivation (REMSD), followed by intrastriatal: D2 receptor agonist injection (piribedil, 3 µg/µl), antagonist (raclopride, 10 µg/µl) or vehicle (DMSO). The animals were subjected to the object recognition test (ORT) after the REMSD and after the sleep rebound period (REB) and the sleep recording occurred during the REB period for 24 hours.

Results: The piribedil PPT-lesioned REMSD group exhibited an increase in REM sleep compared to the raclopride group ($P<0.01$) and this augment did not corresponded to the memory consolidation since there was not a difference between this groups in the time exploring the novel object. However, it was possible to observe a similarity between time spent in REM sleep and memory consolidation since the raclopride PPT-lesioned REMSD group spent less time in REM sleep compared to its control ($P<0.01$) and was not able to recognize the novel object.

Conclusion: We suggest a mutual involvement of the nigrostriatal dopaminergic system with the PPT, both contributing in sleep regulation and memory consolidation. Thus, we propose that REM sleep is probably the key player in modulating such events triggered by this PPT-nigrostriatal circuitry.

ADPD5-1783

OLFACTORY DEFICIT PRODUCED BY PARADOXICAL SLEEP DEPRIVATION AND INTRANIGRAL ROTENONE LESION IN RATS

M. Aurich[1], L. Rodrigues[1], A. Targa[1], A. Noseda[1], P. Dos Santos[1], M. Lima[1]
[1]Physiology, Federal University of Paraná, Curitiba, Brazil

Objectives

We Investigated the occurrence of olfactory deficits produced by paradoxical sleep deprivation (PSD) associated to a dopaminergic nigrostriatal lesion induced by intranigral rotenone administration in rats.

Methods

Animals were distributed into two groups: rotenone that received a bilateral intranigral infusion of rotenone (12 µg/µL) by stereotaxic surgery; other group received only dimethylsulfoxide (DMSO) as a vehicle. After 7 days the olfactory (social and non-social odor) and open field tests were performed. Subsequently rats underwent PSD protocol for 24 h and were re-tested. After PSD, they were allowed to perform the rebound sleep in the next 24 h, followed by another re-test. Finally, the animals were decapitated for the quantification of tyrosine hydroxylase immunoreactivity (TH-ir) neurons within the substantia nigra.

Results

The densities of the TH-ir neurons showed a significant decrease of about 30% ($p<0.0001$) in the rotenone group compared to the sham. We found that the rotenone group demonstrated an olfactory impairment ($p<0.05$), which remained after the PSD ($p<0.01$), that was counteracted by the rebound. Besides the lesion and PSD generated impairment in the discrimination of non-social odors ($p<0.05$) without motor bias.

Conclusions

Both the decrease of dopaminergic neurons in the substantia nigra and PSD were able to generate a similar olfactory loss.

LEVODOPA ATTENUATES FATIGUE IN RESERPINE-TREATED MICE – AN ANIMAL MODEL OF PARKINSON'S DISEASE

A.S. Aguiar Jr[1], D.L. Scheffer[2], R.D.S. Prediger[1], A. Latini[1]
[1]PPG Neurociências, Federal University of Santa Catarina, Florianópolis, Brazil
[2]PPG Educação Física, Federal University of Santa Catarina, Florianópolis, Brazil

There is a great demand for knowledge of perceived exertion during physical activity. Decreased ability to work or exercise until failure is known as fatigue, which has central and peripheral components, and is also a common symptom in neurology. In order to understand the mechanisms of fatigue, it is important to distinguish symptoms of peripheral neuromuscular fatigue from the symptoms of central fatigue characteristic of basal ganglia disorders, such as Parkinson's disease. Some evidence suggests the role of increased serotonin/dopamine (5-HT/DA) ratio in the pathophysiology of this central fatigue. We depleted striatal DA in mice (Swiss, 10-12 weeks age, 30-40 g) by systemic treatment with reserpine (1 mg/kg, i.p.), an animal model of Parkinsonism. This increased the 5-HT/DA ratio in the striatum of animals. The reserpinized animals also showed fatigue intolerance in the treadmill test, characterized by reduced mechanical work and muscular recruitment. Levodopa (100 mg/kg, i.p) plus Benserazide (50 mg/kg, i.p) partially reversed DA depletion reversed, Parkinsonism and fatigue tolerance. We consider that increased striatal 5-HT/DA ratio played a crucial role in the development of central fatigue because reserpine did not alter mitochondrial physiology and anatomy, and glucose uptake in muscle tissue. The results suggest that striatal DA may be involved in the development of central fatigue. Furthermore, the effectiveness of levodopa suggests an important motor component of this symptom in the Parkinsonism, which does not discard non-motor components, such as motivation and attention.

THE INTERACTION BETWEEN DECREASED SHORT-TERM SPATIAL MEMORY AND INCREASED OXIDATIVE STRESS IN A SCOPOLAMINE-INDUCED RAT MODEL OF ALZHEIMER'S DISEASE

A. Ciobica[1], L. Hritcu[1], R. Lefter[2], B. Stoica[3], Z. Olteanu[1], I.M. Balmus[1], E. Anton[3], D. Timofte[3]

[1]Biology, Alexandru Ioan Cuza University Iasi, Iasi, Romania

[2]SOP HRD/159/1.5/S/133675 Project, Romanian Academy, Iasi, Romania

[3]Medicine, "Gr.T.Popa" University, Iasi, Romania

· Objectives

Scopolamine is a well known muscarinic cholinergic competitive antagonist involved in human and animal memory processes, particularly in the processes of learning acquisition and short-term memory and it has been one of the most used drugs to induce animal models of Alzheimer disease (AD). Also, there is an increased awareness regarding the relevance of the oxidative stress in the progression of AD.

· Methods

In this context, we were interested in studying the effects that scopolamine induction of a rat model of AD has on oxidative stress, as expressed by the Total Antioxidant Status (TAS) from the temporal lobe, the most sensitive brain area to the effects of the oxidative stress status.

· Results

The cognitive deficits of scopolamine were confirmed in the Y maze task, as expressed through a significant decrease of the spontaneous alternation. Also, our data indicated that the administration of scopolamine has a significant prooxidant effect, which is manifested by a decrease in the TAS of the temporal lobe, as compared to the controls. Moreover, a significant Pearson correlation was observed between the levels of the behavioural tasks and the values of the TAs in the temporal lobe.

· Conclusions

In this study we have demonstrated the presence of increased oxidative stress in a rat model of Alzheimer's disease obtained through the administration of scopolamine. Moreover, there is a significant correlation between the behavioral markers in the Y maze and the levels of TAS, as a result of scopolamine administration.

ONE SINGLE ADMINISTRATION OF MPTP IS ENOUGH TO PRODUCE MEMORY DEFICITS IN A RAT MODEL OF PARKINSON'S DISEASE

A. Ciobica[1], R. Lefter[2], I.M. Balmus[1], I. Antioch[1], M. Paulet[2], D. Ababei[3], E. Anton[4], D. Timofte[4]
[1]Biology, Alexandru Ioan Cuza University Iasi, Iasi, Romania
[2]SOP HRD/159/1.5/S/133675 Project, Romanian Academy, Iasi, Romania
[3]Pharmacy, "Gr.T.Popa" University, Iasi, Romania
[4]Medicine, "Gr.T.Popa" University, Iasi, Romania

Background:
Besides the well known locomotory aspects, the various neuropsychological investigations of patients with Parkinson's disease (PD) have shown specific cognitive impairments, ranging from minor disturbances in memory to intellectual function or even dementia.
Also, one of the most used animal models of PD in rats in referring to the administration of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP).
Methods:
In this way, while most of the administration patterns are including several different intraperitoneally (i.p.) injections of MPTP (e.g. 4 injections X·20mg/kg, 2 h apart; 1–2 daily injections of MPTP, 20–30mg/kg, 5 days), here we were interested, for the first time in our best of knowledge, to see if just one acute administration of a single injection of MPTP 20mg/kg i.p. will result in any cognitive deficits in rats, as studies in the Y maze task. The behavioral testing was performed one week after the MPTP administration, while the control group received saline.
Results:
In this way, the administration of single i.p. MPTP dose resulted in a significant decrease of the spontaneous alternation percentage in the Y maze task (77.5± 6.2% in controls vs. 52.2± 4.1% in MPTP group), suggesting deficits in the immediate working memory. Moreover, these results were not generated by some locomotor deficiencies, considering that there was no significant difference in the number of arm entries between the two groups of rats.
Conclusions:
One single i.p. administration of MPTP 20 mg/kg is enough to produce memory deficits in a rat model of PD, as studies in the Y maze task.

ADPD5-2190

INFLUENCE OF A PARTIAL LESION OF DOPAMINERGIC SYSTEM AND CHRONIC ANTIDEPRESSANTS ON SERT AND DAT IN BRAIN STRUCTURES IN RATS

K. Berghauzen-Maciejewska[1], J. Wardas[1], U. Głowacka[1], B. Kosmowska[1], K. Ossowska[1]

[1]Department of Neuropsychopharmacology,
Institute of Pharmacology Polish Academy of Sciences, Krakow, Poland

Binding to serotonin (SERT) and dopamine (DAT) transporters is used by imaging techniques in Parkinson's disease (PD). However, no studies are available concerning SERT and DAT binding and its possible relationship with depression of preclinical phase of PD.

The aim of the present study was to investigate the influence of a moderate dopaminergic lesion and chronic administration of pramipexole and imipramine on the "depressive-like" behavior, as well as binding of radioligands to DAT and SERT in limbic and nigrostriatal structures.

Rats were bilaterally injected with 6-OHDA into the caudate-putamen (CP). Imipramine was injected (10 mg/kg) once a day and pramipexole (1 mg/kg) twice a day for 2 weeks. 24 h after the last drug injection rats were tested in the forced swimming test (FST) and actimeters. After decapitation dopamine and serotonin levels (HPLC), as well as radioligand binding to DAT and SERT were investigated (autoradiography).

6-OHDA administration increased immobility in FST, without influencing locomotion of rats. 6-OHDA decreased dopamine but did not influence serotonin levels in CP, nucleus accumbens (NAC) and frontal cortex. 6-OHDA reduced DAT in CP and NAC, and SERT in these structures, as well as in hippocampus, amygdala, habenula, prefrontal cortex, substantia nigra and VTA. Pramipexole but not imipramine reversed immobility prolongation in lesioned animals. Both pramipexole and imipramine decreased SERT in mesolimbic and nigrostriatal systems but had no influence on DAT.

These results seem to indicate that 6-OHDA-induced partial dopaminergic but not serotonergic lesion, as well as chronic antidepressants, evoked adaptive changes in SERT binding.

CANINE MODEL FOR HUMAN NEURODEGENERATIVE DISORDERS
J. Farbakova[1], T. Smolek[2], T. Weissova[1], D. Baranova[1], M. Fialkovicova[1], V. Ledecky[1], A. Madari[1]
[1]Small Animal Clinic, University of Veterinary Medicine and Pharmacy in Kosice, Kosice, Slovakia
[2]The Institute of Neuroimmunology, Slovak Academy of Scieces, Bratislava, Slovakia
Objectives: The study of the pathogenesis of human neurodegenerative disorders including Alzheimer´s disease (AD) requires the use of proper animal models that develop age-related neurodegenerative process in the brain. Previously it has been shown that aged canines suffered from cognitive dysfunction (CCD) and developed characteristic features of Alzheimer´s disease brain pathology. The scope of this study is to diagnose CCD by differential exclusion, physical examination, diagnostic testing and the screening checklist with owner cooperation.
Methods: We were studying fifteen aged dogs (from 9 to 17 years) with severe behavioural and cognitive deficits. The testing includes clinical and neurological examination, hematology, blood biochemistry, serology, autopsy as well as histopathology, immunohistochemical and proteomic analyses of dog brain. Moreover we analyzed proteome of cerebrospinal fluid (CSF) to identify potential biomarkers for disease progression.
Results: Test of cognition by CCD questionnaire showed marked deficits in two dogs. We found increase senile plaques in neocortex and hippocampus only in two investigated brains of the 15 aged dogs, this pathology does not correlate with cognitive impairment. On the other hand, we found in majority of tested brain tissue samples increased number of activated microglia in white matter.
Conclusion: Our findings indicate that neuroinflammation rather that senile plaques pathology may correlate with cognitive impairment of aged dogs. Results of the study could lead to use of the dog as an animal model in research of human brain ageing and neurodegenerative disorders.
Acknowledgement: This work was supported by the grant APVV-0206-11.

ADPD5-1551
PHENOTYPIC CHARACTERIZATION OF THE CAENORHABDITIS ELEGANS STRAIN N2 WITH ETHANOLIC EXTRACTS OF OF WITHERINGIA COCCOLOBOIDES

R. Sanchez[1], M. Gómez[1], C. Coronel Robayo[1], L. Parada Ferro[1], J. Tovar Bohórquez[1]
[1]Bacteriologia, Universidad Colegio Mayor de Cundinamarca, Bogotá, Colombia

Neurodegenerative diseases have a high prevalence, causing a major *public health problem.* The lack of treatments has allowed the use of alternative therapies in the pharmaceutical industry and the use of plant secondary metabolites (*Witheringia coccoloboides* native of Colombia) to prevent and control the disease. Using a biological model as *Caenorhabditis elegans (Ce)*, which has been used in different studies of neuroscience, allowing to will evaluate in vivo the ethanol extract of the plant, as a promising treatment for these diseases. **Aim:** Analyze the phenotypic characteristics of the strain N2 with the aim to be used as a model for screening the extract of plant.
Materials and Methods: The nematode was cultured and grown in NGM medium with E. coli OP50. Strain was synchronized from eggs to L1 larvae. The extract was performed and standardized for phenotypic characterization of the strain N2 using the length, longevity, reproduction thermal stress trials.
Results and Conclusion: the longevity of the control strain N2 was 16 to 22 days; however using the extract with a concentration of 1 mg was 28 days. The offspring reproduction was 225, when used extract the reproduction was affected at the highest concentration where there was a decreasing the number of offspring. The nematode length was approximately 1100 +/- 50 µm using extract where there was on length increment of 1400µm. Also it was showed that the extract does not affect nematode thermo tolerance and it is not toxic to the N2 Strain.

STUDYING PAIN MANIFESTATIONS IN AN MPTP-INDUCED RAT MODEL OF PARKINSON'S DISEASE

A. Ciobica[1], R. Lefter[2], I. Antioch[1], M. Paulet[1], D. Ababei[3], V. Bild[3], E. Anton[4], D. Timofte[4]
[1]Biology, Alexandru Ioan Cuza University Iasi, Iasi, Romania
[2]SOP HRD/159/1.5/S/133675 Project, Romanian Academy, Iasi, Romania
[3]Pharmacy, "Gr.T.Popa" University, Iasi, Romania
[4]Medicine, "Gr.T.Popa" University, Iasi, Romania

Background
Generally, Parkinson's disease (PD) is less widely appreciated as a disease causing pain syndromes, although pain is found in 40-80 % of PD patients, as described by the very few reports in this area of research. Moreover, in some PD patients, pain is so severe and intractable that it overshadows the motor symptoms of the disorder. Still, pain in PD frequently goes underacknowledged and undertreated. Also, the studies regarding pain perception in the existing animal models of PD are very few.
Methods
We experimentally induced the PD model in rats by injecting subcutaneously one dose of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), 20mg/kg, while the control group received saline. The behavioral testing for pain included the hot-plate task and was performed 7 days after MPTP injection.
Results
In this way, our rat model resulted from the acute treatment with a low dose of MPTP, exhibited an increased sensitivity to pain perception, as demonstrated by the significant decrease in the values of the latency time in hot-plate for rats treated with MPTP, as compared to the controls. The latency time is expressed in seconds and is referring to the reaction time to two different types of behavior: licking the paw and jumping (11.33 ± 2.1 in controls vs. 6.8 ± 0.9 in MPTP group).
Conclusions
Our data is suggesting, for the first time in our best of knowledge, an increased sensitivity to pain in a MPTP-induced rat model of PD. In this way, further studies in this area of research seem warranted.

Title: Male caregivers to persons with Lewy Body Dementia have higher stress level than male caregivers to persons with Alzheimers Dementia.

Authors: Ellen Svendsbø, Toril Terum, Ingelin Testad, Dag Aarsland & Arvid Rongve.

Objectives: To identify distress for male caregivers to persons with Dementia with Lewy bodies (DLB) compared to male caregivers to persons with Alzheimers dementia.

Method: The study sample comprised 126 caregivers for persons with AD and 90 caregivers for persons with DLB, recruited for a longitudinal dementia study (DEMVEST) and from a register (HUKLI), both from Norway. To get the gender differences in this study we selected the persons that were married to or lived together (opposite gender).The caregivers answered the Relative Stress Scale (RSS). RSS is divided into three groups, Emotional distress, Social distress and negative feelings. DLB were diagnosed according to the revised consensus criteria. Patients were home-dwelling outpatients referred to memory clinics, and had standardized comprehensive assessment.

Result:16 male DLB caregivers together with 29 male AD caregivers answered the RSS form. Mean score from male DLB caregivers (22.47) differed significantly from mean score from male AD caregivers (11.07, p=0.002). Sub items like RSS emotional distress was 10.67 for male DLB caregivers and 3.64 for male AD caregivers (p=0.001) Social distress score was for male caregivers 9.44 DLB and 5.07 AD (p=0.032) and negative feeling 3.78 for male DLB and 2.34 for male AD (p=0.234).

