STRESS AND TELOMERE MAINTENANCE MECHANISMS IN HUMAN LIFE TRAJECTORIES

E. Blackburn[1]

[1]*Department of Biochemistry and Biophysics, University of California San Francisco, San Francisco, USA*

Telomeres are the protective, specialized DNA-protein complexes at the tips of chromosomes that help stabilize the genetic information. Their integrity is necessary for normal cell functioning as well as cellular replenishment. The enzyme telomerase can add DNA to telomeres, counteracting the processes that shorten them. Telomere length in humans is thus dynamic, continuously determined by systemic and cell-specific regulation of shortening and lengthening processes. However, throughout human lives, in many cells these chromosomal tips erode, with the potential eventually to cause some cells to malfunction or die. Shortening of telomeres has been shown to precede major chronic diseases linked to human aging such as cardiovascular diseases, diabetes and certain cancers, and from genetic evidence appears to contribute to some diseases. Recent emerging data suggest that telomere shortening, as typically measured in white cells from blood draws, is linked to dementias and brain functions. Telomere shortening has also been linked to chronic psychological distress, including effects coming from external influences. Conversely, exercise and other lifestyle factors have been associated with longer telomeres and their slower attrition over time. These findings raise the possibility of finding ways to slow or even alleviate the telomere shortening occurring throughout aging. An important challenge is to apply knowledge of the effects of telomere maintenance on the biological processes in aging and co-morbid diseases to improve human health.

THE CONCEPT OF SUBCONSCIOUSNESS IN ALZHEIMER AND PARKINSON DISEASES

Y. Agid[1]

[1]*Institut du Cerveau et de la Moelle épinière (ICM), CHU Pitié-Salpêtrière, 47 boulevard de l'hôpital, 75013 Paris, France*

Patients with Alzheimer disease progressively lose non-automatic cognitive abilities as a result of the loss of neurones in the cerebral cortex, whereas the basal ganglia, known to be involved in automatic behaviours, are essentially intact. This explains why automatic activities (ex: gait) are usually preserved in the disease. In contrast, patients with Parkinson disease have lost automatic behaviours as the result of the dysfunction of the basal ganglia, whereas the cerebral cortex is essentially preserved, thus explaining the absence of severe cognitive disorders in most patients. This suggests that the basal ganglia are playing a major role in the processing of automatic motor behaviours, and the cerebral cortex in non-automatic behaviours. The basal ganglia are composed of motor, associative and limbic territories, thus suggesting that the basal ganglia are involved in the processing of motor, but also of intellectual and emotional functions. This is what we call subconsciousness. Several examples using neuroimaging and deep brain stimulation will be provided to demonstrate that phylogenetically ancient and small structures such as the basal ganglia are directly involved in the subconscious processing of emotions in normal subjects or of emotional disturbances in patients with neuropsychiatric disorders.

[2]Neurology, University of Texas Southwestern Medical Center, Dallas, USA

Evidence supports the idea that neurodegenerative diseases linked to protein amyloids could be caused by trans-cellular propagation of protein aggregates—a fundamental mechanism of prion diseases. We study this process in the tauopathies, which are characterized by intraneuronal accumulation of tau amyloids. We have defined heparan sulfate proteoglycans as the cell surface receptors to which tau and synuclein aggregates bind to trigger uptake and seeding into vulnerable neurons. We have also described essential strain characteristics of tau prions, in which unique conformations are propagated indefinitely in cells and in animals. Further, the conformation of the tau aggregate that enters a cell defines subsequent the structural and biochemical properties of the amplified aggregates, intracellular inclusion morphology, and subsequent neuronal pathology. Human tauopathies can now be linked to distinct groups of tau prion strains. We additionally define the minimal tau aggregate size in AD samples that is sufficient to trigger spontaneous intracellular uptake and seeding. To quantify tau seeding activity, and to test the role of proteopathic seeds in the development of pathology, we have developed a FRET-based biosensor cell assay based on induction of tau reporter aggregation. This identifies tau seeding activity far in advance of pathology detected by any other means. Our results suggest a very proximal role for seed development in pathogenesis. Finally, we have developed a new microfluidic method that we term the Multiplex Avidity Profile to rapidly define aggregate composition in patient material. We hypothesize this will enable syndromic classification of tauopathies based entirely on aggregate structure.

HOW DO WE TREAT ALZHEIMER'S DISEASE A DECADE BEFORE DEMENTIA?

R. Sperling[1]

[1]*Neurology,*

Center for Alzheimer Research and Treatment Brigham and Women's Hospital Mass achusetts General Hospital Harvard Medical School, Boston, USA

Converging data from PET amyloid imaging, cerebrospinal fluid studies and large autopsy series suggest that one-third of clinically normal older individuals harbor a substantial burden of cerebral amyloid-ß. It remains unknown whether these individuals are in the preclinical stages of Alzheimer's disease (AD) and what proportion will progress to dementia over time. Our multi-modality imaging studies in normal older individuals have demonstrated that Aß deposition is associated with aberrant default network fMRI activity and cortical thinning in amyloid-laden regions, in a pattern similar to that observed in AD dementia. Recent studies have also reported an association between Aß burden and memory performance, and increased subjective cognitive concerns. The most compelling data come from longitudinal studies suggesting that elevated Aß burden confers a significantly increased risk of cognitive decline, particularly among older individuals with markers of both amyloid accumulation and neurodegeneration. Several secondary prevention trials in both genetic at-risk and age at-risk individuals are now ongoing, testing anti-amyloid mechanisms. The Anti-Amyloid Treatment in Asymptomatic AD (A4) trial will enroll over 1000 older individuals with evidence of amyloid accumulation on screening PET scans to determine if treatment with an anti-amyloid antibody, initiated prior to cognitive impairment, will slow neurodegeneration and the progression of memory decline towards AD dementia. A similar trial design with a BACE inhibitor in an asymptomatic AD population is being planned for a 2015 launch. One of the continued dilemmas in the field is how best to identify individuals who are clearly on the trajectory of late onset AD but at an earlier enough stage of pathology to be maximally responsive to therapeutic intervention.

ADPD5-1878

NOVEL NEUROPROTECTIVE APPROACHES IN PARKINSON´DISEASE EXPLORED IN ALPHA-SYNUCLEIN OVEREXPRESSION MODELS

A. Björklund[1]

[1]*Wallenberg Neuroscience Center, Lund University, Lund, Sweden*

The transcription factor Nurr 1 is a key regulator of the survival of dopamine neurons during embryonic development. Recently, it has been recognized that this gene regulator may play an important role also in adult dopamine neurons, and as a mediator of the degenerative changes seen in Parkinson´s disease (PD). Rare cases of familiar PD have been associated point mutations in the Nurr1 gene, and recent observations in brains from PD patients show that the expression of Nurr 1 is reduced in affected dopamine neurons. These data suggest that reduced cellular levels of Nurr1 may be associated with increased vulnerability and impaired function in the dopaminergic system. Studies in rodents have provided further support for this idea, showing that overexpression of the disease-causing protein alpha-synuclein causes down-regulation of Nurr1, which in turn leads to impaired dopamine neurotransmission and loss of responsiveness to the neurotrophic factor GDNF. Conversely, GDNF signaling is effectively restored by overexpression of Nurr1, providing near-complete protection of nigral dopamine neurons against alpha-synuclein toxicity also in the absence of exogenous GDNF. These observations suggest that reduced Nurr1 expression, induced by increased cellular levels of alpha-synuclein, is a key element in the induction of dopamine neuron dysfunction seen in early stages of the disease, and that loss of Nurr1 contributes to the progression of the disease. Together, the clinical and experimental data point to Nurr 1 as key player in the pathogenesis of PD and identifies Nurr 1 an interesting novel therapeutic target for disease intervention in PD.

ALZHEIMER'S DISEASE: FROM PRECLINICAL STATES TO DEMENTIA

B. Dubois[1], S. Epelbaum[1], H. Bakardjian[1], E. Cavedo[1], S. Lista[1], M. Levy[1], A. Dos Santos[1], H. Hampel[1]

[1]Département de Neurologie,

Centre des Maladies Cognitives et Comportementales (IM2A), Paris, France

How should we define Alzheimer disease today? Should it be defined as a clinical disease, which starts with a dementia (classical definition)? Should it be defined as a clinical disease, which starts with the first clinical symptoms (IWG definition)? Should it be defined biologically by the presence of a positive biomarker (BM+) even in the absence of clinical symptoms (NIA-AA definition)?

If in vivo evidence of Alzheimer pathology is a fundamental feature for the further conversion to a clinical disease, it is not definitely established that all healthy subjects BM+ will develop the disease during their lifetime. At present, the risk of conversion to a clinical AD has been estimated to be around 25% after a 3-year long follow-up. Longer follow-ups are needed to demonstrate that all subjects will convert to AD. In parallel, several factors may have a negative/positive influence on the conversion: age, presence of co-morbidity, vascular risk factors, genetic predisposition, or in the opposite, significant cognitive reserve, other compensatory mechanisms of the brain, preventive genetic/episodic and life-style factors. For these reasons, normal BM+ individuals should only be considered as « asymptomatic at risk for AD (AR-AD)». Therefore, the next steps will be to identify the factors that activate or delay the dynamic process of conversion and the subtle brain changes that anticipate the clinical onset. The main clinical issue will be to identify AR-AD having the highest likelihood to convert to definite clinical AD in the subsequent months. This is especially important, as the later will be the main target population for treatment with disease-modifying drugs. When such drugs become available, the important step will be to treat AR-AD subjects to delay the onset of clinical symptoms.

THE ADIPOCYTE DIFFERENTIATION PROTEIN APMAP IS AN ENDOGENOUS SUPPRESSOR OF A-BETA PRODUCTION IN THE BRAIN

S. Mosser[1], J.R. Alattia[1], M. Dimitrov[1], A. Matz[1], J. Pascual[1], B. Schneider[1], P. Fraering[1],

[1]Brain Mind Institute, Ecole polytechnique fédérale de Lausanne, Lausanne, Switzerland

OBJECTIVES: Cerebral amyloid-beta (Abeta) deposition is a major pathological hallmark of Alzheimer's disease (AD). Abeta is generated by the proteolytic processing of the amyloid precursor protein (APP-C99) by gamma-secretase, an intramembrane-cleaving protease with multiple substrates. Because clinical inhibition of gamma-secretase resulted in severe side effects attributed to impaired Notch cleavage, we aimed at identifying new endogenous gamma-secretase modulating proteins that specifically affect Abeta production.

METHODS: The proteome of highly purified active gamma-secretase was analyzed by LC-MS/MS mass spectrometry. Next, the physical interactions between the newly identified endogenous gamma-secretase interacting proteins (GSPs), gamma-secretase and APP were studied in cell-based systems. Finally, the effects of the genetic inhibition of the GSPs on Abeta production were analyzed *in vitro* and *in vivo,* both in wild type and AD mice.

RESULTS: We identified the adipocyte plasma membrane associated protein **(**APMAP), a key player of adipocyte differentiation, to interact physically both with gamma-secretase and its substrate APP. In cells, partial depletion of APMAP was associated with drastic increases in APP-CTFs levels and Abeta production. In wild type and APP/PS1 transgenic mice, adeno-associated virus-mediated partial APMAP knockdown in the hippocampus increased Abeta production by ~20% and ~55%, respectively.

CONCLUSION: We demonstrate that APMAP is a negative regulator of Abeta production, through a mechanism involving APP-C99 degradation via the lysosomal-autophagic system.

[2]Neurology, Graduate School of Medicine The University of Tokyo, Tokyo, Japan

[3]Neuropathology, Graduate School of Medicine The University of Tokyo, Tokyo, Japan

Recent GWAS studies revealed that variants at *PICALM* as well as *BIN1* locus are associated with the onset of Alzheimer disease (AD) that is characterized by deposition of amyloid-β proteins (Aβ). *PICALM* gene encodes a protein called CALM which has a PtdIns(4,5)P_2-binding AP180 N-terminal homology domain at its N terminus, along with several AP2/clathrin binding motifs in the C-terminal region. BIN1 is a membrane trafficking-related adapter protein that contain N-terminal BAR and C-terminal SH3 domains. BAR domains recognize specific phospholipids and sculpt membranes to generate protrusions or invaginations. In the previous study, we showed that γ-secretase is constitutively endocytosed via clathrin-mediated pathway in a CALM dependent manner. And partial loss of CALM function decreased the rate of clathrin-mediated endocytosis of γ-secretase as well as production of the pathogenic Aβ species, Aβ42 (Kanatsu et al., *Nat Comm* 2014). Furthermore, we found that the amyloid plaque burden was significantly decreased in the piriform cortex of congenic *Picalm*$^{+/-}$ mice crossed with APP transgenic A7 mice at 12 months old, supporting our notion that partial loss-of-function of CALM is protective against AD. In contrast, we have found that BIN1 promotes BACE1 degradation by lysosomal targeting from endosome. Ablation of Bin1 expression in mouse primary neurons resulted in the increased production of Aβ and sAPPβ by augmentation of BACE1 proteins. These data suggest that Aβ production is modulated by the genetic risk factor proteins and impacts on the onset of AD.

ADPD5-1226

SYNAPTIC LOCALIZATION OF APP PROCESSING ENZYMES

S. Frykman[1], J.L. Lundgren[1], S. Ahmed[2], S. Schedin-Weiss[1], G.K. Gouras[3], B. Winblad[1], L.O. Tjernberg[1]

[1]NVS, Karolinska Institutet, Huddinge, Sweden

[2]Trans-Synaptic Signaling Group, European Neuroscience Institute, Göttingen, Germany

[3]Experimental Dementia Research, Lund University, Lund, Sweden

Objectives

The objectives of this study were to investigate the synaptic localization of the Amyloid Precursor Protein (APP) processing enzymes alpha-, beta- and gamma-secretase, in order to more specifically and effectively target the production of the amyloid beta-peptide (Abeta) and thereby reduce the synaptic dysfunction in AD.

Methods

Subcellular fractionation was used to prepare crude synaptic vesicle and synaptic membrane fractions. Ultra-pure synaptic vesicles were purified by a controlled-pore glass chromatography. In situ localization of the secretases was assessed by immunocytochemistry or proximity ligation assay in hippocampal primary neurons using antibodies or a probe for active gamma-secretase. Abeta production was measured by an in vitro gamma-secretase assay followed by ELISA and beta-secretase (BACE1) activity was measured by a commercial kit.

Results

Gamma-secretase activity was found to be enriched in crude synaptic fractions but not in ultra-pure synaptic vesicles. On the contrary, BACE1 and the intermediate APP fragment APP-CTF were highly enriched in pure synaptic vesicles. In accordance with this finding, BACE1 co-localized with the synaptic vesicle marker synaptophysin in primary neurons whereas BACE1 and gamma-secretase did not co-localize.

Conclusions

We conclude that the APP-processing enzymes are present at different synaptic locations. The high enrichment of BACE1 in synaptic vesicles can enable specific targeting of synaptic BACE1.

Alzheimer's disease (AD) is a memory disorder for which the exact cause is unknown. A defining feature of AD is the presence of amyloid-b (Ab) which is causally linked to neurodegeneration. The key molecular events leading to the generation of the amyloid b (Ab) peptide are well characterized. In principle, Ab can be produced employing only three primary components i.e., APP, b-secretase and g-secretase complex. But this entire process requires the involvement of several gene products in the cellular context. Identification of genes that regulate APP processing and Ab levels would give a clear picture of AD and would also be suitable candidates for drug development. To elucidate the cellular mechanisms that regulate APP processing we used gene-silencing strategies using small interfering RNAs (siRNA) and performed genome wide screen of all kinases and complemented it with an activity-inhibiting small molecule kinase inhibitor screen to identify key regulators of APP processing. We identified a large set of kinases as regulators of APP processing. We also found that signaling networks regulate Ab metabolism. Our results reveal that many genes regulate APP processing and many signaling networks and pathways regulate Ab metabolism. We provide experimental validation of AD being a multifactorial syndrome rather than a single disease. Moreover, we believe that systems biology approaches will play a crucial role in our future understanding of networks involved in AD pathogenesis.

ADPD5-2071
THE T-BOX FACTOR TBX2: ITS ROLE IN REGULATING THE ALZHEIMER-RELATED PROTEINASE ADAM10

S. Reinhardt[1], K. Hilger[1], A. Bruns[1], M. Grimm[2], T. Hartmann[2], K. Endres[1]
[1]Clinic of Psychiatry and Psychotherapy, University Medical Center, Mainz, Germany
[2]Neurodegeneration and Neurobiology, Saarland University, Homburg/Saar, Germany

Increased synthesis of A-beta peptides by a disturbed homeostasis of the proteinases competing for their substrate APP (amyloid precursor protein) represents a pivotal event in Alzheimer's disease pathogenesis: ADAM10 (a disintegrin and metalloproteinase 10), the physiological alpha-secretase, is decreased in favor of the A-beta generating enzyme BACE-1 (beta site APP cleaving enzyme-1). Therefore, identifying transcription factors (TFs), which contribute to the disturbed homeostasis of APP-processing by regulating the gene expression of either proteinase, might elucidate molecular mechanisms underlying AD-pathology.

Here we demonstrate that the senescence-associated TF T-box2 is a repressor of ADAM10 transcription in neuronal cells. The decrease of ADAM10 gene expression is mediated via a Tbx2 binding site within the basal promoter region as demonstrated by shift assay analysis. Coexpression and inhibition experiments revealed that the decrease of ADAM10 transcriptional activity by Tbx2 is partly conducted by its binding partner HDAC1. Analyses of cortical samples of AD patients hint at a potential contribution of Tbx2 in AD-pathogenesis: mRNA level of Tbx2 but not of the T-box gene family members Tbx3 and 21 was significantly increased in post-mortem frontal cortex tissue of AD-patients as compared to healthy age matched controls. This was paralleled by reduced ADAM10 mRNA as demonstrated earlier.

In summary, our results indicate that Tbx2 might contribute to the disturbed homeostasis of APP-processing in AD-pathogenesis.

MODELING OF BRAIN INSULIN RESISTANCE AS A TRIGGER FOR SPORADIC ALZHEIMER'S DISEASE

M. Salkovic-Petrisic[1]
[1]*School of Medicine, University of Zagreb, Zagreb, Croatia*

Growing evidence indicates that dysfunctionalbrain insulin and alterations downstream the insulin receptor (IR)signalling pathways in the brain precede cognitive impairment in sporadic Alzheimer's disease (sAD). Attempts to create experimental sAD condition have revealed that intracerebroventricular administration of streptozotocin (STZ-icv), a compound selectively toxic to IR and insulin producing/secreting cells, generatesan animal model which develops brain insulin resistance as a starting point and eventually demonstrates cognitive deficits and some other sAD-like features.Considering the long developmental phase in human sAD pathology, duration of post-STZ-icv treatment time might be important in validation of STZ-icv model in modelling of sAD. Characterization of STZ-icv model usually refers to the pathology developed ≤3 months post STZ-treatment. Our 9-month follow-up study of STZ-icv rat model indicates a biphasic pattern (partly reversible changes at ≤1 month,AD-like ones at ≥6 months post treatment) in onset and progression of changes in brain insulin and IR signalling accompanied by STZ dose-dependent biphasic time-pattern of memory decline. However, structural changes, particularly intracellular amyloid-β_{1-42} accumulation,become apparent not earlier than 3 months post treatment and follow a slow linear mode of progression up to 9 months. STZ-icv model provides a strong evidence of the relevance of brain insulin resistance in development of sAD-like condition.Given the resemblance of medium/late post-STZ-icv treatment stage to human sAD condition,attention should be paid to planning of preclinical drug trials in this modelwhich might contribute to better translational AD research leading to more successful clinical AD trials.

[5]Banner Sun Health Research Institute, Banner Sun Health, Sun City, USA
[6]Department of Pathology, University of Virginia, Charlottesville, USA

We recently reported that neuronal cell cycle re-entry (CCR), which precedes neuron death in AD, results from Aβ oligomers (AβOs) stimulating tau phosphorylation at Y18, S409 and S416 (*J Cell Sci* 126:1278). We now describe how mTOR cooperates with AβOs, tau and Rac1 to drive neuronal CCR. In cultured neurons, CCR was prevented by reducing the abundance or activity of NCAM, Gαs, Rac1, mTORC1 or mTORC2, and required mTORC1-dependent tau phosphorylation at S262. FRET biosensors for mTORC1 revealed AβO-induced activation at plasma membrane (PM), but not lysosomes, where mTOR is activated instead by insulin, which blocks CCR. Reducing Rac1-dependent targetting of mTOR to PM or forcing mTORC1 onto lysosomes also prevented CCR. Reduction of mTor in Tg2576 mice strongly suppressed CCR and tau phosphorylation at S262, the latter of which was also reduced in 3xTg AD model mice treated with rapamycin. Finally, preliminary studies of rapidly fixed brain biopsy samples from human normal pressure hydrocephalus patients with coincident AD pathology revealed that plaque and tangle density strongly correlate with CCR markers, and tau phosphorylation at S262 and S409. AβOs thus initiate two pathways that synergistically lead to mTOR dysregulation and are obligatory for CCR: mistargetting of mTOR to PM, and tau phosphorylation at Y18, S409 and S416. The requirement for tau phosphorylation at S262 establishes that bidirectional regulation of tau and mTor integrates the pathways. Moreover, the insulin insensitivity of AD neurons, which has prompted AD's classification as "type 3 diabetes", unleashes AβOs' tau-dependent ability to induce CCR.

THE MTOR/P70S6K PATHWAY PLAYS A KEY ROLE IN THE PATHOGENESIS OF ALZHEIMER'S DISEASE

S. Oddo[1], A. Caccamo[2], C. Branca[2], D. Shaw[2]
[1]Basic Medical Sciences,
Banner Sun Health Research Institute and University of Arizona, Phoenix, USA
[2]Basic Research, Banner Sun Health Research Institute, Phoenix, USA

Objectives. Aging is the major risk factor for Alzheimer' disease (AD); however, little is known as to how the aging process facilitates the development of AD. Changes that occur in the brain as a function of age may facilitate the development of AD. Reducing the activity of the mammalian target of rapamycin (mTOR), and its downstream target p706SK, increases lifespan and health-span in genetically different species. mTOR is a protein kinase that plays a key role in regulating protein translation (via p70S6K) and degradation. Therefore, mTOR is key in controlling protein homeostasis, a process that is altered in AD and other proteinopathies. The goal of this work is to assess the role of the mTOR/p70S6K pathways in the pathogenesis of AD.
Methods: Using several mouse models, we employed multidisciplinary approaches to dissect the role of the mTOR/p70S6K signaling in AD.
Results: We will show that genetic and pharmacologic reduction of mTOR and p70S6K signaling reduced amyloid-β and tau pathology and rescued memory deficits. Mechanistically, the reduction in mTOR signaling led to an increase in autophagy induction and restored the hippocampal gene expression signature of the Tg2576 mice to wild type levels.
Conclusions: Given that mTOR and p70S6K regulate lifespan and health span, the data presented here have profound clinical implications for aging and Alzheimer's disease and provide the molecular basis for how aging may contribute to AD pathology. Our results implicate hyperactive mTOR/p70S6K signaling as a previous unidentified signaling pathway underlying gene-expression dysregulation and cognitive deficits in Alzheimer's disease.

A NOVEL METABOLIC GENE THERAPY-BASED STRATEGY FOR THE TREATMENT OF ALZHEIMER'S DISEASE

P. Leone[1], S. McPhee[2], P. Francis[1]
[1]Cell Biology, RowanSOM, Stratford, USA
[2]Gene Therapy, Asklepios Biopharmaceutical Inc., Chapel Hill, USA

Objectives: To develop a therapeutic intervention targeting neuronal metabolic integrity in Alzheimer's Disease (AD). Recompartmentalization of neuronal N-acetyl-L-aspartic acid (NAA) catabolism is proposed to provide resistance to Aß-induced energetic crisis. Reductions in NAA in AD parallel compromised energetic status, and reflect a threshold effect with respect to the available metabolic resources. NAA synthesis is energy-intensive, taking place in neurons, while NAA catabolism uncouples fatty acid synthesis from the ATP-generating tricarboxylic acid (TCA) cycle in myelinating oligodendrocytes (Francis et al. 2012). We hypothesized that providing neurons with the ability to catabolize NAA in a model of familial AD would result in heightened resistance to metabolic stress via the promotion of TCA cycle integrity and overall mitochondrial function. Methods: gene therapy using recombinant adeno-associated viral vectors (AAV) was employed to recompartmentalize ASPA activity to neurons. HPLC, unbiased stereology, and cognitive testing was employed to assess the ability of this strategy to promote phenotypic rescue in the 5XFAD model of AD. Results: AAV-mediated expression of NAA-deacetylating ASPA in neurons of 5xFAD mice resulted in improved energetic status, reduced amyloid burden, the promotion of cell survival, and long-term cognitive improvement. Conclusions: The genetic recompartmentalization of NAA catabolism is a novel therapeutic strategy for AD that appears to rescue phenotype in 5xFAD mice. The utilization of a gene therapy platform, with proven clinical safety and efficacy, to target energetic integrity has relevance for the clinical development of an AD therapeutic, and for a broad spectrum of neurodegenerative diseases that manifest energetic crisis

[3]Department of Pathology, Wake Forest University, Winstom-Salem, USA
[4]Department of Physiology and Pharmacology, Wake Forest University, Winstom-Salem, USA

Objectives: Given that epidemiologic studies have shown that diabetes mellitus increases the risk of Alzheimer's disease (AD), our objective was to examine the mechanistic links between the two diseases in a non-human primate.
Methods: Tissue from multiple brain regions of a vervet monkey model of streptozotocin-induced type 1 diabetes (n=10 control; n=7 diabetic) was examined by Western blot analysis, sandwich ELISA, and qPCR for biochemical changes in tau protein and Abeta peptide, as well as changes in key enzymes that contribute to their processing and posttranslational modification.
Results: Regional brain analyses showed a global increase in tau phosphorylation in areas vulnerable to AD pathology as well as in spared structures such as the cerebellum. An examination of tau phosphatases and kinases showed a brain-wide increase in active ERK1/2. A diabetes-induced increase in Abeta levels, however, was specific to brain regions affected during the early stages of AD pathogenesis, with the greatest increase observed in the hippocampus. Examination of the amyloid precursor protein, its metabolites, and proteins involved in the clearance and degradation of brain Abeta indicated that a hippocampal-specific decrease in the Abeta-degrading enzyme neprilysin is a major contributor to this localized Abeta increase.
Conclusions: Our study suggests protein changes in the brain that link diabetes to AD risk: decreased neprilysin expression leads to an increase in Abeta in the temporal lobe structures that are at the earliest risk in AD while increased ERK1/2 activity appears to contribute to a brain-wide increase in tau phosphorylation.

Symposium 04: METABOLISM 1

ADPD5-1718
DUAL EFFECTS OF METFORMIN ON TAUOPATHY IN THE P301S MUTANT HUMAN TAU TRANSGENIC MOUSE

L. Gasparini[1], O. Antico[1], E. Barini[1]
[1]Neuroscience and Brain Technologies Department, Istituto Italiano di Tecnologia, Genoa, Italy

Objectives:
In Alzheimer disease (AD), the progression of cerebral tau pathology correlates with cognitive impairment and appears to be influenced by several risk factors, including brain insulin resistance and the use of antidiabetic drugs such as metformin. Indeed, there is evidence that metformin enhances protein phosphatase 2A (PP2A) activity and dephosphorylates tau in cultured mouse primary cortical neurons, suggesting a potential effect on tau pathology. Here, we investigated the potential use of metformin as a therapy for tauopathy in a relevant transgenic mouse model.

Methods:
Metformin was administered in the drinking water (2mg/ml) to P301S mutant human tau (P301S-tau) transgenic and C57BL6/J wild type (WT) mice starting from 4 weeks of age for 4 months. Weight, glycemia, food and water intake were monitored weekly. Cerebral tau phosphorylation and tau inclusions were evaluated by biochemical and immunohistochemical analyses.

Results:
Chronic administration of metformin did not alter weight, glycemia, water and food intake in both WT and P301S-tau mice. In P301S-tau mice, chronic treatment with metformin affected the expression levels of PP2A and significantly decreased the levels of phosphorylated tau in the cortex and hippocampus. We also found that metformin promoted the aggregation of recombinant P301S mutant human tau in vitro. Moreover, when administered chronically, metformin significantly increased the number of β-sheet filamentous tau inclusions in the P301S-tau brain.

Conclusions:
These results indicate that chronic use metformin may favor the development of tau filamentous inclusions and suggest that metformin should be used with caution in elderly patients with dementia.

ADPD5-0347

RECONSTRUCTING THE COMPLEXITY OF ALZHEIMER DISEASES BY USING QUANTITATIVE SYSTEMS PHARMACOLOGY AS A POSSIBLE ALTERNATIVE FOR PRECLINICAL ANIMAL MODELS

H. Geerts[1], *A. Spiros*[1], *R. Carr*[1]
[1]*Computational Neuropharmacology, In Silico Biosciences, Berwyn, USA*

Objectives. Succesful clinical trial development is extremely challenging in CNS neurodegenerative diseases. Possible reasons include limited predictability of preclinical animal models, and clinical trial flaws or insufficient target engagement. Most importantly is the lack of recognition of the many complex processes in the aged Alzheimer patient, driven by comorbidities, genotypes, comedications and different life histories.

Methods. We present an advanced computer-based Quantitative Systems Pharmacology (QSP) platform, a mechanism-based computer model of relevant humanized cortical networks for clinical readouts in psychiatry and neurology, calibrated with group average clinical data and has been able to blindly and correctly predict unexpected clinical outcome for a new candidate AD drug. This method differs from the traditional preclinical animal models in that it is focused primarily on clinical neurology, human neuropathology and patient outcome.

Results. We discuss a high-level QSP approach integrating many isolated preclinical experiments. A key part is the integration of this information in a web-based database, called NESTOR (NErvous SysTems Organized References). The interaction between neurotoxic and compensatory processes is described as dynamic state changes in a multi-parameter state space. These state changes are likely different from patient to patient; we explore how to possibly identify biomarkers for the individual disease trajectories. Transition rates between states are derived from preclinical and clinical data and the system output is constrained by clinical data on functional clinical scales, imaging or biochemical biomarkers.

Discussion. A novel innovative strategy for generating actionable knowledge for pharma R&D is outlined based on a humanized mechanism-based computer platform.

ANIMAL MODELS OF NEURODEGENERATIVE DISORDERS AND APPROACHES TO IMPROVE TRANSLATION IN DRUG DISCOVERY

E. Leahy[1], D. Brunner[1], S. Ramboz[1], T. Hanania[1]
[1]Company, PsychoGenics Inc, Tarrytown, USA

The major problem facing CNS drug discovery is that drugs that show good efficacy in preclinical models often fail efficacy endpoints in humans, with an impressive failure rate of about 99,6 % in clinical trial of AD. As a result, pharmaceutical companies may be taking the wrong compounds into clinical trials and abandoning potentially good ones. This raises the question of whether the models of neurodegeneration recapitulate the deficits seen in patients. While no mouse model is likely to capture all aspects of a human condition we can greatly improve the outcome of preclinical testing by improving the design, standardization, data collection, and interpretation of research results. Blinded studies, transparent protocols and reporting negative data are some of the ways we can improve translation in drug discovery. More thorough phenotyping rather of relying on single endpoints can also improve the predictive value of animal models. We have developed highly sensitive, automated behavioral testing systems that capture hundreds to thousands of behavioral features in a single test session, and thus can detect and track those behaviors that best define a disease model and treatment profile. The application of computer vision, robotics and bioinformatics avoids any investigator bias. Employing these technologies in early preclinical testing could have a dramatic impact on the efficiency of drug development.

ADPD5-1906
HUMANIZATION OF ENTIRE MURINE TAU GENE FOR A BETTER MODEL OF AD

T. Saido[1], K. Tsukakoshi[1], T. Saito[1]
[1]Laboratory for Proteolytic Neuroscience, RIKEN Brain Science Institute, Wako, Japan

None of the mouse models of Aβ amyloidosis reconstitute tauopathy, or NFT, without using tau mutation(s), which are causes of FTDP-17, not of AD. We consider there to exist two reasons. One is that the time necessary for Aβ amyloidosis to induce tauopathy, approximately a decade in human cases, is not enough for mice. If this happens to be true, we need to identify pathway(s) that link the two major pathologies and find measures to accelerate the processes. The other is that the physiochemical properties including the splicing profile of murine *tau* (gene) differ from those of human *tau* (gene) and thus could result in a failure of tauopathy reconstitution. To address the second question, we generated mice, in which the whole *tau* gene has been humanized. The mice appear to live normally. We have crossed these mice with single *App* knock-in mice (Saito *et al.*, ***Nat Neurosci***, 2014) and will present the latest data obtained using these mutant mice.

APPLICATION OF HUMAN INDUCED PLURIPOTENT STEM CELL TECHNOLOGY IN THE CONTEXT OF DRUG DISCOVERY FOR NEURODEGENERATIVE DISEASES

G.C. Terstappen[1]
[1]*Neuroscience Discovery - Biology, AbbVie Deutschland GmbH and Co. KG, Ludwigshafen, Germany*

Application of human induced pluripotent stem cell technology for drug discovery of neurodegenerative diseases

The use of innovative human induced pluripotent stem cell (hiPSC)-derived model systems in pharmaceutical research is expected to lead to increased disease understanding and the development of highly disease-relevant assay systems for drug screening. IPSC technology also promises to be impactful in other related areas of drug discovery & development including more predictive safety/toxicity testing, accelerated drug repositioning and patient stratification for clinical trials. Thus, IPSC technology has the potential to become a key 'translational' tool.
StemBANCC is a large-scale public-private partnership funded by the Innovative Medicines Initiative (IMI) which brings together a consortium of 35 partners from academia and industry who share their experience and work together in 12 work packages. The overall aim of this collaborative research project is the generation and characterization of high-quality human induced pluripotent stem cell lines for the investigation of a range of chronic diseases and drug safety evaluation.
In this presentation I will highlight StemBANCC activities from the work package investigating neurodegenerative diseases with a focus on Alzheimer's and Parkinson's disease which is jointly led by the University of Oxford and AbbVie.

Recent evidence suggests that specific extracellular ALPHA-synuclein (AS) strains are implicated in the progression of Parkinson's disease (PD) pathology. It is plausible that deregulation in the normal processing of secreted AS may be a causative risk factor for PD. Thus, elucidation of the mechanisms that regulate the protein levels of extracellular AS becomes essential. Our recent work has suggested that kallikrein-related peptidase 6 (KLK6), an extracellular enzyme physiologically present in the CSF known to cleave recombinant AS is also implicated in the regulation of naturally secreted α-syn turnover (Ximerakis et al., FASEB J, 2014). Importantly, this processing appears to be inhibited by the association of secreted α-syn with lipids. Here, we sought to investigate factors and mechanisms that regulate α-syn extracellular levels in vivo. Using KLK6 knockout mice crossed with a transgenic AS- PD mouse model we show for the first time that secreted AS oligomeric species are regulated through a proteolytic cascade involving KLK6. The effect of the protease on the in vivo propagation capacity of specific protofibrilar AS species has also been examined. Our findings clearly suggest that physiologic modifications affect the biochemical behavior of secreted AS and provide novel insights into transmission mechanisms and potential targets for therapeutic interventions.

Objectives: Intraneuronal accumulation of alpha-synuclein (alpha-syn) is a major neuropathological hallmark of PD. Increasing evidence suggests that this also occurs in the enteric nervous system (ENS), perhaps as prodromal event leading to clinical PD. Here we explore the role of inflammation in the accumulation of alpha-syn in enteric nerves.

Methods: A dextran sodium sulfate (DSS) colitis paradigm was applied in human alpha-syn transgenic mouse lines and compared to LPS induced inflammation. The macrophage phenotype was altered by crossing one alpha-syn transgenic line with CX3CR1-eGFP transgenic mice which lack fractalkine signaling. Accumulated alpha-syn in the ENS was stereologically quantified and immune mediators were assessed based on their mRNA expression levels. Colon samples of patients with colitis ulcerosa or Crohn's disease were analyzed by immunohistochemistry.

Results: Systemic administration of DSS and LPS resulted in different types of colitis as demonstrated histologically and by cytokine/chemokine expression pattern. Whereas LPS did not induce further accumulation of human alpha-syn, DSS colitis did most prominently in submucosal plexi, which was further aggravated by the lack of CX3CR1. Also, alpha-syn aggregates persisted over 2 months after the mice had recovered from colitis. Accumulation of alpha-syn was also observed in the colon of colitis ulcerosa patients, whereas patients with Crohn's disease were devoid of it.

Conclusions: Our results in mice and humans support the hypothesis that certain types of systemic inflammation can promote alpha-syn accumulation in the ENS and that macrophages may be in involved. The relevance of this observation in PD needs to be further explored.

Michigan State University College of Human Medicine, Grand Rapids, USA
[2]Psychiatry & Neurosurgery, Yale School of Medicine, New Haven, USA

1.Objectives

Alpha-synuclein (a-syn) has been implicated to confer a toxic gain-of function in PD and other synucleinopathies. However, we hypothesize that a-syn is not the primary toxic species in disease; rather, a-syn aggregation produces pathology by decreasing levels of functional α-syn. Here we test our hypothesis by reducing a-syn expression in the non-human primate.

2.Methods

African Green monkeys (n=1/vector) were injected unilaterally in the substantia nigra (SN) with low ($5x10^{12}$ vector genomes (vg)/ml) or high ($2x10^{13}$vg/ml) titer AAV2/5 (including GFP as a transduction marker) expressing a shRNA designed against a-syn or scrambled shRNA as control. Animals were monitored for behavioral deficits indicative of nigrostriatal denervation for three months until sacrifice. Brains were analyzed for catecholamine content and neuropathology of the SN.

3.Results

One animal treated with a-syn shRNA exhibited a progressive deficit in a summary score of healthy behaviors. Analysis of tissue indicated that a-syn shRNA treated animals contained reduced striatal dopamine (DA). GFP+ neurons were observed throughout the SN of scrambled-shRNA treated subjects. In contrast, GFP was only seen in dorsomedial neurons of a-syn shRNA treated animals. Degeneration of TH+ neurons, preferably in the ventral tier of the a-syn shRNA treated SN, was observed. In addition, several TH- neuromelanin+ neurons were observed with a-syn shRNA treatment.

4.Conclusions

Our findings suggest that non-human primate nigral (particularly ventral tier) neurons are sensitive to the loss of a-syn. This sensitivity is not due to non-specific shRNA toxicity. Our results suggest that sufficient levels of a-syn is crucial to neuronal survival.

[5]Department of Pathology and Medicine, UCSD, San Diego (CA), USA
[6]Department of Chemistry, ETH Zurich, Zurich, Switzerland

Objectives
Alpha-synuclein (α-Syn), displays remarkable structural diversity. In physiological buffers α-Syn adopts an intrinsically disordered conformation, which can be readily switched by prolonged incubation to an amyloid structure, thought to resemble material found in Lewy bodies. Pore-like oligomers of α-Syn have also been reported and α-Syn adopts at least two different alpha-helical structures upon lipid binding. Most of our current knowledge of the structural states of α-Syn derives however from *in vitro* experiments. It would be of paramount importance to evaluate whether and which of the structures characterized so far *in vitro* resemble those formed by α-Syn *in vivo*, under physiological and pathological conditions.
Methods
To probe the conformational states of α-Syn directly in complex samples, we developed a novel approach that couples proteolytic probes and selected-reaction-monitoring mass spectrometry (Feng *et al.*, *Nat. Biotechnology*, 2014). It relies on the generation of proteolytic patterns that depend on the conformational states of a protein and can be quantified directly in complex biological backgrounds.
Results
Our approach probed the structural conversions of α-Syn directly in complex cell extracts, with a structural resolution of ~10 amino acids. It enabled the extraction of conformational markers (conformotypic peptides) for the quantification of different α-Syn conformers in biological specimens. Using a library of conformotypic peptides for different α-Syn states, we evaluated the conformational properties of α-Syn in various biological samples.
Conclusions
Our approach opens up exciting new possibilities in the analysis of α-Syn amyloidogenesis and the exploration of the novel concept of “conformational biomarkers” of PD.

[4]Center for Neuropathology and Prion Research, Faculty of Medicine LMU, Munich, Germany

OBJECTIVES: The pathogenesis of PD and other alpha-synucleinopathies is associated with misfolding and aggregation of alpha-synuclein into oligomers and filaments with the former considered the toxic species. We have previously produced a transgenic mouse expressing 1-120 truncated alpha-synuclein with striatal synaptic alpha-synuclein aggregation and altered dopamine release but no dopaminergic cell death. We have now generated a new transgenic mouse line (called MI2) expressing higher amounts of the same 1-120 alpha-synuclein transgene under the TH promoter. Here we investigated its characteristics and the effect of the oligomer modifier anle138b on pathological markers in the nigrostriatal dopaminergic system.
RESULTS: MI2 mice showed alpha-synuclein synaptic aggregation and SNARE proteins redistribution, which were associated with a reduction in striatal dopamine release. Unlike the previous model, these changes appeared at 6 months rather than 12 months of age. Moreover, 12 month-old MI2 mice showed significant dopaminergic cell death in the substantia nigra. We also found that treatment with the oligomer modifier compound anle138b, which restores FM1-43 dye release in alpha-synuclein overexpressing PC12 cells, reduced alpha-synuclein synaptic accumulation and dopaminergic cell death. Importantly, the protective effect of anle138b on dopaminergic cells was present when treatment was started after the detection of reduced dopamine release in the striatum.
CONCLUSIONS: Our results support the hypothesis that presynaptic aggregation of alpha-synuclein and impaired striatal dopamine release precede the loss of nigral dopaminergic neurons. Importantly, we show that these deficits can be rescued by treatment with the oligomer modifier anle138b.

TOWARDS CLARITY FROM CONTROVERSY: A NEW MODEL FOR THE INITIATION OF PARKINSON'S DISEASE

D. Selkoe[1], T.I.M. Bartels[1], U.L.F. Dettmer[1]
[1]Neurology, Harvard Medical School/Brigham and Women's Hospital, Boston, USA

Misfolding and accumulation of α-synuclein (αS) occurs at low levels during brain aging and far more abundantly in 'synucleinopathies', including PD. αS missense mutations, copy number variants, and upregulated expression have each been associated with familial PD, and all 'sporadic' cases also have αS inclusions. For two decades, αS has been defined as a 'natively unfolded monomer'. In contrast, we observed in 2011 that a substantial portion of αS in healthy cells occurs as α-helical multimers sizing principally as a ~58 kDa tetramer of four N-acetylated monomers. This finding has been controversial, but our 2013 report of a protocol for crosslinking αS in intact neurons can readily reveal the tetramers and related multimers in the cytosol. We now show that levels of these multimers are relevant to PD pathogenesis by examining 5 PD-causing αS missense mutations in intact neuronal cells. By two independent methods (cell-penetrant crosslinking; fluorescent protein complementation), all 5 mutations significantly decreased the multimer:monomer ratio. Inserting the one fPD mutation (E46K) that occurs in a 'repeat motif' into two additional such motifs caused a stepwise decrease in multimerization. An engineered repeat-motif mutation (KTKEGV à KLKEGV) placed into 6 repeats abolished tetramers, raised monomers, and induced marked neurotoxicity by three different assays, accompanied by cytoplasmic aggregates. These data indicate that tetramers are a principal physiological form of αS in neurons and that destabilizing tetramers leads to neurotoxic accumulation of monomer-derived aggregates, analogous to transthyretin amyloidosis. Compounds which stabilize normal tetramers/multimers could prevent a very early event in PD pathogenesis.

Symposium 09: PROPAGATION OF TAU-PATHOLOGY

ADPD5-0718
THE ROLE OF LYSOSOMES IN TAU MISFOLDED STATE PROPAGATION
C. Michel[1], *C. Kaminski*[1], *G. Kaminski Schierle*[1]
[1]*Chemical Engineering and Biotechnology, University of Cambridge, Cambridge, United Kingdom*
Objectives: Tau levels are increased in the CSF of patients suffering from Alzheimer's disease but also from traumatic brain injuries and related tauopathies. Previous results have indicated that the presence of excess monomeric extracellular Tau may form a greater pathological risk to patients than hitherto suspected. We thus investigated the cellular pathway leading to exogenous Tau-derived aggregation inside cells with the aim to understand this pathway at a molecular level.
Methods: We apply super-resolution microscopy and multi-parametric imaging, both of which have been developed for the study of amyloid aggregation by our group. In particular, *d*STORM (*direct* stochastic optical reconstruction microscopy) permits imaging of amyloid species in two colours with a resolution of 20 nm, and FLIM (fluorescence lifetime imaging microscopy) permits the monitoring of amyloid aggregation in live cells with the help of a FRET sensor.
Results: We show that Tau first localises to endosomes and later to lysosomes with super-resolution microscopy. In lysosomes, exogenous Tau encounters endogenous Tau, the latter of which is naturally present due to normal physiological degradation of proteins. We further show that the low pH encountered in lysosomes is responsible for the formation of heterogeneous aggregates, the process of which can be inhibited by alkalising lysosomes.
Conclusions: Our results clearly point at lysosomes as key players in triggering Tau aggregation and thus propagation. Therefore, reducing the amount of Tau in the extracellular space could be a promising strategy to prevent disease progression.

[5]Laboratoire d'enzymologie et de biochimie structurale, UPR 3082, Gif-sur-Yvette, France

1. Objective

Tau, a microtubule-associated protein, aggregates in neurodegenerative disorders known as tauopathies but its secretion in the extracellular fluids may also play a role in neural network signalling. Once deregulated, secreted Tau probably participates in the spreading of Tau pathology in hierarchical pathways of neurodegeneration. The mechanisms underlying neuron-to neuron Tau transfer are still unknown. Given the place of extra-cellular vesicles (EVs) in cell-to-cell communication, we wondered whether they could involve secreted Tau. We then investigated in cell cultures, cell media and body fluids (rat and primate) if Tau might be present into 1) plasma membrane originating vesicles; the ectosomes and/or 2) in multi-vesicular bodies deriving vesicles; the exosomes.

2. Methods

EVs were purified by differential centrifugations from culture media of cell lines, neuronal primary cultures and brain interstitial fluid coming from *in vivo* models of Tauopathie. The presence of Tau was analysed using electron microscopy and biochemical assays.

3. Results

Among EVs and under basal conditions, Tau is mainly found in ectosomes, which supports the concept of a new physiological function for Tau. These specific vesicles enabled cytosolic Tau to be shuttled to the extracellular media. Moreover, the presence of Tau in vesicles coming from our pathological *in vivo* models also suggest that the over-accumulation of intra-cellular Tau results in targeting to MVBs, leading to release in exosomes.

3. Conclusions

This study brings new direct evidences that Tau transfers between cells at least via vesicular systems. This process may be involved in Tau pathology spreading.

Symposium 09: PROPAGATION OF TAU-PATHOLOGY

PROPAGATION OF TAU PATHOLOGY BY ALZHEIMER PHF: SEEDING OF TAU ISOFORMS IN WILD-TYPE MOUSE AND IN CELLS

J.P. Brion[1], E. Audouard[1], C. Masaracchia[1], K. Leroy[1], S. Houben[1], A. Boom[1], K. Ando[1]

[1]Laboratory of Histology Neuroanatomy and Neuropathology, Université Libre de Bruxelles, Brussels, Belgium

Objectives: In Alzheimer's disease, the propagation of neurofibrillary tangles during progression of the disease follows neuroanatomical pathways and can reflect transysnaptic passage of abnormal tau proteins that recruit normal tau proteins in connected cells to transmit from cell to cell tau misfolding leading to aggregation. Internalisation in cells and experimental propagation in mice has been shown with synthetic tau fibrils and tau oligomers but has been less documented with bona fide "Paired helical filaments" (PHF) made of all tau isoforms extracted from human brain. This study was aimed at analyzing the propagation of tau pathology in mice after injection of human PHF, their toxic properties, and the internalisation of human PHF into cultured cells expressing different tau isoforms.

Methods : Sarkosyl-insoluble PHF were extracted from the frontal cortex of AD patients. PHF were stereotaxically injected into the dentate gyrus of wild-type mice, or added to the culture medium of cultured cells.

Results : After 3 months of incubation, mice injected with human PHF developed tau positive aggregates into neurons of the dentate gyrus that extended into Mossy fibres and away from the injection side. These tau aggregates were made only of mouse tau, and were Gallyas positive and immunoreactive with phosphotau antibodies and conformational tau antibodies. Human PHF internalized into cultured cells recruited all types of endogenous tau isoforms and tau bound to microtubules.

Conclusion : Human PHF have the ability to seed aggregation of normal tau isoforms in wild-type mice and in cells, forcing phosphorylation and conformational changes characteristic of human PHF-tau.

Symposium 09: PROPAGATION OF TAU-PATHOLOGY

ADPD5-1844
CELL TO CELL PROPAGATION OF TAU THROUGH THE EXTRACELLULAR SPACE AND THE IMPACT OF NEURONAL EXCITABILITY

K. Duff[1], J.W. Wu[1], H. Fu[1], N. Myeku[1], A. Hussiani[1]
[1]Taub Pathology, Columbia University Medical Center, New York City, USA

Objectives: To determine the mechanism by which tau can propagate between neurons in vitro and in vivo, and to determine the impact of neuronal hyperexcitability on tau propagation.

Methods: We have examined the transfer of endogenously generated tau between cells in physiologically relevant cell systems (primary cultures, microfluidics, induced neurons) and compared data to what is seen in affected circuits in a transgenic mouse model of tau propagation. Neuronal hyperexcitability has been induced by optogenetic stimulation and the propagation of tauopathy has been assessed in vitro, and through brian circuits.

Results: Endogenously generated full length tau can propagate between primary cell populations in culture. Tau is released into the conditioned medium and can be transferred to recipient cells suggesting that one mechanism by which it passes between cells is through the extracellular space. Uptake is via the endosomal pathways, and clearance mechanisms are induced to remove tau as it accumulates in recipient cells which identifies possible therapeutic targets to prevent tauopathy progression. Neuronal hyperexcitability leads to increased release of tau into the extracellular space, and altered distribution of tau in vivo.

Conclusions: Tau can spread between neurons via the extracellular space and propagation is accelerated by neuronal excitability. Amyloid induced hyperactivity seen in the AD brain may exacerbate the propagation of tauopathy and provide a link between the two pathologies.