Conclusion: Male caregiver to persons diagnosed with DLB reports significantly higher caregiver distress, as compared to male AD caregivers.

ADPD5-1069

SHOULD WE ASSESS FAMILY CAREGIVERS' DEPRESSIVE SYMPTOMS AT THE EARLY PHASE OF CAREGIVING?

T. Välimäki[1], J. Martikainen[2], I. Hallikainen[3], K. Vehviläinen-Julkunen[1], A. Pietilä[1], A. Koivisto[1]

[1]Nursing Science, University of Eastern Finland, Kuopio, Finland
[2]School of Pharmacy, University of Eastern Finland, Kuopio, Finland
[3]School of Medicine, University of Eastern Finland, Kuopio, Finland

Objectives: Family caregivers' Sense of coherence (SOC) is associated with the capacity to cope with caregiving. SOC express the inner trust that life will be understandable, manageable and meaningful despite changes in life situation. The aim was to investigate the trajectory of SOC during 3 year follow-up time.
Methods: Kuopio ALSOVA study is a prospective follow-up Alzheimer Disease (AD) study. Spousal caregivers (n=170) were followed three years after their spouses had been diagnosed with AD. Both person with AD- (CDR-SOB, MMSE, NPI, ADCS-ADL) and caregiver (BDI, SOC) were evaluated annually. Linear mixed models were used to analyze relationship between SOC and potential clinical parameters.
Results: Mean drop-out adjusted SOC score (at baseline 148.5) decreased by -4.56 points (p=0.002) during follow-up. Caregivers' depression at baseline predicted the significant decrease of SOC (every + 1 BDI point decreases 2.181 points in SOC, p=0.0001). When compared to non- depressive caregivers (BDI≤9, n= 95, 56%), minor (BDI 10-18, n= 54, 32%), moderate to severe (BDI 19-30, n= 21, 12%), depressive symptoms decreased (adjusted for length of follow-up) the level of the SOC score by an average of -19.0 (p=0.0001), -38.3 (p=0.0001) points during follow-ups.
Conclusions: The average SOC decreased in all caregivers. Paying attention to family caregivers' health as well as health protecting factors and recourses may help to identify the most vulnerable caregivers at the early stage. Spousal caregivers who suffer even minor depressive symptoms at the beginning of caregiving should be recognized and individualized support and care should be provided for them.

GPS, A SOLUTION FOR THE PATIENT AND THE CAREGIVER
G. Ribas Miquel[1], A. del Valle[2]
[1]Psicologia, Universitat de Girona, llagostera, Spain
[2]Psicologia, Universitat de Girona, Girona, Spain
Target:analyse the experience of Alzheimer patients' caregivers who use GPS.
Analysethe main causes which overload the caregiver.
Design:interpretative and qualitative investigation. Phenomenological perspective.
Participants:caregivers of GPS users and caregivers of non GPS users.
Method:biographical story technique through an interview between the caregiver and theinvestigator,
auto-recorded and transcribed.
Result:analysis of seven stories. The use of the GPS is "releasing" (freedom, distressing,calming),
related to "continuity" the user can stay more time at his own home,keeping on doing his "routines",
playing card games with friends, going for awalk, doing a little bit of shopping.
Conclusions:the caregivers match the GPS with the concept of freedom for themselves and therelease
from stress which is caused by the anxiety of having to close all thedoors and not being able to let the patients walk alone on the street becauseof the fear that they can get lost easily.

09a. Patient Care & Support: caregiver support

ADPD5-2078

INITIAL MEDICAL CONSULTATION OF DEMENTIA PATIENTS DEPENDS ON THEIR CAREGIVERS

K. Shigematsu[1], N. Oka[1], K. Takeuchi[1]
[1]Neurology, National Hospital Organization, Kyoto, Japan

Objectives
To maintain daily and social activities ofdementia patients, supports by caregivers are essential. Moreover, since patientsoften do not aware of their illness and do not consult to hospitals voluntarily,medical consultation tends to be late without caregivers' help. We aim toevaluate care environments and their influence on medical consultation ofdementia patients.
Methods
We surveyed dementia patients who havevisited hospitals for consultation. Patients were stratified in three groups,first, patients who live by themselves, second, patients who live with theirelderly spouse, and third, patients who live with their sons and/or daughters.Items investigated included motivations to consult medical care, the severityof cognitive impairment, BPSD, living conditions, care environments, andcare-giving burdens.
Results
Reasons for seeking treatmentswere mostly core conditions such as: 1) Amnesia, 2) Disorder in Comprehension and Judgment,3) Disorientation, 4) Disability in performing daily routines. The peripheralsymptoms were: 1) Hallucination and Delusion 2) Abnormal Behavior 3) PersonalityChange 4) Lack of Initiative 4. Complaints on physical conditions wererelatively infrequent. Dementia patients visited to hospital without caregiverswere none. Patients who came to theclinic on their own volition for the first time diagnosed as not beingdementia.
Conclusion
On comparison between those living aloneand with other family members, there were differences in such symptoms and thetime of their recognition. Furthermore, in those living with elderly familymembers, the time needed to undergo the initial consultation was longer.

ADPD5-0561
THE EFFECT OF TELEMEDICINE ON THE DURATION OF TREATMENT IN DEMENTIA PATIENTS

J. Jang[1], C. Cheong[2], K. Lim[3], J. Jhoo[2]
[1]Neurology, Kangwon National University Hospital, Chuncheon-Si Gangwon-Do, Korea
[2]Psychiatry, Kangwon National University Hospital, Chuncheon-Si Gangwon-Do, Korea
[3]Internal medicine, Kangwon National University Hospital, Chuncheon-Si Gangwon-Do, Korea

Objectives
The aim of the present study was to evaluate the effectiveness of telemedicine for long-term follow-up of dementia patients in rural South Korea and to identify the factors predicting long-term treatment
Methods
We studied 442 patients who met the DSM criteria for dementia and whose treatment was initiated at the Kangwon National University Hospital (KNUH) in Chuncheon. Over a five-year period, there were 259 patients who regularly visited the KNUH dementia clinic in person, and 168 patients who received medical services from the dementia clinic via telemedicine. The telemedicine patients attended a public health centre in Hongcheon, a facility located in a rural area about 50 km south east of the KNUH.
Results
The mean treatment duration was significantly longer for the telemedicine group than for the clinical visit group (P<0.001), with durations of 26.6 and 14.6 months, respectively. Low Clinical Dementia Rating scores (hazard ratio =1.47, 95% confidence interval=1.26-1.71) and use of telemedicine (hazard ratio=0.55, 95% confidence interval=0.42-0.72) were found to be independent predictive factors of increased treatment duration.

	Hazard ratio (95% CI)	P-value
Age	1.15 (0.95-1.41)	0.15
Clinical Dementia Rating	1.47 (1.26-1.71)	<0.001
Experimental group	0.55 (0.42-0.72)	<0.001

Conclusions
These findings suggest that telemedicine may be useful in slowing disease progression in dementia patients in rural areas

ADPD5-0445
AGITATION PREDICTS MORTALITY IN SEVERE DEMENTIA.
K. Nägga[1], S. Mayer[1], E. Granvik[1], L. Minthon[1]
[1]Memory Clinic Skåne University Hospital Malmö, Clinical Memory Research Unit, Malmö, Sweden
Background:
In dementia, increased severity of cognitive impairment is strongly associated with presence of more severe behavioural and psychological symptoms of dementia (BPSD). BPSD result in distress for the patients, the families, and for the caregivers but is also associated with mortality. The presence and severity of BPSD can be estimated with the Neuropsychiatric Inventory (NPI). The 12-item version of NPI measures different domains such as hallucination, delusion, agitation, depression, anxiety, and apathy. The Swedish BPSD-registry includes repeated NPI-measurements and provides a working tool for the management of BPSD at nursing homes. We investigated the association between different BPSD and mortality in severe dementia.
Method:
The data originate from an 18-month longitudinal study performed at five nursing homes. 95 cases were included in the study. Information on age, gender and dementia diagnosis was registered. Repeated NPI measurements were performed to follow the course of BPSD. 28 cases (29.5%) deceased during the study period.
Results:
There was no significant difference in gender, NPI-score or number of drugs at baseline between deceased and survived cases. The deceased had higher NPI-scores on the items delusion, apathy, and agitation ($p<0.05$). Multivariate logistic regression analysis showed that higher age (OR 1.20 [95% CI 0.07-1.35] per year, $p<0.001$) and higher agitation score (OR 1.24 [95% CI 0.08-1.24] per point, $p<0.005$) increased the risk of mortality.
Conclusions:
Agitation predicted mortality among patients with severe dementia, independent of age, total BPSD burden and other investigated factors. This indicates that special attention should be paid to the presence of agitation.

ADPD5-0477

PREVALENCE, COURSE AND TREATMENT OF NEUROPSYCHIATRIC SYMPTOMS IN CASES WITH SEVERE DEMENTIA - A 4-YEAR UPDATE OF THE SWEDISH BPSD-REGISTRY

S. Mayer[1], E. Granvik[1], L. Minthon[1], K. Nägga[1]
[1]memory Clinic, Clinical Memory Research Unit, Malmö, Sweden

Objectives:
Management and optimal care of patients with behavioural and psychological symptoms of dementia (BPSD) is challenging. Guidelines recommend non-pharmacological interventions as first-line treatment and consider pharmacological treatment as second-line. Based on national guidelines, the Swedish BPSD-registry was initiated in November 2010 to improve dementia care. This quality registry uses the Neuropsychiatric Inventory (NPI) for repeated measurements of the incidence and severity of BPSD at dementia care units throughout the country. The registry provides a systematic working tool for the staff resulting mainly in non-pharmacological interventions. The aim of this study was to describe the prevalence, development, and treatment of neuropsychiatric symptoms in patients at dementia care units in Sweden.
Method:
We extracted data on more than 20 000 cases from the BPSD-registry over a four-year period between November 2010 and November 2014.
Results:
The presentation will include data on more than 20 000 cases included in the registry during four years. Preliminary 3-year data showed a significant reduction of the NPI-score at patients with more than 50 points at baseline and a subsequent stabilization over time and a significant increase in the proportion of tailor-made care-plans from 40% in 2011 to 80% in 2014.
Conclusions:
The Swedish BPSD-registry is a working tool for the multidisciplinary team to reduce prevalence and severity of BPSD through non-pharmacological interventions in cases with severe dementia.

ADPD5-0667
THE RELATIONSHIP BETWEEN GDS STRUCTURE AND COGNITIVE-BEHAVIORAL ASPECTS IN AD

Y. Yang[1], J.H. Kang[1], J.H. Han[1], D.E. Kim[1]
[1]Neurology, Seoul Veterans Hospital, Seoul, Korea

Background: Although 15-item of the Geriatric Depression Scale(GDS15) is a widely used depression screening questionnaire, the implications of GDS15 in AD may be questioned. We designed this study to explore the factor structure of GDS15 and the relation between these factors and cognitive-behavioral aspects.
Methods : GDS15, cognitive function tests, Korean-Neuropsychiatry Inventory(K-NPI) were administered to 310 patients with probable AD, who were not medicated before visiting the hospital. Using Principal component analysis (PCA), three factors were identified. To determine the relationship between factors and neurocognitive, behavior symptoms, bivariate correlation was used.
Results : The factor 2 was correlated with K-BNT(Korean Boston Naming Test), calculation, Go-no-go test, COWAT(Controlled Oral Word Association Test), CWST(Color Word Stroop Test; word and color), aggression, depression, and apathy. The factor 3 was correlated with calculation, SVLT(Seoul Verbal Learning Test) immediate recall, RCFT(Rey-Osterrieth Complex Figure Test) copy, RCFT delayed recall, contrasting, COWAT, CWST word, and delusion. Our study identified three factors and revealed that the GDS15 may be comprised of a heterogeneous scale.
Conclusions : These results suggest that the GDS15 may be comprised of a heterogeneous scale and suggested multi-dimensionality properties of GDS15 in AD.

ADPD5-0699

PRESCRIBING STATUS OF PSYCHOTROPIC DRUGS FOR THE TREATMENT OF BPSD; A SURVEY FOR PRIMARY CARE PHYSICIANS AND DEMENTIA SPECIALISTS IN JAPAN

N. Tsuno[1], Y. Nakamura[1], A. Homma[2]
[1]Department of Neuropsychiatry, Kagawa University, Miki-cho Kita-gun, Japan
[2]Tokyo Center, Dementia Care Research and Training Center, Tokyo, Japan

Background/Objectives; Currently, there are no anti-psychotics officially approved for the treatment of BPSD in Japan. However many physicians often prescribe psychotropic drugs including anti-psychotics for patients with BPSD. This survey aimed to investigate the prescribing status of psychotropic drugs by primary care physicians, and to assess the differences in the prescribing practices between primary care physicians and dementia specialists in Japan.

Methods; A survey was mailed to 3,098 family physicians extracted from active members of the Japan medical association (response rate 19.5%) and to 3,147 dementia specialists affiliated with the Japanese Psychogeriatric Society, the Japan Society for Dementia Research, the Japan Geriatrics Society, or the Japan Psychiatric Medical Conference (response rate 20.3%).

Results; The demographic profiles of the primary care physicians who responded were similar to that of dementia specialists for age, type of clinical practice, and clinical experience. Almost 90% in both primary care physicians and dementia specialists see patients with dementia and prescribe psychotropic drugs for patients with dementia in daily clinical practice. The two groups reported a wide range of psychotropic medication for a great variety of BPSD and similar prescribing practices for the treatment of BPSD. A proportion of physicians who obtained informed consent, when they prescribe anti-psychotics, was approximately as low as 20 %.

Conclusions; The results of the present survey highlight the psychotropic drug prescription status in the management of BPSD. A majority of Japanese clinicians prescribe miscellaneous psychotropic drugs including anti-psychotics for patients with a wide variety of BPSD in daily practice.

CLASSIFICATION OF BEHAVIORS IN DEMENTIA BASED ON THEORIES OF INFORMATION PROCESSING

A. Luthra[1]
[1]*Program for Older Adults, Homewood Health, Guelph, Canada*

Objectives: There is vast heterogeneity in use of terminology and classification of behaviors in dementia with no universally accepted classification system.
Methods: Criteria proposed by Davis, Buckwalter and Burgio (1997) were identified as the basis for classification of behaviors in dementia. A review of the literature was done to identify the "Specification of the Theoretical Construct" (STC) to justify aggregation of similar behavioral symptoms into clinically meaningful categories.
Results: STC identified for these behavioral categories are those based in theories on information processing (TIP). Two behavioral categories emanating from pathological changes in TIP are: Disorganized Behaviors (DOB), and Misidentification Behaviors (MiB).
Discussion: DOB is the result of an alteration in the physiological status of the patient. This result in changes in arousal and attentiveness and this, in turn, leads to impairment of the sequential organization of information processing thereby giving way to fragmentation of the process at many different levels of the brain. MiB are the result of a specific breakdown in two specific steps of TIP; schema identification and pattern recognition. This result in the failure of the usual pairing of old and new information with an altered sense of relatedness between self and persons, places, objects and events.
Keywords: Dementia, Behavioral Symptoms, Classification, Information Processing, Disorganized Behaviors, Misidentification Behaviors

ADPD5-1575
CLASSIFICATION OF BEHAVIORS IN DEMENTIA BASED IN "MOTIVATIONAL" AND "NEEDS BASED" THEORIES

A.S. Luthra[1]
[1]*Program for Older Adults, Homewood Health, Guelph, Canada*

Objectives: There is vast heterogeneity in use of terminology and classification of behaviors in dementia with no universally accepted classification system.

Methods: Criteria proposed by Davis, Buckwalter and Burgio (1997) were identified as the basis for classification of behaviors in dementia. A review of literature was done with a view to identify the "Specification of the Theoretical Construct" to justify aggregation of similar behavioral symptoms into clinically meaningful categories.

Results: "Specification of the Theoretical Construct" identified for these behavioral categories are motivational and needs based theories. Behavioral categories emanating from these constructs are: Apathy Behaviors (AB), Goal Directed Behaviors (GDB), Motor Behaviors (MB), and Importuning Behaviors (IB).

Discussion: Apathy behaviors are the result of a decrease in the motivational drives with an absence of any need fulfillment. Goal-Directed Behaviors are the result of an increase in motivational drives with increase in detection and fulfillment of "belongingness" needs. Motor behaviors are the result of varying degrees of changes in motivational drives and are concomitants to other behavioral categories. Importuning behaviors are the result of preserved motivational drives in detection and fulfillment of "physiological needs".

Keywords: Dementia, Behavioral Symptoms, Motivational Theories, Needs-Based Theories

ADPD5-1576
CLASSIFICATION OF BEHAVIORS IN DEMENTIAS BASED UPON THEORIES OF REGULATION OF EMOTIONS

A.S. Luthra[1]
[1]*Program for Older Adults, Homewood Health, Guelph, Canada*

Objectives: There is vast heterogeneity in use of terminology and classification of behaviors in dementia with no universally accepted classification system.
Methods: Criteria proposed by Davis, Buckwalter and Burgio (1997) were identified as the basis for classification of behaviors in dementia. A review of literature was done with a view to identify the "Specification of the Theoretical Construct" (STC) to justify aggregation of similar behavioral symptoms into clinically meaningful categories.
Results: STC identified for these behavioral categories are theories on regulation of emotions. Behavioral categories emanating from this construct are; Emotional Behaviors (EB), Fretful/Trepidated Behaviors (FTB) and Vocal Behaviors (VB).
Discussion: EB are based in expression of the emotion of melancholy and discontentment. EB based in melancholy provide the patient with a measured catharsis to allow for decompression from pain. EB based in discontentment provide the patient with protection from pain. FTB are based in the expression of emotion of fear. FTB make caregivers aware of the insecurity needs of the patient. VB are based in the expression of emotions of anger and joy. They highlight the 'out of proportion' nature of responses in patients. This response may or may not be associated with functional motor activity (FMA).
Keywords: Dementia, Behavior, Classification, Vocal Behaviors, Fretful/Trepidated Behaviors, Emotional Behaviors

ADPD5-1577
CLASSIFICATION OF BEHAVIORS IN DEMENTIAS BASED ON PRINCIPLES OF COMPLIANCE AND AGGRESSION
A.S. Luthra[1]
[1]*Program for Older Adults, Homewood Health, Guelph, Canada*
Objectives: There is vast heterogeneity in use of terminology and classification of behaviors in dementia with no universally accepted classification system.
Methods: Criteria proposed by Davis, Buckwalter and Burgio (1997) were identified as the basis for classification of behaviors in dementia. A review of literature was done with a view to identify the "Specification of the Theoretical Construct" (STC) to justify aggregation of similar behavioral symptoms into clinically meaningful categories.
Results: STC identified for these behavioral categories are theories on compliance and aggression. Behavioral categories emanating from this construct are; *Oppositional Behaviors* (OB) and *Physically Aggressive Behaviors* (PAB).
Discussion: OB is the result of non-compliance to the directions being given by the care provider. The types of OB are determined by the level of developmental sophistication or conversely by the degree of cognitive impairment in patients with dementia. PAB are the result of perceived impediment by the patient in goal attainment. This results in the emergence of negative emotions. These emotions are 'out of proportion' to the stimulus. The purpose of this behaviour is to warn the care provider of the noxious nature of their involvement in the present situation.
Keywords: Dementia, Behaviors, Opposition, Aggression, Classification

INTEGRATED ONE-STOP COGNITIVE ASSESSMENT CLINIC FOR DEMENTIA PATIENTS

C.Y. YUNG[1], C.C. CHAN[1], M.L. LAU[1], Y.Y. TAM[1], L.N. TANG[1], M.L. LEUNG[2], M.Y. LO[3]
[1]Medicine & Geriatrics, United Christian Hospital, Hong Kong, Hong Kong China
[2]Occupational Therapy, United Christian Hospital, Hong Kong, Hong Kong China
[3]Physiotherapy, United Christian Hospital, Hong Kong, Hong Kong China

Introduction
Patient-centred care planning is vital to dementia patients. Multidisciplinary approach ensures continuity of care and unification of care goals. In a district hospital in Hong Kong, an integrated cognitive assessment clinic was established in 2013, operating with a novel collaborative model of providing an one-stop service.
Objective
To launch an integrated one-stop service for dementia patients through collaboration of an interdisciplinary team
Methodology
An interdisciplinary team comprising geriatricians, nurses, occupational therapists and physiotherapists was established in 2013. During the first consultation patients are assessed on various domains by members of the team. Related investigations including structural imaging are performed beforehand. Geriatricians are responsible to establish the clinical diagnosis. In the subsequent case conference, care planning and goals are aligned and formulated. Anti-dementia medications were prescribed to suitable patients. Cognitive rehabilitation including mind-body exercise was arranged whenever appropriate. Community resources were introduced and recommended so that patients and caregivers could receive maximal community support.
Results
In the recent 12 months, a total of 124 cases were attended. 71 (57.2%) were diagnosed dementia and 47 (37.9%) were mild cognitive impairment. Among those with dementia, 47 (37.9%), 17 (13.7%) and 7 patients (5.6%) were respectively graded as mild, moderate and severe stage of dementia. 31 patients (43.7%) received anti-dementia medications, 62 patients (50%) completed cognitive rehabilitative training, and 35 patients were recruited for SmartMove training (a sort of Mind-Body exercise programme).
Conclusion
An integrated one-stop cognitive assessment clinic could provide a holistic, people-centred framework in assessing and managing patients with dementia.

ANTIPSYCHOTIC INDUCED CATALEPSY – POSSIBLE NEURODEGENERATIVE MARKER IN SCHIZOPHRENIA (ANIMAL MODEL STUDY)

L. Mogoanta[1], D. Marinescu[2], I. Marinescu[2], M. Pirlog[3]
[1]Histology, University of Medicine and Pharmacy of Craiova, Craiova, Romania
[2]Psychiatry, University of Medicine and Pharmacy of Craiova, Craiova, Romania
[3]Medical Sociology, University of Medicine and Pharmacy of Craiova, Craiova, Romania

Objectives
Highlighting on animal model of potentially histological cerebral changes induced by haloperidol (dopamine blocker) and aripiprazole (partially dopamine agonist) associated with catalepsy. This model may be a clinical predictive indicator for the neurodegenerative-type course of schizophrenia.
Methods
Animal study on three samples of Wistar rats (8 per group), male adults, and weight between 200-250 grams, which were kept during the study in standard parameters imposed by ethical norms for animal study (study approved by Ethical Committee). Antipsychotics were intraperitoneal administered in maximum dosage: N1 – haloperidol (0.25mg/kg), N2 – aripiprazole (0.80mg/kg), N0 (control) – saline solution. Were assessed catalepsy (the homolateral limbs of the rats were crossed by the experimenter; animals which maintained this imposed abnormal position for more than 10 seconds were considered to be cataleptic) and abnormal behavior. Rats were sacrificed in day 11, after 12 hours from last injection. Biological material (frontal cortex and hippocampus) was histological prepared.
Results
On N1 sample, all rats presented catalepsy and abnormal behavior (apathy and aggression), while in N2 sample was not identified this phenomena. Histological assessment highlighted neuronal changes in N1 sample: apoptosis, vacuolization, pinocytosis, necrosis and microhemorrhages in frontal cortex and hippocampus. In N2 sample, these changes were minimal.
Conclusions
Haloperidol lead to catalepsy and important histological changes in frontal cortex and hippocampus, compared to aripiprazole, according to the neurodegenerative model.

ADPD5-1331
ASSESSMENT OF BASELINE AND FOLLOW-UP SERUM URIC ACID LEVELS IN ESSENTIAL TREMOR

A. Koçer[1], M. Okay[1], B. Hasirci[1], D. Agircan[1], A. Varoglu[1]
[1]Neurology, Istanbul Medeniyet University, Istanbul, Turkey

Objective: Decreased serum uric acid has been associated with neurodegenerative diseases such as Parkinson's disease (PD) in the elderly. Several studies suggest that there may be a link between PD and Essential tremor (ET) which is thought to be a neurodegenerative disease. Serum uric acid level (UA) and its relationship with prognosis in ET patients have not been addressed.
Method: Subjects with ET were evaluated. We collected serum samples to determine biochemical indicators including UA, glucose, blood lipids, liver function, and renal function. All the patients with vascular risk factors, dementia, depression or other neurodegenerative disorders were excluded, as were subjects on uric acid-lowering therapy or with serious illnesses such as severe anemia, chronic renal failure, hepatic disease or active or ongoing cardiovascular or cerebral vascular disease. One hundred and sixteen subjects (52 isolated ET patients and 64 healthy controls well matched in comparison of age and sex) were enrolled.
Results: UA level was similar between the groups. Follow-up UA levels of the patients was similar to controls, too. UA level correlated to age, ET starting age, cholesterol level and creatinine level ($p<0.05$).
Conclusion: There were reasonable epidemiological evidences to support a link between ET and UA level, but we did not find any difference between serum UA levels of ET patients and controls in follow-up. Age was one of the factors contributing to the increased content of UA. These findings also supported the knowledge about isolated form of ET which was stable and benign.

ADPD5-0744
THE MCCUSKER SUBJECTIVE COGNITIVE IMPAIRMENT INVENTORY: A NEW SELF-REPORT MEASURE OF COGNITIVE CONCERNS

H. Sohrabi[1], M. Weinborn[2], R. Martins[1]
[1]Medical Sciences, Edith Cowan University, Perth, Australia
[2]Psychology, University of Western Australia, Perth, Australia

Subjective Cognitive Impairment (SCI) has recently been acknowledged as an early preclinical stage of dementia. It refers to an individual's concerns about their own cognitive functions. There is a shortage of reliable and valid measures to assess ones concerns in relation to their current cognitive functions as compared to their previous functioning. The currently available measures do not provide information with clinical and research applications. We report on our newly developed 46-item measure, namely the McCusker Subjective Cognitive Impairment Inventory (McSCI). The McSCI captures ones' complaints about the changes they have noticed in their cognitive functions. It measures concerns associated with six cognitive domains including language, orientation, attention and concentration, executive function, memory, and visuoconstructive abilities. Each question is scored on a five point *Likert scale* ranging from four (almost always true) to zero (almost never true). The McSCI has patient and informant versions and provides scores for concerns associated with each cognitive domain in addition to a total SCI score. The McSCI has acceptable reliability and validity and has been examined against objective and subjective cognitive and memory measures. As a short and quick measure, the McSCI provides enough information to be used in research and in clinical settings.

ADPD5-0761

ANTICHOLINESTERASE ACTIVITY OF AN ACTIVE FRACTION OF THE EXTRACT OF LEAVES OF CITRUS LIMON (L.) BURM

C.M. Feitosa[1], R.B.F. Carvalho[1], R.M. Freitas[2], J.S. Costa Junior[3]
[1]Chemistry and Natural Products of Laboratory and Research in Experimental Neurochemistry, Federal University of Piaui, Teresina, Brazil
[2]Natural Products of Laboratory and Research in Experimental Neurochemistry, Federal University of Piaui, Teresina, Brazil
[3]Department of Chemistry, Federal Institute of Piaui, Teresina, Brazil

Objectives: The aim of this study was the qualitative and quantitative evaluation *in vitro* and *ex vivo* of a mix of compounds (5,8-Dimethoxypsoralen and 5,7-Dimethoxycoumarin) isolated from leaves of *Citrus limon* (L.) Burm to verify potential inhibition of acetylcholinesterase. **Methods:** Qualitative inhibitory activity was performed according to Ellman's method (1961) and quantitative activity was evaluated by Ellman and colleagues spectrophotometric method adapted (1961) and Moyo and colleagues (2010). All the *ex vivo* experiments performed in this study got approved by the Animal Experimentation Ethics Committee of the Federal University of Piaui (CEEA / UFPI # 44/09). **Results:** The compound presented positive result in the qualitative inhibition of acetylcholinesterase enzyme, observed through the thin-layer chromatography plate, which presented yellow colored with white spaces. In the qualitative study we noticed an inhibition of 95.9% when neostigmine (positive control) was used at a concentration of 0.1 mg/mL. With the isolated compound at concentrations of 0.1, 0.05, 0.025, 0.0125 and 0.00625 mg/mL we have detected an inhibition of 57.75, 49.89, 35.03, 23.78 and 8.71% in the *in vitro* activity of AChE, respectively. Based on these results, the EC_{50} was also determined as 0.061 mg/mL with confidence interval of 95% (0.033 a 0.18 mg/mL; $r^2 = 0.9935$). *Ex vivo* studies (10 and 25 mg/kg) revealed inhibition of 30.09 and 30.06% of AChE activity compared to neostigmine. **Conclusion:** Compared to results of other studies, our data agree with the hypothesis that coumarinic compounds present anticholinesterase potential.

COPPER CHELATION EFFICACY OF D-PENICILLAMINE NANOPARTICLES IN EXPERIMENTAL RAT MODEL FOR NON-WILSONIAN BRAIN COPPER TOXICOSIS

A. Pal[1], R.K. Vasishta[2], B.R. Thapa[3], R. Prasad[1]
[1]Biochemistry, Post Graduate Institute of Medical Education and Research, Chandigarh, India
[2]histopathology, Post Graduate Institute of Medical Education and Research, Chandigarh, India
[3]gastroenterology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Objective: D-penicillamine is unable to mitigate the brain copper overload and neurological manifestations in Alzheimer's/Wilson's disease patients. The aim of this study was to assess the therapeutic efficacy of orally administered D-penicillamine loaded nanoparticles to that of conventional D-penicillamine for 90 days in Wistar rat model for non-Wilsonian brain copper toxicosis.
Methods: High performance liquid chromatography, atomic absorption spectrophotometry, neurobehavioral and histopathological studies, and nanoparticles preparation/physicochemical characterization were carried out.
Results: D-penicillamine nanoparticles exhibited mean 274.09 nm size and less than 29.32% of D-penicillamine release under in vitro conditions. Pharmacokinetics studies showed augmented levels of D-penicillamine in brain of nanoparticles based D-penicillamine delivery group compared to conventional D-penicillamine delivery group. Conventional and nanoparticles based D-penicillamine therapy resulted in significantly improved neuromuscular coordination and memory along with concomitant increase in urinary copper levels, and acetylcholinesterase activity in rat model of copper toxicosis. Conventional D-penicillamine therapy resulted in negative rhodanine staining of liver and brain sections corroborated by 60.1%, and16.4% reduction in hepatic and brain copper content, respectively compared to non-treated copper-intoxicated group. However, liver and brain sections of nanoparticles based D-penicillamine therapy group demonstrated grade 1 copper and no copper depositions substantiated by 47.2% and 32.8% reduction in hepatic and brain copper content, respectively in comparison to non-treated copper-intoxicated group.
Conclusions: Taken together, the present study reveals the first *in vivo* evidence for therapeutic efficacy of nanoparticles based D-penicillamine therapy in chelating more brain copper and alleviating neurological deficits even at half the dose as given in conventional D-penicillamine therapy.

ADPD5-1713
MODELIZING TOPOGRAPHICAL DISORIENTION, AN ALERT SIGN IN ALZHEIMER'S DISEASE, IN MICE USING A NOVEL COMPLEX MAZE: THE HAMLET TEST®

J. Meunier[1], A. Marie[1], T. Maurice[1]
[1]R&D, AMYLGEN, MONTFERRIER-SUR-LEZ, France

One of the alert signs that Alzheimer's disease in the elderly is disorientation in familiar environment. We designed an apparatus mimicking a small village to examine topographical memory and disorientation in complex environment. The Hamlet Test® comprises a central agora and 20 streets expanding from it in a 5-branch shape, leading to functionalized houses. Five physiological needs are modelized in the different houses : Eat, Drink, Play, Run and Interact. Animals were trained in groups, spending 4h/day during 1d, 1, 2 or 4 weeks in the Hamlet Test and their ability to orientate was tested after different conditions and timing. Topographical memory was assessed in water- or food-deprived animals by measuring the latency and number of errors spent to reach the Drink or Eat house. Animals explored all houses, but differentially, according to their rewarding impact, suggesting that they efficiently integrated the spatial complexity. Deprived animals showed significantly decreased latencies and numbers of errors, particularly after 1 day, 2 or 4 weeks habituation period, showing that topographical memory is activated in the test. Finally, animals trained during 2 weeks were intracerebroventricularly injected with oligomeric amyloid ß25-35 peptide or scrambled control peptide 3 days after training. When retested in the Hamlet Test after 7 days, Aß25-35-treated animals showed memory impairment. We are currently testing transgenic mouse lines. The Hamlet Test appears as a novel behavioral test that can address not only environmental enrichment, but also, more specifically, topographical disorientation observed in Alzheimer's pathology.

[3]Physical Education and Sports, Alexandru Ioan Cuza University Iasi, Iasi, Romania
[4]Pharmacy, "Gr.T.Popa" University, Iasi, Romania
[5]Medicine, "Gr.T.Popa" University, Iasi, Romania

Background
It is well known that in Parkinson's disease (PD), individuals have greater reduction in physical activity levels. Also, inactivity is considered an important factor in accelerating the degenerative process of PD. In addition, PD is known for its cognitive impairments, as well as for depression and anxiety disorders, which may be important causes of morbidity (40% prevalence in PD).
Also, one of the most used animal models of PD is generated by the administration of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP).
Methods:
We want it to see if induced physical exercising in an MPTP-induced rat model of PD (20 mg/kg i.p.), will result in any changes in memory (as tested in Y maze), anxiety (as tested in elevated-plus-maze) and depression-like behaviour (forced-swim-test), as compared to a non-exercised control group of rats which also received MPTP.
The exercising was performed on an adapted treadmill, for 2 weeks (3 series of 5 minutes/day).
Results
In the group of exercised MPTP group we could observe an increased time spent by the rats in the open arms of the elevated-plus-maze, together with a significant decrease of stretching behaviour and increased head dipping, as compared to non-exercised MPTP group, factors with are suggesting an anxiolytic-like manifestation. In addition, spontaneous alternation in Y maze (index for immediate memory), and swim time (anti-depressive index) in forced swim test were increased in the exercised rats with an MPTP-induced model of PD.
Conclusions
Physical exercising seems to reduce anxiety, depression and memory deficits associated with a MPTP-induced rat model of PD.

THE TIME OF THE ONSET OF URINARY SYMPTOMS IN MULTIPLE SYSTEM ATROPHY

T. Yamamoto[1], M. Asahina[1], T. Uchiyama[2], S. Hirano[1], Y. Yamanaka[1], A. Sugiyama[1], M. Yanagisawa[3], M.I.K.I. Fuse[3], R. Sakakibara[4], S. Kuwabara[1]

[1]Neurology, Chiba University, Chiba, Japan

[2]Continence center Neurology, Dokkyo medical university, Tochigi, Japan

[3]Urology, Chiba University, Chiba, Japan

[4]Neurology, Sakura medical center Toho University, Sakura, Japan

Objective

We aimed to clarify the time of the onset of urinary symptoms with respect to the clinical phenotype.