Symposium 09: PROPAGATION OF TAU-PATHOLOGY

ADPD5-1928
TRANSMISSION OF CORTICAL BASAL DEGENERATION-LIKE GLIAL TAU PATHOLOGY: A NEW MODEL FOR THE PROGRESSION OF GLIA TAUOPATHIES

J.Q. Trojanowski[1]
[1]*Pathology, University of Pennsylvania, Philadelphia, USA*

Intracellular inclusions of filamentous tau proteins are the hallmark lesions of several neurodegenerative tauopathies such as Alzheimer's disease (AD) and corticobasal degeneration (CBD) which show cell type-specific and topographically distinct tau inclusions. Growing evidence supports the concept that templated transmission of tauopathies occurs through functionally interconnected neuroanatomical pathways suggesting that different self-propagating strains of pathological tau could account for the diverse manifestations of neurodegenerative tauopathies. Here, we describe the rapid and distinct cell type-specific spread of pathological tau following intracerebral injections of CBD or AD brain extracts enriched in pathological tau (designated CBD-Tau and AD-Tau, respectively) in young human mutant P301S tau transgenic (Tg) mice (line PS19) 6-9 mo before they show onset of the mutant tau transgene induced tau pathology. At 1 mo post-injection of CBD-Tau, tau inclusions developed predominantly in oligodendrocytes in the fimbria and external capsule with infrequent intraneuronal tau aggregates. In contrast, injections of AD-Tau in young PS19 mice induced tau pathology 1 mo post-injection that was predominantly in neuronal perikarya with little or no oligodendrocyte involvement. With longer post-injection survival intervals of up to 6 mo, CBD-Tau and AD-Tau induced tau pathology spread in different patterns to brain regions distant from the injection sites while maintaining the cell type specific pattern noted above, and only AD-Tau resulted in neuron degeneration. Thus, AD-Tau and CBD-Tau represent specific pathological tau strains that may underlie the distinct clinical and pathological features of these two tauopathies and these strains could become targets to develop disease-modifying therapies for CBD and AD.

Symposium 09: PROPAGATION OF TAU-PATHOLOGY

[2]LEBS, CNRS, Gif sur Yvette, France
[3]MIRCen, CEA CNRS, Fontenay aux Roses, France
[4]Clinical Neurotherapy LNCM, CHUV, Lausanne, Switzerland
Tau pathology is characterized by intracellular aggregates of tau proteins. It is encountered in many neurodegenerative disorders, referred to as tauopathies. In the human brain, there are three tau isoforms (10-) with 3 (3R) repeats and three (10+) with 4 repeats (4R). All six Tau isoforms are aggregated in some diseases, such as AD, whereas the preferential aggregation of 3R or 4R isoforms occurs in other diseases, such as Pick's disease and progressive supranuclear palsy, respectively. In contrast to AD, where mutations have not been identified on the Tau gene (MAPT), patients presenting FTDP-17, exhibit Tau mutations. Mutant Tau proteins show a higher nucleation and fibrillogenesis than WT Tau, often leading to rapid neuronal death.
We took advantage of a new lentiviral rat model of tauopathy recently developed in our team to mimic tauopathies. Injection of lentiviral vectors encoding human wild-type (WT) or P332S Tau (3R&4R) in hippocampus resulted in NFD. However, with 3R tau WT and 3R and 4R P332S tau mutants, tau pathology was restricted to the injection site. Conversely, 4R WT human Tau protein was transferred from ventral hippocampus neurons to connected secondary neurons even at distant brain areas indicating a trans-synaptic protein transfer. Analysis of tau secretion in this rat model has been performed showing both secretion of extracellular vesicles and free forms of tau isoforms. Similar viral vector approach has been also developed in non-human primates.
Altogether, these animal models highlight differences in the molecular and cellular mechanisms underlying the pathological processes induced by tau isoforms, WT and mutant. Such observations allow for a better understanding of tau pathology propagation and the development of new approaches in diagnosis and therapeutic strategies for Tauopathies.

Symposium 10: INFLAMMATION 1

ADPD5-0328
INFLAMMATORY RESOLUTION IN ALZHEIMER'S DISEASE
R. Medeiros[1]
[1]*Institute for Memory Impairments and Neurological Disorders, University of California Irvine, Irvine, USA*
The initiation of an inflammatory response is critical to the survival of an organism. However, when inflammation fails to reach resolution (*i.e.*, repair/remodeling), a chronic inflammatory state may occur, and it becomes a major cofactor of many diseases, including Alzheimer's disease (AD). Comprehending the biological basis for altered innate immunity and inflammation in AD is a challenge that has substantial clinical importance, as restoration or preservation of immunological responses is likely to have a great importance to the lengthen of healthier lifespan. The discoveries that resolution of inflammation is a highly coordinated and active process controlled by endogenous pro-resolving and anti-inflammatory mediators, and that inflammatory cells undergo classical and alternative activation, highlight new potential molecular targets to regulate inflammation and treat chronic inflammatory diseases. Here, we will discuss novel findings from studies in human samples that demonstrate a severe impairment in signaling pathways associated with the regulation of inflammatory resolution. In addition, pre-clinical data will be presented to support the idea that restoring the activity of regulatory anti-inflammatory interleukins or pro-resolving lipid pathways can elicit protective immunity and mitigate AD-like pathology. In the future, it may be possible to generate therapies to regenerate and/or replace the endogenous inflammatory resolution pathways to prevent and/or treat AD.

Alzheimer's disease (AD) is a devastating neurodegenerative disorder and the leading cause of senile dementia worldwide; its pathophysiology is associated with unresolved chronic neuroinflammation. In this disease, blood-borne monocyte-derived macrophages (mo-MΦ) have an role in mitigating the neuroinflammatory response, though their spontaneous entry to the CNS appears to be insufficient, and the signals which regulate their trafficking are poorly understood. Our group recently pointed to the brain's choroid plexus (CP), which forms the blood-cerebrospinal fluid-barrier (BCSFB), as a selective gateway through which mo-MΦ are recruited to the CNS following acute injury. Here we show, in 5XFAD transgenic mouse model of AD (AD-Tg), that mo-MΦ trafficking to the CNS is suppressed due to CP dysregulation of IFN-γ signaling, needed for transepithelial migration of leukocytes across the CP. Pharmacological as well as genetic manipulations in AD-Tg mice, which led to increased levels of IFN-γ at the CP, resulted in CP epithelial upregulation of leukocyte trafficking determinants, which was followed by mo-MΦ recruitment via the CP-CSF migratory pathway to cerebral sites of amyloid-beta (Aβ) accumulation, plaque removal in the hippocampus and the cortex, and reversal of cognitive decline. Collectively, our results suggest that lacking mo-MΦ infiltration to the CNS, due to CP dysfunction, takes part in AD pathophysiology, and thus point to the BCSFB as a target amenable for immunomodulation as a potential therapy for AD.

[4]Pathology and Laboratory Medicine, Indiana University, Indiana, USA

OBJECTIVES

Our overall goal is to determine the upstream activators of Caspase-6, an enzyme associated with Alzheimer disease (AD) pathology, age-dependent cognitive impairment and axonal degeneration. Inflammatory Caspase-1 activates Caspase-6 in human primary neurons and Caspase-1 is activated by inflammasomes. Inflammasomes have been well characterized in macrophages, but not in neurons. Here, our objective was to identify which neuronal inflammasome leads to Caspase-1-mediated Caspase-6 activation.

METHODS

The inflammasome receptors of human primary neurons, astrocytes and microglia were assessed by qRT-PCR and western blot analyses. A cell free inflammasome assay, neutralizing antibodies, and inflammasome and Caspase-1 siRNAs determined the functional neuronal inflammasome. Caspase-1 and Caspase-6 activities were measured by fluorogenic assays, and assessment of Caspase-1 or Caspase-6 cleaved proteins by western blotting or ELISA assays. Null mice were used to assess inflammasome-mediated Caspase-1 and Caspase-6 activation in brains.

RESULTS

Human CNS neurons expressed functional Nod-like receptor protein 1 (NLRP1), absent in melanoma 2 (AIM2), and ICE protease activating factor (IPAF-1), but not the NLRP3, inflammasome receptor components. NLRP1 antibodies and siRNAs impeded stress-induced neuronal Caspase-1 and Caspase-6 activation in neurons. Lipopolysaccharide induced Caspase-1 and Caspase-6 in wild-type, but not in *Nlrp1*$^{-/-}$ and *Casp1*$^{-/-}$ mice cortex. NLRP1 expression increased 25 to 30 fold and co-localized with Caspase-6 activity in AD cortical neurons.

CONCLUSIONS

CNS human neurons express functional NLRP1 inflammasomes, which activate Caspase-1 and subsequently Caspase-6. These results reveal a fundamental mechanism linking intraneuronal inflammasome activation to Caspase-1-generated interleukin-1-b-mediated neuroinflammation and Caspase-6-mediated axonal degeneration.

INTRANEURONAL ABETA BURDEN AND PRECLINICAL CNS INFLAMMATION

C. Cuello[1], M.F. Iulita[1], S. Allard[1], E. Wilson[1], S. Do Carmo[1]
[1]Pharmacology and Therapeutics, McGill University, Montreal, Canada

The efficacy of anti-inflammatories in delaying the onset of Alzheimer's disease (AD) is well documented, however, these drugs lack efficacy after clinical diagnosis. These observations would support the occurrence of a disease-aggravating inflammatory process during the preclinical stages of AD.

This presentation will illustrate the occurrence of a pro-inflammatory process in rat and mouse transgenic models of AD. We have observed inflammatory changes before the appearance of amyloid plaques and coincidental with the pathological accumulation of intracellular Aβ-immunoreactive material in hippocampal and cortical pyramidal neurons. The presence and identity of this intraneuronal material as Aβ peptides was documented by confocal and super resolution microscopy. The accompanying inflammatory process was characterized by the intermediate activation of microglia and their mobilization towards Ab-burdened neurons of the hippocampus and cerebral cortex.

At early pathological stages, in the McGill-R-Thy1-APP rat transgenic model, there is also overt astroglia activation. Both, the McGill mice and rat transgenic models show up-regulation of classical inflammatory markers such as Il-1b, COX, TNF-a and fractalkine (CX3CL1), months before the formation of extracellular amyloid plaques. This early pro-inflammatory process differs from the overt, late inflammation surrounding amyloid plaques with fully activated microglia and monocyte infiltration, and thus represents a singular pro-inflammatory modality.

These observations should have a new significance for understanding the AD pathology "ab initio", i.e. decades prior clinical diagnosis. They might also offer opportunities to find new biomarkers signalling an ongoing AD pathology as well as novel therapeutic targets for delaying or arresting disease progression.

THE CELL-AUTONOMOUS ROLE OF ASTROCYTIC DOPAMINE D2 RECEPTOR IN THE SUPPRESSION OF NEUROINFLAMMATION

J.W. Zhou[1]
[1]*Institute of Neuroscience,*
Shanghai Institutes for Biological Sciences Chinese Academy of Sciences, Shanghai, China

Chronic neuroinflammation is a common feature of aging brain and some neurodegenerative disorders, including PD. However, the molecular and cellular mechanism underlying the regulation of innate immunity in the central nervous system remains elusive. In the present study, we investigate the role of astrocytic dopamine D2 receptor (Drd2) in the modulation of innate immunity. We demonstrate that global knockout mice lacking *Drd2*, but not *Drd1* or *Drd3*, showed remarkable inflammatory response in multiple CNS regions and increased vulnerability of nigral dopaminergic neurons to neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-induced neurotoxicity. Astrocytes null for *Drd2* became hyper-responsive to immune stimuli. We found that αB-crystallin (Cryab) was one of downstream effectors of astrocytic Drd2 that might be responsible for regulating inflammatory response. Reduction of CRYAB, that is known to suppress neuroinflammation, was prominently detected in *Drd2*-null mice compared to wild-type counterparts. Interestingly, it was revealed that Cryab was markedly upregulated in the SN of PD brain. Cryab expression was also upregulated in reactive astrocytes in a neurotoxin-induced mouse PD model. Moreover, we showed increased expression of Cryab in cytoplasmic inclusions in a subset of glial cells in Parkinsonian brain. Gain- or loss-of-function studies showed that Cryab is critical for *Drd2*-mediated modulation of innate immune response in astrocytes. Furthermore, treatment of wild-type mice with a selective Drd2 agonist increased resistance of the nigral dopaminergic neurons to MPTP via partial suppression of inflammation. Our study suggests that astrocytic Drd2 activation is normally required for suppression of neuroinflammation via a Cryab-dependent manner and provides new strategy for targeting glia-mediated pathogenesis in PD.

Objective: Chronic neuroinflammation plays an important role in aging and Alzheimer's disease (AD). *In vivo* imaging of microglial activation in patients may allow for selective monitoring of the progression of neuroinflammation and assessment of efficacy in therapeutic trials. The 18 KDa translocator protein (TSPO), a marker for activated microglia, has been used as a positron emission tomography (PET) tracer target to visualize cerebral inflammation *in vivo* in human and transgenic (Tg) mouse models.
Methods: We used the new ^{18}F-labeled GE180 TSPO PET tracer to investigate the differences in neuroinflammation between young wildtype (4 mo-old, n=4), old wildtype (26 mo-old, n=4), and old AD transgenic mice (26 mo-old, n=4).
Results: *In vivo* PET scans revealed an age-dependent elevation in whole brain uptake of ^{18}F-GE180 (peak-uptake and retention) in wildtype mice, with a further significant increase in old AD transgenic mice. A similar result was observed in hippocampal-specific uptake of ^{18}F-GE180 using co-registration of PET images with mouse brain MRI images. *Ex vivo* PET and autoradiagraphy confirmed these results and demonstrated an $SUV_{75\%}$ value reflecting enhanced uptake and specific binding of ^{18}F-GE180 in hippocampus and cortex in old AD transgenic > old wildtype > young wildtype mice. Specificity was confirmed by a cold tracer competition study. A metabolite study indicated that while total radioactivity declined over 2 hours, of the remaining radioactivity, ~90% was parent GE180.
Conclusions: We conclude that PET imaging with ^{18}F-GE180 may be useful for assessing brain inflammation in neurodegenerative diseases, and may be helpful for monitoring treatment.

We have previously demonstrated that alterations in mitochondrial dynamics precede the onset of memory phenotype and the development of amyloid plaques in three transgenic animal models of familial Alzheimer's Disease (FAD). The objective of the study was to develop a treatment to restore mitochondrial dynamics and function. Here we provide evidence that treatment with CP2, a member of a family of tricyclic pyrone compounds, restores axonal trafficking *in vivo*, and averts cognitive and motor deficit in multiple animal models of AD (APP, PS1 and APP/PS1) *in vivo*. Animals were administered CP2 via drinking water. Cognitive and behavior tests were applied at the end of a lifetime treatment (13 months) or short-term treatments (2 and 4 months). Changes in mitochondrial dynamics and function *in vivo* and *in vitro* were evaluated using real-time imaging of mitochondrial motility; an XF24 Seahorse Extracellular Flux Analyzer; the activity of OXFOS Complexes I-V was done using enzymatic reactions; and metabolic changes were measured using LC- and GC-MS-based metabolomics. Behavior and memory functions were detected with a battery of tests. Alleviation of the motor and memory phenotype was accompanied with partial reduction in amyloid burden. Investigation of the molecular mechanism revealed that CP2 modulates mitochondria energetics and activates a cascade of events protecting mitochondrial dynamics. Our findings, for the first time, demonstrate that restoration of mitochondrial trafficking protects against cognitive dysfunction in AD. Our data validate mitochondrial motility as an early therapeutic target for AD and poise CP2 as a promising therapeutic compound.

MITOCHONDRIAL FUNCTION AND PARKINSON'S DISEASE: PINK1 REGULATES COMPLEX I ACTIVITY VIA NDUFA10 UBIQUINONE UNCOUPLING

V. Morais[1], D. Haddad[1], K. Craessaerts[1], J. Swerts[1], L. Aerts[1], P. Seibler[2], C. Klein[2], K. Gevaert[3], P. Verstreken[1], B. De Strooper[1]
[1]Center of Human Genetics, KU Leuven, Leuven, Belgium
[2]Section of Clinical and Molecular Neurogenetics at the Department of Neurology, Univeristy of Lubeck, Lubeck, Germany
[3]Department of Biochemistry, Ghent University, Ghent, Belgium

Objectives: PINK1, a mitochondrial kinase causes Parkinson's Disease (PD), has further strengthened the involvement of mitochondrial dysfunction in PD. The fact that PINK1 regulates Complex I enzymatic activity resulting in loss of mitochondrial membrane potential and compromised synaptic activity suggests a role for this gene in mitochondrial maintenance. However, the underlying molecular mechanisms remain to be elucidated.
Methods: Phosphoproteomics was performed on PINK1 mouse brain and liver to identify putative PINK1 substrates. Mouse and Drosophila PINK1 deficient model, human PINK1 patient fibroblasts and iPSC derived neuron were used to assess mitochondrial membrane potential, ATP content and Complex I enzymatic activity.
Results: Under resting conditions *Pink1* knockout cells and cells derived from patients with *PINK1* mutations display a loss of Complex I activity causing a decrease in the mitochondrial membrane potential. Analyzing the phosphoproteome of Complex I in *Pink1*$^{-/-}$ mice we found specific loss of phosphorylation of Ser^{250} in Complex I subunit NdufA10. Phosphorylation of Ser^{250} was needed for ubiquinone reduction by Complex I. Phosphomimetic NdufA10 reverse Pink1 deficits in mouse knockout cells and rescue mitochondrial depolarization and synaptic transmission defects in *pink*^{B9} null *Drosophila* mutant. Complex I deficits and ATP synthesis were also rescued in cells derived from PINK1 patients.
Conclusions: We show in three different PINK1 models that NdufA10 is phosphorylated in a PINK1-dependent fashion, and this modification is required for Complex I mediated ubiquinone uncoupling. This evolutionary conserved pathway contributes to the pathogenic cascade that eventually leads to Parkinson's Disease in patients with PINK1 mutations.

[3]Center for Neuroscience of Memory Institute of Biomedical Sciences, Faculty of Medicine University of Chile, Santiago, Chile

Objectives: We have reported that persistent RyR-mediated calcium signals invoked by soluble Aβ oligomers (AβOs) prevent the spine remodeling invoked by brain-derived neurotrophic factor, decrease RyR2 mRNA and protein contents and provoke mitochondrial fragmentation. Pre-incubation with N-acetylcysteine (NAC), an effective antioxidant precursor of glutathione, abolishes the cytoplasmic calcium increases and mitochondrial fragmentation induced by AβOs. Here, we investigated whether reactive oxygen species (ROS) modulate the RyR2 expression changes induced by AβOs and if decreased RyR2 expression affects hippocampal-dependent spatial memory. **Methods**: Primary hippocampal neurons were transfected with mito-Pericam or HyPerMito to detect mitochondrial calcium and hydrogen peroxide production, respectively, or incubated with MitoSox to sense mitochondrial superoxide generation. Mitochondrial fragmentation was detected in neurons loaded with MitoTracker. Male rats, bilaterally injected intra-hippocampus with AβOs or antisense oligonucleotide anti-RyR2 (O-RyR2), were trained in the Oasis Maze task to evaluate hippocampal-dependent spatial learning and memory. Fluorescence images acquired by confocal or spinning disk microscopy were analyzed with ImageJ software; RyR2 mRNA expression was evaluated by q-PCR and protein content by WB analysis. **Results:** Intra-hippocampal injections of AβOs or O-RyR2 decreased RyR2 protein content, without alterations in RyR3 protein levels, and impaired spatial learning. The decrease in RyR2 mRNA levels induced by AβOs required mitochondrial ROS generation, but not cytoplasmic ROS production by NOS or NOX. **Conclusions:** Our results suggest that redox-sensitive RyR2-mediated calcium release is crucial for spatial memory processes, and suggest that deficient RyR2-mediated calcium signaling contributes to AβOs-induced learning and memory deficits. **Support:** BNI (P-09-015F); FONDECYT (11110322, 1100052); CENEM-ICM-P10-001-F.

P66SHC ADAPTOR PROTEIN – A PROMISING NOVEL TARGET IN ALZHEIMER'S DISEASE THERAPY?

L. Kulic[1], R. Derungs[1], C. Späni[1], T. Welt[1], F. Wirth[1], C. Hock[1], M. Giese[1], G.G. Camici[1], A. Eckert[1], R.M. Nitsch[1]

[1]Division of Psychiatry Research, University of Zurich, Schlieren, Switzerland

Objectives

The mammalian ShcA adaptor protein p66^{shc} has previously emerged as a key regulator of mitochondrial reactive oxygen species (ROS) production and an important mediator of Aβ-induced ROS generation and cytotoxicity *in vitro*. The involvement of p66^{shc} in mammalian longevity and life span determination has been demonstrated in the p66^{Shc} knockout mice which are characterized by a 30% prolonged lifespan, lower ROS levels, and protection from age-related impairment of physical and cognitive performance. These protective effects have partly been explained by a decrease in cellular ROS production and higher resistance to oxidative stress.

Methods

Building on the hypothesis that p66^{Shc} would also be protective against Aβ-induced mitochondrial dysfunction and ROS production *in vivo*, we investigated mitochondrial function in freshly isolated brain mitochondria of a newly generated p66^{Shc}-ablated APP transgenic mouse model of beta-amyloidosis.

Results

p66^{Shc}-ablated APP transgenic mice were characterized by improved brain mitochondrial respiration, increased ATP production and reduced ROS levels along with a reversal of Aβ-related cognitive deficits. These beneficial metabolic and cognitive effects were independent of Aβ levels and amyloid plaque deposition.

Conclusion

The results of our study suggest that p66^{Shc} inhibition may be an effective novel therapeutic approach against Aβ-induced mitochondrial and synaptic dysfunction *in vivo*.

PD is initially characterized by loss of A9-type dopaminergic (DA) neurons in the substantia nigra pars compacta (SNpc). An association has been reported between PD and exposure to mitochondrial toxins, including environmental pesticides paraquat, maneb, and rotenone. Here, using a robust, patient-derived stem cell model of PD allowing comparison of A53T α-synuclein (α-syn) mutant cells and isogenic mutation-corrected controls, we identify mitochondrial toxin-induced perturbations in A53T α-syn A9 DA neurons (hNs). We report a novel pathway whereby basal and toxin-induced nitrosative/oxidative stress results in S-nitrosylation of transcription factor MEF2C (to form SNO-MEF2C) in A53T hNs compared to corrected controls. This redox reaction inhibits the MEF2C-PGC1α transcriptional network, contributing to mitochondrial dysfunction and apoptotic cell death. Our data provide mechanistic insight into gene-environmental interaction (GxE) in the pathogenesis of PD. Furthermore, using small molecule high-throughput screening, we identify the MEF2C-PGC1α pathway as a therapeutic target to combat PD (Ryan et al., Cell 2013). Recently, we have found similar reaction mechanisms in other neurological diseases, forming SNO-MEF2A or SNO-MEF2C that enhances neuronal apoptosis in stroke and inhibits neurogenesis in AD (Okamoto et al. Cell Rep, 2014).

NICOTINAMIDE RIBOSIDE INCREASES SIRT3 ACTIVITY AND PROTECTS AGAINST MPTP TOXICITY

M. Beal[1], A. Sauve[1], N. Calingasan[1], L. Yang[1]
[1]Neurology and Neuroscience, Weill Cornell Medical College, New York, USA

An optimal neuroprotective therapy for Parkinson's disease (PD) would prevent both the loss of dopaminergic neurons in the substantia nigra as well as their axonal projections. A promising approach is to increase intracellular nicotinamide adenine dinucleotide (NAD+), which activates sirtuins, exerts neuroprotective effects, and prevents axonal degeneration. NAD+ induces PGC-1alpha, a transcriptional coactivator which increases expression of antioxidant enzyme and mitochondrial biogenesis, and whose deficiency is linked to PD. SIRT1 protects against α-synuclein aggregation and increase life span in mice with the A53T α-synuclein. Nicotinamide riboside (NR) is a precursor to NAD+. NR increases NAD+ levels in several cell lines. We showed that NR increases NAD+ levels in brain tissue and in brain mitochondria. The magnitude of the increases exceeds two-fold in brain mitochondria an effect unknown for any other precursor to NAD+ We found that administration of NR to a neuronal cell line increased gene expression of SIRT1, SIRT3, PGC-1α, MnSOD, and downstream mitochondrial genes. NR treatment also protected cells dose dependently against MPP+ toxicity, restored ATP levels and protected against depletion of GSH. NR in vivo increased SIRT1 mRNA, and SIRT1, SIRT3, PGC-1α and mitochondrial electron transport chain complex protein levels. Nicotinamide riboside treatment attenuated MPTP induced dopamine depletion in the striatum, and loss of dopaminergic neurons in the SNpc. Lastly we showed that NR treatment of Q111 striatal cells produced dose-dependent increases in PGC1-alpha protein levels. These studies show that NR is a effective neuroprotective agent with great promise as a disease modifying therapy for PD.

AMYLOID BETA CATABOLISM GENERATES N-TERMINAL TRUNCATIONS THAT ARE LARGELY ASSOCIATED WITH THE PROCESS OF AMYLOIDOGENESIS AND PERPETUATION OF FIBRILLAR DEPOSITS
J. Ghiso[1], E. Cabrera[1], A. Rostagno[1]
[1]Pathology, NYU School of Medicine, New York, USA
Objective: A heterogeneous group of amyloid beta (Abeta) species constitute the parenchymal and cerebrovascular amyloid deposits in Alzheimer's disease (AD). Besides the classic full-length peptides, biochemical and proteomic analysis of AD deposits revealed high degree of Abeta heterogeneity at both N- and C-terminal ends likely resulting from the local action of multiple proteolytic enzymes. Interestingly, many of these fragments are also normal components of cerebrospinal fluid, suggesting their active participation in clearance mechanisms. Increasing evidence indicates that deficient brain clearance largely contributes to Abeta accumulation; thus, we compared the biophysical properties and lesion distribution of various N- and C-terminally degraded Abeta fragments to better understand their biological importance.
Methods: Synthetic homologues of *in vivo* identified truncated peptides were used to compare solubility properties, formation of beta-sheet-rich structures, binding to thioflavin T, self-oligomerization and formation of amyloid-like fibrils. Novel antibodies recognizing specific N- and C-terminal truncations were generated and employed to immunolabel amyloid deposits and conduct biochemical analysis in transgenic models and AD brains.
Results: N- and C-terminally truncated peptides exhibited completely different biophysical properties and brain tissue distribution. C-terminally degraded Abeta fragments were extremely soluble, did not convert to beta-sheet-rich structures, failed to aggregate or form fibrils and did not co-localize with plaque deposits. Contrastingly, those degraded at the N-terminus were poorly soluble, with high tendency to aggregate and fibrillize and specifically co-localize with Congo-red-positive plaque cores.
Conclusions: Degradation at the C-terminal-end of Abeta generates fragments likely associated to catabolic/clearance mechanisms while truncations at the N-terminus favor the process of amyloidogenesis.

[2]Weatheral Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Objectives

A major neuropathological hallmark of PD is the accumulation of alpha-synuclein in ubiquitinated neuronal inclusions termed Lewy bodies. An important outstanding question is whether ubiquitination in Lewy bodies is catalysed by enzymes that are directly relevant to alpha-synuclein degradation and toxicity or represent a non-specific modification.

Methods

Fifteen Lewy body disease brains were used to study the composition of ubiquitin conjugates in inclusions and potential protein interactors, iPSc-derived dopaminergic neurons for localization studies and cell lines for biochemical assays of alpha-synuclein ubiquitination. Toxicity studies were performed by dopaminergic neuron- or eye-specific knockdown of relevant de-ubiquitinases in the alpha-synuclein *Drosophila* model.

Results

Using comparative analysis in human brains, we found that ubiquitin immunoreactivity in Lewy bodies is largely comprised of K63-linked ubiquitin chains, significantly reduced in the substantia nigra compared to the neocortex and inversely correlated with the up-regulation and pathological localisation of the deubiquitinase Usp8. Usp8 recognised alpha-synuclein and directly regulated its degradation by de-ubiquitinating preferentially K63-linked chains on alpha-synuclein. In human iPSc-derived neurons, Usp8 partly co-localised with alpha-synuclein and knockdown of Usp8 in dopaminergic neurons *in vivo* protected *Drosophila* from alpha-synuclein-induced locomotor deficits. Accordingly eye-specific Usp8 knockdown rescued the eye toxicity by reducing specifically the soluble pool of alpha-synuclein.

Conclusions

We present multiple lines of evidence suggesting that enhanced recycling of K63-linked ubiquitin chains by Usp8 is a pathogenic step in Lewy body biogenesis and a potential mechanism by which K63-linked ubiquitin-mediated trafficking of alpha-synuclein fails in dopaminergic neurons in Parkinson's disease.

[5]Centro de Biologia Molecular Severo Ochoa (CSIC/UAM), Laboratory of Neuronal Differentiation and Aging, Madrid, Spain

Objective. Despite the fact that mutations on presenilins and APP genes trigger the Aβ deposition in patients with familiar AD, little is known about the biological processes behind the sporadic AD cases leading to Aβ deposition. Our laboratory demonstrated that specific proteins of the tetraspanins family modulate Aβ production. Based on these findings, we searched for tetraspanins associated to sporadic AD and affecting Aβ production. We centered on tetraspanin 6 (Tspan6) because its levels in AD brains are elevated. **Methods**. We used human brain samples to study Tspan6 levels in healthy people and AD patients. The biological function of Tspan6 and its impact on the amyloidogenic pathway was studied *in vitro*. Finally we created a Tspan6 knockout mouse in order to corroborate our findings *in vivo*. **Results**. Interestingly our findings suggest that Tspan6 enhances the amyloidogenic pathway by interacting and stabilizing the substrate for Aβ production, APP-CTF. We provide evidences of the role played by the autophagosomal/lysosomal pathway. **Conclusions**. We conclude that tspan6 levels are increased in sporadic AD brains and enhance Aβ production by stabilizing the APP-CTF levels. We determined that the impaired degradation of APP-CTF by the autophagosomal/lysosomal pathway is the mechanism driving this effect. Our study corroborates the importance of the lysosomal/autophagosomal pathway in sporadic AD and presents Tspan6 as a key player linking lysosomal-dependent degradation of APP-CTF and Aβ generation.

RIBOSOME FUNCTION UNDER PRESSURE AND IN DISEASES

A. Yonath[1]
[1]*Department of Structural Biology, Weizmann Institute, Rehovot 76100, Israel*

Ribosomes are essential for life of all organisms, as they generate all of the proteins required for cells existence and growth. They are macromolecular assemblies, built of long rRNA chains and many rProteins in stoichiometric ratios. These universal cellular machines translate the genetic code into proteins and perform their basic functions, namely decoding and creation of nascent chains in an almost identical mode in all living cells. However, recent evidence correlate stress and variations in the copy number of part of mRNA chains that code for ribosomal proteins. The likelihoods of actual translation of these mRNA chains, thus creating non stoichiometric ribosomes and their probable functional aspects will be discussed.

Symposium 13: PROTEIN CREATION, FOLDING, MISFOLDING AND DEGRADATION

PROTEOSTASIS AND THE EVOLUTION PATHOLOGY IN ALZHEIMER'S DISEASE

D. Borchelt[1], G. Xu[1]
[1]Neuroscience, University of Florida, Gainesville, USA

The extracellular accumulation of beta-amyloid peptide is a key trigger in the pathogenesis of Alzheimer's disease (AD). As the disease progresses, "secondary" intracellular protein aggregate pathology is formed by proteins such as Tau, α-synuclein, and TDP-43. How the deposition of amyloid triggers the "secondary" pathologies of AD is a topic of intense study. Over the past few years, we have pursued the hypothesis that diminished function of protein homeostatic machinery, trigged by amyloid deposition, may be a primary mechanism in the progression of AD. Although mice with Alzheimer-type amyloidosis do not develop the expected secondary pathology of human AD, we asked whether the accumulation of amyloid may produce abnormalities that would be indicative of altered proteostasis. We developed a sequential detergent extraction method, followed by SDS-PAGE separation of the various fractions, in-gel trypsin digestions, and LC-MS/MS proteomic approaches to identify proteins that lose solubility in the brains of APPswe/PS1dE9 (line 85) mice with high amyloid burden. By this approach, numerous cytosolic proteins were identified as becoming aberrantly insoluble (PMC3690965). These data provided in vivo evidence that the accumulation of extracellular amyloid can lead to diminished function of the intracellular protein homeostasis network. To investigate the mechanisms by which amyloid may interfere with proteostasis, we have begun working in cultured cell models to assess whether exposure to amyloid fibrils, oligomeric Abeta, or monomeric Abeta induces changes in cytosolic protein solubility as was seen in the mice. The outcomes of these studies will be presented at the meeting.

Besides the hallmark pathology of amyloid plaques and neurofibrillary tangles (NFTs), it has been reported that cyclin-dependent kinase 5 (Cdk5), a critical neuronal kinase in nervous system development, function and survival, is deregulated and hyperactivated in AD brains and is, in part, responsible for the AD and other neurodegenerative disease pathology. Under physiological conditions, Cdk5 activity is tightly regulated. The deregulation and hyperactivation of Cdk5/p25 induces neuropathology e.g.AD. Thus Cdk5/p25 becomes prime therapeutic target for AD and neurodegenerative diseases associated with the hyperactivation of Cdk5. In order to prevent hyperactivation of Cdk5/p25, we have designed several small peptides of p25 on the basis of Cdk5/p25 crystal structure and checked for competition with p25 and there by inhibiting the hyperactivity of Cdk5. We discovered a small peptide (p5) comprising of 24 amino acids, inhibited Cdk5 hyperactivation selectively in ***vivo.*** The modification of p5 to TFP5 crosses BBB, was tested in a transgenic AD model mouse. The p25 transgenic AD model (p25Tg) mouse was chosen since these mice show similar phenotypes to other AD model mice as well as in AD patients. Post TFP5 injections in p25Tg mice displayed significant reduction in Cdk5/p25 hyperactivity, A- beta plaque formation along with AD behavioral rescue. TFP5 does not inhibit normal Cdk5/p35 activity, and therefore has no toxic side effects. In addition, treated mice rescued synaptic dysfunction, neuroinflammation and a reduction in phospho-neurofilaments / tau and cell death. These results indicate that TFP5 has a potential to be a therapeutic target for AD.

ADPD5-0488
AMYLOID BETA PROCESSING AND TOXIC MECHANISMS RELATED TO NEURONAL LIPID RAFTS.

R. Marin[1], C. Fernandez-Echevarria[1], A. Canerina-Luis[1], M. Diaz[2]
[1]Ciencias Médicas Básicas, University of La Laguna, SANTA CRUZ DE TENERIFE, Spain
[2]Animal Biology, University of La Laguna, SANTA CRUZ DE TENERIFE, Spain

Lipid rafts are considered functional platforms where several proteins interact and initiate signal transduction. They also appear to be responsible for different aggregating processes, including amyloid beta oligomerization. Structural raft lipids are altered early during neuropathological development.
In this study, we have investigated whether amyloid beta formation and toxicity may be related to neuronal raft impairment.
Using lipid raft fractions isolated from human cortical brain areas as well as immortalized human neuroblastoma cells, we have analyzed by inmunoprecipitation, inmunochemistry and immunoblotting the potential differences in the presence of amyloid beta processing machinery (amyloid precursor protein, APP, and β/γ secretases) in Alzheimer's disease patients of early and late stages, as compared to healthy controls.
Our results demonstrated that b-secretase accumulates in lipid rafts of AD subjects even at the earliest stages, enhancing its interaction with APP. Interestingly, APP and the amyloid were shown to be associated with a voltage dependent anion channel (VDAC) involved in extrinsic apoptosis. This interaction induced VDAC dephosphorylation and neuronal death.
Overall, these results suggest that lipid raft impairments in AD are connected to protein rearrangements that promote amyloid beta formation and activation of toxic signaling pathways.

Alzheimer's disease (AD) is a devastating neurodegenerative disorder and a major medical problem. Here, we have investigated the impact of amyloid-β (Aβ) oligomers, AD-related neurotoxins, in the brains of rats and adult non-human primates (cynomolgus macaques). Soluble Aβ oligomers are known to accumulate in the brains of AD patients and correlate with disease-associated cognitive dysfunction. When injected into the lateral ventricle of rats and macaques, Aβ oligomers diffused into the brain and accumulated in several regions associated with memory and cognitive functions. Cardinal features of AD pathology, including synapse loss, tau hyperphosphorylation, astrocyte and microglial activation were observed in regions of the macaque brain where Aβ oligomers were abundantly detected. Tangles were be detected with different specific antibodies (PHF-1, Alz50, CP13 and MC1) and electron microscopy. Most importantly, oligomer injections induced AD–type neurofibrillary tangle formation in the macaque brain. These outcomes were specifically associated with Ab oligomers, as fibrillar amyloid deposits were not detected in oligomer-injected brains. Human and macaque brains share significant similarities in terms of overall architecture and functional networks. Thus, generation of a macaque model of AD that links Ab oligomers to tau and synaptic pathology has the potential to greatly advance our understanding of mechanisms centrally implicated in AD pathogenesis. Furthermore, development of disease-modifying therapeutics for AD has been hampered by the difficulty in translating therapies that work in rodents to humans. This new approach may be a highly relevant non-human primate model for testing therapeutic interventions for AD.

Symposium 15: AMYLOID PRODUCTION AND ABETA TOXICITY

ADPD5-0950
IN VITRO AND IN VIVO EFFECTS OF LENTIVIRAL BETA-SYNUCLEIN OVEREXPRESSION ON APP AND TAU PROTEIN

S. Kraßnig[1], C. Schweinzer[2], N. Taub[2], D. Havas[2], E. Auer[2], W. Schreibmayer[1], B. Hutter-Paier[2], M. Windisch[3]
[1]Biophysics, Medical University of Graz, Graz, Austria
[2]Neuropharmacology, QPS Austria, Grambach, Austria
[3]Neuroscios GmbH, Neuroscios GmbH, Graz, Austria

Objectives:
Beta-Synuclein (Beta-Syn) belongs to the highly conserved Synuclein protein family. Alpha-Synuclein is the most prominent member as it aggregates in the so called Lewy Bodies, one major hallmark of Parkinson's disease. Remarkably, parts of its hydrophobic peptide backbone (NAC) have been also detected in amyloid plaques of Alzheimer's disease (AD) patients. Beta-Syn lacks the NAC region and is able to prevent Alpha-Synuclein and amyloid aggregation. In addition, Beta-Syn interferes with several intracellular regulatory and signaling pathways. Aim of this study was to clarify whether Beta-Syn overexpression can alter amyloid pathology in an *in vitro* and *in vivo* model of AD.
Methods:
In vitro, human neuroglioma cells expressing human Amyloid Precursor Protein (APP) infected with Beta-Syn expressing lentiviral particles were investigated. *In vivo*, mice overexpressing human APP with Swedish and London mutations ($hAPP_{SL}$) were injected with lentiviral particles encoding human Beta-Syn into the hippocampus. An empty lentiviral vector was used as negative control. Afterwards behavioral, biochemical and histological analyses were performed.
Results:
Exogenous Beta-Syn expression revealed differential effects on APP expression and amyloid aggregation depending on time and concentration. In addition, the influence of Beta-Syn on phosphorylation of Glycogen synthase 3beta (GSK3-beta), a known tau kinase, was shown in cells and the tg-mouse model. As a consequence tau phosphorylation was affected after overexpression of Beta-Syn *in vitro*.
Conclusion:
Depending on the concentration Beta-Syn seems to be able to ameliorate or deteriorate amyloid expression and aggregation. Furthermore, the results indicate an influence on tau phosphorylation by Beta-Syn via regulation of GSK3-beta.

THE ROLE OF THE AMYLOID PRECURSOR PROTEIN IN NEURAL STEM CELL PROLIFERATION AND DIFFERENTIATION

D.H. Small[1], M. Bolos[1], Y. Hu[1], K.M. Young[1], L. Foa[1]
[1]Menzies Research Institute Tasmania, University of Tasmania, Hobart, Australia

The amyloid-β precursor protein (APP) has been very well studied for its role in Alzheimer's disease. However, the normal function of APP remains uncertain. A large number of studies have suggested that APP has a trophic role in stimulating neuronal cell growth. Our own studies have shown that APP can stimulate the proliferation and neuronal differentiation of neural stem or progenitor cells (NSPCs). The effect of APP on NSPC proliferation is mediated by secreted cystatin C. In the present study, we examined the role of APP in NSPC differentiation into neurons. Cystatin C did not induce NSPC differentiation. Therefore, to identify proteins that may mediate the effect of APP on NSPC differentiation, we used a gene array approach to identify genes whose expression correlated with APP-induced neurogenesis. The expression of neurogenin 2 (Ngn2), which is a basic helix-loop-helix transcription factor, was significantly downregulated in NSPCs from APP knockout mice (APPKO). The expression of Ngn2 was increased in NSPCs from APP overexpressing (Tg2576) mice. Ngn2 overexpression in APPKO NSPCs promoted neuronal differentiation, whereas siRNA knockdown of Ngn2 expression in wild-type NSPCs decreased neuronal differentiation. The results demonstrate that APP-stimulated neuronal differentiation of NSPCs is mediated by Ngn2. These experiments are likely to have implications for understanding APP's trophic function in the adult or aging brain.

ADAM10 ENDOCYTOSIS: LOOKING FOR NEW STRATEGIES FOR ALZHEIMER'S DISEASE THERAPY

E. Marcello[1], S. Musardo[1], D. Di Marino[2], S. Pelucchi[1], A. Tramontano[2], F. Gardoni[1], M. Di Luca[1]
[1]Department of Pharmacological and Biomolecular Sciences, University of Milano, MILANO, Italy
[2]Department of Physics, Sapienza University of Rome, MILANO, Italy

Objectives: ADAM10 is the enzyme responsible for preventing Abeta production, thus fostering its activity represents a suitable strategy for Alzheimer's disease (AD) therapy. ADAM10 is active towards its substrates when properly inserted in the postsynaptic membranes. We have recently identified a binding motif for the clathrin adaptor AP2 in ADAM10 tail, which is relevant to ADAM10 endocytosis and to its synaptic localization/activity. Moreover ADAM10/AP2 interaction is significantly increased in AD patients compared to control subjects. We aim at developing cell permeable peptides (CPPs) able to interfere with ADAM10/AP2 complex and, thereby, to reduce ADAM10 endocytosis in order to increase ADAM10 membrane levels/synaptic activity.
Methods: We designed four CPPs. Taking advantage of several approaches we validated CPPs efficacy and specificity both different systems.
Results: We observed that two CPPs were able to interfere with ADAM10/AP2 association. In neuronal cultures the CPPs disrupt ADAM10/AP2 interaction, decrease ADAM10 internalization rate and increase the levels of ADAM10 at synaptic membranes. Moreover they are specific because they do not affect AP2 binding to other partners. We performed acute in vivo treatment and we verified that CPPs are able to cross the blood-brain barrier and are effective in vivo. Indeed, CPPs treatment reduces ADAM10/AP2 binding and increases ADAM10 synaptic levels/activity.
Conclusions: A finely balanced membrane level of ADAM10 is an essential prerequisite to control enzyme activity. We designed a powerful tool able to interfere with mechanisms regulating ADAM10 intracellular trafficking and to modulate its membrane availability, and thereby to shift APP metabolism towards the non-amyloidogenic pathway.

ACAT INHIBITION AND APP PROCESSING

D.M. Kovacs[1], R. Bhattacharyya[1], C. Barren[1]
[1]Neurology, Massachusetts General Hospital/Harvard Medical School, Boston, USA

Alzheimer's disease brains exhibit large deposits of aggregated amyloid β-protein (Aβ). We have previously found that inhibition of the cholesterol-modifying enzyme acyl-coenzyme A: cholesterol acyltransferase (ACAT) results in decreased amyloid pathology. ACAT inhibitors used in cells or AD mouse models and knockdown or knockout of ACAT1 in cells all reduced Aβ production. An independent group has also confirmed our findings in ACAT1 knockout animals. Our recent studies have focused on the mechanism by which ACAT1 inhibition decreases Aβ levels. First, we found that the amyloid precursor protein (APP) is palmitoylated in the ER and palmitoylated APP (*pal*APP) is preferentially targeted to lipid rafts. *Pal*APP appears to be a better β- than α-secretase substrate, especially in lipid raft fractions. APP processing and Aβ levels directly correlate with the amount of *pal*APP in experiments using palmitoyl acyltransferases or palmitoylation inhibitors. Palmitoylation promotes APP dimerization as *pal*APP is three times more likely to form dimers than total APP. Interestingly, we found that ACAT activity regulates palmitoylation of APP. Cells lacking ACAT activity almost entirely lack *pal*APP and do not produce detectable levels of Aβ. Two different ACAT inhibitors decrease total *pal*APP by about 50% and severely reduce lipid raft-associated *pal*APP in cells, while also inhibiting APP processing. Co-immunoprecipitation and FLIM/FRET assays showed that APP dimerization is reduced by ~50% in cells treated with the ACAT inhibitors. Taken together, our data suggest that ACAT inhibitors reduce *pal*APP-dimers to lower Aβ generation and further support development of ACAT inhibitors as a therapeutic strategy for AD.

[2]Adolf-Butenandt-Institute, Ludwig-Maximilians-University Munich, München, Germany

Alzheimer's disease (AD) is a neurodegenerative disease that begins as mild short-term memory deficits and culminates in total loss of cognition and executive functions. Until recently, a main culprit of the disease, resulting from Amyloid-Precursor Protein (APP) processing, has been thought to be amyloid-b peptide (Ab). However, despite the genetic and cell biological evidence that supports the amyloid cascade hypothesis, it is becoming clear that AD etiology is complex and that Ab alone is unable to account for all aspects of AD [Pimplikar *et al.* J Neurosci.30: 14946. 2010]. It is, therefore, currently urgent to identify other possible culprits of the disease in the hope to develop alternative therapeutic strategies. Gamma-secretase not only liberates Ab, but also its C-terminal intracellular counterpart called APP intracellular domain (AICD) [Passer. et al. JAlzheimers Dis.2: 289-301. 2000], which is known to also accumulate in AD patient's brain [Ghosal et al. PNAS.106:18367. 2009], but surprisingly little is known about its functions in hippocampus.

To address this crucial issue, we increased AICD production *in vivo* in adult CA1 pyramidal neurons, mimicking the human pathological condition. Different ex-vivo electrophysiological and pharmacological approaches, including double- patch of neighbor neurons were used.

We clearly demonstrate that AICD strongly affects glutamatergic synaptic transmission. We further show that this effect impairs synaptic plasticity, which we were able to rescue by different pharmacological approaches.

Our results provide convincing and entirely novel evidence that increased *in vivo* production of AICD is enough, *per se*, to cause synaptic dysfunction in CA1 hippocampal neurons.

Symposium 17: NEURONAL NETWORKS AND SYNAPTIC FUNCTION

DYSREGULATION OF EEF1A EXPRESSION IS ASSOCIATED WITH SYNAPTIC PLASTICITY IMPAIRMENTS IN ALZHEIMER MODEL MICE

T. Ma[1], G. Gouras[2], E. Klann[3]
[1]Internal Medicine, Wake Forest School of Medicine, Winston-Salem, USA
[2]Experimental Medical Science, Lund University, Lund, Sweden
[3]Center for Neural Science, New York University, New York, USA

Objective: Synaptic dysfunction has been linked to pathogenesis of Alzheimer's disease (AD). Understanding molecular mechanisms underlying AD-associated synaptic failure may help identify novel therapeutic targets for the disease. Previous studies implicated a critical role of eukaryotic translation elongation factor 1A (eEF1A) in maintaining long-term synaptic plasticity and memory. Our objective is to investigate whether eEF1A expression associated with neuronal plasticity is compromised in AD, and if so, can restoring eEF1A levels help mitigate impairments of synaptic plasticity in AD model mice. **Methods:** Transgenic mice including AD model mice (APP/PS1 and Tg2576), and brain-specific *Tuberin* (TSC2) knockdown mice were used. Electrophysiology experiments were performed on hippocampal slices to measure long-term potentiation (LTP), induced at CA3-CA1 synapses. Western blotting and immunofluorescence combined with confocal microscopy were performed on brain tissue samples, including human AD. **Results:** Levels of eEF1A (CA1 regions of hippocampus) in AD model mice were reduced, compared to those of wild type littermates. Further, treatment of slices with mTORC1 inhibitor rapamycin caused down-regulation of eEF1A levels in wild type, but no effect on AD model mice. Moreover, forskolin (PKA agonist)-induced eEF1A expression was blunted in AD model mice. Finally, amyloid beta-induced LTP failure was alleviated in slices prepared from TSC2 knockdown mice, in which the mTORC1 signaling (upstream regulator of eEF1A expression) is elevated. **Conclusions:** Together, our data indicate that eEF1A dysregulation may contribute to the synaptic plasticity deficits displayed in AD, thus provide insights into molecular mechanisms and accordingly novel therapeutic targets for the disease.

Symposium 17: NEURONAL NETWORKS AND SYNAPTIC FUNCTION

ADPD5-1765
MECHANISMS AND TREATMENT OF NEURAL NETWORK DYSFUNCTION IN DEMENTING DISORDERS

L. Mucke[1]
[1]*Neurology,*
Gladstone Institute of Neurological Disease and University of California San Francisco, San Francisco, USA

Dementing disorders are associated with profound alterations in the activity and connectivity of neural networks, including shifts in spectral power of network oscillations, abnormalities in behavior-associated modulations of brain rhythms, and hypersynchrony that can escalate into epileptic activity. Studies in rodent models suggest that such network dysfunctions is caused by co-pathogenic interactions between proteins that characteristically accumulate in the brains of patients with dementing disorders, particularly amyloid-beta, tau and alpha-synuclein. Potential underlying mechanisms include depletion of specific sodium channels from inhibitory interneurons, imbalances in the activation of intra- versus extra-synaptic NMDA receptors, and changes in intrinsic neuronal excitability. These abnormalities and the network dysfunction they cause likely contribute to cognitive decline. Over time, they may also promote detrimental changes in gene expression and neurodegenerative processes. For example, aberrant network activity can lead to an accumulation of neuronal activity-induced DNA double strand breaks, possibly by interfering with effective DNA repair. Interventions that prevent or reverse network dysfunction and related pathogenic cascades in animal models include reduction of tau, overexpression of the anti-aging factor klotho, treatment with specific anti-epileptic drugs, and enhancement of interneuronal functions. The potential relevance of these models and therapeutic strategies to dementing disorders will be discussed.

COGNITIVE IMPAIRMENT CAUSED BY NON-AMYLOID-RELATED PROTEINS IN THE BRAIN

K. Ashe[1]

[1]*Neurology, University of Minnesota, Minneapolis, USA*

Objective

Amyloid fibrils containing in-register β-sheets accumulate as Aβ-containing amyloid plaques and tau-containing neurofibrillary tangles in Alzheimer's disease (AD), but they do not appear to be directly involved in the pathogenesis of AD. The goal of this talk is to report on the results of recent studies to determine whether non-amyloid-related Aβ and tau proteins, which lack in-register β-sheets, may be involved in the pathogenesis of AD, by evaluating their effects on cognition in mouse models.