Methods

We have retrospectively reviewed the medical records of the 100 patients with MSA who were diagnosed with probable or possible MSA according to the Gilman's second consensus criteria over the past 5 years to identify the initial symptoms, the time of the onset of urinary symptoms and the post-void residuals (PVR).

Results

Our results included 59 patients with MSA-C and 41 patients with MSA-P. Mean disease duration was 3.1 years in both groups. The initial symptoms of MSA-C were as follows: Autonomic symptoms n=12, Cerebellar symptoms n=47.(Fig 1-a) In MSA-P, the initial symptoms were as follows: Autonomic symptoms: n=14, Extrapyramidal: n=27.(Fig 1-b) The time of the onset of urinary symptoms in patients whose initial symptoms were motor dysfunction was 2.2±1.3 years in MSA-C and 2.1±1.2 years in MSA-P without significant difference.(Fig 1-c) The maximum durations between the onset of urinary symptoms and initial motor symptoms were 6.0 years in MSA-C and 4.7 years in MSA-P. The mean PVR at the time of examination was 148±119 ml in MSA-C and 152±111ml in MSA-P without significant difference.

Conclusions

The time of the onset of urinary symptoms were various and seemed to be unrelated to the clinical phenotypes.

A long term examinations of urinary symptoms are necessary for the correct diagnosis of MSA.

Institute of Higher Nervous Activity and Neurophysiology of RAS, Moscow, Russia
[3]Scientific Consulting, Scientific Centre of Neurology of RAS, Moscow, Russia
[4]Computational Matematics, Moscow Institute of Physics and Technology, Moscow, Russia
[5]Applied Informaton Systems, Moscow Institute of Physics and Technology, Moscow, Russia

· Objectives

Electroencephalogram, electromyogram and tremor of the non-treated early stage Parkinson's disease (PD) patients were investigated jointly. The control group and the 1st stage of Hoehn-Yahr scale patients group were consisted of 16 and 25 people respectively.

· Methods

The time-frequency distribution of extrema points of the electroencephalogram, envelope of electromyogram and tremor wavelet spectrograms were analyzed to extract quantitative PD features. Frequency synchronization of electroencephalogram, electromyogram and tremor were found out.

· Results

Figures illustrate the interhemispheric asymmetry of the motor cortex shown by time-frequency extrema points distribution, and the connectivity of 4-6 Hz electroencephalogram rhythm in one cortex area with the contralateral electromyogram and tremor. C3, C4, EMG_RH, EMG_LH, RH, and LH mark the EEG and EMG electrodes, right and left hand accelerometers respectively.

The coincidences with the clinical diagnosis for joint electroencephalogram, electromyogram and tremor investigations is equal to 92 percent's for the 1st stage PD patients and 87 percent's for the control group.

· Conclusions

Joint electroencephalogram, electromyogram, and tremor investigation gives reliable quantitative diagnosis of the 1st stage Parkinson's disease in comparison with the clinical diagnosis.

ADPD5-0799

VALIDATION OF THE KOREAN LEWY BODY COMPOSITE RISK SCORE FOR DISCRIMINATION OF DEMENTIA WITH LEWY BODIES IN THE KOREAN ELDERLY

S. Han[1], H.J. Ryu[1], T.S. Moon[1], M.Y. Kim[1], I.E. Chung[1], J.Y. Han[2], J. Galvin[3]
[1]Neurology, Konkuk University Medical Center, Seoul, Korea
[2]Neurology, Seoul National University Hospital, Seoul, Korea
[3]Neurology Psychiatry Nursing Nutrition and Population Health, New York University Langone School of Medicine, New York, USA

The Lewy Body Composite Risk Score (LBCRS) was developed as an useful tool to enhance the accuracy of the cognitive diagnosis for patients affected by Lewy Bodies' pathological conditions. This study aimed to assess the diagnostic accuracy of the Korean version of the LBCRS (K-LBCRS) among Korean population with Alzheimer's dementia (AD) and Dementia with Lewy bodies (DLB). The 49 subjects who participated in this study have (32 with AD, 17 with DLB) visited the neurology outpatient clinic of KUMC. The subjects' demographic data and administered K-MMSE, Clinical Dementia Rating sum of boxes (CDR-SB), K-LBCRS, NPI, Mayo Fluctuation Scale (MFS), Mayo Sleep Questionnaire (MSQ), Epworth Sleepiness Scale (ESS), and mini Physical Performance Test (PPT) were collected. The K-LBCRS was created through translation and back-translation of the LBCRS. The sensitivity, the specificity, and the area under the curve were evaluated by receiver operator characteristics (ROC) analysis. An ROC curve was used to determine the optimal cut-off values for discrimination of DLB against AD. The ROC analysis showed that the optimal cut-off point of the K-LBCRS for identification of DLB was 2/3, which gave the balance between sensitivity (94%) and specificity (75%). The K-LBCRS was significantly correlated with CDR-SB (r=0.40), MFQ (r=0.75) in AD group, whereas ESS (r=0.71), MFQ (r=0.82) was significant in DLB group. The K-LBCRS has important clinical characteristics of DLB that may differentiate it from AD, and as a result may enable the K-LBCRS as a clinically useful screening tool to discriminate the two groups.

ADPD5-1032

DO REHABILITATION STAFF RECOGNIZE THE DIFFERENCE BETWEEN LATE PARAPHRENIA AND DEMENTIA? A QUESTIONNAIRE SURVEY

Y. Funaki[1], R. Hirasawa[1], H. Hanaoka[2], F. Kaneko[2], H. Okamura[2]
[1]Department of Rehabilitation, Hiroshima International University, Higashi-hiroshima, Japan
[2]Institute of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan

Objectives: Medical support staff in Japan are generally unfamiliar with late paraphrenia, and it is easy to misdiagnose elderly patients with paraphrenia as suffering from dementia. Therefore, it is predicted that many patients with late paraphrenia in Japan have been misdiagnosed in this way. A pilot study is reported here that aimed to develop a checklist for judging late paraphrenia and dementia. Our initial purpose was to investigate the knowledge rehabilitation staff have regarding late paraphrenia.
Methods: A questionnaire was sent to 300 occupational therapists working within elder-care institutes in Japan. Names were sampled randomly from an applicable association list. Questionnaires were returned anonymously by mail.
Results: There was a response rate of 36% (108 questionnaires returned), of which most responses were from women over the age of 30. Only 12% of respondents were familiar with late paraphrenia. Three respondents (2.8% of the sample) had encountered patients with late paraphrenia. In contrast, 40% of the therapists had examined a patient in a condition consistent with late paraphrenia. The content of the patient's delusions were what led the therapist to suspect that the patient might have a condition other than dementia.
Conclusion: In Japan, most rehabilitation staff do not know of late paraphrenia, but it is clear that they recognize when a patient might be suffering from a disease inconsistent with their diagnosis of dementia. The content of delusions might help discriminate dementia from late paraphrenia.

WHAT IS THE DIFFERENCE BETWEEN THE COGNITIVE PROFILES OF HUNTINGTON'S AND PD?
G. Yalcin Cakmakli[1], G. Genc Akpulat[2], O. Celebi[3], E. Saka[2], B. Elibol[2]
[1]Institute of Neurological Sciences and Psychiatry, Hacettepe University, ANKARA, Turkey
[2]Neurology, Hacettepe University Medical Faculty, ANKARA, Turkey
[3]Institute Of Neurological Sciences and Psychiatry, Hacettepe University, ANKARA, Turkey
Aim: Huntington's disease (HD) is an autosomal dominant, progressive neurodegenerative disease, characterized by motor, cognitive and behavioral problems. Here, our aim is to define the cognitive profile specific to HD with comparison to PD and to search for its relationship with CAG repeat numbers.
Materials and Methods: Demographics and disease features of non-demented patients with HD (n=24), PD (n=20), control (n=16) groups were noted. For detailed cognitive evaluation, minimental state examination, geriatric/Beck's depression scales, enhanced cued recall (ECR), semantic and phonemic fluency, digit-span forward and backward, trail making test part A-B, reciting months backward, Stroop, clock drawing, Benton's line orientation, Benton's facial recognition and Hooper tests were administered. The relationship between the test results and CAG repeat numbers and CAP scores (product of CAG repeat number and age) for HD was also evaluated.
Results: Age was similar for all groups; disease duration and education were similar for HD and PD. All test results of HD group were significantly worse than those of controls; the results for ECR, semantic fluency, digit-span forward, reciting months backward and Benton's facial recognition were significantly worse than PD. CAP score, which determines the duration and severity of exposure to the mutant gene product, is found to be significantly correlated with the results of digit-span forward, Stroop and trail making test part B.
Conclusion: This study showed that HD has a cognitive profile with certain particular features, which differentiates it from PD. Also executive functions were found to have correlation with CAP score.

ADPD5-1618
IDENTIFICATION OF VERY MILD DEMENTIA BY ACTIVITIES OF DAILY LIVING: A CREDOS STUDY
S. Moon[1], S. Lee[1], H. Lee[1]
[1]Neurology, Ajou University School of Medicine, Suwon, Korea
Background: We aimed to select more sensitive items in instrumental ADL questionnaires and make a identification system of very mild dementia.
Methods: We recruited 8779 patients who were diagnosed with healthy subject, subjective memory impairment (SMI), mild cognitive impairment (MCI), and dementia from the Clinical Research Center for Dementia of Korea (CREDOS) registry. All subjects were classified into three patient groups by clinical diagnosis and Clinical Dementia Rating (CDR) score: predementia, very mild dementia (CDR 0.5), and remaining dementia. Multivariate logistic regression were used for identifying discriminative items in Seoul instrumental ADL (SIADL) in men or women, respectively. Prediction model was made with equations including discriminative items and age.
Results: At first, we compared dementia patients with predementia patients. In male, SIADL questionnaire excepting 2 items (outgoing for a short distance and securing a door) had same discrimination ability as original questionnaire with 15 items (area under the curve, 0.903 vs 0.903). In female, SIADL questionnaire excepting 5 items (outgoing for a short distance, grooming, using household appliances, managing belongings, and securing a door) presented almost same results (area under the curve , 0.914 vs 0.913). With the same method, we compared very mild dementia patients with remaining dementia patients. SIADL questionnaire excepting 9 items in male and excepting 5 items in female showed good discrimination ability (area under the curve, 0.834 and 0.833, respectively).
Conclusions: We expect that this result could be helpful for primary physician examining suspicious dementia patients in Korea.

Cryptogenic temporal lobe epilepsy (CTLE). has no evidence of morphological changes in brain structure, that can be revealed using conventional neurovisualisation tools. Patients with CTLE usually suffer memory dysfunction. It is considered that verbal memory is affected by left-sided Hippocampal sclerosis (HS), whereas visuo-spatial memory is more affected by right HS. But what if there's no HS take place along with functional abnormality mentioned above. Some of these impairments may be related to breakdown of the network in which hippocampus may take part. Functional connectivity establishment can lead to understanding how the hippocampi interact with other brain areas. It can be estimated with the help of resting state fMRI by evaluating patterns of functional networks. In this study we investigated functional connectivity patterns of 19 controls, 31 patients with right CTLE and 25 with left-sided CTLE.

We found differences in functional connectivity within and between hippocampi in patients with unilateral CTLE. Functional connectivity turned out to be more impaired ipsilateral to the seizure focus in both patient groups when compared to control subjects. This effect was even more obvious in the left-sided CTLE patient group. These results suggest that left-sided CTLE meets more reduction of functional connectivity than right-sided one in subjects with left hemisphere language dominance. Still morphological study must take place to dicover if there are any brain matter volume changes, especially in critical for brain network functional areas.

OBJECTIVE MEASUREMENT OF GAIT PARAMETERS IN HEALTHY AND COGNITIVELY IMPAIRED ELDERLY USING THE DUAL TASK PARADIGM

L. Klaming[1], A. Koenig[2], M. Pijl[3]
[1]Behavior Cognition & Perception, Philips Research, Eindhoven, Netherlands
[2]School for Mental Health and Neuroscience, Maastricht University, Maastricht, Netherlands
[3]Personal Health, Philips Research, Eindhoven, Netherlands

Background
Motor function involves the integration of various cognitive functions including visuospatial perception, attention, and planning. Deficits in these cognitive functions can affect motor performance. Subtle changes in motor function can therefore be an early indicator of cognitive decline. Attentional deficits are of particular interest because motor function requires attentional resources and these decline in very early stages of dementia. Research has only recently started to look into ways to objectively measure subtle changes in attention.
Methods
A study including 60 participants is currently conducted to explore the effect of attentional deficits on gait parameters. The sample consists of MCI and AD patients and healthy age-matched controls. Neuropsychological measures include the MMSE and the Trail Making Test. All participants perform a single walking task and a dual task. The dual task involves walking while counting backwards. During these tasks, participants wear a wrist-worn accelerometer from which objective measures for gait speed, variability and cadence are derived. We hypothesize that walking speed is slower, cadence is lower and variability is greater in participants with cognitive impairment under the single task condition compared to healthy controls, and that these differences are more pronounced under the dual task condition.
Results
The study is ongoing and results will be presented at the conference.
Conclusions
The findings will add to the growing body of research on the relation between cognitive functions and motor performance and are relevant for clinical practice. An assessment using the dual task paradigm can contribute to an improvement of clinical decision-making.

SPIRITUAL WELL-BEING QUESTIONNAIRE SHALOM, CZECH VERSION – A VALIDATION STUDY. DATA FROM THE CZECH BRAIN AGING STUDY

R. Marciniak[1], K. Sheardova[1], D. Hudecek[1], O. Hromkova[1], M. Urbanova[1], M. Vyhnalek[1], J. Hort[1]

[1]Neuro 2 program,

International Clinical Research Center St. Anne's University Hospital Brno Brno Czech R epublic, Brno, Czech Republic

Objectives: The Czech Republic is one of most atheistic countries in the world. Interestingly one third of population identifies themselves in sociological researches as a 'spiritual' in some way, but they do not want to be associated with any form of institutionalized religion. Spirituality was identified in few studies as a protective factor in neurodegenerative diseases. To verify this finding we need reliable tool for measuring spirituality. The aim of this study is to examin validity of Czech version of Spiritual well-being questionnaire SHALOM and to examine limits of this questionnaire for subjects with cognitive impairment.

Methods: 107 elderly subjects devided into three groups: mild cognitive impairment (MCI), subjective memory complaints (SMC), and healthly eldrely (HE), completed SHALOM questionnaires. All subjests also underwent complete neuropsychological examination.

Results: Reliability was determined using Cronbach's alpha for internal consistency. The results indicate that the Cronbach's alpha coefficients showed acceptable and satisfactory internal consistencies, standardized Cronbach Coefficient Alpha was 0.951. Results also suggested that the SHALOM questionnaire is reliable tool to measure spirituality also in population with mild cognitive impairment.

Conclusion: The results showed that SHALOM questionnaire is reliable tool for measuring spirituality in Czech elderly population, including subjects with mild cognitive impairment.

PARKINSONIAN MOVEMENT DISORDER FROM PONTINE INFACRTIONS
V. Khanna[1]
[1]*Medicine, Warrington Hospital, Warrington, United Kingdom*
BackGround:
61 year old female was treated for Parkinsonian Disorder with Co Carledopa and Amantadine 11 years ago. Until a few years ago she was managing life fairly Independently with some help from the family.In January she noticed multiple falls And distinctive movment disorder set in which was not akin to levo-dopa induced dyskinesia. She was ataxic and off balance with Lying BP 130/70mmHg and Standing BP of 130/70mmHg Sinus rhythm of 78 bpm.
Hospitalisation
In January, she was admitted after a fall, found to have nystagmus, ataxic quadriparesis with lateropulsion and left to right sway. In addition she had athetoid head , neck, hands,pelvis and leg movement disorder. She had grade 3 motor deficit but no sensory impairment. No Horner,s or internuclear opthalmoplegia were noted.
Pursuit movement was positively saccadic. Her initial dysphonia and dysphasia resolved after a few days. Vascular screen was negative.
Radiology
MR scan confirmed 2 lacunar infarcts in the right pons and one in the left pons. Carotid dopplers showed minimal stenosis at the origin of the carotid arteries.
Diagnosis:
Bilateral Pontine Infacrtions with movement disorder mimicking worsening of Parkinsonian Symptoms.
Management:
She improved with slight reduction of Levodopa dosage and introduction of Procyclidine. Intensive rehabilitation helped get her back to mobility and vastly
improved movement disorder.

SHOULD DSM-5 HAVE RECOGNIZED "NEUROCOGNITIVE DISORDER DUE TO SCHIZOPHRENIA" AS A SEPARATE DIAGNOSIS?

S. malladi[1]
[1]*general psychiatry, institute of mental health, Singapore, Singapore*

Diagnostic and Statistical Manual of Mental Disorders-5 (DSM-5) introduced the term Neurocognitive disorder (NCD) and subsumed dementia into it. While it is known that Schizophrenia can lead to cognitive impairment it's exclusion from NCD is unclear. Through this presentation, the speaker will discuss the reasons why the diagnosis "Neurocognitive disorder due to Schizophrenia" should have been included. While mental illnesses are excluded with the consideration that cognitive deficits are not a core feature, NCDs due to Parkinson's disease and stroke are included which are primarily non-cognitive in nature. Functional decline is an expected feature in the proposed "NCD due to Schizophrenia" like all the other NCDs. Age of presentation of cognitive problems may vary from young-old just as may do with NCD due to traumatic brain injury and HIV. While it may be debated whether cognitive impairment in Schizophrenia takes a progressively deteriorating course or remains static, this becomes irrelevant considering that Substance induced and HIV related NCDs have a static course or may even improve.