Methods

Fibrillation assays or polyclonal OC antibodies were used to identify amyloid-related tau and Aβ proteins; Aβ and tau proteins that were non-reactive or non-fibrillar were defined as non-amyloid-related. Tests of spatial reference memory were used to assess the effects of these proteins on cognition in various lines of transgenic mice expressing tau and APP variants.

Results

Two non-amyloid-related proteins associated with impaired cognition were identified; one tau and one Aβ protein. In rTg4510 mice, a 35 kDa non-amyloid-related tau cleavage product (TCP35), formed by proteolysis by caspase-2, correlated with impaired memory, and reducing caspase-2 levels lowered TCP35 and restored memory. In J20, Tg2576 and APP/TTA mice, there were non-amyloid-related Aβ oligomers, including Aβ*56, which correlated with impaired learning and memory. In APP/TTA mice, reducing APP selectively reduced non-amyloid related Aβ oligomers and improved learning and memory.

Conclusion

Two non-amyloid-related tau and Aβ proteins have been shown to disrupt cognitive function in mice, suggesting they may be directly involved in the pathogenesis of AD and therefore useful targets for diagnosing and treating AD.

Symposium 17: NEURONAL NETWORKS AND SYNAPTIC FUNCTION

ADPD5-2048
NOT ONLY PRESYNAPTIC TERMINALS: ALPHA-SYNUCLEIN EXCESS MODIFIES THE EXCITABILITY OF POST-SYNAPTIC NEURONS AT RISK IN PARKINSON'S DISEASE

E. Lasser-Katz[1], A. Simchovitz[2], S. Abed Elhadi[3], D. Gorovici[1], H. Soreq[2], R. Sharon[3], J.A. Goldberg[1]

[3]Biochemistry and Molecular Biology, The Hebrew University of Jerusalem, Jerusalem, Israel

The pathological impact of alpha-synuclein (aSyn) overexpression (ASOX) is typically identified with presynaptic terminals where aSyn interacts with phosphatidylinositol 4,5-bisphosphate (PIP2). However, PIP2 is also a potent modulator of voltage-activated calcium (Cav) channels that are major determinants of post-synaptic neuronal excitability. Calcium influx through Cav channels gives rise to excessive mitochondrial oxidative stress (mOS) in neurons vulnerable in Parkinson's disease (PD). Here, we report that ASOX, which is also associated with excessive mOS, alters calcium influx while maintaining normal autonomous pacemaking in vulnerable neurons.

We found that Cav currents in vagal motoneurons of the A53T-haSyn mouse that overexpresses mutant (A53T) human aSyn were down-regulated and that the voltage half-activation of Cav channels was depolarized relative to wild-type animals. Together, these modifications reduced the calcium influx associated with individual action potentials, while maintaining normal pacemaking rates. Furthermore, we identified an upstream control of these dramatic Cav channel phenotypes, such that up-regulation of microRNA silencers of Cav1.2 channels was accompanied by a down-regulation of neuronal Cav1.2 and Cav2.3 channel transcripts. This is likely to represent an adaptive response of DMV motoneurons to the aSyn insult. Preliminary results indicate that Cav channel down-regulation reflects modified binding of aSyn to PIP2. Taken together, our findings point to a novel pathophysiological role of aSyn and a novel neuroprotective strategy that identifies PIP2 as a viable therapeutic target to regulate mOS in pacemaking neurons, such as mesencephalic dopamine neurons, whose degeneration and Lewy body accumulation more directly impacts PD symptoms.

Symposium 17: NEURONAL NETWORKS AND SYNAPTIC FUNCTION

ADPD5-2317
ABETA INDUCED SYNAPTIC TOXICITY
E. Koo[1]
[1]*Neurosciences, University of California San Diego, La Jolla, USA*
Increasing evidence favors the synapse as one of the initial sites of neuronal damage by amyloid b-protein (Aβ) and this synaptic injury is thought to underlie the cognitive deficits seen in Alzhiemer's disease. An interesting picture has emerged whereby neuronal activity augments processing of the amyloid precursor protein (APP) to enhance Aβ production and release, which in turn depresses synaptic activity and synaptic plasticity as well as causing synapse loss. However, while a number of plausible pathways have been proposed, the molecular mechanisms of Aβ-induced synaptic injury remain to be clearly elucidated. Of these, one centers on the involvement of APP in Aβ-initiated synaptic damage. Specifically, previous studies have indicated that caspase cleavage of APP in the cytosolic domain after the aspartate residue at position 664 leads to neuronal injury, possibly through release of a peptide containing the last 31 amino acids the C-terminus of APP, coined C31. However, transgenic mice overexpressing human APP with the D664A mutation, engineered to abrogate this cleavage event, produced mixed results. Consequently, it is unclear whether cleavage of APP at position 664 is synaptotoxic in brain. In this presentation, I will present data on expression of the D664A construct in organotypic slice cultures as well as from an APP knockin mouse line. Both sets of experiments do show that substituting alanine for aspartate at this position attenuates Aβ-induced synaptic injury. It remains unclear, however, whether it is specifically the loss of C31 that is responsible for this protective effect.

Symposium 20: DISEASE MECHANISMS

ADPD5-0383
SHARED MOLECULAR MECHANISMS IN ALZHEIMER'S DISEASE AND ALS: NEUROFILAMENT-DEPENDENT TRANSPORT OF SAPP, FUS, AND TDP-43 WITH ENDOPLASMIC RETICULUM TUBULES

V. Muresan[1], Z. Ladescu Muresan[1]
[1]Pharmacology and Physiology, Rutgers - New Jersey Medical School, Newark, USA

Objectives. Amyotrophic lateral sclerosis (ALS), a debilitating neurodegenerative disorder of brainstem and motor neurons, involves the deterioration of the neuromuscular junctions by poorly understood mechanisms. The proper function of the neuromuscular junction requires sAPP, a proteolytic fragment of amyloid-beta precursor protein (APP) - a transmembrane protein implicated in the pathology of Alzheimer's disease (AD) - and also the RNA binding proteins TDP-43 and FUS; these proteins cause ALS when mutated. A general trait of ALS-afflicted neurons is the disorganization of neurofilaments (NFs). Now, we show that the anterograde transport of sAPP, TDP-43, and FUS occurs together with endoplasmic reticulum (ER) tubules, and requires peripherin NFs. **Methods.** The transport of sAPP, TDP-43, FUS, and the translocation of the ER protein Reticulon 4 (Rtn4) into neurites was studied in CAD cells, a brainstem-derived neuronal cell line relevant to AD and ALS. **Results.** We show that sAPP is generated in the soma, at a juxtanuclear ER subdomain colocalized with, and stabilized by, NFs. Along neurites, sAPP localizes to Rtn4-positive ER tubules that extend from the soma into the growth cone, and colocalize with peripherin NFs. Knocking down peripherin with siRNA disrupts the NF network, and diminishes the accumulation of sAPP, TDP-43, FUS, and Rtn4 at terminals. **Conclusions.** We propose that deficient ER translocation into neurites prevents the transport of proteins with essential function at the synapse, including sAPP, TDP-43, and FUS, and could be part of the mechanisms leading to AD and ALS. Symposium 20: DISEASE MECHANISMS

ADPD5-1067
MICROGLIA INVOLVED IN A COMMON CELLULAR MECHANISM OF NEURODEGNERATION

C. Haass[1], G. Kleinberger[1]
[1]Biochemistry LMU, German Center for Neurodegenerative Diseases, Munich, Germany

Genetic variants in the triggering receptor expressed on myeloid cells 2 (TREM2) have been linked to Nasu-Hakola disease, Alzheimer's disease (AD), PD, amyotrophic lateral sclerosis, frontotemporal dementia (FTD) and FTD-like syndrome without bone involvement. TREM2 is an innate immune receptor preferentially expressed in microglia and involved in inflammation and phagocytosis. Whether and how TREM2 missense mutations affect TREM2 function is elusive. Here we report that missense mutations associated with FTD and FTD-like syndrome reduce TREM2 maturation, abolish shedding by ADAM proteases and impair phagocytosis. As a consequence of reduced shedding TREM2 is virtually absent in the cerebrospinal fluid (CSF) and plasma of a patient with FTD-like syndrome. Lower levels of TREM2 were also observed in CSF of AD and FTD patients further supporting that reduced TREM2 function may contribute to the risk for two prominent neurodegenerative disorders.

[3]Institute of Clinical Epidemiology and applied Biostatistics, University of Tübingen, Tübingen, Germany

Background and objectives: Alzheimer's Disease (AD) is thought to start decades before the first clinical symptoms emerge. The diagnosis of patients at this 'Pre-clinical AD' stage relies exclusively in fluid (CSF) or imaging (MRI or amyloid-PET scans) biomarkers and is limited by the lack of long-term biomarker profile changes and lack of pathological confirmation of the disease in such patients. To this end APP transgenic (APP-tg) mouse models can be consistently used for translational biomarker research, as AD pathology is easily assessable, followed over time and can be correlated directly to the fluid biomarker changes of the same animals.

Methods: We assessed CSF Aβ40 and 42 levels in 3 different APP-tg mouse models (APP23, APP24 and APP51) and compared the observed biomarker changes to Aβ pathological and biochemical changes in the brain.

Results: We observed a temporary 20-30% increase in CSF Aβ 40 and 42 in all the models before the CSF Aβ42 decline associated to Aβ-pathology progression. Remarkably, such initial CSF Aβ peak coincided with the first plaques appearing throughout the brain cortex, which corresponded to the initial increase in brain Aβ levels in every model. Increased brain APP processing and insufficient brain to blood Aβ clearance, probably underlie this finding in the early stages of Aβ deposition in mice.

Conclusion: If confirmed in humans, our observation may constitute the first detectable biomarker changes in AD pathological process, opening new perspectives in patient selection and stratification for preventive treatment strategies and in the discovery additional early 'Pre-clinical AD' biomarkers.

MOLECULAR PATHOLOGY AND TRANSLATIONAL APPROACHES ON ALZHEIMER'S DISEASE

T. Iwatsubo[1]
[1]*Neuropathology, The University of Tokyo, Tokyo, Japan*

Deposition of amyloid beta peptides (Abeta) as senile plaques and that of tau as neurofibrillary changes are the hallmark neuropathological lesions of Alzheimer's disease (AD), which are implicated in its pathogenesis and deemed as the prime target for the disease-modifying therapies (DMT). Abeta is produced by sequential proteolytic cleavages by beta- and gamma-secretases. gamma-Secretase, harboring presenilins (PS) as the catalytic center, forms the C terminus of Abeta that determines its propensity to aggregate: missense mutations in PS genes cause familial AD by altering the preferred gamma-secretase cleavage sites to increase production of pathogenic Abeta42 species. Recently, the relationship between neural activity and secretion or extracellular release of Abeta and tau is highlighted as the key events underlying the progression of the AD pathology, which may be novel targets for DMT of AD. Efforts to clinically develop the DMTs for AD, including establishment of imaging and fluid biomarkers that surrogate the AD pathology, through longitudinal multi-center clinical studies like AD Neuroimaging Initiative (ADNI), are underway worldwide, towards the goal of very early treatment hopefully at the preclinical AD stage. The current status of Japanese ADNI will also be presented.

ADPD5-1885
IMPACT OF CO-MORBIDITIES ON ALZHEIMER'S PATHOGENESIS AND COGNITIVE FUNCTION IN MOUSE MODELS

F. LaFerla[1]
[1]*Neurobiology & Behavior, University of California Irvine, Irvine, USA*

"Impact of co-morbidities on Alzheimer's pathogenesis and cognitive function in mouse models."

Introduction: The etiology of Alzheimer disease (AD) is complex, as a combination of genetic and epigenetic causes along with lifestyle factors contribute to disease progression. Additionally, elderly subjects with AD suffer from a variety of co-morbidities including stroke (ischemia), stress, diabetes, seizures, osteoporosis, cancer, and renal disease. Understanding the molecular interactions between co-morbid disorders is of critical significance, and to date, largely remains an unexplored area of investigation. Here, we seek to determine the effect of three clinically relevant co-morbid conditions (including, stress, cerebral ischemia and diabetes) on AD pathology and cognition.

Methods: To properly address this question, we used a combination of newly developed transgenic mouse models along with biochemical, histological and behavioral approaches to elucidate the underlying molecular mechanism by which several comorbid conditions impact AD pathogenesis and cognition.

Results: Our studies show that stress, cerebral ischemia and diabetes can contribute to AD pathogenesis by modulating both Ab and tau pathology and profoundly affecting synaptic and cognitive function.

Conclusions: Our studies reveal that comorbid conditions (i.e. stress, cerebral ischemia and diabetes) are key factors that trigger AD pathogenesis and severely affect synaptic and cognitive function. Therefore, therapies aimed to reduce these comorbid conditions (i.e. stress, cerebral ischemia, and diabetes) might be a promising approach to mitigate AD pathology and alleviate cognitive impairments.

USING INDUCED PLURIPOTENT STEM CELLS TO PROBE MECHANISMS OF ALZHEIMER'S DISEASE

L. Goldstein[1]
[1]*CELL AND MOLEC MED/NEUROSCI, UCSD, LA JOLLA, USA*

Although animal models of Alzheimer's disease have been very useful, they have not yet led to an effective treatment or a complete understanding of what goes wrong in the human brain during AD. Human in vitro models derived from human induced pluripotent stem cells (hIPSC) may prove to be of substantial utility given that they are euploid and can differentiate to bona fide cell types. In addition, purified cells with controlled genetic background and content can be cultured and differentiated together to develop functional cell structures composed of different cell types and genomes. In my talk, I will discuss our recent progress including a description of our drug screening efforts with FAD APP duplication neurons, which have turned up some very interesting potential leads. I will also summarize our efforts studying and comparing early phenotypes of FAD mutations in isogenic backgrounds. Finally, I will discuss how we are using naturally occurring variants that increase or decrease risk of developing AD in the human population using hIPSC to study complex human haplotypes.

PEAKS AND CLIFFS IN THE PATHOGENESIS OF PRECLINICAL PRION DISEASE

D. Westaway[1], C. Mays[1], C. Kim[2], J. van de Merwe[1], J. Safar[2]
[1]Faculty of Medicine and Dentistry, Centre for Prions and Protein Folding Diseases, Edmonton, Canada
[2]Department of Pathology, National Prion Disease Surveillance Center, Cleveland, USA

Objectives: Prion diseases exhibit a preclinical phase that can last for decades followed by rapid progression after clinical onset. We hypothesized that down-regulation noted for the PrP-like shadoo protein during prion infections[1] might also apply to PrP^{C}, the precursor to PrP^{Sc}. We set out to measure PrP^{C} reductions and their relationship to a two-step model of disease pathogenesis[2].

Methods: Sucrose gradient fractionations of prion-infected brains in conjunction with conformation dependent immunoassay (CDI), scrapie cell assay (SCA) and *in vitro* misfolding reactions.

Results: PrP^{C} is quantitatively reduced at endpoint in rodent models of scrapie, CJD and CWD and altered qualitatively in glycotype profile[3]. We now show that reduction occurs at or before the midpoint of the preclinical phase, with the kinetics of PrP^{C} down-regulation in two paradigms matching plateau effects for infectivity. Wt and *Prnp*$^{+/o}$ mice at disease end-stage had different profiles of infectivity and PrP isoforms.

Conclusions: As PrP^{C} is the precursor for the generation of misfolded forms of the prion protein and is also required for pathogenic signaling from misfolded PrP, down-regulation must impact disease pathogenesis; this effect may represent a generalized host defence mechanism and is the likely cause of a plateau in infectivity[1]. However, the concept of a lethal PrP isoform (PrP^{L}) common to wt and *Prnp*$^{+/o}$ mice at disease end-stage[1] was not supported by CDI and SCA analyses.

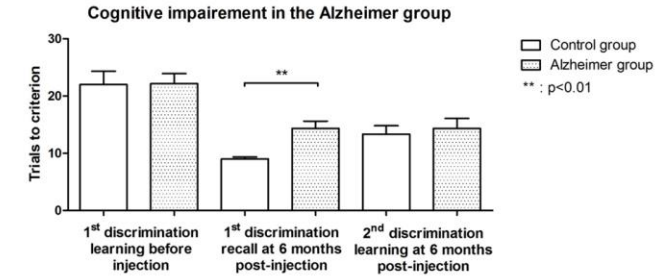
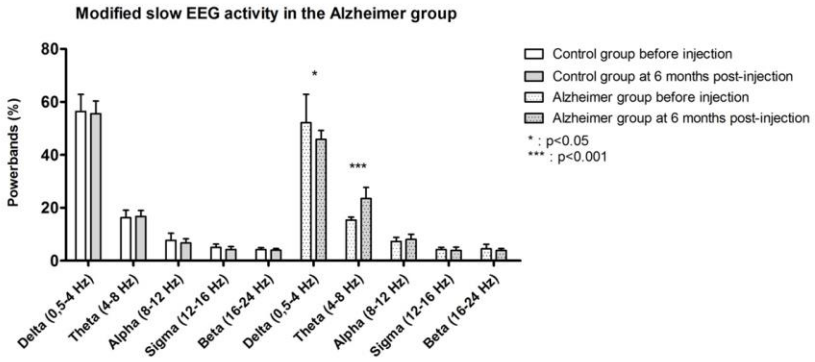
Objectives: Alzheimer's disease (AD) is a fatal chronic neurodegenerative disorder characterized by the intracerebral accumulation of abnormal beta-amyloid peptides and tau proteins. In transgenic mice overexpressing mutated forms of these proteins, the intracerebral injection of brain extracts containing these lesions accelerates the occurrence of amyloid and tau pathologies [1, 2]. We aim to determine if administration of human Alzheimer brain homogenates can also induce spontaneous amyloid and tau pathologies in the mouse lemur primate.

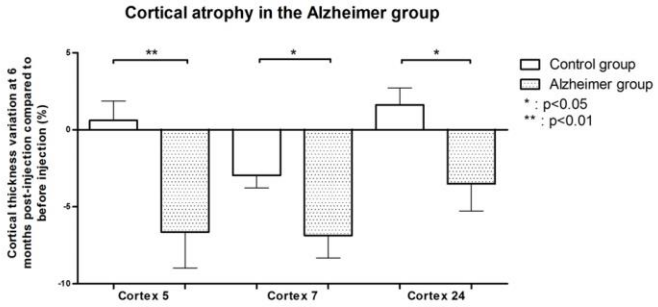
Methods: Brain extracts from two patients with AD and one control subject were injected to 12 mouse lemur primates (n=6 in the control group and n=6 in the “Alzheimer” group; 4x6.25µl, hippocampus and subjacent cortex (Brodmann area 5)). We present here 6 months of follow-up with behavioral, electroencephalography and Magnetic Resonance Imaging studies.

Results: Before injection, all the animals were able to memorize a discrimination task. However, 6 months post-injection, the Alzheimer group lost the ability to remember this task although they were still able to learn a new discrimination paradigm. As soon as 6 months post-injection, electroencephalogram slow activity was modified with decreased delta and increased theta frequency bands and cerebral atrophy was detected in the cingulate and parietal cortices in the Alzheimer group as

compared to the control group.







Conclusion: Our observations suggest that administration of Alzheimer brain homogenates could rapidly induce pathologic events leading to cognitive impairment, functional alterations and cortical atrophy in primates.

NEUROPROTECTIVE REGULATION OF EXOSOME SECRETION BY CYSTATIN C

E. Levy[1], R. Pérez-González[2]
[1]Psychiatry Biochemistry and Molecular Pharmacology, Nathan S. Kline Institute, Orangeburg, USA
[2]Center for Dementia Research, Nathan S. Kline Institute, Orangeburg, USA

Objectives: The extracellular secretion of exosomes, generated within endosomal multivesicular bodies, can serve as an alternative pathway for the release of endocytosed material that does not reach the lysosome. We have demonstrated the presence in exosomes of cystatin C (CysC), which is implicated in neuroprotection and repair in the nervous system. In this study, we have examined the role that CysC plays in modulating exosome secretion.
Methods: Using a novel method developed in our laboratory, the levels of brain exosomes were compared between transgenic mice with increased CysC expression and littermate wild-type mice. Exosomal content in the extracellular space was quantified by measuring exosomal total protein as well as levels of the exosomal markers, standardized relative to protein content in brain homogenates.
Results: Higher exosome levels were observed in the brain extracellular space of CysC overexpressing mice as compared to littermate controls, demonstrating that increased CysC expression enhances exosome secretion *in vivo*.
Conclusions: Our studies of exosome levels in the brain have identified CysC as a previously unappreciated regulator of exosome secretion. Our finding that CysC expression positively regulates exosome secretion lays the foundation for the development of CysC-loaded exosomes as a treatment for neurodegenerative disorders where endosomal disruption occurs, such as Alzheimer's disease, Down's syndrome, amyotrophic lateral sclerosis, CHMP2B-frontotemporal dementia, and Niemann-Pick type C. We hypothesize that dysfunctions in the endocytic system that disrupt the efficient transport of membrane lipids and cargo for degradation in lysosomes can be alleviated by clearance of accumulated vesicular content through exosome secretion.

EVIDENCE OF SELF-PROPAGATION OF AMYLOID-BETA MISFOLDING IN VIVO BY LIMITING DILUTIONS AND DIFFERENT ROUTES OF ADMINISTRATION

R. Morales[1], J. Bravo-Alegria[1], C. Duran-Aniotz[1], C. Soto[1]
[1]Neurology, University of Texas Medical School at Houston, Houston, USA

Objectives: We and others have shown that amyloid-beta (Abeta) pathology can be induced in animals in a similar way as described for prion diseases. These findings call for additional experiments directed to understand how Abeta misfolding spreads in Alzheimer's disease.

Methods: In this study, two prion-like properties were tested *in vivo* for misfolded Abeta: titration of the inducible agent by limiting dilutions and induction of pathological changes by different routes of exposure. Experiments were done in Tg2576 mice. Induced pathological changes were compared to amyloid deposition naturally developed in transgenic animals at different ages.

Results: Our results show that induction of Abeta was titrable and the minimum amount of Abeta seeds able to accelerate pathological changes was equivalent to a million-fold dilution of the brain, which is in the range of what is found for *bona fide* prions. In addition, several routes of administration of Abeta seeds were tested, including oral gavages, eye drops, and intra-muscular and intra-peritoneal injections. Many of them were able to induce pathological changes in the brain, although in different degrees.

Conclusions: Our findings, together with previously published reports, suggest that some aspects of AD pathology might be transmissible. These results may contribute to understand the mechanisms implicated in the initiation of Abeta pathology and therefore be useful to develop new therapeutic strategies for the prevention and treatment of this devastating disease.

Buck Institute for Research on Aging UCLA, Novato, USA

Abstract - AD/PD 2015
Dale E. Bredesen, MD
UCLA and Buck Institute for Research on Aging

Title: Prionic Loops, Dependence Receptors, and Systems Therapeutics for Alzheimer's Disease

Alzheimer's disease (AD) represents a major healthcare problem, affecting over 5 million Americans and approximately 30 million globally, without truly effective therapy.

In studies of neural cell death, we identified dependence receptors which induce pcd when their trophic ligands are withdrawn. Over 20 such receptors have been identified to date, including the beta-amyloid precursor protein, APP, which functions as a molecular switch: interaction with netrin-1 enhances cleavage at the alpha-cleavage site, producing sAPPalpha and alphaCTF, which mediate neurite extension, caspase inhibition, and the inhibition of Abeta peptide formation. Conversely, interaction of APP with Abeta itself leads to cleavage of APP at three sites, producing four peptides—sAPPbeta, Abeta, Jcasp, and C31—that mediate neurite retraction, caspase activation, and synaptic reorganization. Thus Abeta may function as an anti-trophin, creating a prionic loop with APP.

These alternative APP-mediated signals can be manipulated genetically or pharmacologically to inhibit the Alzheimer's phenotype. Furthermore, ApoE4 alters this critical balance in favor of the pro-AD signaling, at least in part via a reduction in SirT1.

These results suggest a model in which AD results from a chronic imbalance between synaptoblastic signaling and synaptoclastic signaling, amplified by prionic loops such as APP-Abeta. Since this balance is affected by many different factors in the environment—the same supportive factors whose reduction is associated with increased risk of AD—we have created an extensive therapeutic program that alters the balance to favor synaptoblastic signaling, instead of attempting to treat AD with a monotherapy that fails to address the many members of the underlying network.

ADPD5-2263
TRANSMISSION OF PATHOLOGY IN NEURODEGENERATIVE DISEASES
V. Lee[1]
[1]*Medicine, University of Pennsylvania, Philadelphia, USA*
The accumulation of misfolded proteins is a fundamental pathogenic process in neurodegenerative diseases. However, the factors that trigger aggregation and spreading of these disease proteins in brain are poorly understood. Recent studies demonstrate that misfolded disease proteins including alpha-synuclein in Parkinson's disease and tau in Alzheimer's disease and frontotemporal degeneration can be propagated from cell-to-cell through the recruitment of their endogenous normal counterparts. Moreover, pathologic misfolded aggregates propagated along major central nervous system (CNS) pathways to regions far beyond injection sites and appear to follow neuroanatomical interconnectomes. This spreading of pathology is progressive and leads to behavior impairments and eventually compromises neuronal survival but immune therapy reduces the spread of pathology, rescue behavior phenotypes and neuron loss. Our findings open up new avenues for understanding the mechanisms of disease progression and for developing novel therapeutics.

ADPD5-0200
LOW PREDICTIVE VALIDITY OF ANIMAL MODEL IN AD: DID WE ASK THE RIGHT QUESTIONS?

M. Windisch[1,2], E. Leahy[2]
[1]NeuroScios GmbH, Graz, Austria
[2]PsychoGenics Inc., Tarrytown, USA

Over the last 20 years a wide range of genetically modified animal models to study Alzheimer´s disease has been developed, some of them specific for different pathogenically important targets of the disease, others combining different features of the human disorders in a complex way, like combining up to 5 transgenes. Drugs designed for different targets have been successfully tested in these models, what is contrasted by the fact that during the last 10 years about 99.6 % of all clinical AD trials failed! First we have to ask was defined a success in the animals? In most of the cases it was a pronounced influence on brain pathology and brain biochemistry, functional readouts were sometimes missing or weak. Reviewing the quality of papers concerning behavioral results raises doubts that this was done in the best possible way. There was the optimistic assumption that prevention or reduction of pathology will automatically result in an improvement of cognitive performance in patients! What do we call failure in the clinical trial? Many of the drugs were also able to shift biomarkers in human subjects very similar as they did animal models, the failure is they did not succeed to improve or stabilize the cognitive performance and the functional status. This translational problem advocates for more refined studies on behavioral effects of drugs for AD. As an alternative to the traditional behavioral test systems, the use of high-tech methods for phenotypic screening should be considered. The application of state of the art robotics, computer vision and bioinformatics can produce complex datasets like acquisition and analysis of more than2000 different behavioral features in an automatic, high-throughput way. These “big data” provide outstanding statistical power and allow precise conclusions about the influence of compounds on distinct behavioral patterns. An advantage is that experiments are performed without influence of a human investigator in a highly standardized way. Steadily growing databases allow direct comparison to effects of standard compound, which is integrated in the overall data analysis process. Based on experience from other CNS disorders this high-tech approach in combination with robust and already well-characterized and phenotyped animal models could bring a breakthrough in predictive preclinical in vivo drug testing.

EPILEPTOGENICITY AND PRECOCIOUS MORTALITY OF BIGENIC BIAT MICE THAT EXPRESS AMYLOID AND TAU.

F. Van Leuven[1], H. Maurin[1], C. Theunis[1], A. Kremer[1], S.C. Chong[1], N. Crespo-Biel[1], P. Borghgraef[1], B. Lechat[1], H. Devijver[1], G. Callewaert[1]

[1]LEGTEGG - Human Genetics, KU Leuven, Leuven, Belgium

Bigenic biAT mice express APP.V717I and Tau.P301L and develop combined Alzheimer pathology when ageing (>10-12 months) (Terwel et al, 2005, 2008, Crespo-Biel et al, 2014).

Results

Important precocious mortality of young biAT mice (<6 months) with epileptic symptoms was totally absent in the parental monogenic mice. No authentic amyloid or tauopathy was evident yet in brain of young biAT mice. Amyloid accumulation and pathology in biAT and parental APP.V717I mice was similar, while tau phosphorylation and oligomerization was more early and more extensive than in age-matched Tau.P301L mice. Surprisingly, tangles were less in brainstem of old biAT mice that escaped early epileptic death. To explain survival beyond 12 months, the age-limit of Tau.P301L mice, we demonstrated activation of GSK3 by amyloid in biAT mice, resorting the same effects as co-expression of GSK3β with Tau.P301L in biGT mice. Despite different timing the biochemical pathway to tauopathy was similar: progressive tau-phosphorylation, soluble oligomers, insoluble oligomers, aggregates, tangles and threads.

Conclusions

The death of young biAT mice is caused by epileptogenic activity, demonstrated by clinical symptoms in the homecage and during tests: seizures, convulsions, freezing, salivation, tongue biting, posture of corpses. Moreover, high spontaneous and induced epileptogenic activity was evident during electrophysiological recordings from brain sections of young biAT mice. Additionally, young biAT mice already suffer functional and structural defects in synapses and dendritic spines in cortex and hippocampus that underlie or contribute to electric hyperactivity.

The reported high incidence of epilepsy in AD patients deserves further attention by retrospective and prospective studies.

Evaluation of biomarkers and therapies for Alzheimer's disease (AD) suffers from lack of models close to disease progression in human. Most of transgenic models express supraphysiological levels of APP metabolites to mimic AD lesions such as amyloid plaques and neurofibrillary tangles.

We describe here the development of an innovative AAV-based mouse model with two major objectives: create a relevant model closer to human physiopathology and mimic early stages of AD. This model was obtained by co-injection of two AAV vectors coding the human Amyloid Protein Precursor (APPsl) and the human Presinilin 1 (PS1M146L). Our strategy allows a stable and low expression of transgenes without overexpression of APP. This leads to βCTF and Aβ42 production as soon as 1 month post-injection without late symptoms appearance like senile plaque.

Interestingly, only co-injection of both viruses increased the ratio Aβ42/Aβ40 and triggered hyperphosphorylation of the murine Tau protein which was correlated with increased levels of GSK-3β. Otherwise, we measured physiopathological amounts of APP, βCTF and Aβ peptides compared to human samples and transgenic mice. We therefore measured a decrease of PSD95 associated with synaptic defects such as extrasynaptic NMDAR activity and an alteration of the GABA metabolism pathway. Finally significant behavior impairments appeared from 3 months post-injection.

This strategy overcame major pitfalls of transgenic models such as continuous expression of transgenes from *in utero* and limitations to the transfer to other species. Moreover, results highlighted here are strong evidences that a lot of various mechanisms appear long before the hallmarks of AD.

ADPD5-1285
STRUCTURAL AND FUNCTIONAL MRI COMPARISON OF APP TRANSGENIC LINES

J. Grandjean[1], L. Kulic[2], T. Welt[2], R.M. Nitsch[2], M. Rudin[1]
[1]Institute for Biomedical Engineering, ETH and University of Zurich, Zurich, Switzerland
[2]Division of Psychiatry Research, University of Zurich, Zurich, Switzerland

Alterations in brain structure or in functional connectivity (FC) as detected with MRI occur early in Alzheimer's disease, already affecting asymptomatic and pre-clinical cases. MRI studies in transgenic mice may enable understanding the mechanisms underlying these changes. We applied a comparative approach to identify structural and functional deficits in three mouse lines expressing different aspects of amyloid pathology.
ArcAbeta (Swe/Arc), Osaka (E693Δ), and PSAPP (Swe + PSEN1 L166P) transgenic mice and wild-type littermates were imaged at 13-15 months (n = 10-15) using an animal MRI scanner operating at 9.4T. Resting-state fMRI in mice anesthetized with medetomidine/isoflurane yielded information on functional connectivity (FC) diffusion tensor imaging on white matter integrity (fractional anisotropy, FA), and high resolution 3D images on volume changes of brain structures (voxel-based morphometric analysis, VBM).
ArcAbeta mice presented significant alterations in cortical FC in contrast to PSAPP and Osaka mice. Cortical volume was reduced in ArcAbeta and increased volume in cholinergic nuclei in pons and basal forebrain, while FA values were reduced in the anterior external capsule and corpus callosum. PSAPP mice presented increased cortical volume and increased FA in most white matter tracts while no significant structural alteration were observed in Osaka mice neither with FA nor VBM.
We observed high variability in structural and functional phenotype among different APP mouse lines, which has to be taken into consideration when comparing such models. Specific structure-function relationship may yield important insight into the role of amyloid in determining these pathological changes.

DEVELOPING ANIMAL MODELS TO STUDY THE CO-MORBIDITY OF ALZHEIMER'S DISEASE AND VASCULAR DEMENTIA

E.M. Weekman[1], H.M. Brothers[1], T.L. Sudduth[1], D. Wilcock[1]
[1]Sanders-Brown Center on Aging, University of Kentucky, Lexington, USA

Vascular contributions to cognitive impairment and dementia (VCID) is the second most common cause of dementia after Alzheimer's disease (AD). In addition, it is estimated that almost half of all AD patients have significant cerebrovascular disease co-morbid with their AD pathology. We hypothesize that cerebrovascular disease alters the neuroinflammatory response of the brain to Alzheimer's disease pathology. We have developed the hyperhomocysteinemia (HHCy) model of VCID that results in hemorrhagic cerebrovascular pathology. We have induced this model in both wild type mice as a model of VCID and APP/PS1 transgenic mice as as model of AD/VCID co-morbidity. We have examined amyloid pathology, learning and memory and neuroinflammation.

In wild type mice, HHCy results in significant cortical micro hemorrhage, M1 type neuroinflammation and spatial memory impairment in the radial arm water maze. Under normal conditions, the APP/PS1 mice with established amyloid pathology show high expression of alternative, M2a inflammatory markers. When cerebrovascular disease is present, there is a distinct switch in the inflammatory state toward an M1, pro-inflammatory bias. Furthermore, the presence of cerebrovascular disease with amyloid pathology results in an additive effect on memory impairment. Despite unchanging Abeta load, the distribution of amyloid is altered, favoring cerebrovascular deposition.

Overall, our data suggests that cerebrovascular disease alters amyloid distribution and results in further cognitive impairment. This is in association with a dramatic shift in the neuroinflammatory state of the brain. We believe this data has significant implications to the treatment of dementia patients who have Alzheimer's and cerebrovascular pathologies present.

ADPD5-1834
WNT SIGNALING IS INVOLVED IN THE OCTODDON DEGUS MODEL OF ALZHEIMER DISEASE

N. Inestrosa[1]
[1]*Cell and Molecular Biology,*
Centre for Ageing and Regeneration (CARE) Catholic University of Chile, Santiago, Chile

Alzheimer's disease (AD) is a common neurodegenerative disorder and the leading cause of age-related dementia worldwide. Some AD models for AD have been described, however, these models do not recapitulate the entire spectrum of lesions present in human AD brains. Thus, the identification and validation of a natural, wild-type AD model that mimic the pathological hallmarks observed in AD would be highly useful to unravel the mechanisms of AD. The Chilean rodent *Octodon degus* (*O. degus*) naturally develops extracellular amyloid plaques, neurofibrillary tangles and synaptic dysfunction in an age-related manner, all pathological hallmarks described in the beginning and progression of the AD. Wnt signaling has been widely implicated in the pathogenesis of AD, and plays a crucial role in maintaining the structure and function of neuronal circuits. Hence, elucidating the molecular mechanisms of Wnt dysfunction and synaptic disassembly in a 'natural' model that recapitulates AD pathology has the potential to identify targets to slow down AD-like neuropathology. We have explored age-related changes in the expression of Wnt components in *O. degus* brain. Down-regulation of Wnt ligands and receptors with an increase in GSK-3b activity plus an increment in the sFRPs and Dickkopf-1 antagonists was observed. These molecular changes indicate that Wnt signaling is deregulated during 'physiological' ageing, and may contribute to progressive neuronal degeneration, memory loss and cognitive deficits such as those observed in AD. Our results support the idea that Wnt signaling might be a novel therapeutic target for AD.

[2]Biomedicine, Aarhus University, Aarhus, Denmark
[3]EBRI, European Brain Research Institute, Rome, Italy
[4]Neurobiology, National Research Council, Rome, Italy

Recently emerging evidence supports a pivotal role for the intracellular domain of amyloid precursor protein (APP) for the function of APP. In particular, we are interested in studying the highly conserved 682-YENPTY-687 motif, which is recognized by proteins containing phosphotyrosine interaction domains (PIDs) (Tamayev et al., 2009). The APP intracellular domain contains eight potential phosphorylation sites; seven of these (Y653, S655, T668, S675, Y682, T686 and Y687) were phosphorylated in APP from brains of AD patients (Lee *et al*.2003). Often located in protein interaction sites, phosphorylatable residues may interfere with binding to cytoplasmic adaptor proteins, and thus we predict with APP function. To address this hypothesis we have recently characterized a knock-in (KI) mouse model of dementia and premature aging in which the Y682 of the 682-YENPTY-687 motif is replaced by glycine (Y682G). We unexpectedly found a key role for Y682 in development and aging, with age-dependent cognitive and locomotor decline, loss of synaptic connections, decreased cholinergic tone, and defects in nerve growth factor signaling in mice (Matrone *et al*., 2011; 2012). In addition, Y682G neurons show an anomalous compartmentalization of APP, a defect in the autophagic machinery, and an alteration in APP binding to several adaptor proteins, clearly suggesting that Y682 plays a crucial role in all the events described above (La Rosa *et al*., submitted). Taken together, our studies provide novel information on the function of the 682-YENPTY-687 motif in the physiological function of APP paving the way for potential therapeutic strategies to address AD in humans.

THE ROLE OF AMYLOID ABETA IN LIPID-MEDIATED TOXICITY
G. Multhaup[1], C. Barucker[1], V. Althoff[2], M. Hancock[1], A. McKinney[1]
[1]Pharmacology & Therapeutics, McGill University, Montreal, Canada
[2]Chemistry and Biochemistry, FU Berlin, Berlin, Germany
Objectives:
The transmembrane sequence (TMS) of APP (Aβ residues 29 to 49) is a key determinant of Aβ42 oligomerization and toxicity, with G33 being the critical residue (Harmeier et al., 2009). Our systematic analysis of Aβ-lipid interactions revealed that the neurotoxic Aβ42 binds significantly to sphingomyelin (SM), GM1, phosphatidylcholine (PC), and brain total lipid extract (BTLE) as compared to its non-toxic counterparts Aβ40 and Aβ42 G33I. Developing molecules that interfere with Aβ-lipid interactions may enable the design of amyloid selective therapeutics to combat Alzheimer disease (AD).
Methods:
Surface plasmon resonance (SPR), Size-exclusion chromatography (SEC), organotypic slice cultures, electrophysiology, microscopy techniques, MALDI-MS, and *Drosophila melanogaster* as an *in vivo* model for AD.
Results:
To date, we have found that an eight amino acid peptide with alternating hydrophobic and hydrophilic amino acids ('aggregation inhibitory peptide' - AIP) neutralizes Aβ42-induced neurotoxicity by preferentially binding to the C-terminal region of highly toxic Aβ tetra-/hexamers. Our data indicate (i) that co-administration of AIP with Aβ42 prevents the loss of excitatory synapses and rescues long-term potentiation (LTP) in CA1 organotypic hippocampal slice cultures, and (ii) that the AIP exhibits protective effects in our *in vivo* AD model.
Conclusions:
Membrane regions with a high percentage of SM, (e.g., 'lipid rafts') could be of particular importance for the interaction with Aβ42 and may play a crucial role in mediating amyloid toxicity *in vivo*. The development of compounds that interfere with toxic Aβ-lipid interactions may have a preventive and therapeutic potential.

AMYLOID PRECURSOR PROTEIN SYNAPTIC FUNCTION INVOLVES TRANS-DIMERIZATION AND FE65/FE65L1 SIGNALING

S. Kins[1], P. Strecker[1], S. Schilling[1], N. Schmidt[1], F. Baumkötter[1], M. Korte[2], S. Ludewig[2], M. Rust[3], S. Eggert[1], S. Guénette[4]

[3]Molecular Neurobiology, Institute of physiological Chemistry Philipps-University Marburg, Marburg, Germany
[4]Genetics and Aging Research Unit, MassGeneral Institute for Neurodegenerative Disease, Charlestown MA, USA

Objectives
Accumulating evidence suggests that the Amyloid Precursor Protein (APP) has an essential synaptic function. The current data suggest that sAPP as well as trans-directed dimerization of membrane bound APP are involved in this function.
Methods
We performed a cell-clustering assay with semi-adherent cells and a mixed co-culture assay of HEK293 cells and primary neurons, previously used to show that APP can promote presynaptic differentiation of contacting axons. Further we used for analysis of Fe65/Fe65L1 knockout mice different immunohistochemical and electrophysiological methods as well as behavioral studies.
Results
Here we report that inhibition of APP shedding increases its cell adhesion features and increases its synaptogenic function in a mixed co-culture assay of HEK293 cells and primary neurons. This suggests that trans-interaction of APP is required to induce presynaptic differentiation of contacting axons. Further, we show that mice lacking the Fe65 and Fe65L1 APP adaptor protein exhibit severe deficits in formation of the peripheral synapse, and deficits in pre-and postsynaptic function of the central synapse associated with deficits in LTP and learning. These phenotypes resemble some key characteristics of genetically modified APP/APLP2 knockout mice, lacking the intracellular domain that mediates binding to Fe65/Fe65L1. This indicates that Fe65/Fe65L1 might mediate APP signaling at the synapse.
Conclusions
Together our data corroborate the view that APP function depends on trans-dimerization at the synapse and suggest that Fe65/Fe65L1 is involved in APP synaptic signaling.

[3]Institute for Pathobiochemistry, Mainz University, Mainz, Germany
[4]4Department of Bioinformatics and Functional Genomics, University of Heidelberg, Heidelberg, Germany

Here we investigated the neuroprotective function of the soluble APP ectodomain sAPPalpha which is generated by cleavage of APP by alpha-secretase along the non-amyloidogenic pathway. Recombinant sAPPalpha protected primary hippocampal neurons and SH-SY5Y neuroblastoma cells from cell death induced by trophic factor deprivation. We show that this protective effect is abrogated in neurons from APP-knockout animals and APP-depleted SH-SY5Y cells, but not in APP-like protein 1- and 2- (APLP1 and APLP2) depleted cells, indicating that expression of membrane-bound holo-APP is required for sAPPα-dependent neuroprotection. Trophic factor deprivation diminished the activity of the Akt survival pathway. Strikingly, both recombinant sAPPα and the APP-E1 domain were able to stimulate Akt activity in wild-type (wt) fibroblasts, SH-SY5Y cells and neurons, but failed to rescue in APP-deficient neurons or fibroblasts. The ADAM10 (a disintegrin and metalloproteinase domain-containing protein 10) inhibitor GI254023X exacerbated neuron death in organotypic (hippocampal) slice cultures of wt mice subjected to trophic factor and glucose deprivation. This cell death-enhancing effect of GI254023X could be completely rescued by applying exogenous sAPPalpha. Interestingly, sAPPalpha-dependent Akt induction was unaffected in neurons of APP-ΔCT15 mice that lack the C-terminal YENPTY motif of the APP intracellular region. In contrast, sAPPalpha-dependent rescue of Akt activation was completely abolished in cells expressing an APP mutant lacking the G-protein interaction motif located in the APP C-terminus. Collectively, our data provide new mechanistic insights into the physiologic role of APP in antagonizing neurotoxic stress: they suggest that cell surface APP mediates sAPPα-induced neuroprotection via G-protein-coupled activation of the Akt pathway.

DECIPHERING THE MECHANISMS BY WHICH INHIBITING APP DIMERIZATION REDUCES ABETA PRODUCTION

C.R. Abraham[1], E. Zeldich[1], L.E. Brown[2], J.A. Porco Jr[2], C.D. Chen[1]
[1]Biochemistry, Boston University School of Medicine, Boston, USA
[2]Chemistry, Boston University, Boston, USA

Objectives: Increased amyloid precursor protein (APP) dimerization has been shown to enhance Abeta peptide formation. Our goal is to identify small molecules that inhibit APP dimerization and lower Abeta levels.
Methods: To define the mechanism by which APP dimerization affects the production of Abeta, a high throughput screen (HTS) for small molecule modulators of APP dimerization was conducted using APP-*Firefly* luciferase enzyme complementation to detect APP dimerization. Selected modulators identified from a library of 77,440 compounds were tested for their effects on Abeta and other APP fragments using ELISA and western blotting, respectively. APP phosphorylation was examined by IP-western blotting using anti Abeta/APP antibody for IP, and anti-phospho-tyrosine for western blot.
Results: One APP dimerization inhibitor significantly lowered Abeta and sAPPbeta levels without affecting sAPPalpha or gamma-CTF levels, suggesting that blocking the dimerization is preventing the cleavage by beta-secretase in the amyloidogenic processing pathway of APP. Interestingly, this inhibitor and its analog increased APP phosphorylation on tyrosine.
Conclusions: Inhibition of APP dimerization has previously been suggested as a therapeutic target for AD. To our knowledge, this is the first HTS effort to identify small molecule modulators of APP dimerization. The findings reported here further support the notion that modulation of APP dimerization could be a viable means of reducing the production of Abeta. The precise mechanism of action of the identified inhibitors is currently being investigated.

ADPD5-0833
FUNCTION AND MECHANISM OF GAMMA-SECRETASE: A SIGNALING RECEPTOR INVOLVED IN NEUROINFLAMMATION IS AN UNUSUAL SUBSTRATE

S.F. Lichtenthaler[1], S. Laurent[2], F. Hoffmann[2], P.H. Kuhn[1], J. Wanngren[1], E. Meinl[2]
[1]DZNE, Technische Universität München, München, Germany
[2]Institute for clinical neuroimmunology, Ludwig-Maximilians-Universität, München, Germany

Objectives: The use of gamma-secretase as a drug target in Alzheimer's disease (AD) is hampered by the fact that it cleaves many different membrane protein substrates. A better understanding of the molecular mechanisms of substrate cleavage and substrate specificity may allow to selectively inhibit amyloid beta production without interfering with other gamma-secretase functions.
Methods: Pharmacologic and genetic inhibition of gamma-secretase in cell lines and primary human B cells.
Results: The dogma holds that gamma-secretase does not directly cleave a membrane protein, but requires the previous truncation of the membrane protein-ectodomain by another protease, e.g. alpha-secretase. Here, we discovered a novel function for gamma-secretase, namely the direct shedding of a full-length membrane protein-receptor of the TNF receptor-superfamily, the B cell maturation antigen (BCMA). BCMA did not require prior ectodomain truncation. Gamma-secretase cleavage was found to control both BCMA protein levels at the cell surface and BCMA signaling, which is required for the survival of immunoglobulin-secreting plasma-cells. BCMA has an unusually short ectodomain of 54 amino acids. Increasing the length of the ectodomain reduced gamma-cleavage efficiency, suggesting that the short length of the ectodomain allows direct shedding by gamma-secretase. However, other natural membrane proteins with short ectodomains were not cleaved by gamma-secretase demonstrating that short ectodomain length is not sufficient for gamma-cleavage.
Conclusions: Together, BCMA is identified as the first membrane protein directly shed by gamma-secretase, suggesting that gamma-secretase cleaves a whole new class of transmembrane proteins. Moreover, BCMA gamma-cleavage constitutes a novel immunoregulatory mechanism which may be affected by AD drugs targeting gamma-secretase.

ADPD5-0889
THE ROLE OF PRESENILIN IN THE PRESYNAPTIC MECHANISMS AT HIPPOCAMPAL MOSSY FIBERS REVEALED BY A GRANULE CELL-TARGETED OPTOGENETIC APPROACH

G. Barthet[1], J. Rumi-Masante[1], S. Bianchi[1], C. Mulle[1]
[1]Physiology of Glutamatergic Synapses, Interdisciplinary Institute for NeuroScience, Bordeaux, France

Presenilin (PS), the catalytic subunit of the intramembrane protease gamma-secretase, cleaves various synaptic proteins including APP, N-cadherin, neurexin, ephrin, nectin and alcadein but the role of these processings in synaptic function is not known. Importantly, more than 150 missense mutations have been found on PS1 gene which cause the early-onset form of familial Alzheimer's disease (FAD) and decrease the proteolytic activity of PS.

PS has been recently found to regulate presynaptic plasticity by an unknown mechanism. The aim of this project is to understand the role of presenilin in presynaptic plasticity. We examine the role of PS at the synapse between the dentate gyrus granule cells and the CA3 pyramidal neurons of the hippocampus which is characterized by a large presynaptic plasticity essential to memory encoding.

This project involves new optogenetic tools specifically targeted to the dentate gyrus which combine cell-specific activation to cell-specific genetic manipulation. We developed a bicistronic lentiviral tool to co-express the variant of channelrhodopsin ChIEF together with a transgene of interest separated by a 2A-peptide. This construct is specifically targeted to dentate gyrus granule cells via the use of a promoter specific of hippocampal granule cells cloned for the first time. Stereotaxic injection of a virus which allows to co-express channelrodopsin with Cre recombinase permitted to knock-down PS1 gene in PS1-floxed mouse and helped to reveal the role of PS1 in presynaptic facilitation. This regulation also depends on the fragment CTFbeta of APP, a main substrate of gamma-secretase, which accumulates in absence of PS1.

Symposium 33: PRESENILIN BIOLOGY

ADPD5-1565
FUNCTION AND DYSFUNCTION OF PRESENILIN IN ALZHEIMER'S DISEASE
J. Shen[1]
[1]*Neurology, Harvard Medical School, Boston, USA*
Mutations in *presenilin-1* (*PSEN1*) are the major cause of familial Alzheimer's disease (FAD). How *PSEN1* mutations perturb Presenilin-1 (PS1) function in the brain to produce FAD is unresolved. To determine the impact of pathogenic mutations on PS1 function *in vivo*, we generated two independent *Psen1* knock-in (KI) mice in which the FAD mutation L435F or C410Y was introduced into the genomic *Psen1* locus. Surprisingly, homozygous KI/KI mice display perinatal lethality and developmental defects indistinguishable from those of *Psen1*-null mice. *Psen1* mRNA levels are unchanged in KI/KI mice, but PS1 endoproteolysis is impaired. In *vitro* γ-secretase assay revealed that γ-secretase-mediated cleavage of APP, Notch and N-Cadherin is abolished in KI/KI embryonic brains and reduced (~50%) in KI/+ brains. Levels of mouse endogenous Aβ40 and Aβ42 are reduced in the adult cerebral cortex of KI/+ mice, and the Aβ42/40 ratio is increased at ~15% due to the greater reduction of Aβ40. Similarly, levels of human Aβ derived from transgenic mice are also reduced in the cerebral cortex of KI/+ mice, and the Aβ42/40 ratio is increased, leading to accelerated amyloid deposition. Using three behavioral paradigms assessing hippocampal memory, we found that spatial memory and pattern completion are impaired. Electrophysiological analysis of the hippocampal Schaeffer collateral and commissural/associational synapses showed reduced short-term and long-term synaptic plasticity. Stereological analysis revealed that the *PSEN1* mutation causes age-dependent neurodegeneration, increased apoptosis and gliosis. Collectively, our results demonstrate that pathogenic *PSEN1* mutations produce a full spectrum of AD related phenotypes through a loss of Presenilin function mechanism.

MODULATION OF GAMMA-SECRETASE ACTIVITY BY NICASTRIN
S. Sisodia[1], S. koide[2], X. zhang[1]
[1]Neurobiology, Univ of Chicago, chicago, USA
[2]Biochemistry and Molecular Biology, Univ of Chicago, chicago, USA

The g-secretase complex, composed of PS, PEN-2, Aph1 and nicastrin (NCT), is essential for intramembranous processing of APP, Notch and several type I membrane proteins. In view of evidence that NCT plays a critical role in substrate recognition, we and others have examined the feasibility of modulating NCT function using antibody-based approaches, with the notion that NCT-specific antibodies could bind to, and modulate the binding of NCT to individual substrates. In this regard, we have reported that a synthetic antibody fragment that targets the NCT ectodomain (ECD) impairs g-secretase-mediated processing of both Notch and APP in *in vitro* assays. We generated additional NCT-specific synthetic antibodies using phage display technology, then reformatted the cDNAs encoding these antibodies to corresponding cDNAs encoding single-chain variable fragments (scFv) that were then stably expressed in HEK293 cells expressing the APP "Swedish" (APPswe) variant. We have analyzed two anti-NCT-specific antibodies, which following conversion to scFvs, bind to the NCT ECD *in vitro*. In HEK293 cells that stably express one of these antibodies, NCT maturation is impaired and leads to reduced levels on the cell surface, where the Notch derivative, NEXT, is subject to g-secretase processing. On the other hand, g-secretase that is present in the Golgi apparatus and endosomal/recycling compartments in cells expressing scFv G9 is fully capable of processing APPswe to generate Ab peptides. Thus, we suggest that scFvG9 affects both the maturation of NCT and subcellular distribution of g-secretase that leads to differential processing of APP versus Notch.

PRESENILIN1 FUNCTIONS AS A POSITIVE REGULATOR OF NEURONAL, BUT NOT GLIAL, RECEPTORS AND LIGAND-DEPENDENT NEUROPROTECTION

N. Robakis[1]

[1]*Psychiatry/Neuroscience, Icahn School of Medicine at Mount Sinai, New York, USA*

Epidermal growth factor receptor (EGFR) plays pivotal roles in cell growth, differentiation and tissue function acting as integrator where extracellular growth and survival signals converge and transform into intracellular outputs. In the brain, binding of EGF ligands to EGFR regulates neuronal function and stimulates survival kinases providing neuroprotection against toxic insults. Functions of EGFR are implicated in aging and neurometabolic disorders such as diabetes and Alzheimer's disease (AD). Genome-wide and protein-protein interaction studies identified EGFR as a risk factor for AD while transcriptional profiling indicates that ApoE4 affects the brain expression of EGFR. Furthermore, EGFR functions may mediate Aβ42-induced memory loss in animal models. Additional work indicates that EGFR interacts with presenilin (PS) and that PS1 regulates differentiation of brain neural progenitor cells through EGFR. We found that PS1 null cortical neurons contain little EGFR and show no EGF-dependent phosphorylation of survival kinases or neuroprotection. In contrast, absence of PS1 has no effect on the EGFR of primary glial cells. Acute downregulation of PS1 suppresses neuronal EGFR while exogenous PS1 stimulates expression of EGFR. Absence of PS1 results in dramatic decrease (>95%) of neuronal EGFR mRNA although PS1 affects the stability of neither EGFR nor its mRNA. Furthermore, expression of neuronal EGFR is independent of both γ-secretase and PS2 suggesting that PS1-dependent downregulation of this receptor may contribute to developmental abnormalities and lethal phenotypes specifically found in PS1, but not in PS2, null mice. In summary, the data shows that PS1 is necessary for the expression of neuronal, but not glial, EGFR thus controlling its biological functions in a cell-specific manner. This lecture will also discuss effects of PS FAD mutants on PS-dependent transcriptional mechanisms regulating expression of neuronal receptors.

ADPD5-0299
N-TRUNCATED ABETA 4-42 A TARGET FOR ALZHEIMER'S DISEASE
T.A. Bayer[1], H. Borgers[1], B. Richard[1], G. Antonios[1], O. Wirths[1], Y. Bouter[1]
[1]Psychiatry, University Medicine Göttingen, Göttingen, Germany
Objectives: N-truncated $Abeta_{4-42}$ is highly abundant in AD brain. We have recently generated a novel transgenic mouse model expressing $A\beta_{4-42}$ (named Tg4-42), which develops a massive CA1 pyramidal neuron loss without plaque formation. The hippocampus-specific neurodegeneration correlates well with age-dependent spatial reference memory deficits assessed by the Morris water maze test. In addition we have generated a novel monoclonal antibody NT4X-167 specific for the N-terminus of $Abeta_{4-42}$. One objective was to identify the level of neuron loss correlating with behavioural deficits in an age-dependent manner. The second objective was whether NT4X-167 can be used to treat two AD mouse models (Tg4-42 and 5XFAD).
Methods: Morris water maze, stereology for neuron count, passive immunization, mouse transgenic model, neuropathology, plaque load.
Results: 4-month-old Tg4-42 mice show a loss of 45% CA1 neurons and are still able to learn, whereas 5-month-old mice have a 55% neuron death and are impaired in the reference memory task of the Morris water maze. We have treated Tg4-42 mice by passive immunization with NT4X-167 between 3 and 6 months of age. The treatment results in rescue of spatial memory deficits. Moreover by passive immunization of the conventional amyloid mouse model 5XFAD we demonstrate that the antibody NT4X-167 significantly reduces plaque load.
Conclusions: $A\beta_{4-42}$ induces neuron loss without plaque formation. Passive immunization with NT4X-167 rescues behavioural deficits associated with neuron loss and reduces plaque load. These observations demonstrate that $A\beta_{4-42}$ is a relevant disease target and that the antibody NT4X-167 has potential as a therapeutic tool.

MEPRIN BETA, BUT NOT ITS ISOENZYME MEPRIN ALPHA, CATALYZES THE FORMATION OF N-TRUNCATED ABETA PEPTIDES IN VITRO

S. Schilling[1], D. Schlenzig[1], H. Cynis[1], H.U. Demuth[1]
[1]Drug Design and Target Validation,
Fraunhofer Institute for Cell Therapy and Immunology, Halle (Saale), Germany

Objective: A significant proportion of amyloid-beta (Aβ) peptides in Alzheimer's disease (AD) is truncated at the N-terminus. Among these N-truncated peptides, pGlu-modified amyloid Aβ3pE-40/42 and Aβ11pE-40/42, have been shown to correlate with disease progression and being overrepresented in early-onset forms of inherited AD. After truncation, these peptides are modified by the enzyme glutaminyl cyclase (QC), which has been shown to be upregulated in AD.
Methods: We expressed different APP proteins (wt or familial Alzheimer's mutations) in the cell lines HEK293 and CHO. The APP processing and production was assessed using Western Blot analysis and ELISAs detecting N-truncated or full length Aβ. Maldi-TOF mass spectrometry was used to analyze cleavage of APP-derived peptides.
Results: We could show that APP carrying the Swedish (APP^{695} [$KM^{595,596}NL$]) mutation leads to generation of full-length Aβ (Aβ(1-40/42)), whereas processing of APP wt results in significant formation of N-truncated peptides suggesting alternative processing. Co-expression of Meprin β, but not Meprin α, resulted in production of N-truncated Aβ peptides Aβ(2-40/42). These results were corroborated by cleavage of APP-related peptides by Meprin *in vitro*. Interestingly, Meprin β cleaved preferably APPwt and not APPswedish, which contrasts to the β-secretase BACE.
Conclusion: The data support a BACE-independent processing of APPwt that may contribute to formation of N-truncated Aβ. These truncated forms, in turn, might be prone to further post-translational modification. Thus, Meprin β might represent a potential upstream target to suppress formation of pGlu-Abeta.

ADPD5-1079

AT LEAST 2 INDEPENDENT PROTEOLYTIC PATHWAYS CONTRIBUTE TO THE FORMATION OF BETA-AMYLOID IN PRIMARY NEURONS AND MAMMALIAN CELLS

H. Cynis[1], D. Schlenzig[1], U. Zeitschel[2], M. Hartlage-Rübsamen[2], S. Rossner[2], V. Hook[3], S. Schilling[1], H.U. Demuth[1]
[1]Drug Design and Target Validation,
Fraunhofer Institute for Cell Therapy and Immunology, Halle (Saale), Germany
[2]Neurochemistry, Paul-Flechsig-Institute for Brain Research, Leipzig, Germany
[3]Pharmacology, Skaggs School of Pharmacy and Parmaceutical Sciences,
San Diego, USA

Objectives:
To date no BACE I inhibitor passed clinical development for the treatment of AD. Mounting evidence shows that a heterogeneous mixture of Aβ peptides is deposited in AD and it is unclear what molecular pathways lead to their generation. Since truncated forms of Aβ, e.g. pGlu-3 Aβ generated by catalysis of Glutaminyl Cyclase (QC), show an overt aggregation propensity and neurotoxicity *in vitro* and *in vivo*, we analyzed pathways of N-truncated Aβ liberation.

Methods:
Co-secretion of Aβ with QC and neurotransmitters was studied in primary bovine chromaffin cells and neuroblastoma cells. Liberation of N-truncated Aβ was studied in cells lines transfected with APP (wt) or APP “Swedish” (sw), in primary neurons from APP (wt) and APP (sw) expressing mice and in primary human neurons derived from iPS cells. Analysis comprised immunofluorescence, ELISA, Western Blot and mass spectrometry.

Results:
Aβ and QC show an activity-dependent, regulated co-secretion from dense-core secretory vesicles together with neurotransmitters. Furthermore, the secretion of N-truncated Aβ peptides from different cell types was only partially dependent on BACE I as demonstrated by application of a BACE I inhibitor and BACE I siRNA nucleotides or in experiments using cells derived from BACE ko mice. This suggests the presence of alternative cleavage by yet unknown proteases generating truncated Aβ species.

Conclusions:
We discovered at least 2 independent pathways leading to the generation of the total Abeta pool secreted from cellular models. This might have implications for the development of additional treatment strategies for Alzheimer’s disease.

ISOGLUTAMINYL CYCLASE CONTRIBUTES TO CCL2-DRIVEN NEUROINFLAMMATION IN ALZHEIMER'S DISEASE

S. Rossner[1], M. Hartlage-Rübsamen[1], J. Meißner[1], A. Waniek[1], M. Morawski[1], S. Schilling[2], B. Koch[2], H. Cynis[2], A. Kehlen[2], H.U. Demuth[2]
[1]Neurochemistry, Paul Flechsig Institute, Leipzig, Germany
[2]Drug Design and Target Validation,
Fraunhofer Institute for Cell Therapy and Immunology, Halle/Saale, Germany

Objectives: The brains of Alzheimer's disease (AD) patients are characterized by deposits of Abeta peptides and by accompanying chronic inflammation. Here, we provide evidence that the enzyme isoglutaminyl cyclase (isoQC) is a novel factor contributing to both aspects of AD pathology.
Methods: We used APP-transgenic mouse and human control and AD brains for enzymatic activity assays, ELISAs, qRT-PCR and double immunoflourescent labellings to reveal the expression of isoQC, pGlu-CCL2 and pGlu-Abeta.
Results: Two putative substrates of isoQC, N-truncated Abeta peptides and the monocyte chemoattractant chemokine CCL2, undergo isoQC-catalyzed pyroglutamate (pGlu) modification. This triggers Abeta aggregation and facilitates the biological activity of CCL2, which collectively results in the formation of high molecular weight Abeta aggregates, glial cell activation, neuroinflammation and neuronal cell death. In mouse brain we found isoQC to be neuron-specifically expressed and co-localized with its substrate CCL2. During aging of wild type and Tg2576 mice, isoQC and CCL2 proteins are up-regulated and were found to be co-induced in Abeta plaque-associated reactive astrocytes. Also, in mouse primary astrocyte culture, a simultaneous up-regulation of isoQC and CCL2 expression was revealed upon pro-inflammatory LPS/IFN-g stimulation. In brains of AD patients, the expression of isoQC and CCL2 mRNA and protein is up-regulated compared to controls and correlates with pGlu-Abeta load and with the decline in mini mental state examination.
Conclusions: Our observations provide evidence for a dual involvement of isoQC in AD pathogenesis by catalysis of pGlu-Abeta and pGlu-CCL2 formation which mutually stimulate inflammatory events and affect cognition.

TWO SOMATOSTATIN RECEPTOR SUBTYPES REGULATE THE MAJOR ABETA DEGRADING ENZYME NEPRILYSIN

P. Nilsson[1], K. Sörgjerd[1], N. Kakiya[1], M. Sekiguchi[1], A. Petrich[2], S. Schulz[2], N. Iwata[3], T. Saito[1], T.C. Saido[1]

[1]Laboratory for Proteolytic Neuroscience, RIKEN BSI, Wako-shi, Japan
[2]Institute for Pharmacology and Toxicology, Jena University Hospital, Jena, Germany
[3]Dept of Biotechnology Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan

Objectives

Neprilysin is a major Aβ degrading enzyme, the expression of which declines upon aging. This increases Aβ levels which may lead to Alzheimer's disease (AD). In a previous search for activators of neprilysin, we identified the neuropeptide somatostatin (Saito et al., Nat Med 2005). Somatostatin binds to G protein-coupled somatostatin receptors (SSTR), four of which are expressed in hippocampus and cortex, and induces translocation of neprilysin to cell surface (Kakiya et al., JBC 2012). Here we identified the SSTR subtypes which regulate neprilysin.

Methods

SSTR single knockout mice were investigated but no changes in neprilysin occurred. We therefore generated knockout mice lacking two of the four SSTR subtypes in a combinatorial manner. Neprilysin levels and localization and Aβ levels were investigated. Primary neurons were used to investigate in vitro the effects on neprilysin of SSTR knockout.

Results

We found that the simultaneous knockout of two of the SSTR subtypes significantly decrease the levels of neprilysin in lacunosum molecular layer of dendate gyrus. Importantly, the lowered neprilysin levels lead to markedly increased Aβ levels in hippocampus. Consistently, stimulation of primary neurons derived from wildtype mice with receptor agonists specific for these two receptors significantly increased neprilysin activity while neurons from double SSTR knockout mice did not respond to somatostatin.

Conclusions

Our resul**ts sho**w unambiguously that two subtypes of the SSTRs regulate in parallel neprilysin in hippocampus and therefore directly control the Aβ levels. This opens up for a potential AD treatment using specific agonists targeting these two receptor subtypes to activate neprilysin.

Symposium 39: PROTEIN MODIFICATION AND DEGRADATION

[3]Center for Neurologic Diseases, Brigham and Women's Hospital, Boston, USA
[4]Protein Structure Determination, DZNE and Max-Plank-Institute for Biophysical Chemistry, Göttingen, Germany
[5]Neuropathology, University of Ulm Institute of Pathology, Ulm, Germany

Objective
Aβ is generated by proteolytic processing involving sequential cleavages of the amyloid precursor protein (APP) by β- and γ-secretase. Several familial AD (FAD) mutations that cause early onset AD are found within the Aβ and result in alterations of peptide conformation and promote its aggregation. However, such mutations are very rare and account for only a very small number of cases. We recently demonstrated that extracellular Aβ undergoes phosphorylation by secreted variants of protein kinase A and that the phosphorylation of Aβ at serine residue 8 promotes its aggregation into oligomeric and fibrillar assemblies.
Methods
We applied cell biological, biochemical, biophysical and neuropathological methods to characterize the phosphorylation of Aβ in cell culture models as well as in brains of human AD cases and transgenic mice.
Results
Phosphorylated Aβ shows increased propensity to form oligomeric and fibrillar aggregates and adopt β-sheet conformation. By using highly specific phosphorylation state specific antibodies, we demonstrate abundant presence of phosphorylated Aβ in human AD and APP transgenic mouse brain. Phosphorylated Aβ species were detected in extracellular plaques, inside of neurons, and in cerebral vessels, thereby indicating a contribution to all characteristic Aβ associated lesions in AD brains. Phosphorylated Aβ species appear enriched in clinically manifested AD as compared to pathologically preclinical stages.
Conclusions
Phosphorylated Aβ peptides are common and abundant species in human AD brains and transgenic mouse models. The detection of these variants could be further explored as targets for AD therapy and prevention as well as markers for AD pathogenesis.

Symposium 40: DEMENTIA WITH LEWY BODIES: UPDATES FROM PRE-CLINICAL AND CLINICAL STUDIES, PART I

ADPD5-1021
PATHOLOGICAL PHENOTYPING: WHAT IS THE BEST CORRELATE FOR DLB?
G.M. Halliday[1]
[1]*Neuroscience Research Australia, University of New South Wales, Randwick, Australia*
Objectives: Describe the pathology and its progression in different phenotypes of patients with alpha-synuclein-immunoreactive Lewy bodies
Methods: Examination of immunohistochemically stained brain tissue sections with antibodies to alpha-synuclein in a large longitudinally studied cohort.
Results: Lewy bodies are intraneuronal cytoplasmic inclusions made of many proteins, but the core fibrils are made from the abnormal aggregation of alpha-synuclein. Lewy bodies form from a build up of punctate membrane aggregates of phosphorylated alpha-synuclein that coalesce into loosely packed filaments that undergo ubiquitination but not degradation, rather “maturing” by truncation and compaction. Lewy bodies occur to a small degree in the elderly (now considered preclinical) and in patients with diverse neurological and psychiatric disorders. At autopsy, the largest numbers of patients with Lewy bodies are 1) those with PD, 2) those with dementia with Lewy bodies (DLB), and 3) those with Alzheimer’s disease (AD). These patient types are separated by the early onset of dementia (DLB and AD) and by the regional distribution and severity of Lewy body and AD-type pathologies. Assessment of these different pathological cohorts suggests that the timing and tempo of the different pathologies relates to the clinical phenotype and that such pathophysiological differences are likely to involve different molecular interactions.
Conclusion: A slow pace of relatively restricted regional Lewy body involvement occurs in PD, while the most rapid and spatially expansive molecular involvement occurs in patients with DLB.

[5]R&D, ToolGen, Seoul, Korea

Deposition of alpha-synuclein aggregates occurs widely in the central and peripheral nervous systems in Parkinson's disease (PD). Although recent evidence has suggested that cell-to-cell transmission of alpha-synuclein aggregates is associated with the progression of PD, the mechanism by which alpha-synuclein aggregates spread remains undefined. In this talk, I will show that alpha-synuclein aggregates are transmitted from cell to cell through a cycle involving uptake of external aggregates, co-aggregation with endogenous alpha-synuclein, and exocytosis of the co-aggregates. Moreover, my colleague and I found that glucocerebrosidase depletion, which has previously been strongly associated with PD and increased cognitive impairment, promoted propagation of alpha-synuclein aggregates. Depletion of other genes such as ctsd (cathepsin D) and ATP13A2, resulted in mixed outcomes in lysosomal functions. The cell lines with these gene depletions further confirmed that lysosomal dysfunction is the key modulator of spreading of synucleinopathy. These studies define how alpha-synuclein aggregates spread among neuronal cells and may provide an explanation for how glucocerebrosidase mutations increase the risk of developing PD and other synucleinopathies.

GBA1-LINKED PARKINSONISM: FOCUS ON COGNITION AMONG ASHKENAZI JEWS IN ISRAEL

N. Giladi[1], A. Mirelman[1], T. Shiner[1], A. Zimran[1], A. Orr-Urtreger[1]
[1]Neurology, Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel

Background: Subjects who are heterozygotes with severe mutations in the *GBA* gene have a higher risk to develop PD. The aim of this study was to establish a well characterized group of Ashkenazi Jewish PD patients and asymptomatic subjects, carriers of severe mutations in the *GBA* gene.
Methods: Genotype was assessed in 1050 Ashkenazi PD cohorts, 220 of them were GBA mutation carriers (20.9%) and 54 were carriers of severe GBA mutations (24.5%). 83 asymptomatic relatives were also assessed, 39 of them were carriers of severe GBA mutations (47%). All participants underwent a thorough neurological assessment.
Results: Patients with PD carriers of severe GBA mutations tended to have an earlier age of motor symptoms onset (56.9±8.8 vs. 59.55±10.3). PD patients, carriers of severe GBA mutations, demonstrated lower performance on cognitive tests compared to carriers of mild mutations and patients with PD who were non-carriers . Patients with PD who are carriers of severe GBA mutations also reported more REM Sleep Behavior Disorder symptoms than carriers of mild mutations and patients with PD who were non-carriers ($p<0.030$). No differences were observed in age, gender, years of education, autonomic function, behavioral profile or smell identification, between asymptomatic carriers of severe GBA mutations and carriers of mild mutations or non-carriers. However, asymptomatic carriers of severe GBA mutations performed poorer on executive function tasks (TMT).
Conclusions: PD patients and asymptomatic carriers with severe GBA mutations have specific cognitive profile among PD patients and healthy heterozygotes.

ADPD5-1645
RADIOLOGICAL PHENOTYPING OF DLB: HOW COULD IMAGING HELP DIAGNOSTIC ACCURACY?
S. Gomperts[1]
[1]*Neurology, Massachusetts General Hospital, Boston, USA*
Background: The sensitivity and specificity of clinical criteria of the Third Consortium on Dementia with Lewy bodies (DLB) for neuropathologically proven DLB approach 85% and 75%, respectively, at tertiary care centers.
Goals: To assess imaging biomarkers that differentiate DLB from related Lewy body diseases, AD and HCS.
Methods: Cross-sectional and longitudinal prospective studies in subjects with DLB, PD with normal cognition (PD-nl), PD with mild cognitive impairment (PD-MCI), and PD with dementia (PDD), contrasted with Alzheimer's disease (AD) and healthy control subjects (HCS). Subjects underwent formal neurologic examination, detailed neuropsychological assessments, MRI, and PET scans with radioligands altropane (DAT: dopamine transporter), PiB (Aβ amyloid) and FDG (glucose metabolism).
Results: Putamen DAT concentrations were similar in DLB and PD and differentiated DLB from HCS and AD. Decreased caudate DAT concentration related to cognitive impairment in DLB. PiB uptake was greatest in DLB and AD. However, cortical PiB retention was common in PD and predicted cognitive decline. In contrast to DAT and PiB, FDG distinguished PD-MCI from PD-nl groups on the basis of cortical hypometabolism. PET imaging of paired helical filament tau has potential for differentiating DLB and AD from the parkinsonian tauopathies.
Conclusion:
Multimodal PET imaging differentiates DLB from other disease groups and may increase diagnostic accuracy in the clinic, improve cohort uniformity for clinical trials, and serve as biomarkers for targeted molecular therapies.

ADPD5-1755
CLINICAL CHARACTERIZATION OF PRODROMAL DLB
I. McKeith[1]
[1]*Institute for Ageing, Newcastle University, Newcastle upon Tyne, United Kingdom*
Prodromal DLB can be defined by a relevant clinical deficit which is combined with a biomarker suggestive of an underlying alpha-synucleinopathy. Cases presenting with prodromal cognitive symptoms are most likely to be characterised as non-amnestic MCI with prominent attentional, executive and visuo-perceptual dysfunction. Conversion to DLB is reported to occur in two-thirds of such cases within a seven year follow up with baseline presence of REM sleep behaviour disorder, fluctuations, daytime sleepiness and mild parkinsonism increasing risk. Non-cognitive prodromal presentations include psychiatric (unexplained delirium, stupor, mood disorders and psychosis), hyposmia and autonomic dysfunction (constipation, orthostatic dizziness and urinary incontinence). Since most of these symptoms lack disease specificity, it is the order of their appearance and the total number of symptoms experienced that may be most important in identifying early stage Lewy body disease.
Biomarkers available for current use include structural MRI for medial temporal lobe preservation, perfusion and metabolic SPECT/PET for occipital hypofunction, dopamine transporter SPECT for nigro-striatal dysfunction and cardiac scintigraphy. Although these techniques may in combination be useful for confirmation of moderate or advanced LB disease cases, it is as yet unclear how they can contribute to prodromal diagnosis. Histological confirmation by autonomic ganglia or cutaneous nerve biopsy may ultimately provide the best evidence of an underlying alpha-synucleinopathy in early stage cases and might be considered necessary before starting long-term, disease-specific preventative treatment.

ADPD5-1972
TECHNOLOGIES FOR STUDYING AD AND PD GENE FUNCTIONS IN HUMAN NEURONS: POTENTIAL AND LIMITATIONS OF iN Cells

C.S. Thomas[1]
[1]*Department of Cellular & Molecular Physiology and Howard Hughes Medical Institute, Stanford University School of Medicine, SIM1 Building 265 Campus Drive, Stanford*

Over the last five years, my laboratory has developed approaches to study human neurons in collaboration with the Wernig laboratory (also at Stanford). We have described protocols for the rapid trans-differentiation of fibroblasts and iPS/ES cells into neurons (referred to as iN cells), and for the efficient introduction of conditional mutations into these neurons using AAV- or CRISPR-mediated homologous recombination. Our present goal, as described in my lecture, is twofold: First, to optimize and standardize this method, to clarify the biological basis for its success, and to apply it to study synaptic function both in healthy and diseased human neurons. Second, to generate mutations in AD- and PD-linked genes in these human neurons, and to analyze the effects of such mutations on neuronal function, in particular synaptic transmission. I will discuss the iN cell technology and outline present results towards these goals with the hope of convincing the audience of the utility of the approach.

[2]Laboratory of Drug Discovery in Neurodegeneration, Brigham and Women's Hospital, Boston, USA
[3]Dept. of Pharmacology and Neurology, Boston University, Boston, USA
[4]Center for Regenerative Medicine, Boston University, Boston, USA

We have identified compounds that inhibit cellular aggregation of TDP-43, which is genetically linked to amyotrophic lateral sclerosis (ALS), and accumulates as pathology in ALS and frontotemporal dementia (FTLD-TDP). Pathological TDP-43 forms insoluble protein aggregates that accumulate predominantly in the cytoplasm, but can also appear in the nucleus. Extensive research suggests that these insoluble protein aggregates form via the stress granules (SG), which are a type of RNA granule that forms in response to many different types of cellular stress. Accumulating data suggests that TDP-43 aggregates lead to disease by sequestering TDP-43 in the insoluble aggregates, perhaps because of reduced availability of soluble, functional TDP-43, or by directly stimulating RNA degradation and cell death pathways through the SG pathway. In both scenarios, inhibiting formation of SG containing insoluble TDP-43 could inhibit the pathophysiology of ALS and FTLD-TDP and delay disease.

Using a cell based screening approach, we identified a series of compounds that inhibit TDP-43 inclusion formation in a reproducible and dose-dependent manner, while showing little-to-no cytotoxicity. Inhibition of TPD-43 aggregation is observed in cell lines, primary cortical neurons and in induced pluripotent stem cells from controls and ALS subjects. Biochemical studies indicate that our lead compound preferentially reduces TDP-43 aggregates and cleavage products, while only slightly reducing levels of TDP-43 monomer. The compounds appear to act through a mechanism independent of TDP-43 ubiquitination. The compounds also reduce the deleterious effects of TDP-43 expression in *C. elegans*. This work potentially identifies a novel therapeutic approach for treating ALS and FTLD-TDP.

TRANSTHYRETIN EXPRESSION IS INCREASED IN HUMAN AD AND BEHAVES AS A NEURONAL STRESS PROTEIN IN APP23 AD MODEL MICE DETOXIFYING A BETA AND MODULATING ITS PRODUCTION

J. Buxbaum[1], *X. Li*[1]
[1]*MEM, The Scripps Research Institute, La Jolla, USA*

Background: We have shown that neurons from human AD brains stain with an anti-transthyretin (TTR) antibody, that over-expression of a wild type human *TTR* gene suppresses the AD phenotype in APP23 mice and that TTR inhibits Aβ aggregation, fibril formation and cytotoxicity *in vitro* and in tissue culture by binding to monomers, small oligomers and fibrils. In cultured neurons and hippocampi of APP23 mice *TTR* transcription is increased through the action of the stress response transcription factor HSF1. In analyses of brains from APP23 mice genetically programmed to over-express human TTR we noted that the production of Aβ fragments appeared to be reduced, raising the question of whether TTR could bind to Aβ precursors perhaps interfering with processing.

Methods and Results: Collaborative NMR studies with Y. Song in the Sanders laboratory at Vanderbilt University showed that TTR interacted with C99 at residues G659, A665, T668 (APP 695 numbering). Transfection of Aβ-producing 7PA2 CHO cells with a human TTR construct resulted in diminished Aβ in the culture medium while immunoprecipitation of DSP cross-linked lysates of the cells with an anti-TTR antibody pulled down both C99 and APP.

Conclusions: human TTR appears to behave as a neuronal chaperone regulated by HSF1 and interferes with Aβ aggregation *in vivo* and *in vitro*. We now find that it interacts with the Aβ precursors APP and C99 and appears to interfere with their processing and release of Aβ into the media. The effect is likely to be related to interference with phosphorylation of threonine 668.

TDP-43 MEDIATED SYNAPTIC ALTERATIONS IN THE PATHOGENESIS OF TDP-43 PROTEINOPATHIES

C. Blizzard[1], E. Handley[1], T. Fielder[1], B. Turner[2], T. Dickson[1]
[1]Menzies Research Institute Tasmania Neurodegenerative Diseases/Brain Injury, University of Tasmania, Hobart Tasmania, Australia
[2]Florey Institute of Neuroscience and Mental Health, University of Melbourne, Melbourne, Australia

Background: TPD-43 mediated neurodegeneration results from the pathological miss-processing and/or functional change of this RND-binding-protein. Recent research has indicated that TDP-43 alterations may have an early, underappreciated, pathological role at the synapse.
Objectives: Characterise the pre- and post-synaptic pathology occurring in the cortex of the TDP-43^{A315T} mouse model of ALS with regional immunohistochemistry and spine density analysis. Spine analysis was investigated in TDP-43^{A315T} YFP-H fluorescent mice.
Methods: Pre-synaptic pathology was investigated using immunohistochemistry (Synaptophysin, VGluT and VGAT1). Dendrite spines in the TDP-43^{A315T}YFP-H mice were investigated on the Zeiss LSM-510-Meta confocal microscope using Neurolucida™ software.
Results: Whilst there was no significant difference in Synaptophysin labelled puncta**,** Glutamatergic and GABAergic pre-synaptic vesicle transporters were significantly reduced at day 90 (symptom onset) in the TDP-43^{A315T} mice compared to wild-type controls (Figure 1). These changes were specific to motor cortex and not present in somatosensory cortex. However, there was significant total reduction in spine densities in somatodendritic and apical TDP-43^{A315T} x YFP-H dendrites at this symptom onset, day 90, time-point. There was no significant difference in spine densities during the development of the TDP-43^{A315T} x YFP-H mouse, investigated at day 30.
Conclusion: Our investigations highlight potential pathogenic roles for mutated TDP-43 at the synapse. Understanding the role that TDP-43 plays in synaptic dysfunction may reveal new therapeutic windows for intervention in TDP-43 proteinopathies.

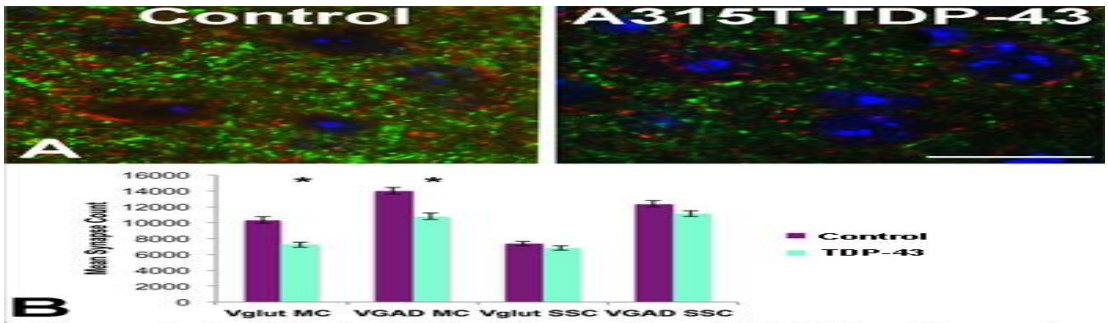

Figure 1. A. IHC for VGlut (green) and VGAD (red) puncta in the motor cortex (MC) in control and A315T TDP-43 mice at day 90 (blue = DAPI) B. Synapse counts for both VGlut and VGAD were significantly reduced in the motor cortex with no change in the somatosensory cortex (SSC) at day 90, in comparison to control (*p<0.05). Scale bar = 50µm

ADPD5-1567
FULL-LENGTH TDP-43 FORMS TOXIC AMYLOID OLIGOMERS THAT ARE PRESENT IN FRONTOTEMPORAL LOBAR DEMENTIA-TDP PATIENTS
Y.R. Chen[1]
[1]*Genomics Research Center, Academia Sinica, Taipei, Taiwan*
Proteinaceous inclusions are common hallmarks of many neurodegenerative diseases. TDP-43 proteinopathies, consisting of several neurodegenerative diseases including frontotemporal lobar dementia (FTLD) and amyotrophic lateral sclerosis (ALS), are characterized by inclusion bodies formed by polyubiquitinated and hyperphosphorylated full-length and truncated TDP-43. The structural properties of TDP-43 aggregates and their relationship to the pathogenesis are still ambiguous. Here, we demonstrated that the recombinant full-length human TDP-43 forms structurally stable, spherical oligomers that share common epitopes with an anti-amyloid oligomer-specific antibody. The TDP-43 oligomers are stable, have exposed hydrophobic surfaces, exhibit reduced DNA binding capability, and are neurotoxic *in vitro* and *in vivo*. Moreover, TDP-43 oligomers are capable of cross-seeding Alzheimer's amyloid-β to form amyloid oligomers, showing the inter-convertibility between the amyloid species. Such oligomers are present in the forebrain of transgenic TDP-43 mice and FTLD-TDP patients. Our results suggest aside from filamentous aggregates TDP-43 oligomers may play a role in TDP-43 pathogenesis.

[3]Research, ISIS Pharmaceuticals, Carlsbad, USA
[4]Center for Neurodegeneration Research, Medical Research Council King's college, London, United Kingdom

Objectives:

Expanded hexanucleotide repeats in a non-coding region of the *C9orf72* gene were recently identified as the most common genetic cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). The pathogenic mechanisms of this expansion are not understood, but initial observations point to either a loss of function of the endogenous *C9orf72* gene, and/or a toxic gain of function of the expanded RNA. The latter may be mediated either by sequestration of RNA binding proteins into RNA foci or by production of aberrant polypeptide(s) through repeat-associated non-ATG-dependent (RAN) translation. Our objectives are to develop cellular and animal models to dissect disease mechanisms and develop a therapeutic strategy lowering *C9orf72* RNAs.

Methods:

To test the efficacy and tolerability of antisense oligonucleotides (ASOs) targeting *C9orf72* expanded RNAs in transgenic mice and neurons directly converted from patient fibroblasts.

Results:

We have generated mice modeling either a loss of C9orf72 function or a toxic gain of function to unravel the relative contributions of each mechanism. We established multiple lines of BAC transgenic mice expressing different repeat lengths of a repeat-containing human *C9orf72* gene. Pathologic RNA foci containing both sense and antisense repeat RNAs and RAN dipeptides are identified in brains and spinal cords of these *C9orf72* mouse models and in neurons derived from *C9orf72* patient fibroblasts.

Conclusions:

A therapeutic strategy using antisense oligonucleotides (ASOs) that mediate degradation of RNAs carrying the *C9orf72* hexanucleotide expansion is developed to target a gain of toxic function from expanded *C9orf72* in ALS and FTD patients.

1. Objectives: To show that protein kinase CK-1 inhibitors are useful innovative drug candidates for TDP-43 mediated neurodegenerative diseases and also Parkinson disease [1,2]
2. Methods: Chemical genetics approach to identify new CK-1 inhibitors using an in-house chemical library of heterocyclic small molecules. Hit to lead optimization trough medicinal chemistry programs. Lead to candidate selection based on ADME-Tox properties. Cell based and animal studies with leads and candidates to confirm the efficacy of CK-1 inhibitors.
3. Results: Identification of two new families of CK-1 inhibitors. A reduction of TDP-43 phosphorylation is observed after CK-1 inhibitors treatment in cell cultures. Neuronal toxicity induced by hTDP-43 protein on transgenic flies is decreased after the treatment with our CK-1 inhibitors. CK-1 inhibitors also shown neuroprotection in cell based and in vivo models of Parkinson disease
4. Conclusions: CK-1 inhibitors, and specially our small molecule candidate IGS2.7, are promising drug candidates for the future treatment of neurodegenerative diseases such as Alzheimer disease, amyotrophic lateral sclerosis, frontotemporal dementia and Parkinson disease

[7]Alzheimer Program, CIBERNED, Madrid, Spain

Objectives: To investigate biomarkers in CSF of relevant pathophysiological pathways in a large multicentre cohort of cognitively normal subjects.
Methods: We measured markers of amyloid precursor protein processing (A[beta]42, sAPP-[beta], [beta]-secretase activity), neuronal damage (t-Tau, p-Tau) and neuroinflammation (YKL-40) in the cerebrospinal fluid (CSF) of 266 cognitively normal subjects recruited as part of a large multicentre study. We used NIA-AA research criteria for classification into different stages of preclinical AD. We analyzed the relationship between CSF biomarkers, clinical variables and *APOE* genotype, and we compared CSF biomarkers across diagnostic groups.
Results: Age showed a positive correlation with CSF t-Tau, p-Tau and YKL-40. Age also correlated with CSF A[beta]42, but only in APOE[epsilon]4 carriers. CSF A[beta]42 correlated positively with Tau, sAPP[beta] and YKL-40 in subjects with normal A[beta]42 levels. These correlations were negative or non-significant in participants with low A[beta]42 levels. Subjects labelled as preclinical AD (stage 2 and 3), and 'suspected non-amyloid pathology' (SNAP) had higher levels of YKL-40 than participants in Stage 0 and Stage 1. No differences in sAPP[beta]levels of [beta]-secretase activity in CSF were detected across groups.
Conclusions: CSF [beta]-secretase is not altered in preclinical AD. CSF A[beta]42 correlates with tau but the directionality of the correlations differs depending on the A[beta]42 status. Moreover, subjects in preclinical stages 2-3 of AD and with SNAP showed high levels of YKL-40. This suggests that inflammation is a very early process in neurodegenerative diseases.

Symposium 43: FUNCTIONS OF ETA SECRETASE AND BACE1

ADPD5-1023
A PHYSIOLOGICAL ROLE FOR THE ALZHEIMER'S DISEASE-RELATED BACE1 IN REGENERATING NEURONS

R.M.D. Holsinger[1], S. Ebrahimkhani[2], M.B. Graeber[2]
[1]Sydney Medical School, University of Sydney, Sydney, Australia
[2]Brain & Mind Research Institute, University of Sydney, Sydney, Australia

Objectives: To identify a physiological role for BACE1 in the central nervous system.
Methods: Animals were anaesthetized and the right facial nerve was transected at its exit from the stylomastoid foramen. The contralateral side was left intact and served as a paired internal control. Survival times studied were 3, 7, 14 and 21 days. Sixteen-micrometer-thick coronal cryosections of the brain stem were collected onto glass slides, fixed in buffered formaldehyde solution, washed in 0.01 M PBS and incubated with rabbit polyclonal anti-BACE1 antibody (00/6) for two hours at room temperature. Slides were subsequently incubated with Alexa 488-conjugated goat anti-rabbit secondary antibody for 1h at room temperature and viewed under confocal microscopy.
Results: We observed a rapid and sustained up regulation of BACE1 protein expression in activated microglia and astrocytes. In addition, we also observed an increase in BACE1 protein expression in injured neurons in the facial nucleus up to 21 days (longest time-point evaluated) following axotomy of the facial nerve.
Conclusions: Up regulation of BACE1 expression in astrocyte cultures has been previously reported. However, its expression *in vivo* in both activated astrocytes and microglia is novel. Its up regulation in neurons might point to an association with repair mechanisms whereas its presence in activated glia may constitute a signaling mechanism whereby its expression in proliferating glial cells surrounding the damaged site may aid in the clean up and repair processes. The high level of BACE1 expression in regenerating neurons highlights a novel physiological role for BACE1 in the CNS.

[7]Metabolic Biochemistry, LMU München & DZNE-München, München, Germany

Alzheimer's disease (AD) pathology is characterized by the accumulation of amyloid plaques, which are predominantly composed of amyloid b-peptide (Aβ). Two principal physiological pathways either prevent or promote Aβ generation from its precursor (amyloid precursor protein; APP) in a competitive manner. Modulation of the amyloidogenic pathway is currently exploited by anti-Aβ therapeutic strategies. Although APP processing has been studied in great detail, unknown proteolytic events appear to hinder stoichiometric analyses of APP metabolism in vivo. We now identified a higher molecular weight C-terminal fragment of APP (CTF-η) in addition to the long-known fragments CTF-α and CTF-β, which are generated by α- and β-secretase (a disintegrin and metalloproteinase; ADAM10 and β-site APP cleaving enzyme 1; BACE1). CTF-η is generated by MT5-MMP, a membrane bound matrix-metalloproteinase referred to as η-secretase, which co-localizes with senile plaques in AD. MT5-MMP mediated cleavage results in the release of a truncated, soluble APP ectodomain (sAPP-η). Upon shedding of sAPP-η, CTF-η is further processed by ADAM10 and BACE1 to release long and short Aβ peptides (Aη-α and Aη-β). η-Secretase activity is enriched in dystrophic neurites in an AD mouse model and human AD brains. Genetic and pharmacological inhibition of BACE1 activity results in a robust accumulation of CTF-η and Aη-α. Strikingly, Aη-α lowers hippocampal long-term potentiation similar to synaptotoxic Aβ oligomers. These findings not only demonstrate a novel physiologically and pathologically relevant APP processing pathway but are also of immediate translational relevance.

LOSS OF FUNCTION OF SPINOCEREBELLAR ATAXIA TYPE-1 PROTEIN, ATXN1, ENHANCES BACE1 LEVELS AND BETA-AMYLOID PATHOLOGY IN THE CEREBRUM

J. Suh[1], D.M. Romano[1], J.D. Schmahmann[2], R.E. Tanzi[1]
[1]Neurology / MIND, Massachusetts General Hospital/ Harvard Medical School, Charlestown, USA
[2]Neurology, Massachusetts General Hospital/ Harvard Medical School, Boston, USA

1. Objectives

Abnormal expansion of CAG repeat in the ataxin-1 gene (*ATXN1*) causes the degeneration of Purkinje cells and cerebellar ataxia type 1 (SCA1), a neurodegenerative movement disease. Previously our laboratory has reported *ATXN1* is associated with Alzheimer's disease (AD) and knockdown of ATXN1 increases Abeta generation in cultured mammalian cells. Here, we investigate whether ATXN1 expression affects the processing of amyloid precursor protein (APP) and the pathogenesis of AD.

2. Methods

We examined the levels of APP cleavage products and the secretases in the brains of ATXN1 knockout (KO) and wild-type mice. APP processing and Abeta pathology were further analyzed after crossing the ATXN1 mice with APPswe/PS1deltaE9 AD mice.

3. Results

We found ATXN1 KO increases BACE1 levels in cortex and hippocampus, but not in cerebellum and brain stem. This increase of BACE1 is concordant with the shift of APP processing into the beta-secretase cleavage pathway along with an increase in Abeta levels and plaque load in the brains of APPswe/PS1deltaE9 mice. In addition, the dendritic development of immature neurons, a neurogenic marker in adult brain, was impaired in the hippocampus of ATXN1 KO mice.

4. Conclusions

Together, these findings suggest that the loss of ATXN1 function potentiates beta-amyloid pathology by increasing BACE1 levels and the subsequent beta-secretase cleavage of APP.

SCHWANN CELL BACE1 IS REQUIRED FOR REMYELINATION OF PERIPHERAL NERVES

X. Hu[1], B. Trapp[1], R. Yan[1]
[1]Neurosciences, Cleveland Clinic Lerner Research Institute, Cleveland, USA

Objectives: Inhibition of BACE1 is being pursued as a therapeutic target for treating patients suffering from Alzheimer's disease because BACE1 is a critical β-secretase for generating β-amyloid peptide. Knowledge regarding the other cellular functions of BACE1 is therefore critical for the safe use of BACE1 inhibitors in human patients. BACE1 deficiency in mice causes hypomyelination during development and impairs remyelination in injured sciatic nerves. Since BACE1 is expressed by both neurons and myelinating Schwann cells, we asked whether axonal or Schwann cell BACE1 is required for optimal remyelination. **Methods:** By swapping sciatic nerve segments from BACE1-null mice with the corresponding wild-type nerve segments or vice versa, we tested how deficiency of BACE1 in Schwann cells or axons affected remyelination. **Results:** Our results show that BACE1 in axons and Schwann cells is similarly important for remyelination of regenerated axons. We found that neuregulin 1 (Nrg1) is expressed by Schwann cells and that abolished Nrg1 cleavage in BACE1-null Schwann cells contributes to decreased remyelination of regenerated axons. Although the myelin sheath was thinned in BACE1-null mice, the number of Schwann cells in BACE1-null mice was higher than wild-type. **Conclusions:** This study is the first to provide evidence that remyelination requires non-neuronal sources of BACE1.

Symposium 43: FUNCTIONS OF ETA SECRETASE AND BACE1

ADPD5-1747
BACE1 IN HEALTH AND ALZHEIMER'S DISEASE
R. Vassar[1], K. Sadleir[1], P. Kandalepas[1]
[1]Cell and Molecular Biology, Northwestern University Feinberg School of Medicine, Chicago, USA
The β-secretase, β-site amyloid precursor protein (APP) cleaving enzyme 1 (BACE1), is the first of two proteases (the second being γ-secretase) to cut APP to generate the β-amyloid peptide (Aβ) implicated in Alzheimer's disease (AD) pathogenesis. As such, BACE1 is a prime therapeutic target for lowering cerebral Aβ levels as a treatment strategy for AD. The highest levels of BACE1 in the body are found in neurons of the brain, where it is localized within endosomal compartments of cell bodies and presynaptic terminals under non-pathologic conditions. However, in AD brain, BACE1 levels increase several fold, and vesicles containing the enzyme accumulate within swollen, distended axons that pass near amyloid plaques. These peri-plaque dystrophic axons also accumulate APP, suggesting the possibility that increased enzyme and substrate might accelerate Aβ production near amyloid deposits, thus exacerbating plaque growth and AD progression. Indeed, we will present evidence that BACE1 accumulation in dystrophic axons is associated with increased levels of BACE1-cleaved fragments of APP and Aβ in our 5XFAD mouse model of AD amyloidosis. Possible mechanisms of Aβ-induced BACE1 accumulation will be discussed. We conclude that Aβ causes increased levels of BACE1 that in turn lead to further Aβ production, instigating a vicious cycle of AD pathogenesis.

AGE-DEPENDENT, SELECTIVE DOPAMINERGIC NEURODEGENERATION, PROTEIN ACCUMULATION AND AUTOPHAGY IMPAIRMENT IN LRRK-DEFICIENT MICE

E. Giaime[1], *Y. Tong*[1], *J. Shen*[1]
[1]*Center for Neurologic Diseases Department of Neurology, Brigham & Women's Hospital Program in Neuroscience Harvard Medical School, Boston, USA*

Mutations in the *leucine-rich repeat kinase 2* (*LRRK2*) gene are the most common genetic cause of Parkinson's disease (PD), but the pathogenic mechanism is unclear. We previously generated *LRRK2*-/- mice and found no detectable phenotypes in the brain, but the kidney develops striking age-dependent PD-like changes, including accumulation of alpha-synuclein and ubiquitinated proteins, impairment of the autophagy-lysosomal pathway, increases of apoptosis, inflammatory responses, and oxidative damage. To determine whether the absence of the phenotypes in the *LRRK2*-/- brain might be due to the relative high expression of LRRK1 in the brain, we developed double knockout mice lacking both LRRK1 and LRRK2. *LRRK1/2*-/- mice are viable and fertile, but show reduced weight gain in adulthood and early mortality at ~15 months of age. Interestingly, stereological neuron counting revealed significant loss of dopaminergic neurons in the *substantia nigra pars compacta* and noradrenergic neurons in the *locus coeruleus* of *LRRK1/2*-/- mice at 15 months of age, whereas the number of dopaminergic neurons is normal in early ages. Furthermore, the volume of the cerebral cortex and the number of cortical neurons are normal in *LRRK1/2*-/- old mice, suggesting that the loss of dopaminergic and noradrenergic neurons is specific. In addition, at 15 months we observed increased levels of α-synuclein, impairment of autophagy function, increases of apoptosis, astrogliosis and microgliosis in *LRRK1/2*-/- brains. These findings show that loss of LRRK function results in age-dependent autophagy impairment and selective loss of dopaminergic neurons, indicating essential role of LRRK in autophagy regulation and survival of dopaminergic neurons.

[4]Cornell University, Division of Nutritional Science, New York, USA

- Unfolded Protein Response that has been linked to the physiopathology of Parkinson's disease (PD) is a cellular response to Endoplasmic Reticulum (ER) stress induced by the accumulation of protein aggregates. Interestingly the E3 ubiquitin ligase Parkin and the chaperone protein DJ-1, two proteins related to autosomal recessive early-onset PD, are regulated by ER stress. Moreover, Parkin was reported to interact in stress conditions with DJ-1monomeres. We have unraveled that Parkin is also a transcription factor that modulates p53, presenilin 1 and 2 transcription. In this study we have investigated whether Parkin could control, in basal or ER stress conditions, DJ-1 expression through its transcription factor activity.
- We have overexpressed in different cell types (SH-SY5Y, TSM1, HEK293) wild-type Parkin or its ubiquintin ligase active or inactive mutants. We have used MEF cells invalidated or not for the gene coding for Parkin, p53 and also for the ER stress induced transcription factor: XBP-1S. mRNAs and proteins expression were recorded using Q-PCR and Western-blot techniques, while promoter activity and XBP-1S responsive element were analysed and identified by reporter gene assay, mutagenesis, gel shift and ChIP experiments.
- PK ubiquitine ligase activity is not involved in DJ-1 regulation. In contrast, in ER stress conditions, PK transcriptional repression of p53, activates XBP-1S that directly interacts with *DJ-1* promoter ultimately leading to the up regulation of DJ-1.
- Our study unravels an ER stress signalling pathway by which Parkin and the chaperone protein DJ-1 could control part of the UPR response in PD.