The above explanation suggests that "NCD due to Schizophrenia" should be considered for inclusion in the future revision of DSM and should be kept in mind by authors of other classification systems. This is also important considering that the pathology and resultant profile of affected cognitive domains are less likely to match those of other NCDs. Recognizing this as a separate entity can potentially help with focused research, improved access to care and treatment, and better support for patients and carers.

GOAL-DIRECTED MOTOR CONTROL FUNCTION ESTIMATION IN A MAN-MACHINE INTERACTION SET-UP FOR THE OBJECTIVE EVALUATION OF MOVEMENT DISORDERS.

E. Staderini[1], *J. Tatangelo*[1]

[1]*Industrial Technologies Dept. - Industrial Automation Institute, HEIG-VD Western Switzerland University of Applied Sciences, Yverdon-les-Bains, Switzerland*

This study concerns the application of control-theory to humans for the modelling and the numerical estimation of goal-directed motor control and learning. Control-theory is a concept largely used in engineering for conceiving automatic systems (like automatic pilot in aircrafts). In our case we were interested in modelling the process implemented by the brain in controlling by hand an external machine. We use a black-box numerical identification of the human operator performances in a man-machine control-loop, where the human is asked to impose to the machine a given behaviour.

In the standard experiment set-up, a pursuit task is proposed to the subject under test. On the screen a target spot (yellow) is presented which the subject has to follow with a joystick controlled spot (red). In the figure the position of the yellow spot is the forcing function or reference while the red spot position is the system output. The task of the human under test is that of minimizing the error, i.e. the difference in position of the two spots. The machine under control is the couple of the joystick and the red spot whose transfer function can be modified by software. A system identification software (MATLAB) evaluates the parameters of the transfer function implemented by the subject providing a "finger-print" numerical assessment of the operator performance. Being the behaviour of the subject simultaneously affected by the cortex (goal-directed) and basal ganglia (habitual control), the proposed method should in principle show a high sensibility and sensitivity to central movement disorders.

CORTICAL THICKNESS IN ALZHEIMER'S DISEASE WITH POSTURAL INSTALBILITY MEASURED BY COMPUTERIZED DYNAMIC POSTUROGRAPHY

H. Yi[1], H. Lee[1]
[1]Dept. of Neurology, Keimyung University Dongsan medical center, Daegu, Korea

Background

Postural instability in the elderly may be affected by cognitive functions such as attention, executive and visuospatial functions besides underlying physical conditions. The aim of our study is to view the association between dynamic postural instability, cognitive dysfunction and cortical thinning in Alzheimer's disease (AD).

Methods

We investigated 107 AD and 37 controls. All of the participants were taken neuropsychological evaluation, brain MRI, and computerized dynamic posturography (CDP). Image analyses were done by multiple regression under measuring cortical thickness using freesurfer. The demographic features and CDP performances were compared between groups and within AD.

Results

Control showed better performance of CDP and neuropsychological evaluation, and less cortical thinning than AD group. The performance of the unilateral stance in AD, such as swaying distances, velocities, the frequencies of falling, were poorer than controls after adjusting for age and gender. Within AD, falling frequency was correlated with visual memory and COWAT test. However, motor latency and sensory organization test were not significant. Imaging analyses revealed that cortical thinning in the right temporal and frontal area and bilateral precuneus, was correlated with CDP parameters.

Conclusion

Our study represents dysequilibrium in AD is associated with localized cortical thinning of the prefrontal and the temporal cortex, and cognitive dysfunction such as frontal executive functions, visual memory and naming ability. Imbalance might be the epiphenomenon of AD.

STANDARD MOLECULES IN OLIGOMER-BASED DIAGNOSIS FOR ALZHEIMER'S DISEASE

M. Huelsemann[1], C. Zafiu[1], O. Bannach[1], D. Willbold[1]
[1]ICS-6, Juelich Research Center, Juelich, Germany

Objectives:

The sFIDA (surface-based fluorescence intensity distribution analysis) technology for early diagnosis of Alzheimer's disease is based on highly specific counting of amyloid beta (Aβ) oligomers in body fluids. For assay calibration and absolute quantification of Aβ oligomers, internal standards with defined numbers of Aβ molecules are required.

Methods:

Standard molecules were synthesized and serially diluted in CSF and plasma and applied to the sFIDA assay.

Results:

TEM micrographs show standard molecules of defined size. Analysis by FTIR spectroscopy demonstrates the efficiency of the synthesis.
By sFIDA we could successfully detect and quantify the standard molecules down to a femto-molar range.

Conclusion:

We observed reliable and biochemically stable standard molecules of known size and defined number of binding sites for applications in diagnostic assays and for spiking experiments in Alzheimer's disease diagnosis assay development.

[4]Early Phase, PAREXEL International, London, United Kingdom
[5]Radiology, Arcadia MRI & Imaging Center, Arcadia, USA
[6]Medical Group, California Clinical Trials, Los Angeles, USA

OBJECTIVE: To evaluate the effects of scopolamine on circuitry mediating cognitive performance using fMRI to evaluate pro-cognitive compounds in AD.
METHODS: Ten healthy Korean subjects participated in a randomized, double-blind, placebo-controlled, cross-over, single-dose, study to investigate the effects of scopolamine on working memory load (2-back vs 0-back) and resting state functional connectivity using fMRI. Subjects were randomized to receive scopolamine (0.5 mg) or placebo administered subcutaneously under fasted conditions 90-min prior to initiating fMRI scanning protocol. A Siemens 3T-Verio scanner, with an 18-channel head coil, was used to capture EPI-BOLD sequences during resting state and cognitive challenges using an established version of the n-back paradigm. Dosing and fMRI scanning procedures were conducted over 2 separate clinic visits for each subject separated by a 2-4 day washout.
RESULTS: Subcutaneous scopolamine during increased WM load resulted in decreased accuracy (p=0.08) and increased errors (p=0.09), with a moderate effect size in decreased accuracy in the 2-back condition (d=-0.5). Scopolamine significantly decreased activity in cholinergically-relevant regions involved in WM including the vmPFc, basal forebrain and cuneus/precuneus. Scopolamine reduced functional connectivity between bilateral DLPFc, the PCC and other regions involved in WM.
CONCLUSIONS: Our results demonstrate the utility of scopolamine disruption of WM task in an fMRI paradigm that may aid in evaluation of novel pro-cognitive compounds for neurodegenerative disorders. We suggest that neurocircuitry derived measures from fMRI may allow a more sensitive assessment of the reversal of scopolamine effects by potential pro-cognitive treaments than achieved with traditional cognitive testing

[5]Ophthalmology, Afyon Kocatepe University School of Medicine, Afyonkarahisar, Turkey
[6]Radiology, Afyon Kocatepe University School of Medicine, Afyonkarahisar, Turkey

Background: Alzheimer Disease (AD) is the most common cause of dementia. As previous studies indicate optic nerve damage occurs in AD occurs related to the loss of the retinal ganglion cells that contribute fibers to the optic nerve and reduction of the density of optic nerve.
Objective: To evaluate weather the patients with AD show optic nerve atrophy or not and evaluate the relation between the cerebrum volume and optic nerve volume in AD patients.
Materials and Methods: The study evaluated the volumetric measurements of optic nerve by applying stereo logical method on magnetic resonance images (MRI). It included age matched study and control groups of which were composed of 20 patients with probable AD and 20 healthy subjects respectively. MRI images were analyzed by using point counting approach holding the Cavalieri's principle.
Results: There were statistically significant optic nerve and cerebral atrophy in AD patients compared with the age matched health subjects ($p=0.013$, $p<0.001$, respectively) but there was no correlation between the optic nerve and cerebral volumes in AD patients ($r=0.326$, $p=0.160$).
Conclusions: There was significant atrophy in optic nerves between the AD patients and control subjects. The stereo logical evaluation of optic nerve volume is of importance for both clinicians and anatomists and it can provide valuable information in the evaluation of morphological changes of AD in vivo.

HYPOGLYCEMIA AS A TRIGGER FOR THE SYNDROME OF ACUTE BILATERAL BASAL GANGLIA LESIONS IN PATIENTS TREATED WITH REGULAR DIALYSIS: TWO CASE REPORTS

S. Cagirici[1], A. Bajrami[1], B. Aslan[1], N. Sozer Topcular[1], B. Erkilinc[1], D. Bozkurt[1], V. Yayla[1]

[1]Neurology, Bakirkoy Dr Sadi Konuk Training and Research Hospital, ISTANBUL, Turkey

Acute movement disorder associated with symmetrical basal ganglia lesions occurring on the background of diabetic end stage renal disease (ESRD) is a recently described condition with distinct clinico-radiological features: Reversible symmetrical lesions located in basal ganglia on MRI are hallmarks of this syndrome. Parkinsonism and/or involuntary movements are the prominent clinical presentations. Pathophysiology is still unclear, but metabolic and vascular factors are thought to play an important role. We aimed to draw attention to this clinical picture with two cases of diabetic ESRD, showing common clinical and radiological features following episodes of hypoglycemia. Bilateral hypointense lesions on T1-weighted and hyperintense lesions on T2-weighted images at basal ganglia level were detected in both patients (Figures A_1-B_1). Repeated scans in a period ranging from 3 weeks to 2 months after initial insult showed the vanishing of the lesions (Figures A_2-B_2). As previously reported, we also consider hypoglycemia as a candidate trigger factor for the syndrome of acute bilateral basal ganglia lesions, especially in diabetic ESRD patients. We would like to highlight these two cases to raise awareness of this syndrome and to emphasize the importance of adequate dialysis, prevention and correction of hypotension, acid-base and electrolyte imbalances and strict glucose control in uremic patients.

ADPD5-1238
PREVENTION OF FALLS IN PD: EFFECTS OF STOCHASTIC WHOLE BODY VIBRATION
D. Brenig[1], O. Kaut[1], M. Marek[1], N. Allert[2], U. Wüllner[3]
[1]Department of Neurology, University of Bonn, Bonn, Germany
[2]Neurological Rehabilitation Center, Godeshoehe, Bonn, Germany
[3]Department of Neurology,
University of Bonn & German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany
Objective: Postural instability confers a high risk of falls and shows insufficient response or even aggravation to dopaminergic therapy in Parkinson's disease (PD) patients. We performed a double-blind randomized controlled study to test the effects of stochastic whole body vibration (sWBV).
Methods: 56 PD patients were allocated either to the experimental or sham group. The experimental group received 4 cycles of sWBV on four days, each cycle consisting of 6 stimulus trains of 60 seconds duration (frequency 6-7 Hz) and 30 seconds resting time in between stimuli using the SRT zeptor system. Patients allocated to the control group received a sham treatment with 1 Hz. United Parkinson's Disease Rating Scale ($UPDRS_{III}$), Tinetti Balance-and-Gait, 8-Meter-Walk (8MW), Timed-Up-and-Go-Test and posturography were performed prior to and after treatment (days 1 and 4). The reduction of subscores relative to baseline served as primary outcome measure.
Results: In the experimental-group several items improved significantly after the 4 day course: rigor 41.6% (P = 0.001), bradykinesia 23.7% (P = 0.001), tremor 30.8% (P = 0.006), pull-test 17.9% (P = 0.032), $UPDRS_{III-}$ sum-score 23.9% (P = 0,000), 8MW 8.75% (P = 0.011), posturography 17.5% (P = 0.005). When patients were subdivided based on fall frequency, fallers showed a more pronounced improvement in posturography 19.9% (P = 0.019).
Conclusion: SWBV alleviated motor symptoms and significantly enhanced postural stability in PD-patients even in patients with increased risk of falling. SWBV thus offers a supplementation to canonical physical treatments of PD.

[3]Radiology, University of California, San Francisco, USA
[4]Psychiatry, University of California, San Francisco, USA
[5]Consultant, Rosenberg Alzheimer's Project, San Francisco, USA
[6]Neurology, University of California, San Francisco, USA
[7]Neurology, University of California, Davis, USA

Objective: The identification and recruitment of older adults in the earliest stage of cognitive decline represents the most challenging inclusion criteria for many clinical trials for Alzheimer's disease. The BrainHealthRegistry.org (BHR) is an online research registry developed to facilitate neuroscience clinical trials. The purpose of this study is to evaluate the large scale use of online neuropsychological tests as a mechanism to identify older adults with early stage cognitive decline for participation in clinical trials.
Methods: The BHR is IRB approved. After participants register at the BHR website they can complete a series of health questionnaires and an online neuropsychological test battery including tests of attention, working memory, learning, and psychomotor speed. Evidence of cognitive dysfunction was identified for individuals over the age of 55 scoring $\geq$ 1.5 standard deviations below mean age adjusted performance for each neuropsychological test.
Results: In the past 7 months more than 9500 participants have registered with the BHR and 2798 individuals over the age of 55 have completed neuropsychological tests. Approximately 7% of older adults showed evidence of cognitive dysfunction on each cognitive test. Cognitive dysfunction is strongly associated with diagnosis of memory problem and participant report of memory complaint ($p<0.001$ for both). Results of ongoing data collection will be presented including validation with traditional neuropsychological measures and clinical characteristics of the sample.
Conclusions: Preliminary results suggest online neuropsychological tests may be very useful for the identification of individuals who are in the earliest stage of cognitive decline for participation in clinical trials.

Relationship between fatigue and depression in patients with idiopathic PD
Introduction: Idiopathic Parkinson's disease (IPD) is a progressive and debilitating. Among non motor symptoms fatigue is common and disabling.Study deals with fatigue as a feeling of exhaustion, with different phenomenology of depression or muscle weakness.
Objective: Scale fatigue and depression as a major symptom in DPI, through appropriate scales.
Material and Methods: This study was conducted using two groups, experimental control with 40 subjects each, both sexes and varying ages. Scales of UPDRS, Hoehn and Yahr, Schwab and England, Hamilton, Beck, Mini-mental fatigue scale of Chalder, Inventory Fatigue Severity Scale and Fatigue Severity were applied.
Results: The 40 patients with ILD 22.5 were at stage 1.The, 45% and 32.5 stages stages 1.5 and 2.0 in the control subject were all at zero stage according to Hoehn and Yahr. Noted in the Schwab and England scale of the patients with ILD
to zero according to Hoehn and Yahr.Obervou in the range Schwab and England patients with ILD 5% of subjects had ADL performance of 60%, 5% were 70%, 65% had 80% of subjects had depression and through the Hamilton Rating Scale 90%. On the scale of Chalder demonstrated presence of fatigue in 80% of subjects with DPI in the control group none of the subjects had such symptoms.
Conclusion. Observed association between depression and fatigue in 90% of patients with ILD. No association between cognitive impairment and fatigue.

PERSONALITY TRAITS MAY MEDIATE LIFESTYLE FACTORS RESULTING IN DIFFERENTIAL COGNITIVE TRAJECTORY LATER IN LIFE

H. Sohrabi[1], M. Weinborn[2], S. Rainey-Smith[1], B. Brown[1], K. Goozee[3], R. Martins[1]
[1]Medical Sciences, Edith Cowan University, Perth, Australia
[2]Psychology, University of Western Australia, Perth, Australia
[3]Psychiatry and Clinical Neurosciences, University of Western Australia, Perth, Australia

There is a consensus that interplay between genetic, environmental and behavioural factors may account for the increasing number of late onset Alzheimer's disease (AD) patients. Lifestyle has been proposed as a significant factor involved in cognitive decline and dementia. Interestingly, personality as the underlying construct controlling our lifestyle and behaviour has been spared. Personality is a relatively stable, but dynamic psychological construct affecting a person's cognitive functions, motivation, and behaviour. Research has indicated significant relationship between personality traits, brain volume, and specific brain regions. Apparently, only in severe brain pathology, personality changes in mid to late adulthood can be expected. AD is one of the main neurodegenerative diseases resulting in personality changes. There are evidence that neuropathological changes due to AD may begin >20 years prior to any diagnosable signs and symptoms. These changes may be delayed or stopped given a healthy lifestyle is followed. In a study of personality traits and genetic, imaging and biological markers associated with AD, we examined personality characteristics in 150 individuals aged 60 years and over using the Neuroticism-Extroversion-Openness Five Factor Inventory (NEO-FFI). This is the first study to examine the relationship between personality traits and various markers associated with pathological cognitive decline and will further our understanding of the relationship between these factors. If personality modulates neurodegenerative processes through lifestyle choices, then psychological intervention may prove useful in promoting healthy lifestyle that may prevent or delay AD.

ADPD5-1846

SUCCESSFUL INITIAL ZINC THERAPY IN WILSON'S DISEASE WITH ACUTE LIVER FAILURE AND COPPER INTOXICATION: WONDER DRUG EXISTS

A. Avan[1], H.R. Kianifar[2], T.U. Hoogenraad3[3]
[1]Department of Neurology,
Ghaem Educational Hospital Mashhad University of Medical Sciences (MUMS), Mashhad, Iran
[2]Department of Pediatrics Gastroenterology division,
Ghaem Educational Hospital Mashhad University of Medical Sciences (MUMS), Mashhad, Iran
[3]Department of Neurology, University Medical Center Utrecht, Utrecht, Netherlands

Objectives: To evaluate initial zinc monotherapy on copper levels and hepatic improvement.

Background: Accumulation of copper in brain and liver is regarded as the cause of Wilson's disease. However, there is evidence suggesting the free copper intoxication as the origin.