[3]Experimental Psychology, University of Oxford, Oxford, United Kingdom

Objectives: Mutations in leucine rich repeat kinase-II (LRRK2) cause autosomal dominant Parkinson's disease (PD). Transgenic animals have been crucial in modelling the mechanisms underlying PD progression. Bacterial artificial chromosome (BAC) transgenics generate physiologically relevant disease models encompassing large genomic DNA sequences using endogenous promoters and regulatory sequences. We have therefore developed BAC transgenic rats expressing human LRRK2. These lines express either G2019S mutant, R1441C mutant or wild-type LRRK2. Utilising rats allows for more advanced behavioural, neuroanatomical and neurophysiological analyses.
Methods: Young and old animals were assessed. Behaviour was assessed using a battery of motor and non-motor behavioural tests. Levodopa was administered in an attempt to rescue motor phenotypes. Striatal dopamine release and content were examined using fast-scan cyclic voltammetry and high-performance liquid chromatography. Stereological counts of neurons in the substantia nigra pars compacta (SNpc) were performed along with molecular assays to assess alterations related proteins. *In vivo* electrophysiological analysis was performed on dopaminergic neurons in the SNpc.
Results: Aged *LRRK2* mutant transgenic rats display impaired dorsal striatal dopamine release and corresponding motor and cognitive deficits. Motor deficits were shown to be levodopa-responsive. R1441C rats show alterations in SNpc neuronal firing patterns. Behavioural and dopamine release deficits occur in the absence of any overt degeneration of the SNpc neurons. *LRRK2* mutant transgenic animals show early changes in LRRK2 phosphorylation at key residues, although no accumulation of α-synuclein was seen in aged animals.
Conclusions: These rats recapitulate many of the key features of PD and inform on the sequence of disease progression.

LRRK2 PHOSPHORYLATES TAU AT LITTLE EXPLORED EPITOPES AND ENHANCES TAU PATHOLOGY AND NEURONAL LOSS IN TRANSGENIC MICE.
J. Lewis[1], M.J. Hamm[1], J. Covy[2], R.M. Bailey[3], B.I. Giasson[3]
[1]Neuroscience, University of Florida College of Medicine, Gainesville, USA
[2]Neuroscience, Stanford University, Palo Alto, USA
[3]Neuroscience, University of Florida, Gainesville, USA
We recently discovered that LRRK2 phosphorylates the T149 and T153 epitopes in tau in vitro, cell culture and in a transgenic mouse model of tauopathy. Few previous studies have been performed on either T149 or T153, and our finding that LRRK2 preferentially targeted these sites and in mouse models enhanced tauopathy was entirely novel. In unpublished work, we have now extended these studies to demonstrate that the presence of tubulin significantly promotes the phosphorylation of tau by LRRK2 at these epitopes. We can also manipulate the degree by which LRRK2 can promote tau phosphorylation with physiologically relevant factors. Additionally, we have now identified a third epitope which appears to be more strongly targeted by LRRK2 than the previously described epitopes. Finally, we now show data that the modest overexpression of wild-type LRRK2 in a tau transgenic model enhances tau-directed neurodegeneration. The data will expand our currently poor understanding of the relationship between LRRK2 and tau pathology.

PARKIN-P53 INTERPLAY IN PARKINSON AND OTHER BRAIN DISEASES
F. Checler[1], E.R.I.C. Duplan[1], C. Alves da Costa[1]
[1]IPMC, UMR7275 CNRS-UNSA, Valbonne, France
Parkin has been described as an ubiquitin-ligase responsible for most of early-recessive cases of Parkinson's disease (PD). Interestingly, we 2 demonstrated that parkin also behaves as a transcriptional repressor of the tumor suppressor p53[1] and Presenilins 1 and 2, allowing to delineate a consensus parkin responsive element[2]. It is noteworthy that there exists an inverse relationship between the risk of developing PD and brain cancer. We showed that parkin levels are inversely correlated to p53 levels but also to the grade of either, oligodendroglioma, mixed gliomas and glioblastomas. We demonstrated that p53 exerts a positive control on parkin transcription i cellq as well as in vivo and that a lack of function of mutant p53 likely accounts for reduced levels of parkin in pathological biopsies[3]. Therefore, parkin is clearly a pleiotropic protein involved in various brain pathologies.

ROLE OF THE PINK1-PARL-PGAM5 AXIS IN PARKINSON DISEASE
B. De Strooper[1], P. Verstreken[1], M. Spinazi[1], V. Morais[1]
[1]Center for the Biology of Disease, VIB and KU Leuven, Leuven, Belgium
Mutations in Pink1 cause a recessive form of Parkinson's disease. These mutations affect mitophagy in cell culture after CCCP depolarization. Interestingly in untreated cells these mutations lead to complex I deficiency which causes a mild depolarization of the mitochondria and a reduced ATP production. Similar observations in mouse brain, Drosophila and iPS cells from patients have led us to postulate that this role of PINK1 in complex I regulation is an early effect in patients. We have shown that Pink1 regulates NdufA10, a complex I component involved in ubiquinone reduction function. Intriguingly Pink1 is cleaved by the rhomboid PARL which resides at the inner membrane of the mitochondrium. PGAM5, a phosphatase, is a second substrate of PARL. PARL knock out mice show a massive neurodegeneration in their brain. We will present experiments that investigate the role of PARL processing of these kinase and phosphatase in the quality control of mitochondria.

[2]Louisiana State University, Pennington Biomedical Research Center, Baton Rouge, USA

Objectives: Neuroinflammation and failure in Abeta clearance are accepted as essential participants in sporadic Alzheimer's disease (AD) evolution. Human evidence suggests that the anti-inflammatory cytokine, interleukin-10 (*Il10*), is etiologically involved in AD. Our goal is to delineate the contribution of IL-10 pathway in AD-like pathology.
Methods: We analyzed IL-10 signaling in AD patient brains *post-mortem* using immunostaining and protein analyses. To determine the impact of *Il10* deficiency on AD, we crossed the APP/PS1 mouse model of cerebral amyloidosis with a mouse deficient for *Il10.* We used 3D confocal reconstruction *in silico* to quantify Abeta phagocytosis in *APP/PS1^{+}Il10$^{-/-}$* mouse brains, and genome-wide RNA sequencing to identify immune genes modulation. We analyzed mice cognitive alteration and measured synaptic damage by synaptophysin labeling. IL-10 effect on phagocytic capacity was examined *in vitro* by live imaging of *Il10$^{-/-}$* versus *Il10$^{+/+}$* primary microglia.
Results: We observed elevated IL-10 signaling in AD patient brains. *Il10* deficiency in APP/PS1 mice activated innate immune cells to restrict cerebral amyloidosis and modulated innate immune genes driving neuroinflammation. Synaptic integrity and cognitive deficits were partially restored. *In vitro*, IL-10 ablation endorsed microglial Abeta uptake into phagolysosomes, whereas IL-10 addition reduced Abeta phagocytosis. Conclusion: Our results suggest that elevated IL-10 signaling in AD patient brains inhibits microglial Abeta phagocytosis and blocking anti-inflammatory

pathways can stimulate microglia to clear Abeta without inducing neurotoxicity.

ADPD5-1205
ABCA7 MEDIATES MICROGLIAL CLEARANCE OF AMYLOID-BETA OLIGOMERS

W.S. Kim[1], J.H. Hsiao[1], G.M. Halliday[1]
[1]Ageing & Neurodegeneration, Neuroscience Research Australia, Sydney, Australia

Objectives: Genome-wide association studies indicate that ATP-binding cassette transporter A7 (ABCA7) is a strong risk factor for late-onset Alzheimer's disease (AD). We have previously demonstrated that deletion of ABCA7 in the J20 amyloidogenic mouse caused significant increases in insoluble amyloid-beta levels with concomitant increases in the number of amyloid-beta plaques in the hippocampus. ABCA7 has also been implicated in the role of phagocytosis. However, the mechanism by which ABCA7 reduces amyloid-beta load in the brain is unknown. In this study we investigated whether ABCA7 mediates microglial clearance of amyloid-beta oligomers.

Methods: We isolated the brain from ABCA7 knockout mice (n=6) and wild type littermates (n=6) following thorough perfusion with Hank's buffer. The whole brains were homogenized, filtered through cell strainer and cultured in flasks using L929 media. Following shaking the floating microglia were harvested and seeded onto chamber slides. They were then treated with FITC-labelled amyloid-beta40 (Ab40) and amyloid-beta42 (Ab42) oligomers, separately, and the uptake of Ab oligomers were analysed using fluorescence microscopy.

Results: The clearance of both Ab40 and Ab42 oligomers was significantly reduced (~50%) in ABCA7 null microglia compared to wild type microglia.

Conclusion: ABCA7 mediates microglial clearance of amyloid-beta oligomers, providing a pathogenic mechanism by which ABCA7 is implicated in AD neuropathology.

[3]MRC Biostatistics, Cambridge Institute of Public Health, Cambridge, United Kingdom
[4]Sheffield Institute for Translational Neuroscience, University of Sheffield, Sheffield, United Kingdom
Genetic risk factors for Alzheimer's disease (AD) recently identified imply that inflammation plays a causal role in AD. Using the MRC Cognitive Function and Ageing Study (CFAS), we investigated the role of microglia in human brain ageing and dementia.
Frontal cortex from 298 cases were analysed for CD68 (phagocytic activity); macrophage scavenger receptor (MSR)-A (plaque related), CD64 (Fcγ receptor I), Iba1 (resting and activated microglia), TREM2 (phagocytic vs proinflammatory microglial activity) and HLA-DR (antigen presenting function). All analyses were adjusted for age of death and sex.
Overall, MMSE was associated negatively with CD68 and HLA-DR and positively with CD64 and Iba1. Among the cases without dementia, associations were observed for: diffuse plaques with all markers except MSR-A which was strongly associated with neuritic plaques. HLA-DR and Iba1 were negatively associated with tangles. In the cases with dementia and AD pathology, CD64 was strongly associated with all neurodegenerative pathologies except tangles, CD68 with plaques and tangles, and MSR-A with neuritic plaques and tangles. HLA-DR was significantly related to plaques and tangles and Iba1 with increase in all neuropathological features. TREM2 recognized only monocytes/macrophages. With regard to the *APOE* polymorphism, ε2 was associated with expression of Iba1 and MSR-A and ε4 with CD68, CD64 and HLA-DR. These data suggest that microglia may respond differently to Aβ and tau in subjects with and without dementia so that the microglial response may influence the likelihood of developing dementia. Interestingly the findings also suggest that *APOE* polymorphism may influence the microglial profile.

[2]Department of Neurobiology Faculty of Life sciences, Tel Aviv University, Tel Aviv 769978, Israel

Parkinson's disease (PD) is a progressive neurodegenerative disorder that affects more than 1% of individuals over the age of 55. A pathological hallmark of PD is intercellular inclusions, which the main component is α-Synuclein (αSyn) protein. To date, 15 genes have been identified as related to PD. These gene mutations can cause both loss and gain of function in their respective proteins, and can result in autosomal recessive and autosomal dominant PD. Microglia activation in PD may result in neuronal cell death. DJ-1 is an oxidative stress sensor that localizes to the mitochondria. We discovered that down-regulation of DJ-1, as found in PD, in microglia, increased cell sensitivity to dopamine, as measured by secreted pro-inflammatory cytokines such as IL-1β and IL-6, and by the elevation of reactive oxygen species (ROS), which resulted in dopaminergic neuronal death. PTEN induced kinase 1(PINK1) has been shown to protect cells against oxidative stress-induced apoptosis. We discovered that down-regulation of PINK1 in microglia results in increased sensitivity to αSyn stimulation resulting in increased secretion of pro-inflammatory cytokines and neurotoxicity**.** Furthermore, we showed that DJ-1 and PINK-1 deficient microglia exhibited reduced autophagy, and impaired degradation of αSyn. Our results imply that DJ-1 and PINK1 deficiency mediates microglia dopaminergic neurotoxicity and affects their ability to phagocytose and to degrade αSyn. Further studies of PD gene-mediated cellular pathways in microglia may provide useful insights into the etiology of PD.

[3]Psychiatry, University of Florida, Gainesville, USA

Altered central nervous system (CNS) proteostasis, characterized by accumulation of extracellular or intracellular proteinaceous deposits, is thought to be a key trigger of many neurodegenerative disorders. There is considerable evidence that various assemblies of the aggregated proteins that form these inclusions can activate the innate immune system which, in turn, can contribute to the degenerative cascade. There is also growing evidence that alterations in innate immune signaling can play a key role in regulating proteostasis of key pathogenic proteins linked to neurodegenerative disorders. We term this complex interplay between the innate immune system and proteinopathy, immunoproteostasis. In a contextually dependent fashion, immunoproteostasis can have positive or negative effects on the proteinopathy and degenerative phenotype. Using our rAAV-based somatic brain and spinal cord transgenic technology, we have explored a number of paradigms to attempt to harness innate immunity for therapeutic benefit. We will present several examples of our preclinical studies showing both the potential and the challenges of our attempts to harness innate immunity for therapeutic benefit. Studies on Il-10 reveal that it is protective in SOD1 familial ALS mouse model, but harmful in APP and a-synuclein models. More recent studies using soluble Toll-like receptor Fc fusion proteins reveal the remarkable potential of these for therapeutic benefit in APP mouse models. In addition, we will discuss how novel theragnostic imaging methods might enable us to evaluate the effects of targeting innate immunity in the living brain.

ADPD5-2297
TREM2 REGULATES MICROGLIAL CELL ACTIVATION IN RESPONSE TO OLIGODENDROCYTE DAMAGE IN VIVO

K. Otero[1], C. Cantoni[2], B. Bollman[2], A.H. Cross[2], L. Piccio[2]
[1]Neuroimmunology, Biogen Idec, Cambridge, USA
[2]Neurology, Washington University School of Medicine, St Louis, USA

Microglia are phagocytic cells that survey the brain and perform neuroprotective functions in response to tissue damage, but their activating receptors are largely unknown. Triggering receptor expressed on myeloid cells 2 (TREM2) is a microglial immunoreceptor whose loss-of-function mutations in humans cause presenile dementia, while genetic variants are associated to increased risk of neurodegenerative diseases. In myeloid cells, TREM2 has been involved in the regulation of phagocytosis, cell proliferation and inflammatory responses *in vitro*. However, it is unknown how TREM2 contributes to microglia function *in vivo*. Here, we identify an essential role for TREM2 in the activation and function of microglia during cuprizone (CPZ)-induced demyelination.
TREM2-deficient (TREM2-/-) mice had defective clearance of myelin debris and more axonal pathology, resulting in impaired clinical performances compared to wild-type (WT) mice. TREM2-/- microglia proliferated less in areas of demyelination and were less activated, displaying a more resting morphology and decreased expression of the activation markers MHC II and iNOS as compared to WT. Mechanistically gene expression and ultrastructural analysis of microglia suggested a defect in myelin degradation and phagosome processing during CPZ intoxication in TREM2-/- microglia. These findings place TREM2 as a key regulator of microglia activation *in vivo* in response to tissue damage.

Symposium 50: RETROMERS IN AD AND PD

ADPD5-1073
MECHANISMS BY WHICH BY RETROMER TRANSPORTS APP VIA SORL1
O. Andersen[1]
[1]*Biomedicine, Aarhus University, Aarhus, Denmark*
Processing of the Amyloid precursor protein (APP) into the Amyloid beta-peptide is considered a major pathological event in the cascade that leads to onset of Alzheimer's disease (AD).
SorLA is a cargo receptor for the retromer complex, genetically and functional linked to Alzheimer's disease (AD). The gene encoding the sorLA protein (*SORL1*) is associated with early- as well as late-onset AD, and sorLA protein levels are decreased in brains from many AD patients.
We have initially identified sorLA as a sorting receptor for APP, where sorLA activity protects against the amyloidogenic cleavage of APP in cell cultures and neurons. A physiological role of sorLA in amyloidogenesis was later demonstrated, as sorLA deficiency accelerates and aggravates pathology in AD mouse models.
We have also shown that sorLA regulates the maturation and exit of APP from the Golgi in the secretory pathway, and that sorLA levels in these compartments are determined by the efficient retrieval from endosomes to the Golgi/TGN by interaction with the retromer complex.
Our recent studies have identified novel ways to regulate the intracellular levels of functional sorLA that is available to act in APP transport. SorLA carries complex glycosylations that actively determine shedding efficiency of the luminal receptor domain, thus having direct impact on functional sorLA activity in the cell. We have also identified a strong regulation of sorLA at the transcriptional level, and determined *cis*- and *trans*-regulatory elements that control the temporal and spatial expression profile of sorLA.

Symposium 50: RETROMERS IN AD AND PD

ADPD5-1884
GENETICALLY LINKING THE RETROMER CORE MOLECULE VPS35 TO PD
M.J. Farrer[1]
[1]*Medical Genetics, University of British Columbia, Vancouver, Canada*
A *de novo* mutation in vacuolar protein sorting 35 (VPS35 p.D620N), a core component of the retromer complex, was recently identified by exome analysis and linked to familial late-onset PD. More recently, in Canadian Mennonite families with late onset PD, a mutation was described in receptor-mediated endocytosis 8 (DNAJC13 p.N855S) by similar methods. The consequences of mutation to specific protein cargos in terms of altered intracellular trafficking to trans-Golgi network, lysosomes or the plasma membrane have yet to be elucidated. However, both knock-down and overexpression of VPS35 alters surface delivery of AMPA-type glutamate receptors and synaptic transmission. Retromer also plays an important role in governing the traffic and processing of proteins important to dementia, including SorLA, amyloid precursor protein and progranulin. Thus an overlapping pathway has emerged in some forms of parkinsonism and dementia, supported by unbiased genetic discovery. While most cargos and their fate have yet to be elucidated in neurons (let alone in the context of pathogenic mutations linked to disease) a model for retromer subunit interactions with the WASH-complex, receptor-mediated endocytosis 8 and sorting nexins has recently been described. Genetic analysis of these protein components will be reviewed.

Symposium 50: RETROMERS IN AD AND PD

ADPD5-1888
GENETICALLY LINKING SORL1 AND OTHER RETROMER RECEPTORS TO AD
R. Mayeux[1], B. Vardarajan[1], C. Reitz[1], Y. Zhang[2], C. Bohm[2], M. Ghani[2], E. Rogaeva[2], P. St George-Hyslop[3]

[3]MedicineUniversity of Toronto and Clinical Neurosciences,
Tanz Centre for Research in Neurodegenerative Diseases and Cambridge Institute fo r Medical Research, Toronto, Canada
Common single nucleotide polymorphisms in the *SORL1* gene have been associated with late onset Alzheimer's disease (LOAD) but causal variants have not been fully characterized nor has the mechanism been established. We conducted a combined family- and cohort-based genetic association study. Caribbean Hispanics with familial and sporadic LOAD and similarly aged controls recruited from the United States and the Dominican Republic, and patients with sporadic disease of Northern European origin recruited from Canada.
Prioritized coding variants in *SORL1* detected by targeted re-sequencing were validated by genotyping in additional family members and unrelated healthy controls. Variants were then transfected into human embryonic kidney 293 (HEK) cell lines and tested for Aβ40 and Aβ42 secretion and the amount of the amyloid precursor protein (APP) secreted at the cell surface.
We identified 17 coding exonic variants that were significantly associated with LOAD. Two rare variants (rs117260922-E270K and rs143571823-T947M) with MAF<1% and one common variant (rs2298813-A528T) with MAF=14.9% segregated within families and were deemed deleterious to the coding protein. Transfected cell lines showed increased Aβ40 and Aβ42 secretion for the rare variants (E270K and T947M) and increased Aβ42 secretion for the common variant (A528T). All mutants increased the amount of APP at the cell surface, though in slightly different ways, thereby failing to direct full-length APP into the retromer-recycling endosome pathway.
Common and rare variants in *SORL1* elevate the risk of LOAD by directly affecting APP processing which in turn can result in increased Aβ40 and Aβ42 secretion.

Symposium 50: RETROMERS IN AD AND PD

ADPD5-1890
THE CELL BIOLOGY OF RETROMER GENES IMPLICATED IN AD AND PD
M. Seaman[1]
[1]*Cambridge Institute for Medical Research, University of Cambridge, Cambridge, United Kingdom*
The Retromer complex is a conserved protein assembly that operates in endosomal protein sorting. Retromer is responsible for sorting membrane proteins into two distinct pathways: endosome-to-Golgi retrieval and endosome-to-cell surface recycling and its activity has been linked to the pathogenesis of Alzheimer disease (AD) through the role that retromer plays in controlling the localisation of the SorL1 protein that interacts with amyloid precursor protein (APP). Additionally retromer serves as a hub for recruiting additional endosomal sorting machinery to the membrane including the F-actin-promoting WASH complex.
A key element of the retromer complex is the VPS35 protein that, together with VPS26 and VPS29 forms the cargo-selective subcomplex. A point mutation in VPS35 has been shown to cause an inherited form of PD. I will report experiments from my lab that have investigated the effect of the PD-causing VPS35 mutation on the assembly of retromer and its association with accessory factors such as the WASH complex. Additionally I will report the results of a genome-wide RNAi screen for novel components of the endosome-to-Golgi retrieval pathway that has revealed an unexpected role for multi-pass membrane proteins in this pathway.

THE RETROMER TRANSPORT PATHWAY IN THE PATHOGENESIS OF PD
A. Abeliovich[1]
[1]*Pathology Cell Biology Neurology and Taub Institute, Columbia University, New York, USA*
Human genetic studies have linked mutations in over a dozen genes with rare familial forms of Parkinson's disease (PD). Furthermore, large-scale genome-wide association studies have implicated additional genetic loci in PD risk in the general population. We have pursued potential common mechanisms of action of such disease-associated mutations and common variants. Using a variety of strategies -- including the analysis of human brain transcriptome datasets, primary rodent neuron in vitro models, and model organism in vivo approaches -- our studies support a role for multiple PD-associated genetic loci within an essential cellular pathway that regulates intraneuronal protein trafficking through endosomes. Disease-associated forms of the LRRK2, RAB7L1, and VPS35 genetic loci appear to be associated with endolysosomal and retromer complex sorting defects. Taken together, these studies further implicate retromer and lysosomal pathway alterations in PD risk. We will present additional components of this putative disease pathway, based on cell and in vivo analyses.

RETROMER MEDIATES AMYLOID, TAU, AND MICROGLIA PATHOLOGY THROUGH SEPARATE MECHANISMS

S. Small[1]
[1]*Neurology, Columbia University Medical Center, New York, USA*

Retromer is an assembly of proteins that traffics and transports cargo out of endosomes. A range genetic and expression studies have implicated retromer in the pathogenesis of Alzheimer's disease (AD). Retromer dysfunction in the brain can lead to different but well-defined pathophysiological consequences. I will review these pathophysiological consequences and how each might be separately linked to core features of AD—amyloid accumulation, glia abnormalities, and tau toxicity.

Huntington's disease (HD) is caused by a genetically encoded pathological protein (mutant huntingtin (mHtt)), which is thought to exert its effects in a cell-autonomous manner where degeneration occurs within individual cells that carry the aberrant gene. Here, we investigated the hypothesis that mHtt is capable of spreading within cerebral tissue.
The brains of four patients with HD who received genetically unrelated fetal neural allografts at least a decade earlier were examined post-mortem. The presence of mHtt aggregates within the grafted tissue was confirmed using an array of techniques including microscopy, western immunoblotting and infrared spectroscopy, and a number of different antibodies targeting different epitopes of mHtt aggregates.
A number of mHtt protein aggregates were located within intracerebral allografts of striatal tissue in three of these HD patients. The mHtt+ aggregates were observed in the extracellular matrix of the genetically unrelated transplanted tissue while in the host brain they were localized in neurons, neuropil, extracellular matrix and blood vessels. In addition, peripheral immune cells in separate HD patients contained mHtt. There are a thus a number of non cell-autonomous mechanisms which could explain these observations including transynaptic propagation as well as hematogenous transport of mHtt, among others.
This is the first demonstration for the presence of mHtt in genetically normal and unrelated allografted neural tissue transplanted into the brains of HD patients. These observations raise questions on the importance of non-cell autonomous mechanisms of protein spread in genetic disorders of the CNS, and further provide new targets for the development of therapeutic strategies.

EXTRACELLULAR AND INTRACELLULAR EFFECTS OF LOW-N OLIGOMERS OF PRO-AGGREGANT TAU REPEAT DOMAIN (TAURD-DELTA K280)

S. Kaniyappan[1], R.R. Chandupatla[1], K. Tepper[1], J. Biernat[1], E.M. Mandelkow[1], E. Mandelkow[1]

[1]Neurodegeneration,

(1)German Centre for Neurodegenerative Diseases (DZNE) (2) Caesar Research Ce nter (3) Max-planck Institute for Metabolism Research (Hamburg outstation), Bonn, Germany

Objectives:

The repeat domain of Tau protein with the pro-aggregant mutation (TauRD-Delta-K280) induces toxicity in transgenic mice and organotypic hippocampal slice culture models (Sydow et al., JN 2011, Messing et al., NBA 2013). One current concept of Tau-mediated toxicity is that it is based on low-n oligomeric species, rather than higher aggregated forms. Therefore, we investigated structural and functional aspects of low-n oligomers of TauRD-DeltaK280.

Methods:

Recombinant TauRD-DeltaK280 oligomers were purified by hydrophobic interaction chromatography. Biophysical and structural characterization was performed by ThS, ANS, CD, AFM and DLS. Functional aspects of oligomers were investigated by MTT, LDH, ROS production and calcium assays. Protein transfection, FACS and western blotting were employed to investigate the role of low-n oligomers at intracellular space.

Results:

The TauRD-DeltaK280 oligomers have predominantly disordered structure (by ThS, CD), but reveal conformational changes compared with monomers (by ANS). AFM reveals globular shapes with sizes from 1.6-5.4 nm. The hydrodynamic radius of oligomers (~5.2 nm) is dominated by that of tetramers (DLS). In neurons, TauRD-DeltaK280 oligomers cause an increase in ROS production, elevation of intracellular calcium and synapse loss without affecting cell viability (MTT, LDH). Intracellular transduction of oligomers induces the aggregation of endogenous tau in SH-SY5Y cells.

Conclusions:

Extracellular applications of TauRD-DeltaK280 oligomers are toxic to the synapse. TauRD-DeltaK280 oligomers induce the aggregation of endogenous tau when present inside the neurons.

[4]Pathology, VU medical center, Amsterdam, Netherlands

[5]Clinical Chemistry, VU medical center, Amsterdam, Netherlands

Introduction

Alzheimer's disease (AD) is characterized by the presence of amyloid beta (Aβ) plaques and neurofibrillary tangles (NFT). SPPL2b is a novel enzyme that processes TNFα and BRI2, substrates involved in Aβ plaque and NFT formation. Since changes in BRI2 and TNFα were previously identified in early stages of AD, we have extensively characterized SPPL2b in human brain tissue from controls and AD patients at different stages and its relationship with plaques and NFT.

Methods

SPPL2b expression levels were quantified in post-mortem human hippocampus from AD patients (n=14) and age-matched controls (n=13) by western blot and immunohistochemestry. The relationship of SPPL2b with tau was evaluated by double immunohistochemistry and immunoprecipitation (IP) experiments.

Results

SPPL2b levels were 10-fold increased ($p < 0.0001$) in AD hippocampus compared to non-demented controls. SPPL2b increase strongly correlated to Braak stages ($r = 0.785$, $p < 0.0001$), started in early AD stages (Braak II-III) and showed a drastic increase from Braak III to IV, stages in which cognitive impairment starts. SPPL2b immunoreactivity was associated with both plaques and NFT and immunoprecipitation experiments revealed that SPPL2b is a novel tau binding protein.

Conclusions

We found a dramatic increase of SPPL2b in early stages of AD associated with tau pathology. SPPL2b processes BRI2 and TNFα, proteins involved not only in Aβ homeostasis but also in chronic inflammation and NFT formation. These data reveal a novel potential AD etiological factor that links Aβ plaques and NFT and thus forms a new promising target for disease modifying therapies.

[1]Neuroscience, UTMB, Galveston, USA
[2]Neurology, UTMB, Galveston, USA

Objectives:
As life expectancy and therefore, the amount of people living with neurodegenerative synucleinopathies rise, it is increasingly important that we find an effective prevention and treatment strategy. While Parkinson's disease (PD) and dementia with Lewy bodies (DLB) are characterized by the deposition of alpha-synuclein, multiple disease-causing proteins frequently overlap within a single disorder. Additionally, studies suggest that intermediate aggregates known as oligomers which form prior to fibrils are the true toxic species in disease. Previous work from our lab and others have shown that oligomeric tau and α-synuclein accumulate in disease and in mouse models. Here we directly investigate the relationship of the oligomeric species of both proteins with each other.
Methods:
We have evaluated brain tissue and isolated oligomers from PD and DLB patients and the A53T synucleinopathy mouse model using biochemical and immunohistochemical analysis with our novel antibodies for alpha-synuclein oligomers—F8H7 and Syn33—and for tau oligomers—T22. Immunotherapy studies using anti-tau oligomer monoclonal antibody (TOMA) in A53T mice are ongoing.
Results:
We found that both alpha-synuclein and tau oligomers are elevated in disease and in A53T mice compared to age-matched controls. Moreover, oligomers of tau and alpha-synuclein form "hybrid oligomers" in these patient brains and immunoprecipitated tau oligomer complexes contained α-synuclein oligomers and vice versa.
Conclusions:
Our results suggest that tau and alpha-synuclein oligomers may have a synergistic relationship, implicating tau oligomers in the progression of synucleinopathies. These studies suggest that TOMA may be a viable immunotherapeutic agent against pathological tau and alpha-synuclein in PD and LBD.

TAU MISSORTING AS PART OF GLUCOCORTICOID-TRIGGERED SYNAPTIC PATHOLOGY

I. Sotiropoulos[1], S. Pinheiro[1], J. Silva[1], C. Mota[1], J. Vaz-Silva[1], A. Veloso[1], V. Pinto[1], N. Sousa[1], J.J. Cerqueira[1]
[1]University of Minho, ICVS Institute Life and Health Sciences School, Braga, Portugal

Objectives: Despite mainly axonal protein, Tau is recently found in dendritic tree and spines where may interfere with synaptic structure and function. While sustained elevations in stress hormones, glucocorticoids (GCs), have been implicated in neurodegenerative mechanisms and we previously showed that stress and GC trigger Tau hyperphosphorylation, the exact cellular cascades and mechanisms underlying the GC-evoked dendritic remodeling and spine atrophy are poorly investigated. *Methods*: With the emerging idea that Tau may penetrate into the synaptic compartment, we monitored Tau dynamics and localization in hippocampus of GC-treated, 3-4 months old rats using both WB subcellular fractionation and electron microscope approaches followed by detailed 3-dimensional morphometric analysis of dendritic branches and spines. *Results*: We demonstrated that prolong GC administration resulted in dendritic remodeling and loss of specific spine categories in rats demonstrating Tau missorting to hippocampal synapses with the participation of specific phosphorylated Tau isoforms whereas GC impact on Tau phosphorylation state exhibit a clear subcellularly distinct pattern pointing to differential trafficking of Tau isoforms. *Conclusions:* These *in vivo* findings add to our limited knowledge about the underlying mechanisms of GC-evoked dendritic plasticity and spine atrophy implicating Tau missorting in mechanism(s) of synaptic damage, beyond Alzheimer's disease pathology.

HUNTINGTON'S DISEASE IS A TAUOPATHY: LESSONS FROM MICE MODELS

M. Gratuze[1], A. Noel[1], C. Julien[1], G. Cisbani[1], S.S. Hebert[1], F. Cicchetti[1], J.A. Parker[1], P. Samadi[1], E. Planel[1]

[1]CHU de Québec - Pavillon CHUL, Universite Laval, Quebec City, Canada

Aims: Huntington disease (HD) is an autosomal dominant neurodegenerative disorder caused by a polyglutamine expansion in the N-terminal region of the huntingtin protein. At the cellular level, HD is characterized by proteolytic cleavage, misfolding and aggregation of huntingtin. Aggregates of hyperphosphorylated tau proteins define a class of neurodegenerative disease called tauopathies. HD is not thought to be a tauopathy, but there are several articles reporting limited tau pathology in HD patients. These observations prompted us to hypothesized that HD pathology might promote tau hyperphosphorylation.

Methods: To test this hypothesis, we used two mice models of HD (R6/2, Q175), and analyzed tau phosphorylation before and after the onset of HD symptoms. We also used various cell models.

Results: We found that before the onset of HD symptoms, R6/2 mice presented a slight elevation of tau phosphorylation, while symptomatic mice displayed tau hyperphosphorylation at multiple tau phospho-epitopes. There was no activation of major tau kinases that could explain this observation, but we found that calcineurin/PP2B was downregulated in R6/2 mice. We observed similar changes in tau phosphorylation and calcineurin expression in Q175 mice. Calcineurin was also reduced in Q111 compared to Q7 cells. Finally, pharmacological or genetic inhibition of endogenous calcineurin was sufficient to promote tau hyperphosphorylation in neuronal cells.

Conclusion: Taken together, our data suggest that, in R6/2 and Q175 mice, mutant huntingtin lead to deregulation of calcineurin and consequent tau hyperphosphorylation, and that the mild tau pathology seen in HD might, to some extent, stem from impaired calcineurin regulation.

FUNCTIONAL CHARACTERIZATION OF NEW N-TERMINALLY TRUNCATED TAU FRAGMENTS UNDERLINES THE ROLE OF N-TERMINAL REGION OF TAU IN MICROTUBULE STABILIZATION

M. Hamdane[1], M. Derisbourg[1], C. Leghay[1], G. Chiappetta[2], F. Fernandez-Gomez[1], C. Laurent[1], D. Demeyer[1], S. Carrier[1], V. Buée-Scherrer[1], D. Blum[1], J. Vinh[2], N. Sergeant[1], Y. Verdier[2], L. Buée[1]

[1]Alzheimer & Tauopathies, UMR 837 Inserm-Université Lille 2-CHRU, Lille Cedex, France

[2]USR 3149, CNRS / ESPCI ParisTech, Paris, France

Objectives: Tau is a microtubule-associated protein involved in the regulation of microtubule dynamics and its related functions in neurons. Alzheimer's disease (AD) is characterized by the occurrence of abnormal post-translational modifications of Tau proteins, including the truncation, which can result in either a loss of function or a gain of toxic function. A major step forward in understanding of the role of Tau truncation would be to identify the precise cleavage sites of the several truncated Tau fragments that are observed in AD brains, especially those at N-terminus which are less characterized than those truncated at C-terminus.

Methods: Tau proteins were immunoprecipitated from human brain samples and subjected to primary amines labeling using a covalently linked biotin prior to enzymatic digestion. Peptides were then purified on streptavidin column and identified using LC-MS/MS. Expression vectors containing coding sequences of truncated-Tau were generated and used in cell-based assays. Effects on microtubules were mainly analyzed by biochemical studies.

Results: We have identified several new N-terminally truncated Tau species in the human brain, with N-terminal residues located throughout the Tau sequence. Our cell-based assays showed that the ability of Tau to bind and stabilize microtubules was greater when N-terminal region of Tau is truncated.

Conclusions: Our cell-based assays suggest that N-terminal region of Tau could directly affect microtubule dynamics. Future studies based on our new N-terminally truncated-Tau species will provide new knowledge on the role of truncation in Tau biology as well as in AD pathological process.

Symposium 54: TAU BIOLOGY AND DISEASE MECHANISMS 3

ADPD5-0722
ROLE OF GSK3 AT EACH STEP OF THE DENTATE GYRUS NEUROGENESIS. POSSIBLE CONSEQUENCES IN ALZHEIMER DISEASE

J. Avila[1], M. Llorens-Martin[1], J. Jurado-Arjona[1], A. Fuster-Matanzo[1], N. Pallas[1], F. Hernandez[1]
[1]CSIC-UAM, Centro de Biologia Molecular Severo Ochoa, Madrid, Spain

Alzheimer disease (AD) is characterized by the presence of two aberrant structures: tau and beta amyloid (Aβ) aggregates. Both components (Aβ and tau) play a role in the disease and one connection between both is through GSK3, a kinase that is activated by Aβ and modifies tau.
Adult neurogenesis at the dentate gyrus is related to the appearance of new episodic memories, memories that are impaired in Alzheimer disease.
In this work, we have analyzed, using different models of genetically modify mice, the effect of a GSK3β overexpression, at the dentate gyrus, at different steps of that adult neurogenesis. It seems that tau may play a role in the GSK3 overexpression effect on dentate gyrus adult neurogenesis. Changes in GSK3 activity taken place in AD patients could result in an impairment of adult neurogenesis.

INVESTIGATING THE FUNCTION OF MICROTUBULE-ASSOCIATED PROTEIN TAU (MAPT) AND ITS GENETIC ASSOCIATION WITH PARKINSON'S USING HUMAN IPSC-DERIVED DOPAMINE NEURONS

J.E. Beevers[1], H. Booth[1], F. Zambon[1], J. Vowles[2], S.A. Cowley[2], R. Wade-Martins[1], T.M. Caffrey[1]

[1]Department of Physiology Anatomy and Genetics, University of Oxford, Oxford, United Kingdom

[2]Sir William Dunn School of Pathology, University of Oxford, Oxford, United Kingdom

OBJECTIVES

The microtubule associated protein tau (*MAPT*) locus is highly associated with Parkinson's (PD); however, the mechanisms underlying susceptibility remain unclear. We propose that polymorphisms within the *MAPT* haplotype sequence have functional consequences on *MAPT* expression and tau protein function in the dopamine neurons notably lost in PD. To examine this we chose the following objectives:

- To investigate allele-specific regulation of tau expression in iPSC-derived dopamine neurons.
- To investigate the physiological role of tau in axonal transport by perturbing tau expression.

METHODS

Induced pluripotent stem cells derived from healthy heterozygous (H1/H2) donors were differentiated into midbrain-type neuronal cultures. Dopamine neurons were isolated using rapid fixation immunostaining for tyrosine hydroxylase (TH) followed by fluorescence-activated cell sorting and RNA extraction. For tau perturbation, RNAi targeting specific isoforms or total tau was designed, with initial knockdown performed in neuroblastoma cells.

RESULTS

Transcripts of *TH* were >7-fold enriched in FACS-isolated neurons and mature *MAPT* isoforms (exon 3+ or 10+) were detected with extended culture. siRNA-mediated specific knockdown of exon 3+ (~60%) or exon 10+ (~90%) *MAPT* isoforms was achieved. Isoform-specific and total *MAPT* shRNA sequences were incorporated into lentivirus plasmids for delivery to neuronal cultures, in addition to those expressing fluorescent amyloid precursor protein for imaging of live axonal transport.

CONCLUSIONS

Examining haplotype-specific tau expression and function for the first time in dopamine cultures allows us to understand the effect of haplotype on tau protein in the neurons that degenerate in PD, and to identify therapeutic targets to reduce progression beyond disease's earliest signs.

CELL TYPE-SPECIFIC TAU PATHOLOGY IN PS19 MICE FOLLOWING INTRACEREBRAL INJECTIONS OF PATHOLOGICAL TAU FROM ALZHEIMER'S DISEASE OR CORTICOBASAL DEGENERATION BRAINS

S. Boluda[1], M. Iba[1], B. Zhang[1], K.M. Raible[1], V.M. Lee[1], J.Q. Trojanowski[1]
[1]Center for Neurodegenerative Disease Research Institute on Aging Department of P athology and Laboratory Medicine,
University of Pennsylvania Perelman School of Medicine, Philadelphia, USA

Objective:
Intracellular tau inclusions are the hallmark lesions of tauopathies, a group of diseases that include Alzheimer's disease and corticobasal degeneration, which show distinct topographic and cell type-specific distribution of tau. Recent studies suggest that tau transmits through synaptically connected pathways and that different strains of tau could account for the diverse manifestations of tauopathies. Our aim was to investigate the differential induction and spread of tau pathology in PS19 transgenic mice after intracerebral injection of human brain derived extracts from Alzheimer's disease (AD) and corticobasal degeneration (CBD).
Methods:
We injected enriched pathological tau human extracts from AD and CBD brains into cortex and hippocampus of young PS19 tau transgenic mice (n=24) and analyzed the resulting tau pathology at 1mo, 3mo and 6mo after injection.
Results:
At 1 mo postinjection CBD injected mice showed tau inclusions in oligodendrocytes of fimbria and external capsule near the injection site with infrequent intraneuronal inclusions. In contrast, AD injected mice showed abundant intracellular tau pathology in neurons of the hippocampus without involvement of oligodendrocytes. With prolonged time postinjection pathology increased in intensity and spread to distant regions of the brain. Additionally, AD injected mice showed neuronal loss in CA3 at 3 mo after injection.
Conclusion:
We present mouse models of CBD-like and AD-like tauopathies that rapidly develop distinct glial and intraneuronal tau inclusions, respectively, recapitulating the human counterpart that will provide systems for studies on transmission of tau pathology, tau mediated neurodegeneration and development of disease-modifying therapies for CBD and AD.

[2]Molecular Imaging Research Center (MIRCen),

Atomic Energy Commission (CEA) Institute of Biomedical Imaging (I2BM), Fontenay-aux-Roses, France

1. Objectives

Six tau isoforms with either 3 or 4 microtubule-binding domains (3R or 4R) are expressed in the human brain. They are generated by alternative splicing. Such Tau splicing is defective in fronto-temporal dementia exhibiting some MAPT (tau gene) mutations (FTDP-17). Moreover, these 3R and 4R Tau isoforms differentially aggregate among Tauopathies (3R in Pick's disease, 4R in progressive supranuclear palsy and 3R+4R in Alzheimer's disease). Finally, there is a progressive and hierarchical propagation of Tau pathology in some sporadic tauopathies. In the present work, we analyzed how Tau isoforms and/or FTDP-17mutations act on the propagation of tau pathology.

2. Methods

We took advantage of a lentiviral rat model of tauopathy developed in our team to overexpress either 3R or 4R isoforms in the hippocampus. The propagation of tau pathology was analysed by immunohistochemistry and tau secretion by ELISA tau quantification in cerebro-spinal and interstitial fluids.

3. Results

We demonstrated that Tau isoforms are differentially transferred from the hippocampus to trans-synaptically connected regions. In fact, 4R-Tau is more prone to propagate than 3R-Tau. Such observations are correlated to a dramatic decrease of 3R-Tau secretion in biological fluids compared to 4R-Tau. Interestingly, these observations are also seen when FTDP-17 mutations are present either in 3R or 4R-Tau.

4. Conclusions

Tau isoforms with or without FTDP-17 mutations display differential spreading properties that may participate to various phenotypes associated to specific tauopathies.

[2]Institute for Structural Neurobiology, ZMNH Center for Molecular Neurobiology, Hamburg, Germany

Objectives:

An inducible mouse model expressing the Tau repeat domain (Tau_{RD}) with the pro-aggregant mutation delta-K280 was used to analyze consequences of Tau aggregation on presynaptic function in the hippocampus.

Methods:

We used aged mice either expressing a pro-or anti-aggregant variant of Tau_{RD} and Tau knockout animals. Additionally we used organotypic hippocampal cultures, transiently transfected hippocampal cell-cultures and N2a cells.

Results:

Expression of pro-aggregant Tau_{RD} leads to phosphorylation, aggregation and missorting of Tau in area CA3 and the dentate gyrus. To test presynaptic pathophysiology we used electrophysiology in the mossy fiber tract. Synaptic transmission was severely decreased in pro-aggregant Tau_{RD} and knockout mice. Long-term depression of the mossy fiber tract failed in 12 month old pro-aggregant Tau_{RD} mice, but not at an age of 2 month. In 12 month old mice we observed an increase in bouton size, but a decline in numbers and presynaptic markers. Both pre- and postsynaptic structural deficits are preventable by inhibition of Tau_{RD} aggregation. Calcium imaging revealed progressive, pathological calcium dysregulation in boutons of pro-aggregant Tau_{RD} slice cultures. In N2a cells we observed the same effect even in cells without tangle load. In primary hippocampal cells transient Tau_{RD} expression had a similar effect. By ultrastructural analysis we observed a depletion of the presynaptic vesicle pool leading to impairment of synaptic function together with calcium dysregulation and structural changes.

Conclusions:

We conclude that oligomer -formation during Tau_{RD} aggregation causes pre- and postsynaptic deterioration and plasticity deficits by dysregulation of activity-dependent calcium dynamics.

M2 MICROGLIA ARE NECESSARY AND SUFFICIENT FOR ABETA PLAQUE REDUCTION DURING NEUROINFLAMMATION

J. Cherry[1], J. Olschowka[2], M.K. O'Banion[2]
[1]Pathology and Laboratory Medicine, University of Rochester, Rochester, USA
[2]Neurobiology and Anatomy, University of Rochester, Rochester, USA

Objectives
Neuroinflammation has long been considered a driver of Alzheimer's disease progression. However, experiments developed to explore the interaction between neuroinflammation and AD pathology showed a surprising reduction in Abeta plaque deposition. We sought to understand this unexpected outcome by examining microglial phenotypes using multiple mouse models of chronic neuroinflammation.
Methods
Mice in the first chronic inflammation model harbored a cre-activated human IL-1beta transgene driven by the mouse GFAP promoter. The second model used an adeno associated virus vector carrying a human IL-1beta cDNA to transduce mice. Inflammation was induced in one hippocampus of 8-month-old APP/PS1 mice for 4 weeks, while the other hemisphere received a control injection. The alternatively activated M2 marker Arginase 1 was used to observe the presence of M2 cells and cellular uptake of Abeta was demonstrated by confocal microscopy. Injections of interleukin-4 were used to specifically induce M2 cells and a mini-pump and intra-hippocampal cannula was used to deliver an IL-4Ralpha antibody to block M2 induction.
Results
We observed a robust activation of Arginase 1+ M2 microglia in areas of chronic inflammation and interestingly these cells were shown to contain Abeta. When IL-4 was used to specifically induce M2 microglia, there was significant plaque reduction. Conversely blocking M2 microglia during chronic inflammation impaired plaque clearance.
Conclusions
Together these findings demonstrate that M2 microglia are necessary and sufficient for Abeta plaque reduction during neuroinflammation, opening up possible avenues for immunomodulatory therapy of AD.
This research was supported by NIH/NIA grant RO1AG030149

[2]Center for Neurologic Diseases,
Brigham and Women's Hospital and Harvard Medical School, Boston, USA
[3]Department of Neurobiology, Stanford University School of Medicine, Stanford, USA

1. Objectives: Region-specific synapse loss is an early hallmark of Alzheimer's disease (AD); however, mechanisms behind synapse dysfunction remain unclear. Recent work has identified unexpected roles for an immune pathway—proteins of the classical complement cascade, C1q and C3, and microglia—for elimination and refinement of synaptic connections in the healthy developing mouse brain. Interestingly, AD brains have highly increased levels of complement and certain complement cascade interactors have emerged as AD susceptibility genes. We hypothesized that similar developmental synapse pruning mechanism may drive synapse loss in early stages of AD.
2. Methods: Using *in vivo* high and super resolution imaging, we determined levels of complement and their co-localization at synapses in J20 and APP/PS1 transgenic brains and in an acute *in* vivo model of Aβ oligomer synaptotoxicity. To test whether complement is necessary for Aβ-induced synapse loss, we utilized mice lacking C1qA or C3 and also generated APP/PS1 mice lacking C3. Finally, we developed an assay to measure microglial engulfment of hippocampal synapses *in vivo*.
3. Results: We found a region-specific upregulation and deposition of complement onto synapses well before pathological phenotypes in J20 and APP/PS1 mice and in wildtype mice injected with soluble Aβ oligomers. Microglia in oligomer-injected mice engulfed more synapses vs. monomer-injected. Importantly, genetic deletion of complement protected against synapse loss in these models.
4. Conclusions: Our results suggest that aberrant reactivation of a normal developmental pruning pathway helps mediate early synapse loss in pre-plaque brains, marking an important step in the development of AD synaptic pathology.

T CELL EXTRAVASATION IN ALZHEIMER'S DISEASE: EVIDENCE FROM TRANSGENIC MOUSE MODELS AND POST-MORTEM HUMAN MATERIAL

M.T. Ferretti[1], M. Merlini[1], C. Gericke[1], R.M. Nitsch[1]
[1]Division of psychiatry research, University of Zurich, Schlieren, Switzerland

Objectives. A mounting body of evidence indicates a key role for inflammation in Alzheimer's disease (AD); however, little is known on the involvement of the adaptive immune system. Here, we have performed a systematic study of T cell occurrence in brains from APP transgenic mouse models and post-mortem human AD material.
Methods. CD3-positive T cells were studied via bright field and confocal microscopy in brains from APP-overexpressing mice. Total, intra- and extravascular T cells were quantified from confocal stacks of 100 mm-thick sections. The expression of the adhesion molecules VCAM1 and ICAM1 was investigated using specific monoclonal antibodies. Furthermore, T cell presence was studied in post-mortem human AD and control brains.
Results. Clusters of CD3-positive cells were observed in the brains of all APP-overexpressing models examined. While intravascular counts were not different between transgenic and control animals, extravascular cells were significantly increased in SweArc transgenic mice. No correlation was observed with parenchymal plaques, but several amyloid-laden vessels were accompanied by CD3 cells. Supporting a role for vascular permeability in T cell extravasation, both ICAM1 and VCAM1 were found to be upregulated in brains from APP transgenic mice. T cells were also increased in the hippocampus of AD post-mortem brains, but not in the mid frontal gyrus.
Conclusions. Our results suggest that T cells infiltrate brains affected by AD pathology, likely due to increased vascular permeability. Extravasated T cells could cross-talk with and modulate cells of the CNS. The role of T cells in AD remains to be elucidated.

GENERATION OF AN IMMUNE-DEFICIENT MODEL OF ALZHEIMER'S REVEALS A CRITICAL ROLE FOR THE ADAPTIVE IMMUNE SYSTEM IN DISEASE PATHOGENESIS

S.E. Marsh[1], S.T. Yeung[2], J.G. Weinger[3], T.E. Lane[4], J.L. Davis[2], M. Blurton-Jones[1]

[2]Institute for Memory Impairments and Neurological Disorders, University of California Irvine, Irvine, USA
[3]Molecular Biology & Biochemistry, University of California Irvine, Irvine, USA
[4]Molecular Biology, University of Utah, Salt Lake City, USA

Objectives:

The innate immune system is strongly implicated in Alzheimer disease (AD) pathogenesis. In contrast, very few studies have examined the potential role of the adaptive immune response in this disorder. The extensive testing and clinical assessment of beta-amyloid vaccination strategies has only further heightened the need to better understand the relationships and interplay between the adaptive immune system and AD neuropathology.

Methods:

To address this issue, we generated a novel immune-deficient transgenic AD model by backcrossing 5xfAD mice onto a Rag2-/- il2r-gamma-/- double knockout background. The resulting line, termed Rag-5xfAD mice, lacks B-cells, T-cells, and Natural Killer (NK) cells but overexpress mutant forms of both amyloid precursor protein and presenilin-1.

Results:

While Rag-5xfAD mice replicate many of the salient neuropathological features observed in immune-competent 5xfAD mice, disease pathogenesis is significantly accelerated by the loss of these peripheral immune populations. Levels of both soluble and insoluble beta-amyloid, are almost doubled in Rag-5xfAD mice versus strain-matched immune-competent transgenics. Likewise, AD-associated increases in several pro-inflammatory cytokines are also exacerbated by the deletion of T-, B-, and NK-cell populations. Interestingly, changes in microglial number and reactivity are also detected, suggesting that the adaptive immune system could influence AD at least in part by modulating the innate immune response.

Conclusions:

Taken together, our data reveal that T, B, and NK-cells significantly impact the progression of AD pathogenesis and neuroinflammation. These studies also suggest that peripheral immune health and interactions between adaptive and innate immune systems could dramatically influence the development and progression of AD.

Variants in the *Triggering Receptor Expressed on Myeloid cells 2* (*TREM2*) gene confer risk for Alzheimer's disease (AD), as well as Nasu-Hakola disease, frontrotemporal dementia, Parkinson's disease and amytrophic lateral sclerosis. Therefore, because TREM2 appears to play a central role in numerous age-related neurodegenerative conditions, understanding more about TREM2 biology promises to provide novel avenues for targeting neuroinflammation as a basis for novel neurodegenerative disease therapeutics. The current study examines the role of TREM2 in AD, and specifically demonstrates that loss of function for TREM2 in mouse models of AD alters amyloid-assoicated plaque pathology, with reduced β-amyloid (Aβ) deposition, diminished reactive astrocytosis, reduced phosphorylation of microtubule-associated protein tau (MAPT), lower expression of pro-inflammatory mediators and enhanced expression of some genes associated with alternative macrophage activation. To address mechanisms linking TREM2 loss of function to altered Aβ-plaque pathology, we characterized TREM2 expression. TREM2 is strongly expressed on myeloid cells surrounding Aβ deposits in both AD-autopsy brain sections and mouse models of amyloid deposition. Based on cell surface marker expression, TREM2 positive plaque-associated macrophages are largely derived from peripheral monocytes rather than brain-resident microglia. TREM2 loss of function eliminates association of these macrophages with Aβ deposits. Taken together, these surprising findings suggest that TREM2 is critical for accumulation of infiltrating peripheral monocytes around Aβ deposits and that TREM2 positive cells may promote Aβ-related inflammatory pathologies. These findings document a unique and largely unexpected role of TREM2 in AD and provides an important basis for development of TREM2-directed therapies.

IMAGING INFLAMMATION AND ITS ROLE IN NEURODEGENERATION
D.J. Brooks[1]
[1]*Medicine, Imperial College London, London, United Kingdom*
Microglia comprise around 15% of white cells in the brain and are normally in a resting state monitoring the brain milieu. Any injury to the brain results in microglial activation which provides a marker of disease activity. The function of activated microglia can be both detrimental and beneficial depending on the phenotype. Microglia with the M1 phenotype release cytokines which may drive disease progression. M2 microglia become intrinsic macrophages, express restorative growth factors, help clear cellular debris and abnormal protein aggregations, and re-model connections as an adaptive response to brain damage. In practice the two phenotypes are inter-convertible. All activated microglia express translocator protein (TSPO) on their mitochondrial membrane and M2 type express surface cannabinoid CB2 sites which allows their presence be imaged in vivo with positron emission tomography (PET) radioligands. In this talk the different approaches to microglial imaging will be detailed snd the different patterns of microglial imaging in Parkinsonian disorders, dementias, and other neurodegenerative and inflammatory brain diseases will be presented. The value of suppressing microglial activation and possible strategies to achieve this will be debated.

[7]GPORWE, Eli Lilly and Company Limited, Windlesham, United Kingdom

Objectives: Disease progression definitions of a meaningful magnitude related to cognition and functioning in Alzheimer's disease (AD) were evaluated using costs and caregiver outcomes.
Methods: GERAS is an 18-month European observational study of costs associated with AD which enrolled patients with Mini-Mental State Examination (MMSE) ≤26. Data collected at baseline and 6-month intervals included MMSE, Alzheimer's Disease Cooperative Study – Activities of Daily Living (ADCS-ADL) (baseline and 18-months only), Resource Use in Dementia and Zarit Burden Inventory (ZBI). Health and social care resource use and caregiver time spent on informal care were used for cost estimation. The literature suggests the following meaningful changes in disease progression: (1) cognitive progression - a worsening of ≥3 MMSE points and (2) functional progression - decline in either ≥1 basic ADL item or >20% instrumental ADL items. Generalized linear models adjusting for disease severity, sex, country and baseline score provided estimates of the difference in total societal costs, total caregiver hours, caregiver supervision hours and ZBI total score associated with progression.
Results: N=1495 patients were included in these analyses. Cognitive progression/non-progression was found in 44%/45% (11% missing) and functional progression/non-progression in 48%/17% (35% missing) patients. Functional progression had the largest association with total societal cost (40% increase) and total caregiver hours (45% higher), as well as caregiver burden (greater total mean 5.4). Greater caregiver supervision time was associated with cognitive progression (30% increase).
Conclusion: The present analyses suggest that these literature-derived thresholds of disease progression are associated with meaningful increased costs and care needs.
This study is sponsored and funded by Eli Lilly and Company Limited.

Symposium 01: ADVANCED CHARACTERIZATION OF EARLY DISEASE STAGE

ADPD5-1001
IMPROVING DIAGNOSTIC ACCURACY IN ALZHEIMER'S DISEASE CLINICAL TRIALS

T. Babic[1], H.J. Riordan[2], G. Vucinic[1], A. Carta[1], J. Sramek[3], M.F. Murphy[2], N.R. Cutler[3]
[1]Medical and Scientific Affairs, Worldwide Clinical Trials, London, United Kingdom
[2]Medical and Scientific Affairs, Worldwide Clinical Trials, King of Prussia, USA
[3]Medical and Scientific Affairs, Worldwide Clinical Trials, Beverly Hills, USA

Objectives: Many reasons have been suggested for the recent failures of confirmatory randomized clinical trials (RCT) of drugs for Alzheimer's disease (AD), the most salient being variable diagnostic accuracy. For clinical trials, the diagnosis of AD should be made based on published clinical criteria, documented progression of cognitive decline, and neuroimaging data congruent with a diagnosis of AD. Unfortunately, evidence of progressive cognitive decline in clinical studies is typically neglected and neuroimaging confirmation of AD is often lacking. Poor diagnostic accuracy may produce less than expected cognitive decline with placebo treatment, thereby reducing the perceived efficacy of an active comparator compound. Our objective was to review the accuracy of AD diagnoses in completed clinical trials from external sources and suggest areas for improvement.
Methods: We have provided examples from a series of controlled AD clinical trials from external sources, identifying the most common pitfalls in study enrollment and execution, and presenting techniques to increase diagnostic accuracy and study validity.
Results: The lack of evidence of progressive cognitive decline appears to be the most frequent challenge in current clinical studies. Only a few protocols specifically requested evidence of cognitive deterioration prior to baseline as an inclusion criterion.
Conclusions: Clinical diagnosis of AD among screening subjects in RCTs needs to be carefully evaluated before study participation. We propose integrating centralized eligibility randomization services, focused on diagnoses congruent with protocol-specific criteria, and driven by medical experts, as one potential solution to this problem.

[6]Department of Public Health, University of Helsinki, Helsinki, Finland
[7]Department of Neurology, University of Eastern Finland, Kuopio, Finland

Background: Observational studies indicate that vascular and lifestyle-related risk factors are associated with risk of cognitive impairment and Alzheimer's disease. The Finnish Geriatric Intervention Study to Prevent Cognitive Impairment and Disability (FINGER) is a randomized controlled trial (RCT) investigating whether a multidomain intervention will prevent cognitive impairment. Here we report the main results on cognition after 2 years of intervention.
Methods: FINGER study is a 2-year multicentre randomized controlled trial with 1260 participants aged 60-77 years recruited from previous population-based non-intervention studies. The inclusion criteria were CAIDE dementia risk score $\geq$6 indicating presence of modifiable risk factors, and cognitive performance at the mean level or slightly lower than expected for age. The participants were randomized (1:1) into multidomain intervention consisting of nutritional guidance, exercise, cognitive training, and monitoring of vascular risk factors and control groups. Primary outcome is cognitive performance measured by a comprehensive neuropsychological test battery (NTB) Z score. Linear mixed-model analyses were used.
Results: In the intention-to-treat analyses we found a significant beneficial intervention effect on cognitive performance. The modelled difference between groups (intervention minus control group) in the change of NTB total score per year was 0.022 (95 % confidence interval [CI] 0.002 to 0.042). Drop our rate was only 12.1 %, and adverse events were very few and mild.
Conclusions: This is the first large RCT showing that it is possible to prevent cognitive decline among older at-risk individuals. The results highlight the value of the feasible and effective novel multidomain approach for several cognitive domains.

Symposium 01: ADVANCED CHARACTERIZATION OF EARLY DISEASE STAGE

ADPD5-1761

RELEVANCE OF RHYTHMIC AUDITORY STIMULATION IN FREEZING GAIT FOR PARKINSON'S DISEASE PATIENTS

J. Touchon[1], S. Teissier[1], S. Dalla Bella[1]
[1]Neurology, Universite Montpellier I, Montpellier, France

Objective

The aim of this word was to compare several auditory stimulation modalities during freezing gait episodes in Parkinson's disease.

Methods

43 patients (22 women and 21 men), mean age 77.3 years with idiopathic PD during the fluctuating stage were included in the study. Mean UPDRS score was 33.3. The study was conducted in patients during their OFF period. The LTeM system was used to detect freezing gait, which allowed to apply the auditory stimulation to the patient right from the detection moment.

Four conditions were studied:

Condition A: right from freezing detection: vocal command "stop" followed 10 seconds later by the vocal command "walk".

Condition B: right from freezing detection: vocal command "walk"

Condition C: condition A followed by 19 rhythmic auditory stimuli based on the patient's spontaneous gait pattern during the ON period.

Condition D: Condition B followed by 19 rhythmic auditory stimuli based on the patient's spontaneous gait pattern during the ON period.

The effects of the four conditions on the 3 gait parameters: mean Inter Step Interval (ISI), variation coefficient of mean ISI and number of steps performed without freezing were studied.

Results

Condition C was significantly different from the other three for all 3 gait parameters: greater number of steps, increased mean ISI and lower variation coefficient of the mean ISI.

Conclusion

Using a specific system to detect gait freezing and applying auditory stimulation of 19 stimuli after 10 seconds after having stopped walking could improve gait conditions in patients in advanced stages of PD.

[3]School of Ageing Studies, University of South Florida, Tampa, USA

Alzheimer disease (AD) is considered to be a continuum ranging from preclinical stages, over mild cognitive impairment (MCI) to dementia syndrome. Biomarker-based diagnostic approach may have a limited worldwide utility beyond specialized memory clinics, therefore a growing research interest is focused to identify the first patients' subjective complaints or objective clinical symptoms. Subjective memory complaints (SMC) may occur independently of objective cognitive impairment and precede MCI syndrome. SMC comprise heterogenic group of symptoms, and SMC subjects have various risk of AD. The effort is to investigate predictive value of SMC for AD by analyzing specific complaints and questionnaires. Previously, we have reported that spatial navigation (SN) is similarly impaired in MCI and in early AD subjects, and that SN has been associated with hippocampal atrophy and certain ApoE4 and TOMM40 genotypes. We investigate the association of subjective SN complaints with objective SN performance, neuropsychology and brain volumetry in SMC and MCI subjects. Our data suggest that a specific question may be a useful screening tool for exploring difficulties with SN, the skill, which is impaired very early in the course of AD. This question may help to differentiate SMC subjects with anxiety and depression from those at risk of AD. Screening and timely diagnosis of AD outside of specialized memory clinics at the level of family or primary care physicians would require reliable, inexpensive and less time consuming screening tool. Subjectively reported symptoms, including SN complaints, may guide further decision making on patients at risk of AD.

Symposium 01: ADVANCED CHARACTERIZATION OF EARLY DISEASE STAGE

ADPD5-2311
INFORMATION AND COMMUNICATION TECHNOLOGIES FOR THE ASSESSMENT AND THE TREATMENTS OF NEURODEGENERATIVE DISEASES

P.H. Robert[1]
[1]*EA CoBTeK / IA, University of Nice Sophia Antipolis, France,2 Centre Mémoire de Ressources et de Recherche, CHU de Nice, Nice, France*

Alzheimer disease (AD) and other related dementia represent a major challenge for health care systems within the aging population. It is therefore important to develop better instruments for assessing disease severity and disease progression to optimize patient's care and support to care providers, and also provide better tools for clinical research. In this area, Information and Communication Technologies (ICT) are of particular interest. Such techniques enable accurate and standardized assessments of patients' performance and actions in real time and real life situations. ICT may also help to improve non-pharmacological approaches, stimulation and rehabilitation. The aims of this presentation are to systematically analyze the strengths, weaknesses, opportunities, and threats of employing ICT for assessment, stimulation in AD and other related disorders. This is also the occasion to provide recommendations for the use of ICT in clinical research. This will be illustrated by results coming from EU FP7 program (Dem@Care, VERVE, InMindd) and the from the French Azgame program.

Symposium 03: PROFILING DLB, PD AND FTD

ADPD5-0300
PROSPECTIVE ANALYSIS OF CLINICAL SYMPTOMS IN PRODROMAL DLB: THE NEWCASTLE LEWYPRO STUDY

A.J. Thomas[1], P. Donaghy[1], J.P. Taylor[1], I.G. McKeith[1], J.T. O'Brien[2]
[1]Newcastle University, Institute of Neuroscience, Newcastle upon Tyne, United Kingdom
[2]Cambridge University, Psychiatry, Cambridge, United Kingdom

Objectives
In DLB the underlying synucleinopathy develops over years before clinical symptoms and involves not only the brain but extracranial elements of the nervous system. Thus, unlike Alzheimer's disease, DLB as a synucleinopathy characteristically has a wide range of non-cognitive (including motor, neuropsychiatric, autonomic, sleep) symptoms and these frequently begin before the dementia phase of the illness. Previous studies examining symptoms in people who progressed to DLB have been retrospective and prospective analyses are needed to develop very early diagnostic criteria to identify prodromal disease.
Methods
The LewyPro study is a clinical cohort study conducted in the North East of England to prospectively assess a broad range of symptoms in the prodromal phase of the illness to determine the pattern and timing of symptoms in this pre-dementia stage to facilitate the development of future diagnostic criteria. All subjects receive a medical assessment by a fully qualified psychiatrist, neuropsychological assessment, FP-CIT SPECT imaging and at baseline have a consensus panel clinical diagnosis of mild cognitive impairment (NIA-AA).
Results
These will be of the first 50 subjects comparing those who are biomarker positive (by FP-CIT) versus biomarker negative in six symptom domains: cognitive; neurological; neuropsychiatric; sleep; autonomic; visual. Currently 40% are FP-CIT positive with these having a higher prevalence of symptoms related to sleep and Parkinsonism. Preliminary data on those converting to dementia, comparing DLB with non-LB dementia, will also be presented.
Conclusions
In people presenting to memory and dementia services sleep and parkinsonian symptoms may be early features of prodromal DLB.

Symposium 03: PROFILING DLB, PD AND FTD

ADPD5-0384
DOPAMINE D1, D2, D3 RECEPTORS, VESICULAR MONOAMINE TRANSPORTER TYPE-2 (VMAT2) AND DOPAMINE TRANSPORTER (DAT) DENSITIES IN AGED AND DIFFUSE LEWY BODY DISEASE (DLBD) HUMAN BRAINS

J. Xu[1], J. Sun[1], N. Cairns[1], J. Perlmutter[1], R. Mach[1]
[1]Radiology, Washington University, St. Louis, USA

The dopamine D_1, D_2, D_3 receptors, vesicular monoamine transporter type-2 (VMAT2), and dopamine transporter (DAT) densities were measured in aged and diffuse Lewy body disease (DLBD) human brains by quantitative autoradiography. The density of D_1 receptors, VMAT2, and DAT was measured using [^{3}H]SCH23390, [^{3}H]dihydrotetrabenazine, and [^{3}H]Win35428, respectively. The density of D_2 and D_3 receptors was calculated using the D_3 selective radioligand, [^{3}H]**WC-10** and the D_2-preferring radioligand [^{3}H]raclopride using a mathematical model described previously. Dopamine D_1, D_2, and D_3 receptors are extensively distributed throughout striatum; the highest density of D_3 receptors occurred in the nucleus accumbens (NAc). Dopamine D_3 receptor density exceeded D_1 and D_2 receptor densities in extrastriatal regionse, and thalamus contained a high level of D_3 receptors with negligible D_2 receptors. The density of the DAT was negligible in the extrastriatal regions whereas the VMAT2 was expressed in moderate density. There were no significant changes in the dopamine D_1 and D_2 receptor densities in any brain regions measured. VMAT2 and DAT densities were reduced in all the brain regions measured in DLB/PDD, however the significant reduction was found in putamen for DAT and in the NAc and SN for VMAT2. The decrease of dopamine pre-synaptic markers implies neuronal loss in the substantia nigra pars compacta (SNpc) in these DLB/PDD cases, while the increase of D_3 receptors in striatal regions could be attributed to dopaminergic medication history and psychiatric state such as hallucinations. Whether it also reflects compensatory regulation upon dopaminergic denervation warrants further confirmations on larger populations.

ADPD5-0865
BRAIN GBA1 & GBA2 ACTIVITIES; A FACTOR TO CONSIDER IN PD
D. Burke[1], S. Heales[1]
[1]Chem Path, UCL & Great Ormond Street Hospital, London, United Kingdom
Gaucher disease is a lysosomal storage disorder caused by a deficiency of the lysosomal b-glucosidase (GBA1). An association between Gaucher disease (GD) and Parkinson disease (PD) was recognised in 1996. Previously, we described a patient with very mild GD (N370S/L444P) but a severe early onset PD who had undetectable levels of not just the dopamine metabolite (HVA) but also the serotonin metabolite (5-HIAA) in CSF. Subsequently, we have found that this patient had undetectable leucocyte levels of the non-lysosomal b-glucosidase (GBA2). Recently, we demonstrated that GBA2 is the predominant glucosidase in brain. We have also shown that some GD patients have elevated leucocyte GBA2 while others do not. Furthermore, we have observed undetectable levels of GBA 2 in 5% of GD patients, GD carriers and unaffected persons. This raises the possibility that GBA2 is disease modifying in GD with perhaps both negative and positive effects. GBA1 activity is also decreased in the substantia nigra of not just GD Parkinson's patients but also those with idiopathic PD. Whether this loss of activity directly contributes to PD pathogenesis in such patients is not currently known. Using a neuronal cell culture model (SHSY5Y) we have shown that inhibition of GBA1 and/or GBA2 increases cellular susceptibility to oxidative stress. Loss of activity of either or both glucosidases may therefore be a factor to consider with regards to our understanding of the pathogenesis of GD/PD and idiopathic PD.

ADPD5-1320

THE NEUROPSYCHOLOGICAL DEFICIT PROFILE OF DEMENTIA WITH LEWY BODIES (DLB) IS INFLUENCED BY DEGREE OF ALZHEIMER'S DISEASE (AD) PATHOLOGY

D. Salmon[1], J.M. Hamilton[1], L.A. Hansen[2], E. Masliah[1], D. Galasko[1]
[1]Neurosciences, University California San Diego, San Diego, USA
[2]Pathology, University California San Diego, San Diego, USA

Objective: DLB is characterized by cell loss and Lewy body deposition in brain stem nuclei, limbic regions, and neocortex. Concomitant AD pathology is present to varying degrees in its typical limbic/neocortical distribution. Our objective was to determine if degree of concomitant AD pathology observed at autopsy is related to the pattern of neuropsychological deficits associated with DLB at presentation.

Method: We retrospectively examined the performance of mildly-demented patients with autopsy-confirmed DLB (n=88) or "pure" AD (n=239) on cognitive domain scores. We then reexamined domain scores after subdividing DLB patients into those with high (Braak stage V-VI; n=38) or low (Braak stage II-IV; n=49) degrees of concomitant AD pathology.

Results: Despite similar mental status scores, DLB were more impaired than AD in Visuospatial and Attention/Executive Function, but less impaired in Memory ($F(4,322)=4.09$;$p=.003$;Wilk'sλ=.952). Pattern analysis showed that AD had greatest impairment in Memory and least impairment in Visuospatial, whereas DLB showed the opposite pattern. This difference in deficit patterns was exaggerated when AD and DLB with Low-Braak were compared ($F(4,283)=7.15$;$p<.001$;Wilk'sλ=.908). However, the patterns converged and became indistinguishable when AD and High-Braak DLB were compared ($F(4,273)=0.30$;$p=.878$;Wilk'sλ =.996).

Conclusions: The initial cognitive deficit profile of DLB is influenced by degree of concomitant AD pathology to the extent that DLB with a high degree of AD pathology has a pattern of deficits almost identical to that of pure AD. Thus, a DLB deficit profile may indicate the presence of DLB pathology, but lack of a DLB deficit profile does not rule out DLB pathology.

Symposium 03: PROFILING DLB, PD AND FTD

ADPD5-1452
PREDICTION OF PARKINSON'S DISEASE PROGRESSION USING DIFFUSION TENSOR IMAGING
N. Schuff[1], Y. Zhang[1], I. Wu[1], P. Parkinson Progression Marker Initiative[2]
[1]Radiology, UCSF, San Francisco, USA
[2]PPMI, PPMI, New Haven, USA
Objectives: 1) To determine the degree to which rates of declining motor control in Parkinson's disease (PD) are associated with diffusion tensor imaging (DTI) detected abnormal white matter microstructures at baseline; 2) To determine the value of baseline DTI for predicting fast versus slow PD progression.
Methods: 126 patients with early PD (age=60.3±9) enrolled in the Parkinson's Progression Marker Initiative (PPMI) had DTI scans at baseline and clinical follow-up after 12.6±1 months. DTI processing included estimations of fractional anisotropy (FA), an index of white matter integrity, in 72 brain regions. Linear mixed-effect models were used to examine relations between baseline FA values and rate of motor decline based on UPDRS scores. Machine learning together with a receiver operator characteristic analysis were used to identify the anatomical pattern of FA values that predicted fast versus slow PD progression.
Results: High rates of motor control decline were associated with low baseline FA values primarily of the posterior limb of the internal capsule, the medial lemniscus, and temporal lobe white matter regions (all $p < 0.02$). A moderate accuracy of 63 ± 0.8 % was achieved with baseline DTI in predicting fast versus slow decline in PD motor symptoms. The anatomical pattern of abnormal FA values that contributed to the prediction involved primarily the superior corona radiata, the cingulum as well as superior parietal, superior frontal, superior cerebellar peduncle regions ($p<0.01$).
Conclusions: The findings suggest that an abnormal baseline FA pattern from DTI is a potential predictor of PD progression.

Symposium 03: PROFILING DLB, PD AND FTD

LONGITUDINAL STUDIES OF FAMILIAL FRONTOTEMPORAL DEMENTIA - A WINDOW ON DISEASE PROGRESSION AND POTENTIAL INTERVENTION

M. Rossor[1]

[1]*Dementia Research Centre, University College London, London, United Kingdom*

A family history is common in patients with frontotemporal dementia (FTD) and in approximately 20% the disease is inherited on an autosomal dominant basis. Mutations in three genes, namely, *MAPT, GRN and C9orf,* account for the majority of cases, although an expanding number of rarer genetic causes are being identified. Of the three prototypic syndromes found in association with FTD, behavioural variant, progressive non-fluent aphasia and semantic dementia, the former two are most commonly found in autosomal dominant disease but with considerable phenotypic overlap and neuropathological overlap with sporadic disease. Natural history studies of autosomal dominant neurodegenerative disorders can provide major insights into the development and progression of disease as exemplified by Huntington's Disease and familial Alzheimer's disease (the DIAN study). A number of small studies of familial FTD have indicated a significant premanifest stage of neurodegeneration and changes in biomarkers such as serum progranulin. Recently a multinational consortium (the GENetic Frontotemporal dementia Initiative – GENFI), comprising 11 sites across Europe and Canada, has analysed data from 220 participants consisting of 118 mutation carriers (40 symptomatic, 78 asymptomatic) and 102 non carriers. This has revealed significant changes in neuropsychological measures around five years prior to onset and atrophy on MRI occurring up to 10 years before onset. These studies allow elucidation of the premanifest stage and the identification of biomarkers of proximity to symptomatic onset. Such studies are essential for assessing potential therapeutic interventions prior to irreversible neurodegeneration.

Symposium 07: LIPIDIDIET - NUTRITIONAL INTERVENTION IN PRODROMAL AD

ADPD5-0519

ABCA1 AGONIST PEPTIDES: A NEW THERAPEUTIC AVENUE FOR THE TREATMENT OF ALZHEIMER'S DISEASE

A. Boehm-Cagan[1], J.O. Johansson[2], J.K. Bielicki[3], D.M. Michaelson[1]
[1]Neurobiology, Tel Aviv University, Tel Aviv, Israel
[2]Artery Therapeutics Inc., Artery Therapeutics Inc., San Francisco, USA
[3]Structural Biology and Imaging, Lawrence Berkeley Laboratory, Berkeley, USA

Objectives: ApoE4 is the most prevalent genetic risk factor for Alzheimer's disease (AD). We have previously shown that the pathological effects of apoE4 can be reversed using the RXR agonist, bexarotene, and that this is achieved via upregulation of ABCA1, resulting in increased lipidation of apoE4. Since the RXR system has numerous other targets, it is important to devise the means of activating ABCA1 directly. Accordingly, we presently utilized peptides shown to directly activate ABCA1 *in vitro*, and examined the extent to which they can affect the degree of lipidation of apoE4 *in vivo* and counteract the brain and behavioral pathological effect of apoE4.
Methods: The ABCA1 agonist peptide CS6253 was injected i.p. in 2 dosages (20mg and 60mg/kg/48h) for 8 weeks to 2.5 months old apoE3 and apoE4 targeted replacement mice (n=6/group) after which the resulting effects of the treatment on apoE4-driven brain and behavioral deficits were assessed.
Results: I.p. injection of the ABCA1 agonist CS6253 reversed the hypolipidation of apoE4 relative to apoE3 in a dose-dependent manner, without affecting the levels of apoE. Furthermore, the ABCA1-agonist abolished the apoE4-driven accumulation of Abeta42 and hyperphosphorylated tau in hippocampal neurons and the associated behavioral deficits in an object recognition test.
Conclusion: These findings support the hypothesis that selective ABCA1 agonist treatment can reverse AD phenotype in apoE4 mice suggesting a novel therapeutic approach for the treatment of AD in apoE4 carriers.

IMPACT OF A SPECIFIC NUTRIENT COMBINATION DIET ON CEREBRAL CIRCULATION, NEURONAL INTEGRITY AND COGNITION IN MOUSE MODELS FOR ALZHEIMER'S DISEASE

A. Kiliaan[1]

[1]*Dept. Anatomy, Radboudumc, Nijmegen, Netherlands*

Recently, a combination of omega-3 with precursors and cofactors in membrane synthesis (Fortasyn) was developed for dietary management of AD. This diet enhances formation of neuronal membranes, and support synaptogenesis in rodents. Studies in mild AD patients supplemented with this diet indicate improvements in verbal recall task and better cognitive performance. **Objectives**. Within the EU 7th Framework project Lipididiet (nº 202167) we evaluated impact of a Fortasyn-containing diet on cerebral hemodynamics in relation to cognition and cerebral network integrity in APP/PS1, and ApoE4 mice. **Methods**. We examined 12 and 18 months old $APP_{swe}/PS1_{dE9}$, apoE4, and C57BL6/J mice. From 2 months of age, mice were fed a standard control diet or a specific nutrient-combination diet containing fish oil, phospholipids, UMP, choline, B-vitamins and antioxidants (Fortasyn). All MR measurements (CBF, rs fMRI, MRS, DTI) were performed on a 11.7T scanner. Cognition was assessed in MWM and open field. Neurogenesis and synaptic plasticity was quantified post mortem via IHC. **Results**. The diet restored neurogenesis and decreased anxiety-related behavior in open field and preserves white and gray matter integrity and CBF in AβPP-PS1 mice. The combination diet restores reduced CBF, impaired functional connectivity and white and grey matter integrity in aging ApoE4 mice as well. **Conclusions**. A specific combination diet restores reduced CBF and concomitant impaired functional connectivity and white and grey matter integrity in aging mouse models for AD. Diet may provide in preventive strategies in very early phases of AD.

The research received funding from EU Seventh Framework Programme (FP7/2007-2013) nº 202167

LIPID-BASED DIETS HAVE POSITIVE EFFECT ON MUSCARINIC RECEPTORS-MEDIATED G-PROTEIN ACTIVATION IN FRONTAL CORTEX AND HIPPOCAMPUS OF TRANSGENIC APPSWE/PS1DE9 FEMALE MICE.

V. Dolezal[1], H. Janickova[1], V. Rudajev[1], P. Zimcik[1], H. Koivisto[2], H. Tanila[2], J. Jakubik[1], E. El-Fakahany[3]

[3]Department of Experimental and Clinical Pharmacology, University of Minnesota College of Pharmacy, Minneapolis, USA

Objectives: Transgenic APPswe/PS1dE9 mice overproduce human amyloid-beta (Abeta) and mimic amyloid plaque formation characteristic for human AD. We have previously detected early impairment of presynaptic cholinergic parameters and functionality of muscarinic receptor signal transduction in the course of amyloid accumulation (Machova et al., Neurobiol.Aging 2008 and Neurobiol.Dis. 2010). Now we investigated whether fish oil-based experimental diets (LipiDiDiet endothelial, mitochondrial and combinational) modify markers of cholinergic muscarinic transmission in the hippocampus and frontal cortex.

Methods: Transgenic 3-month-old female mice were fed either control or endothelial, mitochondrial or combinational diet for 10 months. They were killed under deep anesthesia, brain regions dissected, and stored at -80 °C until used for biochemical determinations.

Results: In hippocampus, all experimental diets increased the potency of muscarinic agonist in activation of G-proteins and decreased the concentration of soluble Abeta40. Endothelial diet decreased cholineacetyltransferase activity but increased its gene expression. Mitochondrial diet had no influence on cholineacetyltransferase activity but increased its gene expression. Endothelial and mitochondrial diets increased gene expression of the high-affinty choline transporter (ChT1). In frontal cortex, all tested diets increased the sensitivity of muscarinic receptors-mediated G-protein activation to agonist but had no influence on soluble Abeta40/42. They did not influence cholineacetyltransferase activity but decreased its gene expression. Combinational diet, in addition, decreased gene expression of ChT1.

Conclusions: Compared to control diet, fish oil-based diets differentially influence parameters of muscarinic cholinergic neurotransmission in different brain regions. The common profitable effect of all diets is the potentiation of muscarinic receptor-mediated G-protein activation in middle-aged transgenic mice.

ADPD5-1478
UNDERSTANDING THE MECHANISMS HOW LIPIDS AFFECT AMYLOIDOGENIC PROCESSING

T. Hartmann[1], M.O.W. Grimm[1]
[1]Experimental Neurology, Experimental Neurology, Homburg, Germany

Objectives:
Lipids, including cholesterol, phytosterols, phospholipids, sphingolipids, glycosphingolipids, ceramide, are major factors determining the balance between amyloidogenic versus non-amyloidogenic processing and the total amount of Abeta. One major goal of the LipiDiDiet study is to identify the mechanisms by which lipids are able to change APP processing.
Methods:
We systematically studied the influence of major lipids and their effects on gene transcription, protein levels, secretase activities, interaction with APP and Abeta, subcellular trafficking, lipid microdomain composition, lipid enzymes, protein modification, combinatory effects with other nutritional factors like vitamins, protein stability and degradation, cellular energy, lipid composition, feed-back regulation, lipid homeostatic proteins and validated results in human brains samples.
Results:
Pro- and non-amyloidogenic lipids act by multiple but overlapping and common mechanism. Amyloidogenic processing preferentially takes place in lipid microdomains and is targeted by several lipids. E.g. cholesterol increases raft associated amyloidogenic processing, others, including polyunsaturated fatty acids and the plant sterol stigmasterol cause a displacement of cholesterol to the non-lipid microdomain fraction, shift in gamma-secretase localization, increased alpha-secretase mediated processing and reduced Abeta levels. Other mechanisms include e.g. targeting secretase levels and subcellular trafficking. Biogenesis of several lipids is influenced by Abeta, AICD and APPs, an increase in these lipids triggers release of APP processing products which decrease respective lipid anabolic enzymes.
Conclusions:
Lipid alter APP processing is due to largely similar or overlapping mechanisms. This knowledge can be used for the design of nutrition based AD prevention strategies.

[5]Department of Neurodegeneration and Neurobiology,
Deutsches Institut für Demenzprävention (DIDP), Homburg, Germany

Objectives The specific nutrition combination Fortasyn Connect is designed to support synapse formation and function in patients with Alzheimer's disease (AD) by delivering specific nutritional precursors and cofactors for the formation of neuronal membranes. Two randomised controlled trials (RCTs) have shown that the nutrition combination improves memory performance in drug-naïve mild AD patients (MMSE 20-26 and MMSE≥20), indicating that it may have promising effects in (very)early AD as well. The LipiDiDiet study[1] is one of the first RCTs in prodromal AD, investigating the effects of the nutrition combination on cognitive functioning.
Methods The LipiDiDiet study is a 24-month, double-blind, parallel-group, multi-centre, multi-country RCT in subjects with prodromal AD (criteria Dubois 2007), receiving the nutritional intervention or an iso-caloric control product once daily. Primary outcome measure is cognitive functioning as assessed by a neuropsychological test battery.
Results In total, 312 subjects have been randomised, 197(63%) of whom completed the study, 55(18%) are ongoing and 60(19%) dropped-out (status September 2014). Three optional 12-month double-blind extension studies are ongoing, including respectively 110, 28 and 6 subjects at this moment. Baseline characteristics of the study population conform to the criteria for prodromal AD, with evidence for underlying AD pathology. A planned blinded interim analysis on safety and efficacy was completed in July 2014 and reviewed by an independent Data Monitoring Committee, which advised to continue the study as planned.
Conclusions Further details on the progress of the study will be presented at the conference.

Dementia risk estimation tools and their use in clinical trials

A. Solomon[1,2], H. Soininen[1], M. Kivipelto[1,2]
[1]Institute of Clinical medicine/Neurology University of Eastern Finland, Kuopio, Finland
[2]Center for Alzheimer Research, Karolinska Institutet, Stockholm, Sweden

Background: Many risk factors have been associated with dementia and Alzheimer's disease (AD) in epidemiological studies. Such factors are often studied individually, but it is essential to investigate their combined effects and formulate risk estimation tools for identifying at-risk individuals who may benefit most from preventive interventions.
Methods: During the LipiDiDiet project, several dietary and vascular factors were investigated in relation to AD in epidemiological studies. Based on data from the Cardiovascular Risk Factors, Aging and Dementia (CAIDE) study, a Healthy Diet Index and a Dementia Risk Score were developed. In addition, a novel supervised learning method (Disease State Index, DSI) and accompanying visualisation method (Disease State Fingerprint, DSF) are being tested for dementia risk profiling.
Results: Persons with healthy diet (high score in the Healthy Diet Index) at midlife had significantly decreased risk for AD later in life compared to persons with unhealthy diet. The midlife CAIDE Dementia Risk Score (including several modifiable risk factors) has been validated and it was shown to relate to brain MRI changes up to 30 years later. It was also used to select participants in the FINGER 2-year multidomain randomised trial. DSI performed well in predicting dementia 7 years later in the CAIDE population based on a profile of late-life risk factors.
Conclusions: Several modifiable dietary and vascular risk factors already at midlife are linked with AD risk. Risk scores and profiling tools could be useful for selecting participants in prevention trials and identifying individuals who are most likely to respond to preventive interventions

ADPD5-0242

CEREBRAL MICROBLEEDS AND THE IMPACT ON CEREBROSPINAL FLUID BIOMARKERS IN DEMENTIA

S. Shams[1], T. Granberg[1], J. Martola[1], X. Li[2], M. Shams[1], S.M. Fereshtehnejad[2], L. Cavallin[1], P. Aspelin[1], M. Wiberg-Kristoffersen[1], L.O. Wahlund[2]
[1]Department of Radiology, Karolinska University Hospital, Stockholm, Sweden
[2]Department of Clinical Geriatrics, Karolinska University Hospital, Stockholm, Sweden

Objective: Cerebral microbleeds (CMBs) are hypothesised to have an important, yet unknown role, in the dementia disease pathology. In this study we analysed the impact of CMBs on routine cerebrospinal fluid (CSF) biomarkers in a broad range of dementia diagnoses, in order to determine the importance of CMBs in various dementia diagnoses.
Method: 1039patients undergoing dementia investigation (mean age 62 (±10), 53% female; 10 different dementia diagnoses) were analysed. All patients underwent lumbar puncture, and an MRI scan. CSF samples were analysed for amyloid β (Aβ)42, total tau (T-tau), tau phosphorylated at threonine 18(P-tau) and CSF/serum albumin ratios. Univariate and multivariate linear regression models were used to determine the impact of number/topography of CMBs on CSF biomarkers.
Results: Patients with CMBs had lower levels of Aβ42, and higher CSF/serum albumin ratios, when compared to patients without CMBs, in the whole cohort. In the subgroups Aβ42 decreased with increasing number of CMBs in alcohol related dementia (standardized beta: -1.71, P=0.026), Alzheimer's disease (standardized beta: -0.20, P=0.001), mild cognitive impairment (standardized beta: -0.18, P=0.002) and vascular dementia (standardized beta: -0.50, P=0.013). There was no impact on T-tau and P-tau with number of CMBs. CSF biomarkers varied with CMB topography, demonstrating lower Aβ42 with lobar topographies, and decreased T-tau and P-tau with infratentorial topographies.
Conclusion: Aβ42 is the routine CSF biomarker mostly affected by CMBs in dementia suggesting a direct relationship between CMBs and Alzheimer's pathology. CMBs impact on CSF-biomarkers varies with topography, demonstrating different pathology behind lobar and deep and infratentorial CMBs.

[6]NVS, Center for Alzheimer Research, Huddinge, Sweden
[7]Geriatric Medicine, Karolinska University Hospital, Huddinge, Sweden

Background:
The diagnosis of Alzheimer's disease (AD) has traditionally been made by clinical criteria, but novel research criteria have incorporated biomarkers for diagnosis. In the newly updated guidelines from the International Working Group (IWG-2), a cerebrospinal fluid (CSF) profile with low levels of amyloid beta 1-42 (Abeta42) together with high levels of either total tau (T-tau) or phosphorylated tau (P-tau) has been included as a research diagnostic criterion for AD. The aim of this study was to test how implementation of the new IWG-2 diagnostic criteria would influence AD prevalence using data from the Swedish Dementia Registry (SveDem).
Methods:
By cross-referencing a laboratory database containing measurements of CSF Abeta42, T-tau and P-tau with the SveDem registry, 2375 patients with a clinical diagnosis of AD were acquired. The proportion of patients with pathological CSF biomarkers was evaluated.
Findings:
A pathological biomarker profile was found in 76·5% of patients with a clinical diagnosis of AD, based on levels of Abeta42 and T-tau, and in about 60·4%, based on levels of Abeta42 and P-tau. Altogether, 76·8% fulfilled the IWG-2 CSF biomarker criteria.
Interpretation:
This is the first study to evaluate the new IWG-2 CSF biomarker criteria on patients with diagnosed AD. In a large cohort of AD patients diagnosed in clinical practice about a quarter did not fullfil the IWG-2 biomarker based criteria for AD. This discrepancy may partly reflect false positive clinical diagnosis. Implementation of biomarker informed criteria, such as IWG-2, would reduce the number of patients diagnosed with AD.

[4]Old Age Psychiatry, UZ Leuven, Leuven, Belgium
[5]Gerontology and Geriatrics, UZ Leuven, Leuven, Belgium
[6]Laboratory for Molecular Neurobiomarker Research, KU Leuven, Leuven, Belgium

Objectives: Biomarkers for amyloid play a central role in the NIA-AA research definition of preclinical AD. In a prospective community-recruited cohort of cognitively intact older adults, we compared three amyloid markers within-subjects: ^{11}C-PIB, ^{18}F-flutemetamol, and CSF $A\beta_{42}$.
Methods: 34 cognitively intact healthy subjects (65-80 years) participated (22 underwent all 3 procedures, 12 underwent ^{18}F-flutemetamol together with one of the other tests). CSF $A\beta_{42}$ was measured with ELISA (Fujirebio Europe). The primary outcome measures were the concordance between binary classification based on ^{18}F-flutemetamol versus ^{11}C-PIB according to visual reads or semiquantitative assessment (standardized uptake value ratio in composite cortical volume, $SUVR_{comp}$). Our secondary outcome measures were the concordance between binary classification based on ^{18}F-flutemetamol $SUVR_{comp}$ versus CSF $A\beta_{42}$ cut-off, and the correlation between ^{18}F-flutemetamol and ^{11}C-PIB $SUVR_{comp}$.
Results: Binary classification based on semiquantitative cut-offs was concordant between ^{11}C-PIB and ^{18}F-flutemetamol in 94%. Concordance of blinded binary visual reads between tracers was 84%. Classification based on $A\beta_{42}$ was concordant with ^{18}F-flutemetamol semiquantitative classification in 80% (7 discordant cases were positive according to ^{18}F-flutemetamol but negative according to $A\beta_{42}$). ^{18}F-flutemetamol and ^{11}C-PIB $SUVR_{comp}$ were highly correlated ($\rho=0.84$, $p<0.0001$).
Conclusions: For the definition of preclinical AD based on amyloid imaging semiquantitative cut-offs produce more consistent results than visual reads. Our data provide no indication that CSF $A\beta_{42}$ would be more sensitive than amyloid imaging in this population.

Symposium 08: CSF AND IMAGING BIOMARKERS OF AD

ADPD5-0888
DETECTION OF PHF-TAU PATHOLOGY WITH [18F]T807 IN BRAIN SECTIONS FROM CHRONIC TRAUMATIC ENCEPHALOPATHY (CTE) PATIENTS

G. Attardo[1], Y.G. Lin[1], Q. Liang[1], F. Gomez[1], A. McKee[2], M. Mintun[1]
[1]Discovery Research, Avid Radiopharmaceuticals, Philadelphia, USA
[2]Neurology and Pathology, Boston University, Boston, USA

Objective: To establish the ability of the radiotracer [18F]T807, also known as [18F]AV-1451, to detect Tau aggregates in postmortem human CTE brain tissue.
Methods: Frozen sections from CTE, Alzheimer's disease (positive control) and age matched controls subjects were exposed to [18F]T807 and examined by autoradiography. Adjacent slides from the same tissue samples were stained with PHF Tau antibodies (AT8, AT100, 3R and 4R) in order to establish the presence of pathological Tau aggregation in the [18F]T807 positive regions. In addition, several fluorescent reporter compounds that compete with [18F]T807 binding were used to double stain these tissues to identify any colocalization between the tracer and PHF Tau aggregates revealed by the antibodies.
Results: The positive signals obtained by autoradiography from [18F]T807 in CTE brain tissue were located in areas that contained PHF tau as determined by Tau antibodies. All [18F]T807 surrogate fluorescent compounds colocalized with immunofluorescence signal obtained with antibodies that stain pathological Tau aggregations but also with those that stain the 3R and 4R variants of the protein.
Conclusions: Autoradiography results suggest that the radiotracer [18F]T807 is capable of binding Tau in CTE tissue. There was good colocalization of fluorescent signals from T807 structurally related reporter compounds and tau antibodies AT8, AT100, 3R and 4R in CTE.

[11]Radiology Oncology and Radiation Science, Uppsala University, Uppsala, Sweden
[12]Institute of Psychiatry, King's College London, London, United Kingdom

Objectives. Strict criteria for recruiting participants normally lead to collection of highly selected samples (e.g. ADNI). It is unclear to what extent control groups recruited through these mechanisms are representative of the general population and hence whether results are generalizable. We compared the control groups from three reference large-scale studies (ADNI, AIBL, and AddNeuroMed) and four large population-based cohorts in terms of demographic and clinical characteristics, and studied associations with imaging markers of Alzheimer's disease.

Methods. 1464 healthy controls were included (228 ADNI, 100 AddNeuroMed, 155 AIBL, 59 BRC, 237 GENIC, 279 NOMAS, 406 PIVUS). Differences among cohorts were analysed with ANOVA, ANCOVA, and Chi-square tests. Multiple lineal regression was used to study associations between demographic-clinical variables and imaging markers.

Results. ADNI, BRC and PIVUS recruited the oldest groups and GENIC the youngest one. Subjects in ADNI had higher MMSE scores while subjects in GENIC and PIVUS had the lowest scores. ADNI, BRC and AIBL were the groups with less global brain atrophy and NOMAS the one with greatest global brain atrophy. Differences among cohorts in demographic-clinical variables significantly influenced hippocampal volumes. Moreover, between-cohorts differences were still significant after adjusting for demographic-clinical factors showing that BCR and PIVUS had greater hippocampal atrophy.

Conclusions. This study together with recent research show that highly selected samples are not totally representative of the general population. These findings may

have important implications for research in Alzheimer's disease since most of results from previous studies directly depend on the characteristics of the control groups.

[4]Neurological Surgery, Emory University, Atlanta, USA

[5]Department of Radiology, Harvard Medical School, Boston, USA

Recent studies suggest a relationship between brain perfusion abnormalities and the deposition of beta amyloid. Interpretation of this relationship is limited by the inability to disambiguate cause from effect. It is possible that amyloid pathology causes perfusion abnormalities. Alternatively, areas with normatively increased or decreased perfusion may be susceptible to amyloid deposition. We examined whether PET-derived amyloid uptake values in older adults varied regionally as a function of normative blood flow.

One hundred twenty-eight older adults (mean age=69.8 years) received amyloid PET scans (Pittsburgh Compound B). Mean amyloid uptake values were calculated among these subjects in 31 regions-of-interest (ROIs) defined by a neuroanatomical atlas. A normative blood flow atlas was created by averaging blood flow values from SPECT scans of 47 healthy younger adults (mean age=34.3 years) in the same ROIs. The 31 ROIs were rank ordered from lowest to highest blood flow value and divided into quartiles. We compared the mean amyloid uptake values across the four quartiles.

Areas with higher mean normative blood flow had higher amyloid uptake values [$F(3,27)=3.19$, $p=0.036$]; there was a linear trend ($p=0.029$) showing a monotonic increase in amyloid values across the four quartiles.

Brain areas that have relatively higher blood flow in young, healthy adults are more likely to have higher levels of amyloid deposition in older individuals. Regional increased blood flow throughout life may render the brain parenchyma susceptible to amyloid deposition through mechanisms yet to be determined.

Symposium 11: UPDATE ON TREATMENT OF PD

ADPD5-0357
ASSESSMENT OF MOTOR CONTROL FLUCTUATIONS IN PD PATIENTS UNDER DOPAMINERGIC TREATMENT WITH NEUROSKILL DEVICE: OFFICE AND HOME MONITORING.

R. Shrairman[1], R. Kumar[2], J. Godbold[3], A. Landau[1], C. O'Brien[4]
[1]n/a, VeriFax Corporation, Boulder CO, USA
[2]Rocky Mountain Movement Disorders Center, Colorado Neurological Institute, Denver CO, USA
[3]Department of Community and Preventive Medicine, Mount Sinai School of Medicine, New York NY, USA
[4]n/a, Neurocrine Biosciences, San Diego CA, USA

1. Objectives

To monitor motor fluctuations in PD patients using both Neuroskill and UPDRS-III evaluations in clinic setting and establish correlation between them.
To assess Sensitivity and Specificity of Neuroskill in discriminating PD subjects from healthy subjects.
To home monitor a subset of PD patients.

2. Methods

Neuroskill measures accelerations and pressures during cursive writing tasks and derives Criteria of Stability, Smoothness and Synchronization of handwriting movements.
A clinical study with 45 PD subjects (H&Y Stage II and III; mean age 65±9 years) and 33 healthy, age and gender matched controls was conducted at the Colorado Neurological Institute under IRB approved Protocol. PD subjects continued on their regular dopaminergic medications. In clinic, all subjects were assessed with Neuroskill and UPDRS-III five times at hourly intervals. In addition, 22 PD patients used the device at home for self-monitoring during 24 hours.

3. Results

The study demonstrated significant fluctuations in motor control of PD patients (Cr.I 64.4±8.7) vs. remarkable stability in controls (Cr.I 84.9±4.6). Pearson's correlation between Neuroskill Criterion-I (Stability) and UPDRS-III for 225 concurrent assessments demonstrated an inverse correlation –0.48 ($p<0.00001$).
Using standard ROC curve, it was established that Criterion 1 Signature OFF does extremely well in discriminating PD from non-PD individuals. It exhibited high values of both Sensitivity and Specificity for cutpoints in the range of 75 - 84.

4. Conclusions

Neuroskill appears to provide accurate assessment of motor status in PD subjects and can be utilized in home setting for remote monitoring, which may permit optimization of individual therapy.

Symposium 11: UPDATE ON TREATMENT OF PD

ADPD5-0401
INHIBITION OF RHO KINASE AS A DISEASE-MODIFYING STRATEGY FOR NEURODEGENERATIVE DISORDERS

P. Lingor[1], J.C. Koch[1], L. Tatenhorst[1], M. Zweckstetter[2], K.A. Saal[1], M. Bähr[1], L. Tönges[1]
[1]Neurologie, Georg-August-Universität Göttingen, Göttingen, Germany
[2]Department for NMR-based Structural Biology, Max-Planck-Institute for Biophysical Chemistry, Göttingen, Germany

Disease-modifying therapies for neurodegenerative diseases should attenuate the pathology and foster regeneration. As we could show in cell culture and animal models of Parkinson's disease and Amyotrophic lateral sclerosis, pharmacological inhibition of Rho kinase (ROCK) has protective properties on neuronal survival and acts in a pro-regenerative manner on axonal outgrowth. In the SOD1-G93A mouse model of ALS, oral application of the ROCK inhibitor Fasudil increased survival and improved motor behavior. This was associated with the activation of intracellular pro-survival signaling cascades, e.g. Akt/PKB, and in addition implicated immune-modulatory effects on microglia. In toxin-based models of Parkinson's disease (MPTP and 6-OHDA), Fasudil increased the number of nigral dopaminergic neurons, regenerative sprouting to the striatum and striatal dopamine metabolites. Interestingly, we could also observe that Fasudil affected alpha-synuclein aggregation in cell free aggregation assays and cell cultures in vitro. Since Fasudil is already licensed for human use and has a favorable safety profile, it should be further evaluated in clinical trials for its properties as a disease-modifying drug in human neurodegenerative disorders.