Methods: Retrospectively, a 10-year-old girl with Wilson's disease presented with diffuse jaundice, acute liver failure, hemolytic anemia, and high urine copper, liver function and copper values with a positive family history was evaluated before and after initial zinc monotherapy. The patient was treated with 125 mg elemental zinc per day, and liver transplantation was considered in case of nonresponsiveness.

Results: The patient improved biochemically and clinically in 10 days after zinc therapy, which were in accordance with 86% urinary copper decrease. The revised Wilson's disease prognostic index improved from 13 to 5, and the patient was removed from the transplant list. After 2, 4, 8 weeks on zinc therapy, AST, ALT, bilirubin, urine copper showed constant improvements of up to 62, -26, 82, 77%, respectively by the eighth week,. The results of the second 8-week period indicated a further decrease of 25, 41, 48, 86, respectively, and 33% for serum free copper, compared to the previous results. No side effects, or clinical deterioration has been observed.

Conclusions: The results suggest zinc therapy as a promising, fast-acting, safe and affordable choice for the treatment of copper intoxication in Wilson's disease with acute liver failure. It also supports the hypothesis of normalization of raised serum free copper as a rational targeted-therapeutic strategy.

ADPD5-1849
ZINC THERAPY REVERSES NEURODEGENERATION IN WILSON'S DISEASE PATIENTS WITH PARKINSONISM
A. Avan[1], M.R. Azarpazhooh[2], T.U. Hoogenraad[3]
[1]Department of Neurology,
Ghaem Educational HospitalMashhad University of Medical Sciences (MUMS), Mashhad, Iran
[2]Department of Neurology,
Ghaem Educational Hospital Mashhad University of Medical Sciences (MUMS), Mashhad, Iran
[3]Department of Neurology, University Medical Centre Utrecht, Utrecht, Netherlands
Objective: To evaluate how effective zinc therapy can reverse parkinsonism in Wilson's disease patients who were initially treated with penicillamine.
Background: For years, the treatment of Wilson's disease has been aiming at stimulating the excretion of accumulated copper by chelating agents. The dilemma arises when patients paradoxically deteriorate, which is because chelators increase free copper levels. Conversely, zinc therapy normalizes the raised serum and urine free copper by inducing metallothionein production.
Methods: In a retrospective observational study on four Wilson's disease patients with severe parkinsonism being initially treated with penicillamine with or without zinc, we compared the subjective and objective clinical improvement before and one year after shifting to zinc monotherapy. Global Assessment Scale (GAS) was used for clinical evaluations. Global disability were measured in four domains: liver, cognition and behavior, motor, and osseomuscular, and the neurological dysfunction were assessed in 14 main categories.
Results: Three of the four patients who had been deteriorated on penicillamine (0.5-1 g/d), have improved significantly to a normal biochemical and clinical state on zinc (150 mg/d). The fourth patient on 250 mg/d penicillamine plus 200 mg/d zinc slightly improved in lower extremities after one month, while she considerably improved to a symptom-free state in the following months on zinc monotherapy. Their global disability improved by about 73%, and neurological assessments revealed a 100% amelioration.
Conclusions: The results suggest zinc monotherapy as the safe and promising treatment for copper intoxication, and support normalizing the increased serum and urine copper values as a rational therapeutic strategy.

DISTANT ANTAGONISM BETWEEN PATHOGEN FUNGAL COMMUNICATIVE BODY AND MULTISPOT-ORGANIZED SYNERGISTIC SYNBIOTIC GLYCOCONJUGATES-RECOGNIZING SYSTEMS: ONE OF FACTORS INVOLVING BRAIN MIXED FUNGAL DISSEMINATION

V. Lakhtin[1], M. Lakhtin[1], S. Afanasiev[1], A. Bajrakova[1], V. Aleshkin[1]
[1]Medical Biotechnology, G.N.Gabrichevsky Institute of Epidemiology and Microbiology, Moscow, Russia

Invasive fungal pathogen dissemination to the central nervous system and low effectiveness of antibiotics again brain diseases are important problems. We proposed how human biotope fungal communicative body (FCB) is organized and reply to the presence or absence of antifungals [1-3].

The aim is application of our advanced conception of predicted distant biotope FCB behavior under stress for further understanding brain multifungal distribution (as direct brain degeneration).

Proposals: Development of strategies using synbiotics (glycoconugates-recognized synergistic antimicrobial systems based on bifidobacterial and lactobacillar consortia; their delivery as mosaics in localization and time). Conversion of internal (increased multilayers) resistant (to antimicrobials and other stress factors) areas of FCB into sensitive/sensor border/peripheral areas (landscape-depended sensitization). Limitation of multifungal cascade biofilms (*Candida albicans—Aspergillus spp.—Penicillium spp.*) by anti-*C.albicans* combinative antimicrobial synergistic systems (early disruption of mixed-FCB relationships). Monitoring conversion of “early active one-few-center FCB (antimycotic sensitive)” into “late conservative multi-center FCB (locally disseminated resistant residuals in degenerated brain)”.

NEUROPSYCHOLOGICAL PROFILE OF COTARD'S SYNDROME: REVIEW OF THE LITERATURE AND PRESENTATION OF A SINGLE CASE

F. Rossi[1], D. Lanfranchi[1], V. Noè[1], N. Allegri[1], G. Broich[2], D. Liccione[3]
[1]Alzheimer Section, Pavia-Vigevano Neuropsychological Center, Vigevano, Italy
[2]De Rodolfi Nursing Home, Azienda Speciale Multiservizi, Vigevano, Italy
[3]Brain and Behavioral Science Department, University of Pavia, Pavia, Italy

Objectives: Cotard syndrome (CS) is a rare delusional disorder characterized by the conviction of being dead (Berrios et al, 1995). As pointed out by Colthearth (Colthearth et al. 2010), in every type of delusion a neuropsychological explanation is possible. The aim of this study is twofold: (1) reviewing all cases of CS described in Italian, English and Spanish literature, focusing on neuropsychological impairment, and (2) describing a single case of CS recently evaluated in our clinic (E.M.).
Methods: we reviewed single case publications available until 2014 and we administered a neuropsychological battery, investigating memory, attention, frontal function, visuo-praxic abilities and language to a patient showing nihilistic delusions.
Results: we analyzed 89 CS cases. Thirty-two contain a reference to patients' cognitive status, but only ten provide a detailed description of the neuropsychological evaluation. Results however, appear heterogeneous and do not make any clear neuropsychological explanation possible. The psychometric profile of E.M. showed a neuropsychological impairment limited to Cognitive Estimation Test (CET- Wagner et al, 2011). This result appears interesting because it seems to support recent neuropsychological explanations of delusion (Colthearth et al. 2011).
Conclusions: Neuropsychology of CS has received little attention in literature. The impairments showed by E.M., support Coltheart's model, postulating the existence of two factors responsible for the onset of misidentification delusions (Coltheart et al. 2011): a distorted perception of reality and a difficulty in making inference. This last cognitive ability is exactly what is measured during the CET. Further analysis is needed to explore other possibilities of interpretation.

AN ISOLATED FORM OF RESTLESS ARM WITHOUT LEG RESTLESSNESS

A. Koçer[1], A. Varoglu[1], B. Sanlisoy[1]
[1]Neurology, Istanbul Medeniyet University, Istanbul, Turkey

Background Upper extremity symptoms can develop in restless legs syndrome as an initial symptom., but it is seen very rarely in isolated form.
Objectives To report a case of restless arm syndrome without any leg symptom during 20 year follow-up and to review the literature.
Patient A 61-year-old man had involuntary movements of arm and restlessness which caused sleep disturbance.He reported "twitching and wiggling" sensations in his right arm that was worse at rest, and felt the need to move his right arm. There were extension like movements of fingers and rotatory movements of upper arm. He could not control these involuntary movements. He had not been diagnosed during previous 20 year period. His EMG exam, cranial and cervical MRI exams were normal. He was given pramipexol (3 mg/day), which reduced his symptoms and improved his sleep.
Results The pathogenesis of restless leg or arm syndromes is not known. Compared with those with isolated leg restlessness, subjects with arm restlessness had more severe leg restlessness and worse sleep efficiency. Isolated forms of restless arm problems usually are followed by leg restlessness.
Conclusion Only restless arm syndrome is very rare and our case is the first report without any leg symptom during 20 years.

ADPD5-1843
CADASIL NOVEL MUTATION WITH ATYPICAL MRI FINDINGS
H. Kim[1], S. Kim[1], H. Han[2]
[1]Neurology, Hanyang University, Seoul, Korea
[2]Neurology, Myeongyii Hospital, Ilsan, Korea
More than hundred different mutations in 18 exons have been already described. We present a Korean family with CADASIL with a novel NOTCH3 mutation who presents atypical MRI findings. **Case** 46-year-old woman developed dysarthria for 2 weeks. She did not have vascular risk factors but with positive family history of stroke at a young age. She also manifested headaches over 20 years. On a neurologic examination, right hemiparesis were shown but cognitive function and deep tendon reflexes were normal, and pathologic reflex was absent. In a complex neuropsychological test, her cognitive function was normal. woman's Her brother had repeated stroke for three times, and her father and two aunts were dead due to recurrent strokes. MRI of her brain showed confluent microbleeds in the basal pons and high–signal intensities with inherent microbleeds in the bilateral periventricular white matter, basal ganglia, and thalamus. Genetic testing confirmed a novel Pro1008Ser mutation in exon 19 of NOTCH3 gene. In a familial genetic analysis, her 55-year-old brother (II-2) also carried the same mutation, showing symptoms of stroke and the proband's 45-year-old sister (II-4) was an asymptomatic carrier of the P1008S mutation. This report illustrates a novel mutation in NOTCH3 from Korean CADASIL family with atypical MRI features. Until now, there is no relation between mutation site and clinical or radiological features but further investigations are needed whether atypical findings of massive confluent microbleeds in the patient could be ascribed to chance or whether the P1008S mutation of the gene is responsible.

MEMORY AND QUALITY OF LIFE IN PATIENTS OLDER THAN 50 YEARS WITH EPILEPSY

G. Tedrus[1], L.C. Fonseca[1], M.A. Vidal[1]
[1]Faculdade de Medicina, Pontificia Universidade Catolica de Campinas, Campinas, Brazil

Objectives: To study memory and its relationships with the clinical aspects and quality of life of patients with epilepsy (PWE) older than 50 years.
Methods: Ninety-eight PWE, 63 with epileptic seizure (ES) onset before age 50 (G<50) and 35 with ES onset after age 50 (G≥50) were assessed for epilepsy-related aspects and submitted to the Memory Complaint Questionnaire (MAC-Q), Mini-Mental State Examination (MMS), Brief cognitive battery (BCB), and Quality of Life in Epilepsy Inventory (QOLIE–31). The relationship between MAC-Q data and the other variables was investigated and compared with those of 42 individuals without chronic diseases (CG). The significance level was set at 5%.
Results:In PWE the mean MAC-Q and QOLIE-31 scores were 24.8(±5.4) and 58.7(±17.5), respectively. Forty-seven percent of the PWE complained of loss of memory (MAC-Q≥25), which did not differ significantly from the CG. The MAC-Q of the G<50 and G≥50 groups did not differ significantly. PWE with uncontrolled ES and those with epilepsy of vascular etiology had higher MAC-Q scores. MAC-Q scores were negatively associated with MMS scores, education level, age at ES onset, epilepsy duration, verbal fluency, immediate and incidental memory, and QOLIE-31 scores (p<0.05). Linear regression showed that the MAC-Q score of the study sample was significantly associated with education level and epilepsy duration (p=0.001).
Conclusions: Higher MAC-Q scores reflect appropriate perception of low performance in memory tests, and the most important clinical factor was epilepsy duration. Higher quality of life was associated with lower MAC-Q scores.

ADPD5-2032
THE IMPACT OF NOCTURNAL DISTURBANCES ON QUALITY OF LIFE IN PATIENTS WITH PARKINSON'S DISEASE
R.L. Yu[1], C.H. Tan[2], R.M. Wu[3]
[1]Institute of Behavioral Medicine, National Cheng Kung University, Tainan, Taiwan
[2]Wolfson Centre for Age-Related Diseases, King's College London, London, United Kingdom
[3]Department of Neurology, National Taiwan University Hosptial, Taipei, Taiwan
Objective: The aims of the present study were to explore the sleep disturbances in Taiwanese PD patients and their impact on quality of life (QoL).
Methods: A cross-sectional study was conducted consisting of 211 patients with PD. The participants were interviewed using instruments, including the PD Sleep Scale (PDSS-2), Pittsburgh Sleep Quality Index (PSQI), PD QoL Questionnaire (PDQ39), Epworth Sleepiness Scale (ESS), Hoehn and Yahr staging (H&Y), and Unified Parkinson's Disease Rating Scale (UPDRS). Multiple regression analyses were performed to determine the contribution of predictive variables to quality of life.
Results: There were 54.7% male (age: 63.8 ± 8.9 years, disease duration: 5.9 ± 4.3 years). The H&Y was 2.3 ± 0.85 and the UPDRS was 35.5 ± 16.6. The actual sleep time was 6.1 ± 1.3 hours; average sleep efficiency was 85.1 ± 13.2%. Up to 56% were classified as 'poor" sleeper (PSQI > 5), and 14.4% suffered from daytime sleepiness. The disease duration, stage, UPDRS, and PDSS-2, as well as PSQI were significantly correlated to the quality of life. The final stepwise regression model revealed that daytime dysfunction, PD symptoms at night, and UPDRS-I as significant predictors for the total score of PDQ39 scores (R^2 = 56, F = 27.06, df = 4, p = .000).
Conclusion: Most patients have sleep problem and some have abnormal daytime somnolence. Daytime dysfunction, nocturnal symptoms, and non-motor symptoms are important contributors leading to a worse QoL. More extensive research is needed to explore the possible management programs in the future.

04n. Therapeutic Targets & Mechanisms for Treatment: anti-inflammatory targets

ADPD5-2019

FRUCTUS MUME ALLEVIATES CHRONIC CEREBRAL HYPOPERFUSION-INDUCED HIPPOCAMPAL DAMAGE VIA INHIBITION OF INFLAMMATION AND DOWNREGULATION OF TLR4 AND P38 MAPK SIGNALING

W. Jeon[1]

[1]*Herbal Medicine Research Division, Korea Institute of Oriental Medicine, Daejeon city, Korea*

Objective: We investigated the effects of Fructus mume (FM), a processed unripe fruit of Prunus mume, on hippocampal damage induced by chronic cerebral hypoperfusion.

Methods: Permanent bilateral common carotid artery occlusion (BCCAo) was performed on male Wistar rats to induce chronic cerebral hypoperfusion. Daily administration of FM (200 mg/kg) was started on day 21 after post-BCCAo and continued for 42 days. The experimental groups were divided into three groups: a sham-operated group, a BCCAo group, and a BCCAo group that was administered with the FM extract. The activation of glial cells, including microglia and astrocytes, and the levels of myelin basic protein (MBP), inflammatory mediators, Toll-like receptor 4 (TLR4), myeloid differentiation factor 88 (MyD88), and p38 mitogen-activated protein kinase (MAPK) phosphorylation were measured in the hippocampus from rats subjected to chronic BCCAo.

Results: Our results revealed that FM alleviates the reduction in MBP expression caused by chronic BCCAo in the hippocampus and significantly attenuates microglial and astrocytic activation. In addition, FM treatment reduced the increased expression of cyclooxygenase-2, interleukin-1β and interleukin-6, as well as the activation of TLR4/MyD88 and p38 MAPK signaling, in the hippocampus of rats subjected to chronic BCCAo.

Conclusion: Taken together, our findings demonstrate that brain injury induced by chronic BCCAo is ameliorated by the anti-inflammatory effects of FM via inhibition of MBP degradation, microglial and astrocytic activation, increased inflammatory mediator expression, and activated intracellular signalings, including TLR4 and p38 MAPK, implying that FM is potentially an effective therapeutics for the treatment of vascular dementia.

06b. Imaging & Biomarkers: functional MRI

CHANGES OF WHITE MATTER AND ASSOCIATION FIBER TRACTS IN AMCI AND AD: A DTI STUDY

W. Li[1], C. Chang[2]
[1]Radiology, Affialiated Sixth People's Hospital of Shanghai Jiaotong University, Shanghai, China
[2]Radiology, Affialiated Chest Hospital of Shanghai Jiaotong University, Shanghai, China

Objective : To assess DTI differential diagnosis characteristic between aMCI and AD.

Materials and Methods : Routine MRI and DTI scanning were performed to 20 NC volunteers, 20 aMCI patients and 20 AD patients at Philips 3.0T supraconduction MR scanner. The regions were set in the anterior frontal, temperal, parietal, occipitals, hippocampus, inferiorfronto-occipitalfascicles, corpus callosum (genu was set right, splenium was set left), superior longitudinal fascicles Ⅱ (SLF Ⅱ) and cingulated bundles in the postprocessing workstation after scan. Bilateralis FA and ADC values were measured, pair t test was respectively compared in the bilateralis ROIs every group.

Results : In NC, aMCI and AD groups, the FA values of the genu and splennium of corpus callusum had significantly difference(P<0.05). In NC and aMCI groups, the FA values of inferior fronto-occipital fascicles and cingulate bundles had significantly difference(P<0.05). In aMCI and AD groups, the FA values of cingulate bundles had significantly difference(P<0.05). In NC and AD groups, the FA values of anterior frontal lobe, temporal lobe, hippocampus, inferior fronto-occipital fascicles , genu of corpus callusumand and cingulate bundles had significantly difference(P<0.05). In NC and AD groups, ADC values of temporal lobe and hippocampus had significantly difference(P<0.05).