Symposium 11: UPDATE ON TREATMENT OF PD

ADPD5-1883
PERSONALIZED MEDICINE AND DISEASE COURSE MODIFICATION IN PD
A. Korczyn[1]
[1]*Neurology, Tel-Aviv University Medical School, Tel-Aviv, Israel*
The diagnosis of Parkinson disease (PD) is based on clinical criteria, and is needed for useful symptomatic therapy. However, it became quite clear in recent years that the same features can result from different etiopathogenic mechanisms. Thus, it is accepted now that what is called PD is the result of phenotypic convergence. Even pathological diagnosis of PD, based on the demonstration of typical distribution of alpha-synuclein deposits, is a manifestation of phenotypic convergence at the tissue level.

Since the clinical manifestations of PD can be the result of quite heterogeneous mechanisms, it is unlikely that an intervention can be developed which will be able to influence the development of the disease in all patients. Such disease-modifying therapy should be based not on clinical but rather on understanding the underling pathogenetic processes which differ among cases.

Individualized therapy to interrupt, or at least slow, disease progression must be based on elucidation of the metabolic processes. Some patients may develop PD as a result of mitochondrial damage. Correction of these abnormalities will not affect the progression of the disease among other PD patients, in whom an identical syndrome derives from defects in the proteasome system, etc.

Precision medicine can be used now to identify the underlying pathogenic mechanisms in individual patients, paving the way to the development of real disease modification.

Symposium 11: UPDATE ON TREATMENT OF PD

ADPD5-1893
NEW CONCEPT IN THE TREATMENT OF PD
F. Stocchi[1]
[1]*Neurology, Institute for Research and Medical Care San Raffaele, Rome, Italy*
The approach to Parkinson's disease (PD) imply important decision such as when and how start treatment. The rate of disease progression vary in the early stage being slower in the very early patients. Thus the early period after diagnosis is critical in term of rate of progression but is also in the early stage of the disease that pharmacological intervention may modify the course of the disease. Levodopa remain the gold standard in the treatment of PD but the STRIDE-PD study reinforce the concept that risk of developing dyskinesia and wearing-off each increased with higher levodopa doses. Thus physicians should use the lowest dose of levodopa that provides satisfactory clinical control to minimize the risk of dyskinesia and wearing off. Recently a pragmatic, open label randomized trial to evaluate which of three classes of drug (levodopa, dopamine agonists, or MAOBI), as initial treatment, provides the most effective long-term control of symptoms and best quality of life for people with early PD has been published. The authors found a very small but persistent benefits for patient-rated mobility scores when treatment is initiated with levodopa compared with levodopa-sparing therapy. Today we may also consider a combination of drugs rather than using a single drug at high dose. MAOBI can be successfully combined with DA-agonists and L-dopa and L-dopa can be combined with a DA and MAOBI. Combination of drugs may be more or equally effective but may reduce the dose of each of them minimizing the risks of side effects.

[2]Brain and Mind Research Proramme CEITEC Masaryk University, Masaryk University, Brno, Czech Republic
[3]Brain and Mind Research Proramme CEITEC, Masaryk University, Brno, Czech Republic

Patients with Parkinson's disease (PD) are characterized by motor impairment but also by executive dysfunctions, characterized by deficits in internal control of attention, set shifting, planning, inhibition, conflict resolution, impairment in dual task performance, and on a range of decision-making and social cognition tasks, due to degeneration of dopaminergic neurons in basal ganglia. It has been well demonstrated that levodopa, and dopamine agonists impact not only on parkinsonism but also on executive control. Executive tasks may become easier with L-dopa, suggesting a phenomenon of functional restitution and reallocation of the cortical activity under dopamine.

The lecture will touch upon brain connectivity changes as assessed by functional MRI (fMRI) both at rest and during a specific task performance. Different techniques have been used so far for MRI data analysis including the hypothesis- driven methods (e.g. seed-based functional/ effective connectivity), and data-drive methods (e.g. independent component analysis, graph theory based methods). As compared to age-matched controls, studies in PD and PD-dementia (PDD) have shown early changes particularly in the motor basal ganglia networks while rather variable results have been reported in cognition-related networks including the default mode network (DMN), extrastriate visual network, fronto-parietal and salience networks. The impact of dopaminergic therapy on connectivity of these networks will be discussed, with a special focus on the resting state connectivity of the DMN and the basal ganglia network.

Symposium 11: UPDATE ON TREATMENT OF PD

ADPD5-2303
APATHY AND IMPULSIVITY IN PARKINSON'S DISEASE
J. Kulisevsky[1], S. Martínez-Horta[2], J. Pagonabarraga[3]
[1]Neurology Department,
Sant Pau Hospital Universitat Autónoma de Barcelona Universitat Oberta de Catalun ya and CIBERNED, Barcelona, Spain
[2]Neurology Department, Sant Pau Hospital Universitat Oberta de Catalunya, Barcelona, Spain
[3]Neurology Department,
Sant Pau Hospital Universitat Autónoma de barcelona Ciberned, Barcelona, Spain
From the wide range of neuropsychiatric complications usually seen in Parkinson's disease (PD), disorders of motivation are common manifestations. They range from the decreased emotional reactivity and goal-directed behavior found in apathetic patients, to impulsivity, disinhibition and addictive behaviors as found in those developing impulse control disorders (ICDs). Apathy and ICDs have a major impact on the quality of life of the patients and caregivers. However, proper understanding and management of these entities still represents a challenge.
The meso-cortico-limbic dopaminergic system plays a critical role in reward sensitivity, motivation and reinforcement-learning since it derives the pleasure or pain that results from our actions and guides future decisions and behavior. Dysregulation of this system has been suggested to sub-serve the clinical expression of these alterations of motivation in PD.
Here we review current topics and data supporting the implication of the meso-cortico-limbic dopaminergic system on the development of apathy and impulsivity in PD and how it explains the co-existence of entities that represent opposite sides of the same behavioral and dopamine-dependent continuum. We provide arguments showing that both entities relate to different patterns of dopaminergic dysregulation mainly mediated by a dissimilar course of neurodegeneration and effects of dopaminergic stimulation. We shall also discuss how apathy and ICDs are associated to different clinical characteristics, cognitive profiles and prognosis. We will finally provide insights on future directions to guide research on apathy and motivation in PD.

EXOME SEQUENCING IN NEURODEGENERATIVE DISEASES - MORE THAN A FAMILY BUSINESS

R. Louro Guerreiro[1]
[1]*Molecular Neuroscience, UCL - Institute of Neurology, London, United Kingdom*

The development and application of next-generation sequencing technologies has allowed for an exponential increase in the number of findings of genetic causes associated with disease.
These technologies are now commonly used to study Mendelian forms of neurodegenerative diseases, usually by sequencing the exomes of affected and unaffected family members, and by comparing the resulting variants. This approach has not only identified several new genes, but has also revealed unexpected presentations for mutations in previously known disease genes.
Although extremely well suited to the study of families, these techniques can also be used to study cohorts of deeply phenotyped cases and large case/control samples.
In this talk, I will summarize the major contributions of exome sequencing to the study of neurodegenerative diseases and I will discuss the interface between Mendelian and complex neurological diseases with particular focus on pleiotropic events and the role of rare variants.

DISSECTING THE MOLECULAR MECHANISMS OF THE GENETIC CAUSES OF PD REVEALS NOVEL MECHANISMS OF NEURODEGENERATION

T. Dawson[1], B. Saurav[1], S. Karuppagounder[1], H. Ko[1], V. Dawson[1]
[1]Institute for Cell Engineering, Johns Hopkins University School of Medicine, Baltimore, USA

Parkinson's disease (PD) is characterized by the major clinical features of including bradykinesia, rigidity, rest tremor and postural instability, which are caused by the progressive loss of dopamine neurons in the substantia nigra pars compacta. Autonomic dysfunction, anxiety, depression, abnormalities of sleep, cognitive impairment, among other clinical features are due to the degeneration of other neuronal populations and/or neuronal dysfunction. A major contributor to these pathologic derangements is the accumulation and aggregation of α-synuclein, the major protein constituent of Lewy Bodies and Lewy Neurites. Many fresh insights into the pathogenesis of PD have come from advances in the genetics of PD. Mutations in leucine-rich repeat kinase 2 (LRRK2) and α-synuclein cause autosomal dominant PD. Mutations in parkin, PINK1 and DJ-1 cause autosomal recessive PD. Other genes identified from genome wide association and linkage studies determine one's relative risk of developing PD. Oxidative and nitrosative stress as well as tyrosine phosphorylation of parkin via activation of the non-tyrosine receptor kinase, c-Abl inactivates Parkin in idiopathic PD. PARIS and AIMP2, parkin substrates, accumulate in models of α-synuclein induced degeneration paralleling what occurs in PD due to deletion or inactivation of parkin. α-Synuclein induced degeneration is reversed by knockout of c-Abl via prevention of the inactivation of parkin and the accumulation of the parkin substrates, AIMP2 and PARIS. α-Synuclein induced degeneration is also reversed by deletion of PARIS. Thus, the parkin substrates, AIMP2 and PARIS, are downstream of α-synuclein pathology and highlight the intersection of recessive PD with idiopathic PD.

GENETICS OF EARLY-ONSET ALZHEIMER DEMENTIA: WHAT IS MISSING?
C. Van Broeckhoven[1]
[1]*Neurodegenerative Brain Diseases Group, VIB Institute Born-Bunge University of Antwerp, Antwerp, Belgium*
Molecular genetic studies have contributed greatly to our current knowledge of the pathogenesis of neurodegenerative dementia. Most progress was made in Alzheimer disease (AD) which, at young age, has strong a familial predisposition though onset ages can vary considerably among mutation carriers. In autosomal dominant families, frequent high-penetrant mutations were identified for AD in APP, PSEN1 and PSEN2. The proteins involved are being studied in detail and have resulted in important biological hypotheses that are currently being pursued for the development of suitable and more effective treatments. Nonetheless, a considerable fraction of the genetic etiology has not yet been resolved. Mutations in the known genes cannot explain disease in all early-onset families, suggesting that there have to be other causal genes to be found. In cohorts, mutations are observed in only a small percentage of patients. Furthermore, genetic factors underlying the wide spread in onset ages are largely unmapped.
We systematically screen AD patients using a multiple amplicon, exon-targeted sequencing-based MASTR assay (www.multiplicom.com), for genetic variation in set of 30 genes associated with neurodegenerative brain diseases. In large pedigrees and patient cohorts, we use next-generation sequencing (NGS) to identify new causal and/or genetic modifier genes. For these studies, distant related patients are selected of extended families while of cohorts patients with extreme phenotypes (familial, early-onset age, pathology confirmed, etc.) are included. In mutation carriers, we use different NGS approaches to identify genetic modifiers. To identify putative modifying genetic variants, we link the genetic data to biological data obtained by brain transcriptomics and serum proteomics of mutation carriers.

Symposium 14: GENETICS 1

DECODING ALZHEIMER'S DISEASE IN THE WHOLE GENOME ERA
R. Tanzi[1]
[1]*Genetics and Aging Research Unit, Dept. of Neurology,*
Mass. General Hospital/Harvard Medical School, Boston, USA
Alzheimer's disease (AD) is strongly influenced by genetic factors such as the APP, PSEN1, and PSEN2, and APOE. Since 2005, we have led the Alzheimer's Genome Project, which in 2008, reported novel AD genes including the spinocerebellar ataxia 1 gene, ATXN1, CD33, and ADAM10. ATXN1 knockout increases BACE1 levels in cortex and hippocampus, but not in cerebellum and brain stem. This increase of BACE1 is concordant with the shift of APP processing into the beta-secretase cleavage pathway along with an increase in Abeta levels and plaque load in the brains of APPswe/PS1deltaE9 mice. CD33 is one of several genes involved in the innate immune system of the brain that have been associated with AD risk. CD33 knock-out led to 1. decreased Abeta load owing to enhanced phagocytosis by microglia and 2. reduced numbers of M1-activated microglia in *APP/PS1* and 5XFAD tg mouse brains. Re-sequencing of ADAM10 revealed two rare mutations that tightly co-segregated with AD and impair ADAM10 non-amyloidogenic cleavage of APP in transgenic mice. We also carried out whole genome sequencing on 440 subjects from 452 multiplex NIMH AD families. We then employed a multi-pronged approach to identify highly penetrant functional variants underlying the association of previously reported AD genes that emerged from genome-wide association studies. Our analyses revealed several novel pathogenic variants in the known and GWAS-confirmed AD genes. The elucidation of the genes and functional variants influencing risk for AD should continue to enhance our understanding of AD etiology and pathogenesis. Ultimately, these genes will be used to predict risk for AD and guide novel the development of therapies for the effective treatment and prevention of this terrible disease.

Symposium 14: GENETICS 1

ADPD5-1900
DEFINING THE GENETIC ARCHITECTURE OF ALZHEIMER'S DISEASE. WHERE NEXT?

J. Williams[1]
[1]*Institute of Psychological Medicine and Clinical Neurosciences, Cardiff University, Cardiff, United Kingdom*

For seventeen years, the *APOE* gene was the only known susceptibility gene for late-onset AD. In 2009, we identified three new genome-wide significant susceptibility genes(1,2). Recently, in the IGAP collaboration, we have published fifteen additional susceptibility loci(3–5). IGAP utilised 25,580 AD cases and 48,958 controls to identify eleven new loci reaching genome-wide significance(6), and further new loci through gene-based burden analysis(7). The susceptibility loci we have identified are not randomly distributed with respect to their functions; pathway analysis shows significant evidence for clusters of genes implicating ubiquitination, endocytosis, cholesterol transport, and immunity.

A significant proportion of genetic variation in disease pathology is yet to be detected. Thus, we are investigating rare variants in disease through exome chip and next generation sequencing experiments, which have already identified new AD-protective(8) and AD-risk variants(9). Combining common and rare variant data will provide us with the most comprehensive risk estimates of AD. Using a polygenic score approach we can identify population groups with the greatest and least biological susceptibility to AD. This method has proved more effective in predicting disease status, than individual, genome-wide significant variants of small/moderate effect(10). Future studies will establish the specific functional changes that contribute to disease by piloting novel cellular modelling techniques using reprogrammed induced pluripotent stem cells (iPSc) cells from individuals with selected genetic risk profiles. This will allow a variety of cell and animal models to be produced to help understand disease mechanisms, test new drug therapies and produce iPSc as a research resource.

ACCURATE, NON-INVASIVE AND LOW COST PREDICTIVE MODEL FOR PD

M. Nalls[1], *A. Singleton*[2]
[1]*Statistical Genetics Group, National Institute on Aging, Bethesda, USA*
[2]*Molecular Genetics Section, National Institute on Aging, Bethesda, USA*

Figure 1: Area under the curve.

Objectives: To identify non-invasive and cost-effective factors accurately predicting if participants in longitudinal studies were PD cases. **Methods**: We mined baseline biomarker, clinical and genetic data in the Michael J. Fox foundation's Parkinson's Progression Markers Initiative (PPMI). Stepwise regression models were used to identify candidate factors for modeling based on Akaike information criterion. Factors remaining in the model included a genetic risk score incorporating 28 common risk loci as well as G2019S (LRRK2) and N370S (GBA1), University of Pennsylvania Smell Identification Test score (UPSIT), family history, gender and age. We developed the model using the PPMI cohort and then fit it to the Parkinson Associated Risk Study (PARS) cohort. We are pursuing further replication in the NINDS Parkinson's Disease Biomarker Program (PDBP) cohort. **Results**: Both PPMI and PARS showed > 93% predictive accuracy (area under the curve). Logistic regression examining predictive model fit showed significance at p-value < 2E-16. In the prospective PDBP cohort, we expect further replication and a retrospective estimate of accuracy relative to time from diagnosis. This second replication phase will also address possible recruitment bias in PARS. **Conclusions**: This is an important model as we show we can accurately predict Parkinson's disease in populations using non-invasive and relatively inexpensive information costing no more than $150 USD per sample.

Leucine-rich repeat kinase 2 (LRRK2) is the causative molecule of the autosomal dominant hereditary form of PD, PARK8, which was originally defined in a study of a Japanese family (the Sagamihara family) harboring the I2020T mutation in the kinase domain. Although a number of reported studies have focused on cell death mediated by mutant LRRK2, details of the pathogenetic effect of LRRK2 remain completely unknown. In the present study, to elucidate the mechanism of neurodegeneration in PD caused by LRRK2, we generated induced pluripotent stem cells (iPSC) derived from dermal fibroblasts isolated from two PARK8 patients (LA and LB) in the Sagamihara family using retroviruses carrying Oct4, Sox2, Klf4, and c-Myc genes, as previously described. To evaluate the iPSC lines established from the patient, we characterized their properties. All of the patient iPSC lines demonstrated differentiation of all three germ layers spontaneously in vivo, and maintained a normal karyotype. We found that more than 80% of the differentiated cells were positive for βIII-tubulin (a neuron-specific marker). We also found that I2020T mutant LRRK2 iPSC-derived neurons released less dopamine than control iPSC-derived neurons. Furthermore, we demonstrated that patient iPSC-derived neurons had a lower phospho-AKT level than control iPSCs-derived neurons, and that the former showed an increased incidence of apoptosis relative to the controls. These results suggest that I2020T LRRK2-iPSC could be a promising new tool for reproducing the pathology of PD in the brain caused by the I2020T mutation, and applicable as a model in studies of targeted therapeutics.

LONG NON-CODING RNAS IN NEURODEGENERATIVE BRAIN AND PATIENTS' BLOOD CELLS: FROM STRUCTURE TO FUNCTION

A. Simchovitz[1], M. Hanan[1], D. Greenberg[1], S. Kadener[1], H. Soreq[1]
[1]Biological Chemistry, The Hebrew University of Jerusalem, Jerusalem, Israel

Objectives: Parkinson's disease (PD) is the most prevalent motor disorder, but specific disease biomarkers are still sought and new targets for future therapeutic interference are urgently needed. Long non-coding RNAs (lncRNAs) comprise a novel, important class of RNAs with largely unknown biological functions.
Methods: Using RNA sequencing technology and a computational workflow for in-depth analysis of whole-transcriptome RNA-seq datasets, we detected and analyzed lncRNAs in rRNA-depleted sequenced libraries from PD patients' post-mortem substantia nigra and controls.
Results: We identified a total of 7244 lncRNAs that were detected at or above 1 normalized reads (FPKM) at least in one group of the obtained datasets, with several of those changed significantly in PD substantia nigra. Disease-specific changes in known and novel lncRNAs and corresponding changes in alternative splicing, protein domains and miRNA binding sites demonstrated widespread transcript variations, including a decline in the PD-risk gene antisense lncRNA PINK1-AS as well as decreases in microRNA host genes (e.g. miR124-2HG, miR22-HG) in the substantia nigra from PD patients compared to controls.
Conclusions: Our results suggest lncRNA regulatory involvement in PD; and provide a workflow that will be of use to the increasing number of laboratories producing RNA-Seq data in a wide range of biomedical studies.

ADPD5-1886
IMMUNE AND NEURAL EPIGENOMICS OF ALZHEIMER'S DISEASEIMMUNE AND NEURAL EPIGENOMICS OF ALZHEIMER'S DISEASE

L.H. Tsai[1]
[1]*Department of Brain and Cognitive Sciences,*
The Picower Institute for Learning and Memory MIT, Cambridge, USA

Transcriptomic analyses of human postmortem Alzheimer's disease (AD) brains have revealed global changes in gene expression patterns that are characterized by the downregulation of genes associated with synaptic function, learning, memory, and the upregulation of adaptive as well as innate immune response genes. However, the mechanisms underlying these changes are still poorly understood. Here, we conducted transcriptomic analysis of brains from the CK-p25 mouse model of neurodegeneration, which recapitulates various cardinal hallmark AD phenotypes, found that these mice display gene expression changes that are highly reminiscent of those that are characteristic of AD. In an attempt to understand the chromatin landscape associated with these gene expression changes, we utilized chromatin immunoprecipitation combined with next-generation sequencing (ChIP-seq) in CK-p25 mice and controls. This allows us to assess the distribution of various histone modifications that specify genomic elements, such as promoters and active/inactive enhancers. These studies revealed that neuron-specific enhancers in CK-p25 brains show reduced activity, whereas microglia/monocyte-specific enhancers show increased activity. These increased activity enhancers are enriched for binding sites of the transcription factors ETS1 and PU.1. Furthermore, mouse orthologs of human AD-associated genetic variants map predominantly to higher-activity, immune-related enhancers, and not to lower-activity neuronal enhancers. These results suggest that genetic predisposition to AD is related to immune function, whereas non-genetic factors affect neuronal pathways. We have also conducted global chromatin profiling and gene expression profiling in human induced pluripotent stem cell (iPSC)-derived neural and immune cells from familial and sporadic AD patients as well as healthy individuals. Results from these studies provide further insight into the roles of the brain's neural and immune cells in the pathogenesis of AD, and how AD-related genetic variants impact these distinct cell types.

Genomic studies in PSEN1 E280A kindred: A Protective Variant Delays Onset

We have sequenced the complete genomes of 72 individuals affected with early onset familial Alzheimer's disease (EOFAD) caused by the E280E autosomal dominant, highly penetrant mutation in the presenilin-1 gene (*PSEN1*). We performed a genome-wide association test to identify variants that modify age at onset (AAO) of AD. Our analysis revealed a haplotype of single nucleotide polymorphisms (SNPs) on chromosome 17 associated with a delayed AAO for mild cognitive impairment and dementia. Individuals carrying this haplotype had an average age at onset of mild cognitive impairment at 51.0 ± 5.2 years (mean ± std. dev.) compared to 41.1 ± 7.4 for those without these SNPs. These striking results suggest a genomic locus modifying Alzheimer's AAO conferring a large (~10 year) protective effect.

THE ROLE OF MICRO RNAS IN AD AND PD: A GENETIC PERSPECTIVE
L. Bertram[1]
[1]*Institute of Neurogenetics, University of Lübeck, Lübeck, Germany*
A substantial portion of the susceptibility underlying both Alzheimer's disease (AD) and Parkinson's disease (PD) is genetically determined. Most of the currently known risk genes were identified in genome-wide association studies (GWAS) correlating disease risk with genotypes at millions of polymorphic DNA sequence variants, e.g. single-nucleotide polymorphisms (SNPs). While the genetic evidence underlying these findings is very compelling for most recently identified loci, the mechanisms by which they exert their pathogenic effects remain less well understood. One such mechanism could involve interference with micro-RNA (miRNA) mediated expressional regulation. MiRNAs are a class of small, non-coding RNAs that modulate protein expression by binding to mRNA thereby decreasing translation. Binding between miRNAs to their mRNA targets is largely determined by nucleotide sequence complementarity. Our group has recently begun to investigate the potential role of disease-associated SNPs in interfering with miRNA-to-mRNA binding by affecting this sequence complementarity. To this end, we have developed an *in silico* pipeline systematically modelling the effects of SNPs on miRNA-to-mRNA binding. Application of this algorithm to recent AD or PD GWAS findings highlight a number of variants predicted to exert strong effects on protein expression. In my presentation, I will present a summary of these *in silico* findings and discuss how they correlate with ongoing experiments assessing these predicted effects *in vitro*. In addition, I will discuss how the findings from our genetics-centered approach correspond to studies aimed at identifying profiles of disease-associated miRNAs in blood or cerebrospinal fluid as potential biomarkers for AD or PD.

[3]Institute of Public Health, University of Cambridge, Cambridge, United Kingdom
[4]Faculty of Life Sciences, University of Manchester, Cambridge, United Kingdom

Objective: We have previously demonstrated a wide variation in oxidative stress and a DNA damage response (DDR) in the ageing brain, which shows an inverse relationship to Braak stage [1]. We hypothesise that neuronal dysfunction as a result of oxidative DNA damage accounts for some of the cognitive impairment that is not fully explained by Alzheimer-type pathology.
Methods: Frontal cortex frozen tissue (Braak stage 0-II, 39 cases) was obtained from the Medical Research Council Cognitive Function and Ageing Study cohort. Oxidative stress (malondialdehyde, MDA) and the neuronal DDR (γH2AX and DNA-dependent protein kinase catalytic subunit, DNA-PKcs) were assessed, and the relationship to cognitive impairment determined. Neurones were isolated from 10 cases (5 high and 5 low neuronal DDR) by laser capture microdissection and changes in the neuronal transcriptome identified by microarray analysis.
Results: Both DNA-PKcs+ (r_s=-0.43, p=0.006) and γH2AX+ (r_s=-0.41, p=0.009) neuronal counts correlated inversely with the patients' last MMSE score. 1005 genes were significantly differentially expressed (639 up-regulated, 366 down-regulated genes, p<0.001) in cases with a high neuronal DDR. Functional grouping analysis identified dysregulation of genes associated with insulin signalling and wnt signalling, and upregulation of GSK3B.
Conclusion: We present the gene expression signature of neurones in response to DNA damage at the earliest Braak stages, and propose that down-regulation of insulin and wnt signalling results in the up-regulation of GSK3B which contributes to neuronal dysfunction and cognitive impairment independent of Alzheimer pathology in the ageing brain.

[5]Department of Computer Science, Rensselaer Polytechnic Institute, Troy, USA

Objective: To describe the genetic findings of a kindred with progressive Alzheimer-type dementia in which the proband had autopsy-confirmed tauopathy with TDP-43 proteinopathy.

Methods: We first analysed neurodegeneration-related genes and then performed whole exome sequencing on two affected siblings and one unaffected aunt. By identifying identical by descent regions in both siblings, we uncovered a large number of candidate genes potentially involved in the etiology of the phenotype under study.
Results: Analysis of the *GRN, TARDBP, APP, PSEN 1, 2,* and *MAPT* genes excluded pathogenic mutations. Genes that were found to harbor more variants shared identical by descent among the siblings, included *LRRK2, CSMD1, AHNAK2, PCNT*, and *TMEM176B*. According to our analysis of variants shared among the siblings there is an enrichment in genes involved in nervous system development, synaptic transmission, neurogenesis, muscle structure development, brain and forebrain development, lipid transport and localization, behavior, learning or memory. In addition, pathway analysis revealed pathways related to Alzheimer disease.
Conclusion: This condition does not fit into any previously characterized tauopathy or TDP-43 proteinopathy, and the clinical picture deviated from more frequent presentations like frontotemporal dementia with parkinsonism. Although further genetic studies may eventually disclose the etiology, our results highlight the possibility that there is no single causative gene in this case study but a set of genes working together in different pathways contributing to the etiology of a complex phenotype.

AMYLOIDOSIS AND FORMATION OF OLIGOMERIC TAU STRAINS IN ALZHEIMER'S AND Pd
K. Rakez[1], J.E. Gerson[1], U. Sengupta[1], M.J. Guerrero-Munoz[1], D.L. Castillo-Carranza[1]
[1]Neurology, UTMB, Galveson, USA
Objectives
Tau pathology is implicated in a number of neurodegenerative diseases including Alzheimer's (AD) and Parkinson's disease (PD). Studies repeatedly suggest that oligomeric tau is the most toxic in disease, and spreads in a prion-like mechanism. We found that oligomeric tau forms in both AD and PD. The exact mechanism and the role of these tau species in disease progression are still unknown. We hypothesize that these tau structures represent different oligomeric strains and that their conformational diversity depends upon other amyloid proteins, namely amyloid beta oligomers in AD and alpha-synuclein oligomers in PD. Therefore, it is of great importance to establish immunological and biochemical characteristics of these entities.
Methods
We generated and characterized multiple anti-tau oligomer-specific mouse monoclonal antibodies (TOMAs) and performed preliminary immunological analyses of brain tissue from AD and PD for the presence of tau oligomeric strains. In addition, we are investigating the biochemical characteristics and stability of these strains.
Results
Tau forms multiple oligomeric strains which can be distinguished biochemically and immunohistochemically with different TOMA clones. Different tau strains are capable of seeding in vitro. Strain-specific properties were also analyzed by Proteinase K digestion.
Conclusion
The ability of tau to form different oligomeric conformers may play a critical role in disease phenotype and progression. As TOMA clones display distinct preferences for different subsets of tau oligomers, they have great potential for early diagnostics, the design of strain-specific therapeutic approaches and distinguishing polymorphisms and complexity of tau aggregation in different neurodegenerative tauopathies and for personalized medicine.

A NOVEL MECHANISM UNDERLYING THE PATHOGENESIS OF PROGRESSIVE SUPRANUCLEAR PALSY

H. Xu[1]
[1]*Center for Neuroscience Stem Cell and Aging Research, Sanford-Burnham Medical Research Institute, La Jolla, USA*

Progressive Supranuclear Palsy (PSP) is a movement disorder characterized by the presence of neurofibrillary tangles (NFTs) comprised of abnormally hyperphosporylated/aggregated tau protein, extensive gliosis and neuronal loss within specific brain regions. A clear mechanism and treatment strategy for PSP has been lacking so far. Appoptosin (SLC25A38) is a pro-apoptotic protein that mediates neuronal cell death through intrinsic caspase activation. A single nucleotide polymorphism (rs1768208 C/T) near *SLC25A38* may be a risk factor for PSP. Our study identified a much higher T-allele occurrence as well as increased levels of appoptosin, activated caspase-3 and caspase-cleaved tau in PSP patients. Increased appoptosin associates with T-allele occurrence and correlates with activated caspase-3 and caspase-cleaved tau. Appoptosin overexpression increased caspase-mediated tau cleavage and concomitant tau aggregation and synaptic dysfunction, whereas appoptosin deficiency exhibited reduced tau cleavage and aggregation. Appoptosin transduction in the globus pallidus impaired multiple motor functions and exacerbated neuropathology in tau-transgenic mice, with little effect in tau knockout mice. Our findings reveal a novel role for appoptosin in PSP pathogenesis, linking caspase-mediated tau cleavage to synaptic dysfunction and behavioral/motor defects in tauopathies. In addition, our findings may have implications in other disorders involving caspase-3 dysregulation. Indeed, appoptosin is a component genetically-linked to sideroblastic anemia (*Nat Genet* 2009, 41(6):651-3). We also found that appoptosin knock-out embryos are prenatally inviable due to anemic complications (including defects in heme synthesis) and observed an aberrant upregulation of appoptosin in leukemic B-cells. Hence, we anticipate future work to determine the association of appoptosin variants with many non-neurodegenerative disorders.

COGNITIVE ASPECTS OF PROGRESSIVE SUPRANUCLEAR PALSY
I. Litvan[1], A. Gerstenecker[2]
[1]Neurosciences, University of California San Diego, La Jolla, USA
[2]Psychiatry, University of Louisville, Louisville, USA
Cognitive difficulties are a prevalent clinical feature in progressive supranuclear palsy (PSP). We evaluated a cross-sectional sample of 350 patients who met the NINDS-SPSP Criteria for PSP with a variety of commonly used neuropsychological tests. We found that approximately 1 in 4 patients had a Dementia Rating Scale Total score at or below the 1st percentile and had at least two tests at or below the 5th percentile. More than half of the sample had a primary executive dysfunction (e.g., 63% impaired on the Frontal Assessment Battery), with milder difficulties in memory, construction, and naming. These results have important clinical implications for clinicians following patients with PSP.

Objective

Aggregates of microtubule-associated protein tau constitute the characteristic neuropathological features of several neurodegenerative diseases known as tauopathies such as progressive supranuclear palsy and Alzheimer's disease. The mechanisms of tau toxicity are not yet certain. While studies in human neurons will contribute to clarify tau toxic process, investigations are now performed in mouse models where tau aggregation and toxicity are reproduced. In human P301S tau transgenic mice, we have shown that transplantation of newly differentiated control astrocytes is able to prevent tau induced neuronal death. This effect was surprising because neuronal death occurs in the P301S tau mice despite a clear increase in the number of endogenous astrocytes. The aim of the present study was to determine and compare the neuroprotective effect of endogenous P301S tau and transplanted control astrocytes.

Methods

The characteristics of astrocytes in P301S tau and control mice were investigated using immunohistochemistry, immunoblotting and proteomics. Similar studies were performed in primary cultures of postnatal P301S and control mouse astrocytes in co-cultures of neurons and astrocytes as well as of neurons and astrocyte conditioned medium.

Results

We found that astrocytes grown from human P301S tau transgenic mice are not protective for P301S tau or control neurones. This characteristic is maintained in the supernatant from P301S tau astrocyte cultures.

Conclusions

We have determined that endogenous astrocytes in human P301S tau transgenic mice, differently from transplanted control astrocytes are not neuroprotective. The toxic effect is present also in astrocyte-cultured medium. The identification of the toxic element will help to understand tau pathological mechanisms.

CORRELATION BETWEEN CLINICAL, CEREBROSPINAL AND NEUROPATHOLOGICAL OBSERVATIONS IN SUBJECTS WITH THE CLINICAL DIAGNOSIS OF IDIOPATHIC NORMAL PRESSURE HYDROCEPHALUS

A. Elobeid[1], K. Laurell[2], K. Cesarini[3], I. Alafuzoff[1]
[1]Dept Immunology genetics and pathology, Uppsala University, Uppsala, Sweden
[2]Dept Nueroscience neurology, Uppsala University, Uppsala, Sweden
[3]Dept Nueroscience neurosurgery, Uppsala University, Uppsala, Sweden

Objective: For diagnosis of Alzheimer's Disease (AD) three approaches are implemented: clinical assessment, assessment of cerebrospinal fluid (CSF) biomarkers and imaging applying Pittsburgh Compound B (PiB-PET). Assessment of a brain biopsy is not carried out in AD. In subjects with idiopathic normal pressure hydrocephalus (iNPH) a brain biopsy can be obtained at the ventriculo-peritoneal shunt operation. Here we assessed correlation between AD related clinical, CSF and biopsy findings in subjects with the clinical diagnosis of iNPH.
Methods: 164 brain biopsies measured approximately 20 mm^2 in size were obtained during a shunt operation in 2010 to 2013. A pre-operative clinical assessment of cognitive status and a lumbar puncture was performed on most but the data was available for this study in 111 subjects. For assessment of cognitive function Mini Mental state examination (MMSE) was carried out. Levels of CSF β-amyloid (Aβ42), total tau (T-tau) and hyperphosphorylated tau (HPtau) were measured applying commercial ELISA. The tissue samples were assessed applying Aperio image analysis positive pixel count (PPC) and the area of grey matter assessed for the load of Aβ42 and HPtau measured 9.5 mm^2 ± SE 1,2 mm^2.
Result: Regarding Aβ the correlation was -0.32 ($p<0.001$) biopsy/CSF; -0.23 ($p<0.012$) biopsy/MMSE and 0.3 ($p<0,001$) MMSE/CSF. Regarding HPtau the correlation was 0.32 ($p<0.001$) biopsy/CSF, -0.26 ($p<0.006$) biopsy/MMSE and -0.17 ($p<0,063$) MMSE/CSF
Conclusion: Our results indicate that there is a significant correlation between AD related clinical, CSF and biopsy "markers" but the correlations even if being significant included a considerable number of "outliers"

[3]Anatomy and Neuroscience, VU University Medical Centre Amsterdam, Amsterdam, Netherlands
[4]Clinica Neurologica, Università degli Studi di Perugia, Perugia, Italy
Objectives: To evaluate the potential use of alpha-synuclein (α-syn) species namely total (t-α-syn), oligomeric (o-α-syn) and phosphorylated at serine 129 (p-S129-α-syn) in cerebrospinal fluid (CSF) as progression biomarkers for PD.
Methods: Following the development and validation of novel enzyme-linked immunoadsorbent assays (ELISAs) using our novel specific monoclonal antibodies (mAbs) for α-syn oligomers, phosphorylated Ser129 α-syn or total-α-syn, we examined the levels of α-syn species in CSF from PD patients and age-matched healthy controls. Then, we assessed the potential use of α-syn species as progression markers in CSF samples that were taken at baseline and endpoint from a large cohort of patients that were early diagnosed with PD who participated in the DATATOP study.
Results: Combining the measurements of different CSF α-syn species, we found a clear differential CSF pattern between PD and control subjects. Interestingly, the levels of CSF α-syn species in DATATOP cohort were significantly altered at the end point compared to the baseline.
Conclusion: Our study highlights the usefulness of combining CSF α-syn species in improving PD diagnostic accuracy and prognostic evaluation. However, our findings need to be further confirmed in prospectively planned, independent cohort, particularly in samples where PD has been longitudinally assessed such as the Parkinson's Progression Markers Initiative (PPMI) cohort.

Background: Neurodegenerative parkinsonian syndromes have significant clinical and pathological overlap, making their early diagnosis difficult. They include Parkinson's disease (PD) and atypical parksinsonian syndromes (APS): progressive supranuclear palsy (PSP), multiple system atrophy (MSA) and corticobasal syndrome (CBS).

Objectives: To identify candidate cerebrospinal fluid (CSF) biomarkers, which can discriminate parkinsonian syndromes from healthy controls using proteomics.

Methods: CSF was consecutively collected from 134 participants; patients with PSP (n=36), PD (n=26), MSA (n=28), CBS (n=14), and elderly healthy controls (n=30). Participants were divided into an experimental and a validation set. Proteomic analysis with multiplex isobaric labeling was used for protein identification and quantification. The identified proteins were analyzed using multivariate discriminant analysis. Defining healthy controls and APS patients as two classes, an OPLS model was created using the discovery set. The model was then evaluated on the validation set. Proteins responsible for the separation were further evaluated by performing t-tests on the individual proteins, with multiple testing correction.

Results: There was 100% sensitivity and 70% specificity differentiating APS from healthy controls when the OPLS model created was applied to the validation set. PD data were positioned in between APS and healthy controls. 20 proteins were both significantly discriminant in the multivariate model and in the univariate t-tests. They consisted of acute phase/inflammatory markers and neuronal/synaptic markers, which were respectively increased and decreased in APS compared to healthy controls.

Conclusion Using an unbiased approach, proteins differentiating parkinsonian patients from healthy controls were identified, which may be useful as candidate biomarkers.

[5]Research Statistics, Pfizer, Boston, USA

Background: Mutations in glucocerebrosidase (GBA) represent the most common genetic risk factor for Parkinson's disease (PD) and other synucleinopathies. Many of these mutations lead to decreased enzymatic activity/stability and have been shown to impair lysosomal functionality, including clearance of α-synuclein.
Objective: To determine whether there is a decrease in GBA activity/levels in sporadic PD.
Methods: We sequenced all 11 exons of the GBA gene from 179 PD and 62 controls. GBA enzymatic activity was measured using a fluorescent artificial substrate, 4-methylumbelliferyl-β-d-glucoside. Protein levels were assessed by Western blotting (GBA and α-synuclein) and with a fluorescent GBA-probe, MDW941, which binds irreversibly to GBA.
Results: 18 GBA mutation carriers were identified, all in the PD group. We see a significant (P = 0.0127) 16.2% decrease in GBA enzymatic activity in superior temporal gyrus (STG) tissues from sporadic PD (n=38) compared to controls (*n*=34). GBA mutation carriers (*n*=8) had a further reduction in GBA activity, 55.9% decrease (P < 0.0001), compared to controls. In a subset of the STG samples, we measured a significant (P < 0.0001) increase in α-synuclein which correlates with the decreased GBA activity. Using the fluorescent GBA-probe we show a significant (P < 0.0001) decrease in lysosomal GBA in sporadic PD (*n*=18) compared to control (*n*=18).
Conclusions: These data demonstrate a significant reduction in the levels and activity of GBA in PD cases, both with and without GBA mutations. Additional human data, from other brain regions, together with mechanistic insights will provide a foundation for drug discovery programs.

[7]Department of Neurology/ Alzheimercenter, VU Medical Center, Amsterdam, Netherlands
[8]Department of Neurology,
Insitue of Clinival Medicine Akershus University Hospital University of Oslo, Lørenskog, Norway

Objective. Most biomarker studies in DLB have included small cohorts from single centres. Building on a new pan-European consortium, which aims at collecting large multicentre cohorts of DLB and PD patients to describe longitudinal course and detect diagnostic and prognostic biomarkers, as well as providing guidelines for longitudinal cohort studies, we here describe the proportion with pathological CSF AD biomarkers in DLB and PD.
Methods. Out of a cohort of 1616 patients (DLB 581, PD 887, and PDD 148), CSF levels of abeta42 (Aβ42), total tau (t-tau), and phosphorylated tau (p-tau), as measured at the different centres, were collected. The locally available cut-off values for each marker were used to distinguish between normal and abnormal values
Results. CSF biomarker results were available for 474 patients from nine centres (DLB 367, PDD 46, PD 61) (Table 1 & Table 2). Low Aβ42 was more common in DLB than in PD, and high t-tau and p-tau were more common in DLB than in PDD and PD (Table 2).
Conclusion: In the largest DLB cohort studied for CSF, 49% had pathological Aβ42, and nearly a third had increased t-tau and p-tau values. However, there were large differences in Aβ42-values between centres (Table 1), which are likely due to pre-analytic procedures and the use of different ELISA tests. Future studies should explore the association of CSF markers with clinical phenotype, disease progression, imaging and other biomarkers in DLB.

ADPD5-2312
THE PARKINSON'S PROGRESSION MARKER INITIATIVE – DEVELOPING TRANSLATIONAL TOOLS TO ACCELERATE PD THERAPIES

K. Marek[1]
[1]*Neuology, Insitutute for Neurodegenerative DIsorders, New Haven, USA*

The Parkinson Progression Marker Initiative (PPMI) is designed to identify clinical, imaging and biospecimen biomarkers of PD progression to establish objective outcomes for PD therapeutic studies. The goal of PPMI is to define biomarker subsets throughout the clinical course of PD from prodromal PD to manifest disease that may reflect clinical progression and clinical response to therapeutic intervention. PPMI utilizes standardized methods of acquisition and analysis of biomarker data. Rapid ongoing public access to PPMI data and biospecimen is available at www.ppmi-info.org.

PPMI has completed enrollment of early untreated PD (n=423), healthy (HV) (n=196) and SWEDD (n=64) subjects and is currently enrolling prodromal subjects (n=70) defined by RBD or olfactory loss and DAT deficit, and genetic PD subjects (n=600) defined as subjects with a LRRK2, GBA, and/or SNCA mutation who either are asymptomatic or have manifest PD, at 32 clinical sites worldwide. All subjects are and will be comprehensively followed longitudinally.

Key initial findings include -

· Assessments of non-motor symptoms including cognition, depression, anxiety and autonomic function show abnormalities in PD subjects compared to HS
· DAT striatal binding ratios in putamen are reduced by about 60% in PD compared to HS
· CSF alpha synuclein, p-Tau and T-tau are reduced by about 20% in PD compared to HS
· SWEDD subjects show DAT and CSF finding similar to HS
· About 50% of PD subjects were treated with dopaminergic meds within 12 months.

The PD, HV, and SWEDD subjects have all reached the one-year PPMI follow-up assessment. There have been more than 300,000 data downloads and 45 request for study samples from the PPMI website. The prodromal and all genetic cohorts are expected to complete enrollment in 2015.

CEREBROSPINAL FLUID BIOMARKERS AND CLINICAL PROGRESSION OF PD

S. Hall[1], Y. Surova[1], A. Öhrfelt[2], H. Zetterberg[2], D. Lindqvist[3], O. Hansson[4]
[1]Department of Neurology, Skåne Unviversity Hospital, Lund, Sweden
[2]Department of Psychiatry and Neurochemistry,
Institute of Neuroscience and Physiology the Sahlgrenska Academy at the University of Gothenburg, Gothenburg, Sweden
[3]Skåne University Hospital, Psychiatry Skåne, Lund, Sweden
[4]Skåne University Hospital, Memory Clinic, Malmö, Sweden

Objective
To investigate if certain cerebrospinal fluid (CSF) biomarkers at baseline can predict future progression of motor symptoms and cognitive decline in patients with Parkinson's disease (PD).
Methods
Study participants were recruited from hospitals in southern Sweden as part of the prospective, longitudinal Swedish BioFinder study. In the present study, we included 42 patients with PD and 69 controls with clinical assessment and lumbar puncture at baseline. Baseline CSF were analysed for alpha-synuclein (alpha-syn), $Abeta_{42}$, tau, phosphorylated tau (P-tau) and neurofilament light (NFL). Associations between CSF markers at baseline and change in clinical characteristics after two years were investigated using multivariate models adjusting for age, gender, disease duration, and levodopa-equivalent daily dose.
Results
Higher levels of alpha-syn within the PD group were associated with progression of motor symptoms and cognitive decline over two years, indicated by significant relationships between alpha-syn and change in Hoehn & Yahr (beta=0.394, p=0.043), Unified Parkinson's Disease Rating Scale-3 (UPDRS-3) (beta=0.449, p=0.013), Timed Up and Go (beta=0.406, p=0.023) and A Quick Test of cognitive speed (AQT, beta=0.423, p=0.018). Lower levels of $Abeta_{42}$ were associated with worsening on delayed memory recall (F=5.834, p=0.022). High levels of P-tau were associated with worsening in motor symptoms (UPDRS-3, beta=0.350, p=0.045; Hoehn & Yahr, beta=0.366, p=0.038).
Conclusion
Higher levels of alpha-syn at baseline seem to be associated with worsening of motor symptoms and cognitive speed over two years in PD. Increased alpha-syn might be a marker of more intense synaptic degeneration in PD. Amyloid pathology (low CSF $Abeta_{42}$) is associated with memory decline.

Aims

To assess and compare cortical thickness (CTh) of patients with prodromal Dementia with Lewy bodies (pro-DLB), prodromal Alzheimer's disease (pro-AD), DLB dementia (DLB-d), AD dementia (AD-d) and normal ageing.

Methods

Study participants (N=173) underwent 3 Tesla T1 3D MRI and detailed clinical and cognitive assessments. We used FreeSurfer analysis package to measure CTh and investigated the patterns of cortical thinning across groups.

Results

Comparison of CTh between pro-DLB and pro-AD ($p<0.05$, FDR corrected) showed more right anterior insula thinning in pro-DLB, and more bilateral parietal lobe thinning in pro-AD. Comparison of prodromal patients to healthy elderly controls showed the involvement of the same regions. In DLB-d cortical thinning was found predominantly in the temporo-parietal junctions, insula and cingulate cortices. In AD-d, the most significant areas affected included the temporal and parietal lobes.

Conclusion

Right anterior insula involvement may be a key region at the prodromal stage of DLB and needs further investigation.

Objectives. Hippocampal atrophy is a useful biomarker to identify MCI who progress to dementia from those who remain stable.
This study is aimed to compare subfields hippocampal volumetry between Abeta-negative (Abeta-) and Abeta-positive (Abeta+) aMCI patients in order to identify specific patterns of atrophy in Abeta+ aMCI and correlations with neuropsychological tests.
Methods. 145 MCI patients were enrolled in WP5 of PharmaCOG (E-ADNI) and underwent neuropsychological evaluation (memory, language and executive functions), CSF collection and high resolution 3T MRI. Hippocampus and hippocampal subfields volumes were computed using Freesurfer. Comparisons between Abeta+ and Abeta- were performed using an analysis of covariance model with age and gender as covariates. Correlations were computed using the Pearson's R test.
Results. Right hippocampal atrophy was reported in Abeta+ relative to Abeta- patients (-7.7%, p=.019) and left hippocampus presented a similar trend (-6.0%, p=.052). Greater volume reduction was detected bilaterally in the presubiculum (right: -10.7%, p=.003; left: -8.4, p=.018) of Abeta+ compared to Abeta- MCI and was significantly correlated with long term memory and naming, domains typically impaired in prodromal AD patients (Pearson R ranging from 0.20 to 0.43, all p<.001).
Conclusions. These preliminary data highlight the validity of presubiculum atrophy assessment to increase the accuracy and the sensitivity of total hippocampal atrophy in diagnosing MCI who progress to dementia. Longitudinal analysis is ongoing.

PURPOSE: Neuroanatomical correlates of cognitive changes in Parkinson's disease (PD) are of great interest to understand the underlying pathophysiology and monitor response to treatments. Along with well-characterized atrophy in cortical/subcortical regions, white matter (WM) microstructural changes have been demonstrated. Diffusional kurtosis imaging (DKI) is an extension of diffusion tensor imaging (DTI) that characterizes non-Gaussian water diffusion providing more comprehensive evaluation of WM microstructural integrity.
METHODS: We investigated DKI changes in 20 PD (65.5±5.0y), 17 PD with mild cognitive impairment (PD-MCI, 69.3±8.9y), and 26 normal controls (NC, 70.7±7.2y). The study cohort underwent detailed clinical and neuropsychological evaluations and a 3T DKI-MRI to provide parametric maps of mean diffusivity (MD), axial diffusivity (AD), radial diffusivity (RD), fractional anisotropy (FA), mean kurtosis (MK), axial kurtosis (AK), and radial kurtosis (RK). Using track-based spatial statistics (TBSS), skeletonized voxel-wise analysis identified group differences on the WM skeleton. Also, 44 regions were drawn based on the JHU WM atlas to test for group differences using ANCOVA with age as a covariate.
RESULTS: Both TBSS and ROI-analysis showed widespread differences including decreased AK values in PD vs. NC and decreased FA and increased MD, AD and RD in PD-MCI vs. both NC and PD. ROI with significant differences included cingulum, hippocampus, fornix, and corpus callosum correlating with changes in Visuospatial, Executive, and Memory domains.
CONCLUSION: Disruption of WM connectivity may be a useful biomarker for exploring pathologic mechanisms in PD, predicting cognitive change in PD and as an outcome for PD clinical trials.

OBJECTIVE:PD is a neurodegenerative disorder that is characterized by alpha-synuclein deposition that follows a nonrandom cortical distribution. Our goal was to model in vivo cortical progression in PD based on the change in cortical thickness with disease duration. We compared cortical atrophy between PD patients with short duration (2-10 years) and long duration (>10 years) of disease. We hypothesized that the rates of cortical atrophy would be regionally distinct, and driven by disease duration.
METHODS: All 205 PD patients underwent clinical evaluation and anatomical MRI scan at 3T. Cortical thickness was evaluated with FreeSurfer in brain regions identified by the Destrieux Atlas. A bootstrapped linear regression was performed to estimate rate of decrease in cortical thickness with disease duration (mm/year). Thickness values and rate of thinning were compared between groups.
RESULTS: Thickness decreased bilaterally (p
CONCLUSIONS: In PD, distinct brain regions atrophy at different rates in a manner dependent on duration of disease.