Conclusion : Abnormal change of inferior fronto-occipital fascicles and cingulate bundles can imply that DTI could be as an imaging diagnostic method for aMCI patients. The FA values of cingulate bundles show significantly difference in aMCI and AD patients. Abnormal FA values of anterior frontal lobe, temporal lobe, hippocampus, inferior fronto-occipital fascicles, genu of corpus callusum, cingulated bundles could help us to understand AD patients.

TIME TO TARGET SMALL VASCULAR LESIONS IN AGING BRAINS?

G. Gold[1], C. Bouras[1], P. Giannakopoulos[2], E. Kovari[2]
[1]Internal medicine rehabilitation and geriatrics,
Geneva Medical School and Geneva University Hospitals, Geneva, Switzerland
[2]Psychiatry and mental health,
Geneva Medical School and Geneva University Hospitals, Geneva, Switzerland

Objective: Although neurodegenerative disorders are still considered the most common cause of cognitive impairment in the elderly, recent evidence suggests that small and microvascular pathology are a lot more frequent than previously thought. Our aim was to ascertain the contribution of small and microvascular lesions on cognitive function in aged individuals

Methods: clinicopathological and radiopathological correlation studies were performed and reviewed to determine the consequences of location, type, size and multiplicity of vascular lesions on cognition with special attention to microscopic vascular damage. Capillary density, length and diameter and amyloid angiopathy were also assessed

Results: microinfarcts and thalamic and basal ganglia lacunes are strong vascular correlates of cognitive decline accounting for over one third of the clinical variability. These lesions are common and invisible on MRI suggesting that many cases of pure neurodegenerative dementia may in fact include a clinically essential undiagnosed vascular component.

Conclusion: Small and microvascular pathology are key determinants of cognitive function in older people and may represent important therapeutic targets for the prevention of dementia in the elderly.

DIABETES DECREASES EXPRESSION OF METABOLISM-RELATED PROTEINS IN THE BRAIN AFTER FOCAL CEREBRAL ISCHEMIA

P.O. Koh[1], S.A. Gim[1], F.A. Shah[1]
[1]Department of Anatomy College of Veterinary Medicine, Gyeongsang National University, Jinju, Korea

Stroke is a major cause of disability and death in adults. Diabetes mellitus is a metabolic disorder that strongly increases the risk of severe vascular diseases. This study compared changes in proteins in the cerebral cortex during ischemic brain injury between diabetic and non-diabetic animals. Adult male rats were injected with streptozotocin (40 mg/kg) via the intraperitoneal route to induce diabetes and underwent surgical middle cerebral artery occlusion (MCAO) 4 weeks after streptozotocin treatment. Cerebral cortex tissues were collected 24 h after MCAO and cerebral cortex proteins were analyzed by two-dimensional gel electrophoresis and mass spectrometry. Among the identified proteins, we focused on the following metabolism-related enzymes: glucose-6-phosphate isomerase (neuroleukin), pyruvate kinase, glyceraldehyde-3-phosphate dehydrogenase, isocitrate dehydrogenase, and adenosylhomocysteinase. Expression of these proteins was decreased in animals that underwent MCAO. Moreover, protein expression was reduced to a greater extent in diabetic animals than in non-diabetic animals. Reverse transcription-PCR analysis confirmed that the diabetic condition exacerbates the decrease in expression of metabolism-related proteins after MCAO. Impairment of energy metabolism in brain ischemia causes pathological changes. Thus, these results suggest that the diabetic condition may exacerbate brain damage during focal cerebral ischemia through down-regulation of metabolism-related proteins.

EFFECT OF ANGII-INDUCED HYPERTENSION AND ANTIHYPERTENSIVE TREATMENT ON PATHOLOGICAL CHANGES IN A MOUSE MODEL FOR ALZHEIMER'S DISEASE

M. Wiesmann[1], V. Zerbi[1], M. Roelofs[1], R. van der Lugt[1], A. Heerschap[2], J.A.H.R. Claassen[3], A.J. Kiliaan[1]
[1]Anatomy, RadboudUMC, Nijmegen, Netherlands
[2]Radiology & Nuclear Medicine, RadboudUMC, Nijmegen, Netherlands
[3]Geriatric Medicine, RadboudUMC, Nijmegen, Netherlands

Objectives
Hypertension is a risk factor for Alzheimer's disease (AD). It is a treatable condition which opens important avenues for prevention of AD. Elevated angiotensin II (AngII) is an important cause of essential hypertension and has deleterious effects on endothelial function and cerebral blood flow (CBF). In this study we therefore investigated the interaction between AngII, systolic blood pressure (SBP), and MRI-measurements in the $APP_{swe}/PS1_{[Delta]E9}$ (APP/PS1) mouse model of AD.
Methods
We studied the effect of 2 months of induced hypertension (AngII-infusion using osmotic micropumps, vs saline (sal) as control) and, subsequently (after 1 month of induced hypertension) the effect of treatment (vs placebo) with antihypertensive (eprosartan mesylate (EM), 0.35mg/Kg vs water) on SBP and metabolite levels, functional and neuronal connectivity and CBF in 10 months-old wildtype C57bl6/j (WT) and APP/PS1 mice. SBP was monitored twice a month via tail cuff plethysmography. RsfMRI, DTI, MRS, FAIR-ASL were measured on the 11.7T magnet (Bruker BioSpec).
Results
In this study, chronic AngII-infusion increased BP in both transgenic and WT mice, while at 12-Month under AngII-infusion APP/PS1 mice had a higher SBP than WT mice. Furthermore, only in hypertensive AD mice cortical CBF was lowered compared to hypertensive WT mice. Additional data will be presented on the impact of AngII-induced hypertension and subsequent treatment with EM on Aβ-pathology, cognition, metabolite levels, structural and functional connectivity.
Conclusions
Together, these data suggest an interaction between APP/PS1 induced pathologies, SBP, and antihypertensive treatment. Our results also reveal an association between hypertension (AngII), APP/PS1 and CBF.

THE CLINICAL AND IMAGERY FINDINGS IN PATIENTS WITH POST STROKE DEMENTIA

D. Naço[1], S. Gjeçi[2], D. Dobi[2], M. Rakacolli[2], J. Kruja[2]
[1]Neurology, Specialistic Polyclinic 3, Tirana, Albania
[2]Neurology, UHC Mother Theresa, Tirana, Albania

Aim:
The assessment of poststroke dementia and its correlation with clinical and imaging data.
Methods:
We studied 249 stroke patients who followed up at the neurology unit, during the last four years. They were presented at least three months after the first or recurrent stroke. Diagnosis of dementia was made according to the DSMIV criteria. All patients underwent a detailed neurological examination, imaging of the brain. HIS score was applied. Patients who had previous history of dementia were excluded from the study. SPSS 17.0 program was applied for data analyze.
Results:
There are 71 females, 178 males. The mean age is 68, 5 years old. We analyzed the data of 69 patients who met the criteria for dementia. 41 patients had 4-7 in HIS score (MixD). 28 patients had <7 in HIS score (VaD), 0 patients had > 4 in HIS score)AD(. There is a statistically significant correlation between poststroke dementia and the age of the patients, level of education, cardiovascular diseases, diabetes (p value< 0, 01). There is a statistically significant correlation between poststroke dementia and subcortical vascular lesions, multiple lesions, periventricular white matter lesions. No significant correlation between poststroke dementia and type of stroke, carotid stenosis, hypertension, hypercholesterolemia was found. No significant correlation between types of poststroke dementia and vascular risk factor was found.
Conclusion:
This study suggests that poststroke dementia is most frequent in stroke patients with multiple and subcortical vascular,periventricular white matter lesions. Multiple vascular risk factors are more predictive for post stroke dementia

[4]Lille University Medecine Faculty, EA2686, LILLE Cedex, France
[5]Lille University Pharmacy Faculty, EA4481, LILLE Cedex, France

Objectives.
Selective agonists of sigma-1 protein (S1P) are reported to protect against neuronal damage and modulate oligodendrocyte differentiation. Lymphocytes possess saturable, high-affinity binding sites for sigma ligands and potential immunomodulatory properties have been described for S1P ligands. Fused tetrahydroisoquinoline-hydantoin (TicH) were designed, synthesized and evaluated. Experimental auto-immune encephalomyelitis (EAE) has unequivocal value as a model of the inflammatory aspects of MS. The objective was to evaluate the role of our most efficient S1P ligands in EAE.
Methods.
Fused TicH were optimized thanks to litterature pharmacophoric model. Affinity for S1P, S2P, cytotoxicity and ADME properties were measured. EAE was induced in SJL/J female mice by active immunization with myelin proteolipid protein. Best TicH compound was injected i.p. at immunization time. Disease severity was monitored by clinical and histopathological evaluation in the CNS, cytokine production by ELISA assay and the phenotype of B- and T-cell subsets by flow cytometry.
Results.
Most efficient TicH compounds showed nanomolar S1R affinity, selectivity versus S2P, very low cytotoxicity and ADME properties compatible with therapeutic development. Treatment of EAE-susceptible mice with TicH agonist prevented mononuclear cell infiltration and demyelination in brain and spinal cord and increased T2 B cells in spleen, resulting in an overall reduction in the clinical progression of disease.
Conclusions.
TicH S1P agonist could modulate B cells and most likely their effector functions in inflammatory processes in EAE, suggesting the involvement of S1P in the immunological response. Targeting S1P could thus provide new therapeutic opportunities for MS.

[3]Centre for Advanced Imaging, The University of Queensland, Brisbane, Australia
[4]School of Psychology, The University of Queensland, Brisbane, Australia
[5]Molecular Epidemiology Laboratory, QIMR Berghofer Medical Research Institute, Brisbane, Australia

Genetic risk is thought to play a substantial part in the pathogenesis of multiple sclerosis (MS). Recent GWAS have identified risk variants associated with the disease, building on heritability studies that suggest a polygenic effect. Because MS is primarily a white-matter disease, we tested the association between polygenic MS risk scores and white-matter integrity in healthy young adults. Diffusion tensor imaging (DTI) and genotyping data were obtained from 398 healthy young Australians (mean age 23.6 ± 2.2 years) as part of the Queensland Twin Imaging Study. After LD pruning, 76 remaining SNPs from the top 102 significant variants from in the largest MS GWAS to date [1] were used to estimate individual polygenic scores, based on number of risk alleles an individual possessed weighted by the standardized SNP effect observed in the original GWAS. Final scores are normalized and account for missing SNPs. Associations with scores and FA were tested using mixed-model regression at each white matter voxel in FA maps, which controlled for age, sex and accounted for kinship. FA in several regions was significantly associated ($q < 0.05$) with polygenic risk for MS, including Corpus Callosum, L Inferior longitudinal fasciculus, and R Anterior Thalamic radiation. These results give functional validation to GWAS findings and suggest that an increased genetic risk for MS may have influence over white-matter microstructure before disease onset; highlighting a possible biomarker to be monitored for early intervention.

ADPD5-2172
CHARACTERIZATION OF EXPERIMENTAL ANIMAL MODEL FOR NEUROMYELITIS OPTICA

H. Kim[1], S. Kim[2], M. Seo[1], K. Kang[1], T. Lee[1], C. Kim[1]
[1]Laboratory animal center, Daegu-Gyeongbuk Medical Innovation Foundation, Daegu, Korea
[2]Neurology, Seoul National University Hospital, Seoul, Korea

Neuromyelitis Optica (NMO), also known as Devic's disease, is an inflammatory demyelinating disease of the central nervous system that often produces paralysis and blindness. NMO is more common in Asians than Caucasians. Most NMO patients are seropositive for immunoglobulin G autoantibodies (NMO-IgG) against the astrocyte water channel aquaporin-4 (AQP4). NMO-IgG banded to AQP4 results in complement-dependent cytotoxicity and inflammation, leading to secondary demyelination and neuronal injury. Despite a defining feature of NMO, appropriate animal models of NMO are lacking. Some studies reported that immunoglobulin G from NMO patients has the potential to damage the central nervous system in the presence of human complement. Here, we show that intra-cerebral injection of IgG obtained from NMO patient serum with human complement might produce the characteristic histological features of NMO including inflammatory cell infiltration, loss of myelin, and AQP4 expression.

IMMUNOHISTOCHEMICAL CHARACTERIZATION OF MULTIPLE SCLEROSIS PLAQUES IN THE HUMAN BRAIN

S. Ahmad[1], J. Baun[2], C. Zurhellen[2], C. Segovia[2], R. Switzer III[2]
[1]Occupational Science and Occupational Therapy,
Saint Louis University School of Medicine, St. Louis, USA
[2]Histology, NeuroScience Associates, Knoxville, USA

Multiple Sclerosis (MS) is a demyelinating disease with a complex pathological profile that includes myelin degeneration, neuronal damage, and immune cell infiltration in the areas containing plaques. We evaluated the pathology associated with MS in the brain of a 39 year old female whose cause of death was unrelated to the disease. In acute plaques the amino cupric silver method (de Olmos) revealed a dense core of degenerating nerve cells and fibers. Chronic lesions had little staining of cells or fibers and were devoid of staining by the Nissl counterstain, Neutral Red. Another silver stain, the silver nucleolar stain (AgNOR) was developed to reveal the nucleolar organizing regions in cancerous cells. We utilized the stain here to reveal the differences in interior cellularity between acute and chronic plaques. This is useful in getting accurate counts of the cell populations present in brain regions undergoing demyelination, and has proven to be a useful tool for stereological purposes. Weil-Myelin staining revealed roughly spherical plaques devoid of myelin staining. Nissl staining with Thionine distinguished acute and chronic lesions.. Chronic lesions were surrounded by iron positive cells, some of which appeared to be phagocytic and filled with debris. Iba-1 immunoreactivity in acute plaques was observed both in the center of the plaque and in a dense ring of immunoreactive microglia surrounding the plaque. In chronic lesions the central immunoreactivity was diminished, but the ring of cells surrounding the plaque appeared thicker and more dense.

ADPD5-2116
DIAGNOSING MULTIPLE SYSTEMS ATROPHY AND MULTIPLE SCLEROSIS IN THE SAME PATIENT: A CASE REPORT

S. Syed[1]
[1]*Neurology, Tufts Medical Center, Boston, USA*

Objective: To describe a patient with multiple-sclerosis(MS) and multiple-systems-atrophy-cerebellar(MSA-C) type concurrently.
Methods: We present a case of a 54yo-African-American female with symptoms of autonomic-dysfunction and cerebellar-ataxia for 2yrs, diagnosed with MS on copaxone without any relapses but with continued progression of her symptoms since diagnosis. Her symptoms included orthostatic-hypotension with multiple fainting episodes, urinary-retention, alternating diarrhea and constipation, gait instability, new-onset sleep apnea and tremors. She was treated by a cardiologist with midodrine/hiprex and by a urologist who recommended frequent self-catheterizing. However she continued to have severe orthostasis with near-syncopal attacks particularly when self-catheterizing and needed a cane and walker due to worsening ataxia. The patient also reported an episode of paraparesis 20years ago that was treated with steroids with complete resolution. On exam, she had cerebellar-deficits including nystagmus, dysmetria and impaired tandem-walking and positive orthostatics. On MRI-brain, she had symmetrical, non-enhancing, demyelinating lesions in bilateral cerebellar-peduncles and prominent ponto-cerebellar-atrophy consistent with MSA-C. She also had 3periventricular non-enhancing demyelinating lesions and a faint non-enhancing lesion in the C2-3level on cervical-spine-MRI consistent with MS. Her cervical lesion could represent transverse-myelitis from her episode 20yrs-ago.
Results: There are only 2reported cases of MS and MSA in the same patient but in those cases the patients were know to have MSA and incidentally diagnosed with MS with no significant change in management. However in our case it altered treatment course and prognostication significantly.
Conclusions: This case highlights the complexity of diagnosing white matter diseases and the need for a broad differential diagnosis.

EARLY ONSET PARKINSONISM
D. Ndoja[1], D. Agolli[1], M. Rakacolli[1]
[1]Service of Neurology, UHC Mother Teresa, Tirana, Albania
95 early onset Parkinsonism patients among 335 MD selected during 5 last years youngest than 50 years old,
58 % M and 52% F, were studied retrospectively . Social occupation; 41% of patients were ordinary workers, 20% unemployed , 17% trades, 12% were intellectuals. 65% of patients had no familiar history of MD, 22% had positive familiar history (+ Parkinsonism, AVC (3), Psychotic Disorder (1), 13% have HTA familiar history or without familiar data. Diagnosis 63% had PD; 37% had parkinsonism . **PD :** 42% were unclassified, or with adversal DOPA-effects 30% had the tremorial form 25% the akinetic –hypertonic form, 3% had PD juvenil **PARKINSONISM:** 65% unclassified, 14% probable MSA, 6% vascular, 6% medicamentous, 3% neuroacantocitozis, 3% O-P-C, 3% somatoform. As to the chronicity, pts were divided
: **<1 Year** (8 pt), **≥ 1 y** (11 pt), **< 5 y** (30 pt), **≥ 5 y** (22 pt), **< 10 Y** (5 pt), **≥ 10 Y** (11 pt), **15-20 Y** (7 pt). **NEUROIMAGING :** Not indicated in 47% , performed in 53%; where normal in 50%, Gliozis of GB 12%, cerebral or cerebellar atrophy 8%, calcification of GB 2%, cavernoma 2%, on other 26% patients not available.. **Treatment**; 57% on Madopar only or + Amantadin, anticolinergic/antidepresiv, 24% on dopamine agonist only, 10% in combination with levodopa derivates, 9% with Amantadin or Parkopan combination.
Conclusion;
Among all; 63% had PD; 37% parkinsonism. PD; 30% had the tremorial 25% the akinetic –hypertonic form. **Parkinsonism;** 14% probable MSA, 6% vascular, 6% medicamentous, 3% neuroacantocitoza, 3% O-P-C, 3% somatoform disorder.

04n. Therapeutic Targets & Mechanisms for Treatment: anti-inflammatory targets

ADPD5-1978

IMMUNONEUTRALIZATION OF ENDOGENOUS AMINOPROCALCITONIN ATTENUATES SEPSIS-INDUCED NEUROINFLAMMATION

R. Maldonado[1], E. Carro[2], F.J. Minano[1], E. Tavares[1]
[1]Clinical and Experimental Pharmacology Research Unit, Valme University Hospital, Seville, Spain
[2]Neuroscience, Instituto de Investigacion Hospital 12 de Octubre, Madrid, Spain

Background: A systemic inflammatory reaction may have detrimental effects on the organism, including the central nervous system. During severe sepsis several immunological defense mechanisms initiate a cascade of inflammatory events leading to multi-organ failure (MOF) including septic encephalopathy. Previous studies have demonstrated that systemic lipopolysaccharide (LPS) causes chronic neuroinflammation and progressive neurodegeneration. The hippocampus is the most vulnerable brain region during experimental sepsis. Recently, we have shown that aminoprocalcitonin (NPCT), a neuroendocrine peptide ubiquitously produced during systemic inflammation, plays an important role in the development of sepsis and MOF.
Objective: To investigate the role of NPCT in a rodent model of LPS-induced neuroinflammation. We focused on the reaction and participation of parenchymal *cells in* the *hippocampus*.
Method: Male Wistar rats received 15 mg/kg LPS or vehicle intraperitoneally and were sacrificed for brain collection at 24h after induction of sepsis. One group of animals received 100 µg/kg of a *neutralizing* NPCT-*specific* monoclonal *antibody* or murine *IgG1a isotype control* intraperitoneally 1h before the experiment. Changes in CALCA gene, inducible nitric oxide (iNOS), microglia (OX-42) and astrocyte (GFAP) expression with the pattern of apoptosis (TUNEL) were analyzed.
Results: Immunohistochemical analysis revealed patterns of increased NPCT, iNOS, GFAP and OX-42 expression in hipoccampal cells, paralleled by an increase of apoptotic cells following sepsis. Immunoneutralization of NPCT prevents LPS-induced microglial activation, microglial iNOS expression and neuronal apoptosis.
Conclusions: Our results support a central role of NPCT in the neuroinflammatory responses, and suggest that NPCT might contribute to the uncontrolled neurotoxic glial activation under excessive inflammatory conditions.

MESENCHYMAL STEM CELLS AND THEIR SECRETED EXOSOMES DELIVER EXOGENOUS MIRNAS AND SIRNAS TO NEURAL CELLS: THERAPEUTIC IMPACT IN MOUSE AND IN VITRO MODELS OF ALS

C. Brodie[1], H.K. Lee[1], S. Finniss[1], C. Xiang[1], S. Slavin[2], S. Cazacu[1]
[1]Neurosurgery, Henry Ford Health System, Detroit, USA
[2]CTCI, CTCI, Tel Aviv, Israel

miRNAs and siRNAs emerge as potential therapeutic targets in a variety of pathological conditions in the brain; however, their clinical application is hampered by lack of efficient delivery modes. Mesenchymal stem cells (MSCs) migrate to sites of injury and inflammation and exert therapeutic effects in various pathological conditions. Here, we examined the ability of MSCs to deliver exogenous miRNA mimics and siRNAs to human neural cells and characterized the functional impact of this delivery in ALS models. MSCs efficiently delivered miR-124 mimic to co-cultured NPCs and astrocytes as evident using Cy3-miR-124 and novel reporter plasmids which enable analysis of miRNA delivery in living cells. The delivered miR-124 significantly increased the expression of the glutamate transporters, EAAT1 on NPCs and EAAT2 in both NPCs and astrocytes. The miRNA delivery was mediated by MSC-derived exosomes and their administration exerted similar effects. Moreover, we generated exosomes targeted to neural and muscle cells which preferentially delivered the exogenous miRNA to these cells. Both MSCs and their secreted exosomes delivered mutant SOD1 siRNA which selectively decreased the expression of the mutant protein. We further demonstrated beneficial therapeutic impact of MSCs transduced with pre-miR-124 or the mSOD1 siRNA in motor neurons, astrocytes and microglia cells expressing mSOD1 and in a transgenic ALS mouse model. These results suggest that MSCs can functionally deliver exogenous miRNAs and specific siRNAs to neural cells and provide an efficient route of therapeutic small RNA delivery to the CNS in pathological conditions including ALS with clinical implications for regenerative medicine.

ADPD5-2282

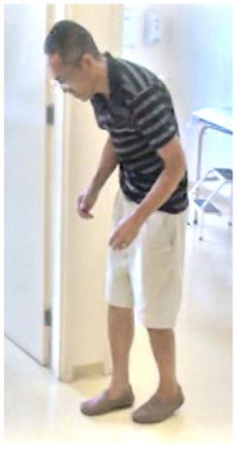
MOTOR CORTEX STIMLATION IN PARKINSONIAN PATIENTS WITH REFRACTORY FREEZING OF GAIT AND BALANCE DISORDERS RESPONSIVE TO TRANSCRANIAL DIRECT CURRENT STIMULATION

E. Urbano da Silva[1], N.A.J.R. Lara[1], J.C.E. Veiga[1], H.C. de Souza[1]
[1]Neurosurgery, Santa casa de Misericordia de Sao Paulo, Sao Paulo, Brazil

Background: Severe gait disturbances (SGD) in idiopathic Parkinson's disease are observed in up to 50% of the patients in advanced disease stages with important impact on quality of life. Few reports suggested improvement of bradykinesia and gait after motor cortex stimulation (MCS). Lately, the possibility of cortex modulation with transcranial magnetic stimulation and transcranial direct cortex stimulation (tDCS) have leaded to new perspectives and non-invasive approaches. Many authors reported changes in gait and motor skills after these modalities, always with short responses.
Methods: In this Open-Study, we selected PD patients, who presented motor fluctuations, SGD, and who showed insufficient improvement of gait after levodopa trial (<30%). All patients underwent *Motor Cortex Stimulation (*EMCS) of the left hemisphere, after positive response, with weekly transcranial direct cortex stimulation (TDCS). Outcome measures included: medication dosage change, Unified Parkinson's Disease Rating Scale (UPDRSII.3), and Gait and Balance Scale (GABS).
Results: All patients showed expressive gait changes, in GABS and UPDRS, following EMCS, in a follow-up of 4-18 mo. However, there was no reduction of mean daily medication intake.
Conclusions: Transcranial Direct Current Stimulation (TDCS) is a promising method of non-invasive brain stimulation to modulate cortical activity. It has been studied in many areas as a cognition and behaviour enhancement. This study suggests that MCS improves gait disturbances in PD and could be considered a safer alternative approach, in selected and refractory patients, in the treatment of Freezing of Gait and Balance disorders.

Case 5(after tDCS): Patient showing normal posture and balance improvement

Case 5 (6mo after MCS): Patient showing one foot stance



Case 5(before tDCS): Patient with severe stooped posture, loss of arm swing and small steps

Case 5(after tDCS): Patient showing normal posture, an increase of arm swing and step length

[5]Radiology, Hospital Universitario 12 de Octubre, Madrid, Spain

[6]I+12, Hospital Universitario 12 de Octubre, Madrid, Spain

Objectives: Amyloidoma is a type of localized amyloidosis that can rarely affect the brain. To our knowledge, this is the first report of PET-Florbetapir findings in cerebral amyloidoma.

Methods: Case report

Results: A 51 year-old man was admitted after presenting with two complex partial seizures. Examination demonstrated an impairment of executive funtion and ideomotor apraxia. A CT scan showed multifocal hyperdense lesions. On MRI, these lesions were isointense with the white matter on T1-weighted images, hyperintense on T2-weighted images, and showed intense contrast enhancement. PET-Florbetapir revealed strong radioligand binding in the same pathological areas, without uptake of normal appearing tissue. Comprehensive evaluation including CSF examination did not reveal any other abnormalities. Stereotactic biopsy of the left parietal white matter showed nodular, confluent amyloid masses, that showed apple-green birefringence with Congo-red staining and intense fluorescence *with Thioflavin*. Amyloid deposits were also present in the wall of parenchymal vessels. Immunohistochemical staining showed strong staining for lambda light chain. There was also weaker staining (probably cross-reactive) for kappa chain and against different types of amyoloid proteins (AA, *beta-amyloid, transthyretin)*. These findings were consistent with the diagnosis of primary cerebral amyloidoma. No evidence of systemic disease was found. A trial of empiric radiotherapy or chemotherapy was discussed with the patient but was finally declined.

Conclusions. The clinical manifestations of cerebral amyloidomas are protean, but the neuroimaging characteristics are quite typical. PET with florbetapir can offer useful information for the diagnosis of patients with presumed cerebral amyloidosis.

REGIONAL FEATURES OF PARKINSON'S DISEASE IN KAZAKHSTAN.

S. Kamenova[1], S. Turuspekova[1], A. Akanova[1], A. Kondybayeva[1]
[1]of internship and residency in neurology, Kazakh National Medical University, Almaty, Kazakhstan

Heterogeneous regional data on the incidence and prevalence of Parkinson's disease in the population, reflect differences in life expectancy in different countries, differences in the organization of the health system, differences in access to primary health care, as well as genetic and environmental features, together with differences in the reporting of cases of the disease.

Objectives: conducting the clinical and epidemiological research of patients with Parkinson's disease.

Methods: On the example of Almaty we conducted a population-based research and get an objective picture of primary and general morbidity of Parkinson's disease, as well as evaluated the age and gender structure the incidence and features of the disease.

Results: One of the major problems of our patients suffering from Parkinson's disease, is a late diagnosis. Beginning of the disease in almost all patients developed gradually, they did not seek medical attention for a long time. More than 80% of patients go to the doctor, already having a late stage of the disease. The prevalence of Parkinson's disease in the adult population in Almaty was 62 per 100 thousand population. Parkinson's disease is 1.5 times more prevalent in women than in men, and more frequently detected in the age groups over 70 years.

Conclusions: The data obtained allow justify the need to improve treatment and diagnostic, medical and social care to patients with Parkinson's disease.

BEHAVIORAL AND PHYSIOLOGICAL EFFECTS OF AGE IN THE MOUSE

A.M. HERNIER[1], R. LEBLANC[2], C. DUVAL[1], S. GOINEAU[1], V. CASTAGNE[1]
[1]Pharmacology, PORSOLT, Le Genest Saint Isle, France
[2]Animal models, JANVIER-LABS, Le Genest Saint Isle, France

Age-related cognitive deficits are widely studied in rodents. Nevertheless, the performances in tests evaluating cognition may be influenced by other effects of age. We compared adult (6 - 13 weeks) and aged (102-109 weeks) C57BL6 mice in behavioral tests evaluating motor, sensory and psychological endpoints and in tests evaluating respiratory, cardiovascular, renal and gastro-intestinal functions.
When compared with adult mice, aged mice displayed piloerection and hypothermia as reflected in the Irwin test and motor deficits in locomotion, beam walking and rotarod tests. Sensory functions were relatively preserved with normal vision and olfaction but deficits in pain sensitivity were observed following tactile and to a lower extent to thermal stimulations. The evaluation of psychological characteristics did not reveal major changes and the slight effects observed in the elevated-plus maze, stress-induced hyperthermia, sucrose preference and forced swimming tests may be partly explained by lowered locomotion. Some aged mice were unable to perform tests of cognitive functions, but the remaining testable aged mice displayed adult-like performances.
At the physiological level, in aged mice the low glycemia and urinary volume may be explained by a reduced food and water intake. The colonic transit was accelerated without modification of the small intestine transit or gastric emptying. The bronchoconstriction index was increased and the aorta phenylephrine-induced constriction was enhanced.
Our data suggest that age-related deficits in tests evaluating cognitive functions should be interpreted with caution and that additional effects of aging, mainly related to motor functions, should be taken into consideration when interpreting the data obtained.

ADPD5-2175
EVALUATION OF THE STANDARDIZED MUSIC CARE© APP IN THE TREATMENT OF PAIN AND NEURODEGENERATIVE DISEASE"

S. Guetin[1], J. Touchon[2]
[1]Neurology CMRR, CHRU Montpellier, Montpellier, France
[2]Neurology CMRR Inserm U1061, CHRU Montpellier, Montpellier, France

Objectives: Numerous studies emphasize the application of music therapy and music medicine in the treatment of pain. The MUSIC CARE© app that was designed at the University Hospital of Montpellier applies the U-shape music composing technique taking into account the available evidence of the literature on relaxation paradigms (Fig.1). The main objective of this article is to summarize recent research on the standardization and evaluation of this new app of music therapy in the treatment of pain and neurodegenerative disease (Fig.2).
Methods: Following a comprehensive review of the literature, a series of controlled, randomized, multi-centered studies were conducted including patients seeking care in such diverse setting as neurology, rheumatology, functional rehabilitation, oncology, geriatrics, and general pain treatment.
Results: The effect of the MUSIC CARE© app has been evaluated on different types of pain and neurodegenerative disease. Physiological effects on hemodynamic and respiratory markers as well as psychological outcomes, including the relationship between care-provider and patient have been emphasized within multiple trials.
Conclusions: The MUSIC CARE© app reduces pain, anxiety and depression to a significant degree and decreases the need for anxiolytics and antidepressants. Our first randomized controlled trials demonstrate the benefit of using MUSIC CARE© application in the management of pain and neurodegenerative disease. Future directions for the use of the app in various settings are discussed.

RAPID DIFFERENTIATION OF ASTROCYTES FROM HUMAN EMBRYONIC STEM CELLS

B. Han[1], *C. Lee*[1]
[1]*Functional Genomics Research Center,*
Korea Research Institute of Bioscience and Biotechnology, Daejon, Korea

Astrocytes are the most abundant cells of the human brain and have the role of biochemical support of endothelial cell, supply of nutrients to the nervous tissue and maintenance of extracellular ion balance etc. In development of nervous tissue, the differentiation of astrocytes is later than neurons. In vitro, it takes more time and more techniques to obtain mature and pure astrocytes.

In this study, we developed the protocol to gain mature and pure astrocytes from human embryonic stem cells. To keep the quality of the differentiated astrocytes and to decrease the variations of the cell properties between batch to batch, we first tried to get neural progenitor cells (NPCs) and expand the cell number. The first step of astrocyte differentiation from neural progenitor cells were performed in astrocyte induction media containing EGF and heparin. Next, the cells were attached to coated plate in astrocyte defined media containing CNTF for 23 days. And then we checked the cell property with immunocytochemistry and western blot using antibodies for astrocyte specific marker proteins. To validate the functional property of the astrocyte, IL-6 release from astrocytes was tested. By FACS analysis, we found that the percentage of astrocytes among the cells differentiated from NPCs was over 90%. Taken together, with our protocol, we can obtain the mature and pure astrocytes within 4 weeks from NPCs and we have the plan to make micro-environment with neurons, astrocyte and endothelial cells.

ADPD5-2222

NIGROSTRIATAL PATHOLOGY CAUSED BY TOXIC AND GENETIC STRESSORS IS EXACERBATED IN PINK1-DEFICIENT MICE

R. Rusconi[1], R.E. Musgrove[1], A. Ulusoy[1], M. Klinkenberg[1], D.A. Di Monte[1]
[1]Bonn, German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany

Objectives:
Loss-of-function mutations of PINK1 are associated with familial parkinsonism. A relatively mild phenotype characterizes PINK1 knock-out mice (PINK1 KO). The aim of this work was to investigate the role of PINK1 deficiency in neurodegenerative processes and, in particular, to determine if more overt Parkinson's disease (PD)-like pathology could be triggered in PINK1 KO by toxic or genetic stressors.
Methods:
To model interactions between PINK1 and toxic insults, PINK1 KO mice were injected intraperitoneally with 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), a mitochondrial toxin. To simulate interactions between PINK1 and other PD-related genes, adeno-associated viral vectors (AAV) carrying either wild-type or mutated (A53T) alpha-synuclein DNA were injected into the substantia nigra of PINK1 KO mice.
Results:
Levels of striatal dopamine and counts of nigral neurons were unaffected in PINK KO as compared to control mice. In the former, MPTP administration induced a more pronounced (20% vs. 10%) degeneration of nigral neurons. Similarly, AAV-induced alpha-synuclein overexpression was associated with greater nigrostriatal toxicity in PINK1-deficient animals. Following overexpression of wild-type alpha-synuclein, striatal dopamine and nigral neurons were decreased by 25% and 33%, respectively, in PINK1 KO mice; in control animals, corresponding values were 12% and 25%. The extent of nigral cell loss caused by overexpression of A53T alpha-synuclein was 40% in KO mice and 28% in controls.
Conclusions:
On the background of PINK1 deficiency, MPTP- and alpha-synuclein-induced pathology was exacerbated. Interestingly, overexpression of mutated alpha-synuclein was associated with greater toxicity than the wild-type protein only in the absence of PINK1.