Objective: Parkinson's disease (PD) is characterized by dopaminergic cell death in the substantia nigra. Post-mortem studies reveal the presence of Lewy pathology in cortical areas, especially in later stages. This study aimed to gain insight into PD-related "macroscopic" cortical changes *in vivo* using longitudinal structural MRI.
Methods: Structural MRI images were obtained at baseline, 18, and 36 months in 78 non-demented PD subjects and 79 controls matched for age, gender, and number of visits. Cortical thickness was compared by region between PD and controls, and between PD subgroups based on disease duration [<1yr (PD-early, n=19), 1-5yr (PD-middle, n=34), >5yr (PD-later, n=25)]. Linear mixed modelling and F-tests were used to compare the amount and rate of cortical thinning between groups and subgroups. Region-level p-values were adjusted using a false discovery rate (FDR) of 0.05.
Results: Compared to controls, PD subjects at all visits had widespread cortical thinning that was particularly prominent in temporal, pre-central, precuneus, para-central, and post-central cortical regions. PD-early and PD-middle subjects had accelerated rates of overall cortical atrophy (p=0.049, p=0.004), whereas PD-later subjects showed no significant difference in atrophy rate (p=0.143).
Conclusions: Widespread cortical atrophy occurs in PD, even in the early stages. Accelerated cortical thinning occurs mainly in early- and middle-stage PD. The plateau of cortical atrophy in later stage is intriguing and further investigation is

warranted.

ELEVATED LEVELS OF THE ALZHEIMER'S DISEASE-RISK FACTOR SORL1 TRIGGER ANXIETY

S. Glerup[1], D. Demontis[1], M. Kaas[1], S.D. Oestergaard[2], H. Buttenschon[2], O. Mors[2], C.M. Petersen[1], A. Nykjaer[1]
[1]Biomedicine, Biomedicine, Århus C, Denmark
[2]Clinical Medicine, Clinical Medicine, Århus C, Denmark

Objectives
SORL1 is a well-studied risk factor in Alzheimer's disease and is known to inhibit amyloidogenic processing of amyloid precursor protein (APP) and mediate lysosomal sorting of the neurotrophic factor GDNF. Both APP and GDNF are involved in neurodegenerative disease but also play important roles in the developing brain. In the present study, we investigated if SORL1 might also be implicated in neurodevelopmental disorders.
Methods and Results
We find highly increased levels of SORL1 among individuals suffering from anxiety disorder compared to controls ($P=1.8x10^{-14}$), and that its encoding gene *SORL1* shows a gene-wise significant association with this disorder. Interestingly, SORL1 is moderately expressed in the embryonic brain cortex but rises steeply after birth until it plateaus during puberty, suggesting that SORL1 expression is strictly controlled in early postnatal development when neuronal circuitries controlling anxiety are established. Indeed, postnatal hippocampal neurons from Sorl1 deficient mice displayed increased survival and dendritic complexity when stimulated with GDNF compared to wildtype controls. Furthermore, lack of Sorl1 rescued the anxiety phenotype observed in mice with reduced GDNF expression while conditional overexpression of human SORL1 triggered anxiety-related behaviour.
Conclusions
Anxiety is an emotional state characterized by extreme nervousness and even panic in the absence of reason. Anxiety-related behavior is conserved through evolution from invertebrates to humans but its biology remains poorly understood. Importantly, our present findings establish SORL1 as a critical regulator of anxiety-related behaviour in both mice and humans.

ADPD5-0568
ANALYSIS OF AUTOANTIBODIES FROM CSF AND SERUM OF AD AND AMCI SUBJECTS: POTENTIAL ROLE IN PATHOLOGY PROGRESSION AND PREDICTION

F. Di Domenico[1], E. Barone[1], J. Vina[2], D.A. Butterfield[3], M. Perluigi[1]
[1]Department of Biochemical Sciences "A. Rossi Fanelli", "Sapienza" Università di Roma, Roma, Italy
[2]Department of Physiology, University of Valencia, Valencia, Spain
[3]Department of Chemistry, University of Kentucky, Lexington KY, USA

Objectives: Mounting evidence support the involvement of immune system in AD progression including the participation of inflammatory and autoimmune components in the neurodegenerative process. Immune system components have been detected in the brain, cerebrospinal fluid (CSF) and serum of AD subjects and their trend of variation correlates with disease progression. Nevertheless, AD patients present significantly lower levels of antibodies against Aß in serum and CSF in respect to healthy controls. Within this scenario, incomplete and often controversial results are reported about CNS immune/autoimmune responses during AD and a better comprehension is needed. Our research aims to shed light on the nature and potential role of autoantibodies in CSF and serum from AD and aMCI patients compared to healthy subjects.
Method: Our method employ immune-proteomics approach in order to discern natural occurring antibodies in human biofluids by the identification of brain antigen targeted by self-IgGs.
Results: Overall our data reveal that the alterations of autoantibodies profiling both in CSF and serum follow disease staging and progression. Furthermore, we demonstrate a fair overlap between CSF and serum auto-IgGs suggesting the existence of different immunogenic events between CNS and periphery. Interestingly, CSF autoantibodies recognized, among others, key players of energy metabolic pathways, including glycolysis and the TCA cycle, found oxidatively modified in previous studies on AD brain.
Conclusions: Our results show the manifestation of autoantibodies targeting brain proteins in AD and aMCI and suggest/propose the occurrence of a chain of events among brain oxidative damage, CSF autoantibodies production and reduced energy metabolism.

Proteins recognized by autoantibodies from AD and aMCI subjects:

CSF	Serum
Dihydropteridine reductase	**Dihydropteridine reductase**
Triosephosphate Isomerase	**Triosephosphate isomerase**
Protein-L-isoaspartate(D-aspartate) O-methyltransferase	Heat shock cognate 71 kDa protein

[3]Departments of Medicine Radiology Psychiatry and Neurology,
Center for Imaging of Neurodegenerative Diseases, San Francisco, USA

Objective
Alzheimer's disease (AD) is characterized by extracellular deposits of aggregated amyloid-β (Aβ) peptides, intracellular tangles, and loss of synapses. Up to recently, no biomarkers reflecting the third hallmark, progressive dysfunction and degeneration of synapses, have been available. The objective of the present study was therefore to evaluate cerebrospinal fluid (CSF) levels of the post-synaptic protein neurogranin (Ng) in the ADNI-1 cohort.

Methods
CSF samples from the ADNI-1 cohort including AD dementia (N=95), mild cognitive impairment (MCI, N=186) and controls (N=105) were analyzed by an in-house developed immunoassay. The immunoassay employs the in-house generated monoclonal antibody Ng7 as capturing antibody.

Results
Higher CSF Ng levels were found in AD dementia and progressive MCI (pMCI, progression to AD dementia during follow-up), but also in stable MCI (sMCI, no progression to AD dementia during at least 2 year follow up) as compared to controls ($p<0.001$). These differences were confined to Aβ positive MCI subjects (CSF Aβ42<192 pg/mL), while Aβ negative cases had CSF Ng levels in the same range as Aβ negative controls. Further, high CSF Ng levels predicted future hippocampal atrophy in controls and sMCI ($P<0.05$), and weakly in pMCI ($P=0.08$), but not in AD dementia cases.

Conclusion
The CSF concentration of Ng is increased in MCI and AD dementia compared to controls. The increase in CSF Ng was dependent on Aβ positivity, and predicted progression of hippocampal atrophy in predementia cases. These findings suggest that CSF Ng is an early biomarker to monitor synaptic function or degeneration.

CSF JKN3 KINASE IS A PROGNOSTIC BIOMARKER IN ALZHEIMER'S DISEASE

J. Hugon[1], S. Gourmaud[1], F. Mouton Liger[1], J. Dumurgier[1], J.L. Laplanche[1], C. Paquet[1]

[1]Paris, GH Lariboisière-Fernand Widal, PARIS, France

Alzheimer's disease (AD) is clinically marked by memory troubles, followed by aphasia, apraxia and agnosia. Senile plaques made of β-amyloid (Aβ) peptides, neurofibrillary tangles formed by hyperphosphorylated tau proteins, and neuronal losses are the typical features of the disease. Cerebrospinal fluid (CSF) Aβ, T-tau and p-tau are now widely used as biomarkers. C-Jun N-terminal kinases (JNKs) are kinases activated by phosphorylation. JNK3 is mainly detected in the brain and JNKs are implicated in neuronal death. The levels of brain JNK isoforms and CSF JNK3 were assessed in AD and neurological disease control patients. In 10 AD and 10 control brains, JNKs levels were evaluated by western blots and $A\beta_{42}$ was measured by ELISA. In 8 AD and 9 control brains JNK immunostainings were also carried out. In addition to classic biomarkers, JNK3 levels were determined by immunoblot in 30 AD patients and 26 neurological disease controls. Patients were followed from two to three years using MMSE scores. Significant increased JNK3 and phosphorylated JNK levels were detected in AD brains and JNK3 levels correlated with $A\beta_{42}$ levels. Confocal microscopy revealed that JNK3 was associated with Aβ in senile plaques. CSF JNK3 levels were significantly enhanced in AD patients and were statistically correlated with the rate of cognitive decline. A moderate increase of CSF JNK3 level was associated with an exacerbated cognitive impairment In conclusion. CSF JNK3 levels are increased in AD are linked to the rate of cognitive decline. CSF JNK3 could be a new biomarker in AD.

DETECTION OF ABETA DEGRADATION INTERMEDIATES IN THE CSF OF PATIENTS WITH MILD COGNITIVE IMPAIRMENT AND ALZHEIMER DISEASE
F. Liebsch[1], L. Kulic[2], C. Hock[2], G. Multhaup[3]
[1]Integrated Program in Neuroscience, McGill University, Montreal, Canada
[2]Division of Psychiatry Research, University of Zurich-Campus Schlieren, Zurich, Switzerland
[3]Department of Pharmacology and Therapeutics, McGill University, Montreal, Canada
An imbalance between production and clearance of the amyloid-beta peptide (Abeta) might be key to start the pathological cascade of sporadic Alzheimer disease (AD). While Abeta is a heterogeneous mixture of peptides with different solubilities, stabilities, and toxic properties, Abeta42 in particular is believed to be one of the chief culprits in AD pathogenesis. A variety of enzymes (including neprilysin 1/2, insulin-degrading enzyme, endothelin-converting enzyme, BACE1/2 and cathepsin B/D) degrade Abeta to different less-toxic intermediates. The intermediate, Abeta34, can either be generated by gamma-secretase, beta-secretase, BACE1 or its close homolog BACE2. In particular, BACE1/2-derived Abeta34 is generated from soluble Abeta40 and 42 substrates.
By studying Abeta catabolism in patients with mild cognitive impairment (MCI) and AD, we strive to understand the enzymatic amyloid clearance in early stages of AD. We have recently generated a monoclonal, neoepitope antibody that specifically recognizes Abeta34 with picomolar affinity. We found that Abeta34 was significantly elevated in cerebrospinal fluid (CSF) samples of patients with MCI compared to those from non-AD and AD individuals. These results suggest that during MCI, there is an elevated enzymatic Abeta-clearance activity, evident by an increase of the intermediate Abeta34, and that this process may become impaired with the progress of AD pathogenesis.
In summary, we hypothesize that at the MCI stage, Abeta40 and 42 can be degraded via stable and non-toxic intermediates (e.g. Abeta34), which can easily be detected in human CSF samples.

ADPD5-1851
HOW TO INTERROGATE LIPID DYSREGULATION IN LATE-ONSET DEMENTIAS?

S. Bennett[1]
[1]*Biochemistry Microbiology Immunology, University of Ottawa, Ottawa, Canada*

The emerging field of neurolipidomics seeks to understand how dynamic changes in membrane composition regulate brain cell function and how these changes can be used a biomarkers to predict disease outcome and track disease fate. Commonly conceptualized as undulating fields of identical molecules, neuronal membranes are, in fact, made up of hundreds of chemically and molecularly diverse lipid species. For the first time, significant technological advances in high performance liquid chromatography (LC), electrospray ionization (ESI), and matrix-assisted laser desorption ionization (MALDI) mass spectrometry (MS) are enabling membrane composition to be profiled comprehensively at the molecular level. Coupled with subcellular fractionation and careful consideration of extraction protocols that enrich for different phospholipid families, species that vary by only one double bond, a single methylene group, or carbon chain linkage can now be quantified directly in synaptic preparations. These advances are allowing for discovery of novel biomarkers of disease transition, progression, and fate and new mechanistic insight into the determinative roles of lipid metabolism in neurodegenerative disease. Yet, as with imaging biomarkers, accuracy and reproducibility are fundamentally dependent on how lipid biomarkers are measured. Here, we ask whether changes in phosphocholine (PC) membrane predict transition from a pre-symptomatic to symptomatic state distinguish normal elderly from mild cognitive impairment (MCI) and AD and we describe challenges in harmonization of protocols, analyses, and lipid identification required for replication of biomarker results obtained in through neurolipidomic investigations.

Symposium 31: PET 1: TAU IMAGING

ADPD5-0741
TAU PET IMAGING ([18F]THK-5117) IN A MULTI-TRACER COHORT
K. Chiotis[1], L. Saint-Aubert[1], A. Wall[2], M. Jonasson[2], M. Lubberink[2], J. Eriksson[3], G. Antoni[2], N. Okamura[4], A. Nordberg[1]
[1]NVS Center for Alzheimer Research Translational Alheimer Neurobiology, Karolinska Institutet, Huddinge, Sweden
[2]Radiology Oncology and Radiation Sciences, Uppsala University, Uppsala, Sweden
[3]Medicinal Chemistry, Uppsala University, Uppsala, Sweden
[4]Pharmacology, Tohoku University School of Medicine, Sendai, Japan
Objectives: The recent advances in PET imaging enabled the development of novel tau tracers that detect neurofibrillary tangles pathology. However, the *in vivo* regional progression of neurofibrillary tangles in relation to the other pathological hallmarks of Alzheimer's Disease (AD) pathology, neurodegeneration and amyloid plaques, remains largely unknown.
Methods: Patients with Mild Cognitive Impairment (MCI), dementia due to AD and Healthy Controls (HC) underwent a dynamic PET scan (0-90 minutes) with the novel tau tracer [18F]THK5117. The age-matched HC, MCI and AD patients were also scanned with [11C]PIB. Additional [18F]FDG scans were performed in the MCI and AD patients. All participating individuals underwent a high-resolution structural MRI (T1). Standard Uptake Value Ratio images were created for all tracers in respect to the grey matter of the cerebellum, and regional sampling was performed based on the Hammer's atlas.
Results: Comparisons were conducted between the [18F]THK5117 retention in cortical and subcortical regions across diagnostic groups. Moreover, the regional distribution of [18F]THK5117 retention was compared with those of [11C]PIB and [18F]FDG.
Conclusions: This study provides further insight into imaging *in vivo* the regional distribution of tau deposition with the novel PET tau tracer [18F]THK5117 at different stages of AD in relation to amyloid plaque pathology and neuronal degeneration.

ADPD5-0994
[11C]PBB3-PET DETECTS TAU-PATHOLOGY IN PROGRESSIVE SUPRANUCLEAR PALSY AND CORTICOBASAL DEGENERATION

H. Shinotoh[1], H. Shimada[1], S. Hirano[2], S. Furukawa[2], F. Niwa[1], S. Kitamura[1], H. Endo[1], K. Takahata[1], S. Kuwabara[2], M. Zhang[1], T. Suhara[1], M. Higuchi[1]
[1]Molecular Imaging Center, National Institute of Radiological Sciences, Chiba, Japan
[2]Neurology, Chiba University, Chiba, Japan

Objectives:[^{11}C]PBB3 has been recently introduced as a tau imaging PET ligand that has high affinity and selectivity for tau deposits. The aim of the present study is to investigate distribution of tau-pathology in progressive supranuclar palsy (PSP) and corticobasal degeneration (CBD) by [^{11}C]PBB3 PET.
Methods: Twelve patients with PSP, 8 patients with corticobasal syndrome (CBS), and 25 age-matched healthy controls (HC) participated in this study. Seventeen patients with Alzheimer's disease (AD) also took part in the study as disease control. Sequential PET scans were performed for 70 min following intravenous injection of [^{11}C]PBB3. Standardized uptake value ratio (SUVR) at 30-50 min was calculated using the cerebellar cortex as reference region. Cerebral beta-amyloid depositions were estimated using [^{11}C]Pittsburgh compound B (PIB) PET.
Results: All patients and HCs were PIB-negative except one patient with CBS and 4 HCs. SPM analysis showed high [^{11}C]PBB3 binding in globus pallidus, putamen, thalamus, midbrain, pons, and peri-rolandic areas in PSP patients compared with 21 HCs. Seven PIB-negative CBS patients showed high [^{11}C]PBB3 binding in peri-rolandic areas, supplementary motor area, and midbrain compared with 21 HCs. One PIB-positive patient with CBS showed high [^{11}C]PBB3 binding in the whole cerebral cortex including limbic cortex like AD patients.
Conclusions: The distribution of [^{11}C]PBB3 binding in the patients was mostly in agreement with the known distribution of tau pathology in PSP and CBD, suggesting that [^{11}C]PBB3-PET may be useful for the diagnosis of these disorders and therapeutic monitoring of anti-tau therapy.

Symposium 31: PET 1: TAU IMAGING

ADPD5-1650
PET RADIOLIGANDS REVEAL THE BASES OF DEMENTIA IN PARKINSON DISEASE

J. Growdon[1]
[1]*neurology, massachusetts general hospital, boston ma, USA*

Background: Cognitive impairments and dementia are among the most feared consequences of PD; the lifetime risk of dementia approaches 80%.
Goals: To identify in life the molecular signature of pathologic changes that have been identified in postmortem brain examinations and that have been linked to PD dementia.
Methods: Cross sectional and longitudinal prospective studies in PD subjects with normal cognition(PD-nl), PD with mild cognitive impairment (PD-MCI), PD with dementia (PDD) and subjects with dementia Lewy body (DLB) contrasted with normal subjects (HCS). All underwent formal neurologic examination, extensive neuropsychological assessments and PET scans with the radioligands altropane (DAT), PiB (β-amyloid), and FDG (synapses).
Results: DAT concentrations in putamen and caudate were similar in PD and DLB and were significantly lower than in HCS; the caudate decrease was related to indices of cognitive impairment in DLB. PiB uptake was greatest in DLB and significantly linked to impaired cognition. There was substantial PiB retention in ~40% of PDs as well; it did not distinguish PD-nl from PD-MCI, but was a strong risk factor for developing dementia over time. In contrast to DAT and PiB, FDG did distinguish PD-MCI from PD-nl, based on multiple cortical areas of hypometabolism in PD-MCI. PET scans with the radioligand T807 that detects tau shows promise in assessing the contribution of neurofibrillary tangles to PDD and even PD-MCI.
Conclusion: PET scans with the appropriate radioligands are powerful ways to assess the biochemical and molecular bases of cognitive impairment and dementia in PD during life.

Objectives: For early detection of disease-related tau pathology in the human brain, we developed a novel tau PET tracer [^{18}F]THK-5351, that displayed high binding affinity and selectivity for PHF-tau. In this study, we evaluated the clinical utility of [^{18}F]THK-5351 in humans with PET.
Methods: Twenty-two participants including 4 young normal, 7 aged normal subjects and 11 Alzheimer's disease (AD) patients underwent [^{18}F]THK-5351 and [^{11}C]PiB PET. Two AD patients additionally performed [^{18}F]THK-5117 PET for comparison with [^{18}F]THK-5351. Standardized uptake value ratios at 50-60 min and 40-70 min post injection were calculated for [^{18}F]THK-5351 and [^{11}C]PiB, respectively, using the cerebellar cortex as the reference region.
Results: AD patients showed significantly higher [^{18}F]THK-5351 retention in the temporal, parietal, posterior cingulate, ventrolateral prefrontal and hippocampus than young and aged normal subjects. In addition, higher [^{18}F]THK-5351 retention was observed in the hippocampus of aged normal subjects when compared to young normal subjects. [^{18}F]THK-5351 showed faster kinetics and lower white matter retention than [^{18}F]THK-5117. The pattern of [^{18}F]THK-5351 retention followed the known distribution of PHF-tau in AD brain and did not correlate with the cortical retention of [^{11}C]PiB.
Conclusion: High signal-to-background ratio of [^{18}F]THK-5351 allows clear visual inspection of PET images and sensitive detection of PHF-tau. Further studies are needed to study longitudinal changes in tau pathology.

TAU PET IMAGING IN ALZHEIMER´S DISEASE
A. Nordberg[1]
[1]*Center for Alzheimer Research Translational Alzheimer Neurobiology, Karolinska institutet, Stockholm, Sweden*
Combination of different biomarkers will not only improve the understanding of AD disease mechanisms but will also probably be necessary for reliable clinical diagnosis.We therefore explore the possibility to visualize the pathological deposition of tau in different stages of AD as well as in other forms of dementia using the PET Tau tracer 18F-(S)THK5117, in order to better understand the temporal evolution of AD pathophysiology and the possible role of tau imaging as a new and early biomarker for AD progression and for evaluation of new drug targets. Our multi-tracer PET system also include 11C-PIB for measurement of fibrillar amyloid plaques and 18F-FDG for cerebral glucose metabolism. Patients with clinical diagnosis of AD, mild cognitive impairment (MCI), different non-AD dementia are included as healthy young and old controls . All patients are undergoing neuropsychology testing and CSF biomarker assays. The introduction of a novel tau PET tracer will provide a crucial non-invasive tool for the investigation of neurofibrillary tangle pathology, in vivo, as they constitute an attractive target for early and accurate AD diagnosis. Moreover, by shedding light onto the underlying interrelationship of tau pathology with other aspects of the disease, such as cognitive decline and amyloid burden. In the future tau imaging will play an important role in the evaluation of new treatment strategies with target on tau pathology such tau immunization .

Tau PET in aging and dementia: initial experience with [18F]T807
K. Johnson[1]
[1]*Neurology and Radiology, Massachusetts General Hospical, Boston, USA*
Detection of focal brain tau deposition during life could greatly facilitate accurate diagnosis of Alzheimer's disease (AD), staging and monitoring of disease progression, and development of disease modifying therapies. We have tested a recently developed PET method for selective imaging of tau pathology in patients with AD dementia, mild impairment with amyloidosis, non-AD dementia, and clinically normal controls. Preliminary results comparing tau PET measures to clinical, cognitive, brain structural, CSF, and amyloid-beta imaging variables will be presented. Our findings support the concept of tau PET as an imaging biomarker for AD pathologic change that may be useful for diagnosis and therapy development.

LONGITUDINAL CEREBROSPINAL FLUID BIOMARKER MEASUREMENTS AND PRECLINICAL SPORADIC ALZHEIMER'S DISEASE: A PROSPECTIVE 9-YEARS COHORT STUDY

E. Stomrud[1], L. Minthon[1], H. Zetterberg[2], K. Blennow[2], O. Hansson[1]
[1]Department of Clinical Sciences Malmö, Lund University, Malmö, Sweden
[2]Clinical Neurochemistry Lab Department of Psychiatry and Neurochemistry, University of Gothenburg, Göteborg, Sweden

Importance: Ascertainment of the pattern and temporal change of biomarkers in preclinical sporadic Alzheimer's disease (AD) will increase knowledge about early pathogenesis and facilitate therapeutic trials.
Methods: In this prospective and longitudinal study 54 cognitively healthy individuals (60-87 years) underwent cognitive assessments and CSF sampling at baseline. Follow-ups were performed after 5 and 9 years, including repeated CSF measurements. Forty-four individuals were followed for at least 9 years and this subgroup was included in the main analyses.
Results: Twelve subjects (27 %) had low CSF Aβ42 levels (<192 ng/L) at baseline and out of these five converted to AD and one to dementia with Lewy Bodies (DLB). In the remaining cases with low baseline Aβ42 levels, four cases were cognitively normal over nine years and two cases developed MCI. CSF Aβ42 predicted development of AD/DLB with a sensitivity of 100 %, specificity 84 %, positive predictive value 50 %, and negative predictive value 100 %.
When analyzing repeated CSF samples no additional decrease in Ab_{1-42} levels was observed in the participants with low baseline levels. In the subjects with normal baseline Aβ42 levels, 19% developed pathologic levels during follow-up, of which none developed AD/DLB/MCI over nine years.
Conclusions: Low CSF Aβ42 levels predict sporadic AD and DLB at least nine years before dementia onset with high sensitivity and Aβ42 levels have already reached a plateau at this time. However, quite many individuals can harbor brain amyloid accumulation over a decade without any signs of cognitive dysfunction.

ADPD5-1055
THE UNBEARABLE LIGHTNESS OF BEING OLIGOMERS
E. Giacobini[1]
[1]*internal medicine rehabilitation and geriatrics,*
university of geneva faculty of medicine, geneva, Switzerland
Immunotherapies targeting a-beta monomers or insoluble aggregates have succeeded in lowering deposits of beta amyloid in brain but not in producing clinically significant results. Shifting from a-beta aggregates , a soluble a-beta hypothesis considers oligomers rather than plaques central toxic species being responsible for synaptic dysfunction . Many candidates of soluble oligomeric species have been proposed to have high affinity to synapses of subsets of hippocampal and cortical neurons causing neurotoxicity via cell surface receptors The exact structure and localization of these toxicologically relevant oligomers and receptors have not been characterized in human brain and a relationship between specific oligomers and the initiation of the disease has not been established. Up to present oligomers secreted from in vitro preparations or extracted from post-mortem brain tissue have been mostly studied , hence, it is not clear if these oligomers are present in the original brain tissue or are products of artifactual oligomerization. We report about the localization of oligomers in neuropathologically confirmed Alzheimer disease (AD), and the relation between oligomeric densities, neuritic plaques , neurofibrllary tangles and synaptic integrity . This study of human autopsy material combines neuropathological assessment and localization of a-beta oligomers, AD lesions and Western blot analyses in cognitively intact and AD diagnosed very old individuals. Our results reveal that mid-range molecular weight a-beta oligomers are present in both normal aging and AD brain areas and are in strict topographic association with fibrillar amyloid deposits. In the cerebellum , despite the absence of fibrillary deposits we demonstrate the presence of oligomers in both normal aging and AD.

LONGITUDINAL IMAGING AND PHENOCONVERSION IN THE PARS PRODROMAL COHORT

D. Jennings[1], M. Stern[2], A. Siderowf[3], K. Marek[4]
[1]Clinical, Institute for Neurodegenerative Disorders, New Haven, USA
[2]Neurology, University of Pennsylvania, Philadelphia, USA
[3]Neurology, Avid Radiopharmaceuticals, Philadelphia, USA
[4]Neurology, Institute for Neurodegenerative Disorders, New Haven, USA

The PARS cohort involves 203 hyposmic and 100 normosmic subjects. Data from the baseline imaging indicates 11% of subjects have DAT deficit (
Methods: Subjects completed baseline, 2-yr and 4-yr clinical and ^{123}I-ß-CIT/SPECT evaluations. Clinical evaluations (UPDRS, cognitive testing, diagnosis assignment) were performed blind to imaging and olfactory data. Change in striatal binding ratio (SBR) between baseline, 2-yr and 4-yr imaging was compared based on olfactory and DAT imaging status. Phenoconversion to PD at baseline, 2-yr and 4-yr imaging was examined.
Results: 203 hyposmics and 100 normosmics completed baseline assessments, 262 completed 2-yr, 173 completed 4-yr visits. Hyposmics with DAT deficit at any scan, 35% (10/31) phenoconverted by year 2 and 51% (21/41) phenoconverted by year 4. SBR mean percent change in hyposmic phenoconverters was -13.4 (±9.4) at yr 2 and -23.2 (±14.7) at yr 4 compared to -2.0 (±16.8) at yr 2 and 4.8 (±16.6) at yr 4 for hyposmic non-converters.
Conclusion: Longitudinal follow-up of PARS cohort demonstrates 51% phenoconversion among hyposmics with DAT deficit within the 4-year follow-up period. Longitudinal DAT imaging indicates that phenoconverters have higher loss in DAT compared to hyposmic non-converters. Additional follow-up will allow for more precise estimation of the phenoconversion rate and identification of markers that may predict the rate of progression in the pre-diagnostic phase of PD.

IDENTIFICATION OF PRE-SYMPTOMATIC ALZHEIMER'S DISEASE IN OLDER ADULTS AT HIGH-RISK: HIGH RESOLUTION RETINAL IMAGING IN PRECLINICAL DISEASE

P.J. Snyder[1], Y.Y. Lim[1], B.M. Fernández[2]
[1]Neurology, Rhode Island Hospital & Alpert Medical School of Brown University, Providence, USA
[2]Medical Sciences, Heidelberg Engineering Inc., Carlsbad, USA

Alzheimers disease (AD) is associated with volume reductions in retinal nerve cell layers, as well as Aβ deposits within the retina and lens. Cross-sectional studies of changes for individual cell layers (MCI/AD vs. cognitively normal [CN] controls) suggest a loss of tissue with increasing disease severity. We sought to characterize structural differences in retinal layers and to determine whether these are associated with visual field impairments in CN older adults at risk for AD.
CN older adults (n=63) underwent ^{18}F-florbetapir PET neuroimaging to determine cortical Aβ burden. All participants also underwent spectral-domain optical coherence tomography (SD-OCT) and visual field testing. Compared to CN older adults with low Aβ (n=53), CN older adults with high Aβ (n=10) showed increased thickness of a moderate magnitude in the parafoveal peripheral measures of the retinal nerve fiber layer (d=0.61, p=.07), inner nuclear layer (d=0.68, p=.18) and inner plexiform layer (d=0.73, p=.04). Increased Aβ burden was significantly associated with worse visual perimetry performance using the SAP stimuli (d=0.55, p=.04).
These results suggest that, in the likely preclinical stage of AD (i.e., CN older adults with high cortical Aβ), several of the retinal nerve cell layers show measurable increases in thickness possibly reflecting an inflammatory process. We believe that this may precede eventual decreases with disease progression. Numerous studies have suggested that Aβ-induced inflammation may play a critical and early role in AD pathogenesis, and one study found similar evidence of inflammation in the rat retina following intravitreal administration of Aβ (Howlett et al., 2011). Impairments in visual fields were also identified with increasing Aβ levels. Taken together, the results provide preliminary but important insights into the early structural and functional retinal changes in preclinical AD.

THE TRAJECTORY OF CSF AMYLOID BETA LEVELS IN PRECLINICAL LOAD

M.J. de Leon[1], E. Pirraglia[1], R. Osorio[1], L. Glodzik[1], Y. Li[1], L. Mosconi[1], L.A. Saint Louis[2], H. Zetterberg[3], K. Blennow[3]

[1]Dept of Psychiatry, NYU School of Medicine, New York, USA

[2]Radiology, Manhattan Diagnostic Radiology, New York, USA

[3]Clinical Chemistry, Salhgrenska Academy, Gothenburg, Sweden

Objective

Reduced CSF Aβ1-42 concentrations are found in the preclinical phase of Alzheimer's disease (AD), but infrequently elevations are reported. Our objective was to test the hypothesis that in the dementia trajectory of late onset AD (LOAD), Aβ1-42 elevations precede reductions.

Methods

Community residing normal subjects were recruited by random population sampling. We conducted a cross sectional study of subjects aged 21-88y (n=270) and a longitudinal study with 2y and 6y follow-ups (n=92 and 39 respectively). All subjects received standardized clinical, LP and imaging exams. Outcome measures included cognition, ventricular enlargement, PIB-PET, and CSF P-tau levels.

Results

Across the adult lifespan, increasing numbers of subjects show both elevations and reductions in CSF Aβ1-42 ($p<.05$). Quadratic relationships between the Aβ1-42 and both P-tau and cognition were observed indicating pathology with both high and low Aβ1-42 levels. Elevated PIB uptake and increased ventricle size also showed a quadratic association with Aβ1-42 levels, providing P-tau levels were elevated. Elevated Aβ1-42 predicted longitudinal reductions in Aβ1-42 levels suggesting direction. Longitudinally, cognitive decline was best predicted by P-tau/Aβ1-42 ratio, which in turn was predominantly driven by reductions in Aβ1-42.

Conclusions

Both elevated and reduced Aβ1-42 levels are found after age 60, and both are related to cognitive decline and elevated P-tau levels. In the presence of elevated P-tau, both elevated and reduced Aβ1-42 levels are further associated with brain atrophy and amyloid load. While still not possible to conclude that in LOAD CSF Aβ1-42 elevations precede the reductions, this trajectory remains a possibility.

WHAT DOES CSF TELLS US ABOUT ALZHEIMER'S AND RELATED DISORDERS?

G.B. Stokin[1]
[1]*St. Anne's University Hospital, International Clinicial Research Center, Brno, Czech Republic*

Past decade witnessed significant effort to translate basic findings about Alzheimer's and related disorders into clinical practice with the goal of improving diagnostics and exploring therapeutics. As a result, today, several hallmark lesions and proteins intimately linked to the pathogenesis of Alzheimer's and related disorders, can be visualized in the brain and measured in body fluids.

As part of these efforts, amyloid, tau and other proteins can be reliably measured in the cerebrospinal fluid. Since specific changes in the cerebrospinal fluid levels of these proteins have been shown to correlate with Alzheimer's and related disease phenotypes, specific combinations of changes in these proteins, in particular, have been widely used as diagnostic biomarkers of Alzheimer's and related disorders. These biomarkers are unique, compared to many others, considering cerebrospinal fluid assessment offers opportunity to critically test for a wide spectrum of pathologies that often need to be excluded in the process of differential diagnostics. To date, despite inclusion of cerebrospinal fluid biomarkers into diagnostic criteria of Alzheimer's and related disorders, the rationale for using cerebrospinal fluid biomarkers per se as well as compared to other biomarkers remains unsettled. Importantly, despite the wealth of data reporting protein changes in the cerebrospinal fluid in Alzheimer's and related disorders few studies and even fewer interpretations elucidate on the value of cerebrospinal fluid findings in understanding the pathogenesis of Alzheimer's and related disorders.

[8]Neuroscience, University of California Berkeley, Berkeley, USA
[9]Radiology, UCSF, San Francisco, USA

Objective: Genome-wide association studies have identified many risk genes for Alzheimer's disease (AD). The mechanism through which many of these genes exert their effect remains unknown. Here we investigated the association between plasma apoE protein and brain amyloidosis and the effect of the top AD risk genes on that association.
Methods: Our dataset consisted of 18 AD, 52 mild cognitive impairment and 3 cognitively normal Alzheimer's Disease Neuroimaging Initiative 1 (ADNI1) subjects with available [11C]-PIB and peripheral blood protein data. We applied the cortical pattern matching methodology to study the associations between plasma ApoE protein and cortical PIB binding in 3D. Next, we studied the effect of carrier/noncarrier status for the remaining top 10 AD risk genes variants available in ADNI1 GWAS on this association. Correction for multiple comparisons was done with permutation testing using the stringent threshold of p
Results: Plasma apoE protein showed a significant negative association with PIB SUVR throughout except for the sensorimotor and entorhinal cortex. Effect on this association was seen for *BIN1* rs744373 where the association was only observed in minor allele carriers, and *CD2AP* rs9349407 and *CR1* rs3818361 where the association was only preserved in minor alleles noncarriers. We did not find evidence for modulation of the ApoE protein-PIB association by the available *CLU, PICALM, ABCA7, BIN1* and *MS4A6A* genotypes.
Conclusion: Our data show that *BIN1* rs744373, *CD2AP* rs9349407, and *CR1* rs3818361 modulate the association between plasma ApoE protein and brain amyloidosis. These findings imply a potential epigenetic or downstream interaction.

[4]Clinical Sciences, Clinical Physiology and Nuclear Medicine Unit Lund University, Lund, Sweden
[5]Clinical Neurophysiology, Skåne University Hospital, Lund, Sweden
[6]Department of Internal Medicine Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

Objectives

Biomarkers of cerebral amyloid β (Aβ) are important for diagnosing Alzheimer's disease (AD) early. We performed a head-to-head comparison of two cerebrospinal fluid (CSF) assays and PET measures of eight regional and global amyloid depositions.

Methods

34 consecutive patients with mild cognitive symptoms who developed AD within 4 years were compared with 122 controls. The amyloid PET tracer [18F]Flutememetamol was used. CSF Aβ42 and P-tau were analysed with ELISA INNOTEST and Aβ42, Aβ42/Aβ40 and Tau with ADx assays.

Results

The best CSF measures were Aβ42/Tau and Aβ42/P-tau (AUC 0.93–0.94, INNOTEST and ADx), which performed equally to the best PET measures (AUC of anterior cingulate, posterior cingulate/precuneus, global/composite score, prefrontal and parietal: 0.91–0.92; $P>0.35$). No PET measure was significantly better than Aβ42 INNOTEST (AUC 0.90) or Aβ42/Aβ40 ADx (AUC 0.86). Using a priori cutoffs, the best sensitivities and specificities for CSF were produced by Aβ42/Tau INNOTEST (97%, 83%) and for PET the prefrontal region (88%, 86%). The combination of composite PET and Aβ42/P-tau or Aβ42/Tau (AUC 0.95–0.96) was not significantly better than either variable alone, but composite PET and Aβ42 INNOTEST (AUC 0.95) were slightly better than Aβ42 INNOTEST alone (AUC 0.90; $P<0.01$).

Conclusions

There was no significant difference between the best CSF and amyloid PET measures and no significant improvement when combining them. Regional PET measures were not better than a composite PET score. The choice between CSF analysis and amyloid PET can be based on availability, costs and doctor/patient preferences since both have equally high diagnostic accuracy.

Symposium 35: PET 2: AMYLOID AND RECEPTORS

ADPD5-0734
PET IMAGING OF SYNAPTIC NORADRENALINE WITH [11C]ORM-13070
M. Scheinin[1], J. Lehto[1], L. Vuorilehto[1], E. Arponen[2], J. Johansson[2], P. Luoto[2], H. Scheinin[2], J. Rouru[3]
[1]Pharmacology Drug Development and Therapeutics, University of Turku, Turku, Finland
[2]University of Turku and Turku University Hospital, Turku PET Centre, Turku, Finland
[3]Orion Pharma, Orion Corporation, Turku, Finland
Objectives: The PET tracer [^{11}C]ORM-13070 was recently validated for receptor occupancy analysis of brain alpha2C-adrenoceptors, and PET experiments in monkeys and humans indicated that tracer uptake into the caudate and putamen was reduced by interventions that increased synaptic noradrenaline concentrations in the brain. This study aimed to confirm the sensitivity of [^{11}C]ORM-13070 binding to increased levels of synaptic noradrenaline.
Methods: PET imaging of the brain was performed with a 3D High Resolution Research Tomograph. Eight subjects underwent a control [^{11}C]ORM-13070 PET scan and two PET scans after two different noradrenaline challenges, i.e. a sub-anaesthetic infusion of ketamine and oral intake of atomoxetine combined with cold stimulation. Tracer uptake in the caudate nucleus and putamen was described with AUC values in scan time windows of 10-20 min and 5-30 min post injection, and quantified with the ratio method. Voxel-based analysis was performed with average B/F images.
Results: Both challenges caused small but statistically significant (10-20%, $p<0.05$) reductions in tracer uptake in both target regions. Voxel-based analysis revealed significant clusters in the dorsal putamen with both challenges. Ketamine was associated with significant elevations in circulating noradrenaline and adrenaline levels, while the atomoxetine + cold treatment was not.
Conclusions: Strong experimental support was gained for the feasibility of [^{11}C]ORM-13070 PET imaging of brain noradrenergic neurotransmission.

Symposium 35: PET 2: AMYLOID AND RECEPTORS

ADPD5-0857
DIFFERENTIAL DIAGNOSTIC ACCURACY OF [11C]PIB PET AND CSF BIOMARKERS IN PRODROMAL ALZHEIMER'S DISEASE

A. Leuzy[1], K. Chiotis[1], S.F. Carter[2], O. Almkvist[1], A. Wall[3], A. Nordberg[1]
[1]Translational Alzheimer Neurobiology, Centre for Alzheimer Research, Stockholm, Sweden
[2]Wolfson Molecular Imaging Centre, University of Manchester, Manchester, United Kingdom
[3]Uppsala University, Department of Radiology Oncology and Radiation Sciences, Uppsala, Sweden

Objectives: While showing good convergence across the spectrum of Alzheimer's disease (AD), some studies highlight imperfect agreement between positron emission tomography (PET) and cerebrospinal fluid (CSF) measures of beta-amyloid (AB_{42}), and differential performance with respect to the identification of prodromal AD. Using a sample of patients with mild cognitive impairment (MCI) and AD, we sought to determine 1) concordance between CSF-AB_{42} (alone, and with tau) and Pittsburgh Compound-B (PIB) PET and 2) classification accuracy of PIB PET and CSF-AB_{42} (alone, and with tau) with respect to stable (sMCI) versus MCI who progressed to AD dementia (pMCI). **Methods:** Diagnosis of MCI (n=34) and AD (n=35) were issued using the 2004 Petersen and the 1984 McKhann criteria, respectively. PIB PET standard uptake value ratio maps were calculated using the cerebellar cortex as a reference region and subsequently registered nonlinearly to a population-based PIB template. CSF levels of $A\beta_{42}$ and phosphorylated tau were determined using sandwich enzyme-linked immunosorbent assay. **Results:** Concordance within groups was highest for sMCI (76%), followed by AD (60%) and pMCI (33%). Using $A\beta_{42}$/p-tau, concordance was highest for pMCI (100%), followed by AD (96%) and sMCI (62%). Logistic regression showed that classification accuracy of PIB-PET was superior to AB_{42} (79% vs. 63%) or AB_{42}/p-tau (65%). **Conclusions:** Relative to CSF measures of AB_{42} or AB_{42}/p-tau, PIB PET may prove a better predictor of progression to AD in patients with MCI. Discordance between PET and CSF markers for AB_{42} suggests they cannot be used interchangeably, as is currently the case.

[5]Food and Nutrition Flagship, CSIRO, Melbourne, Australia
[6]The Florey Institute, University of Melbourne, Melbourne, Australia
[7]Centre for PET, Austin Health, Melbourne, Australia

Objectives. The objective of the study was to characterize a two-imaging marker construct in the preclinical stages of Alzheimer disease.
Methods. 493 cognitively unimpaired individuals (HC, 73.0±6.2years; 56%female) were included in the study. Aβ status (**A**) was determined with either PiB, flutemetamol or florbetapir, while neurodegeneration (**N**) was established using hippocampal volume. Following Jack et al, individuals were categorized as either A-N-, A+N-, A+N+, or suspected non–Alzheimer disease pathophysiology (SNAP, A-N+). Clinical progression, cognitive domain-specific trajectories and global composite scores for 461 HC were assessed.
Results: 65% of HC were classified as A-N-, 18% as A+N-, 5% as A+N+, and 12% as A-N+. Participants in the A-N- group were significantly younger, and while males were more prevalent among A+N+ and A-N+, females were more prevalent among A+N- and A-N-. ApoE4 carriage was more frequent in A+N-(48%) and A+N+(58%) than in A-N-(19%) and A-N+(23%). While no significant differences were observed in baseline scores significantly faster cognitive decline was observed in A+N+(-0.30SD/yr) and A+N-(-0.08SD/yr) when compared to A-N-(+0.02SD/yr). The A-N- and A-N+ groups did not show significant decline over time, although A-N+ was associated with a lower baseline performance. While A+N+ and A+N- were more impaired in memory domains, A-N+ were more impaired in language and executive domains. Within 4.5 years, 22.2% of A+N+ progressed to amnestic MCI/AD, compared to only 7.3% of A-N+(2MCI, 1AD, 1VaD)
Conclusions: Increasing marker abnormality was reflected in faster cognitive decline. Distinct cognitive domains were affected in those with AD and non-AD pathology, likely suggesting different underlying pathophysiological mechanisms.

CEREBRAL GLUCOSE ANALYSIS SERVES AS AN EXCELLENT BIOMARKER FOR NEURODEGENERATIVE BRAIN DISEASES

S. Meles[1], L.K. Teune[1], R. Renken[1], K.L. Leenders[1]
[1]Neurology, University Medical Center Groningen (UMCG), Groningen, Netherlands

Objectives

Reliable and objective diagnosis of parkinsonian disorders on the basis of cerebral glucose imaging (FDG-PET) by applying a multivariate and data-driven technique.

Methods

We studied FDG PET brain data of patients who underwent FDG PET scanning in the context of their clinical workup. Data were analyzed using scaled subprofile model and principal component analysis (SSM PCA). Disease-specific patterns were identified in patients with PD, MSA, PSP and AD. A disease-related pattern can be prospectively applied to the FDG PET data of new patients. For each patient, a score on each pattern can be calculated denoting the extent of its expression in that patient. Pattern expression at baseline was compared with the final clinical diagnosis after follow-up visits.

Results

A multicenter and international website data entry database was developed recently (www.glimpsproject.com) and contains at present more than 200 FDG PET scans. Only on the basis of glucose consumption the multivariate methods (blind for the classes) were able to differentiate in over 90% of selected cases the conditions PD, MSA and PSP. Also new patterns were developed in the domain of dementia.

Conclusion

Glucose metabolism with the application of multivariate analysis techniques can be used as an objective screening tool to achieve high accuracy in diagnosing parkinsonian and dementing disorders in routine clinical practice. In addition, it may be used to identify ideal candidates in clinical trials.

Objectives: Given hexanucleotide (G_4C_2) repeat expansion in *C9orf72* is now known to be the most common genetic cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD), we seek to identify therapeutic strategies to combat *C9orf72*-linked disorders (c9FTD/ALS). We and others have demonstrated that the RNA structure of *C9orf72* repeat expansion may cause neurodegeneration via their accumulation into discrete structures in the nucleus, termed RNA foci, and by serving as a template for the synthesis of aggregation-prone dipeptide repeat (DPR) “c9RAN proteins” by repeat-associated non-ATG (RAN) translation. We have also shown that *C9orf72* mRNA expression is reduced in c9FTD/ALS as a result of epigenetic changes.

Methods: To further elucidate the molecular mechanisms underlying c9FTD/ALS and sporadic ALS (sALS), we used a variety of approaches, including the generation of novel antibodies, *in vitro* and *in vivo* assays as well as analyses of human tissue.

Results: We discover a biomarker and lead small molecules to target r(G_4C_2)-associated defects in c9FTD/ALS. In addition, we show poly(GA) DPRs mediate toxicity in cell culture and animal model systems through endoplasmic-reticulum-associated mechanisms. We also identify an abundance of transcriptome defects and epigenetic modifications in c9ALS and sALS cases.

Conclusions: We demonstrate the viability of therapeutic strategies targeting the RNA structures necessary for RAN translation and foci formation for the treatment of c9FTD/ALS as well as the use of DPRs in patient cerebrospinal fluid as a potential biomarker. Taken together, our findings may be applicable for other neurodegenerative diseases.

INCREASED SURVIVAL AND IMPROVEMENT OF AMYOTROPHIC LATERAL SCLEROSIS (ALS) PATHOLOGY BY INHIBITION THE CXCR4/CXCL12 SIGNALING

B. Solomon[1], I. Rabinovich-Nikitin[1]
[1]Microbiology-Biotechnology, Tel-Aviv university, Tel-Aviv, Israel

Chemokine receptors, including the G-protein-coupled receptor CXCR4, are expressed widely in neurons and glial cell. The ligand of CXCR4, the chemokine stromal-derived factor 1 (SDF-1), also known as CXCL12, evokes glutamate release and thereby modulates neuronal function or apoptosis. Inhibition of the CXCR4/CXCL12 signaling might result in preventing the toxic cascade of glutamate release from astrocytes and the eventual neuronal apoptosis in ALS
.AMD3100 a bicyclam molecule that specifically and reversibly blocks SDF-1 binding to CXCR4 was used in this study as a proof of concept of the new approach
Experimental
The CXCR4/CXCL12 signaling pathway was inhibited by subcutaneous administration of AMD3100. ALS Tg G93A mice were treated with AMD3100 for once and twice a week, and compared with mice treated with PBS. The effect of AMD3100 on ALS pathology was examined regarding survival, weight loss , motor function and pathological markers
Results
AMD3100 treatment extended the survival about 27 days, compared with mice treated with PBS. In addition, the treatment resulted in less weight loss as disease retrogrades and performance in Rotarod test, which resembles motor function, was better **Bi**ochemical analysis showed reduction in inflammatory markers levels and proinflammatory cytokines, increase in integrity of blood-spinal cord-barrier (BSCB) as well as of EEAT2 levels
Conclusion
The multi-faceted action of AMD3100which Inhibits the CXCR4/CXCL12 signaling provide a novel and pleiotropic option for ALS therapy with an increased margin of safety compared to other drugs which improve only one of these aspects of the diseases.

ADVANCES IN THE MOLECULAR NEUROPATHOLOGY OF FRONTOTEMPORAL DEMENTIA AND AMYOTROPHIC LATERAL SCLEROSIS

M. Neumann[1]
[1]*Neuropathology, University of Tubingen and DZNE, Tubingen, Germany*

The most common genetic defect in frontotemporal lobar degeneration (FTLD) and amyotrophic lateral sclerosis (ALS) is the abnormal expansion of a GGGGCC hexanucleotide repeat in a non-coding region of the chromosome 9 open reading frame 72 gene (*C9ORF72*). The neuropathology of *C9ORF72* mutation cases is consistently characterized by TDP-43 pathology in neurons and glia. Cases with clinical FTD show FTLD-TDP which most often fits the type B pattern and cases with clinical ALS show TDP-43 pathology indistinguishable from classical sporadic ALS. However, compared to other TDP-43 proteinopathies, *C9ORF72* mutation cases are associated with additional pathologies which might play pathogenic roles. Aggregates of RNA, composed of the massively expanded repeat, can be frequently demonstrated in neuronal nuclei using fluorescent in situ hybridization. These RNA foci are thought to bind and sequester specific RNA binding proteins, leading to the abnormal splicing of other genes. Another absolutely sensitive and specific pathological change is the presence of TDP-43 negative inclusions in the cerebellum, hippocampus and other neuroanatomical sites being composed of dipeptide repeat (DPR) proteins that result from the unconventional translation of the expanded repeats in both sense and antisense direction (poly-GA, -GP, -GR and poly-PA, -PG, -PR respectively). Clinicopathological correlative studies have shown that the anatomical distribution of TDP-43 pathology correlates closely with the pattern of neurodegeneration and clinical phenotype. In contrast, the distribution of DPR pathology (based on anti-GA and GP) is highly consistent among cases, with no clinical correlation, suggesting that DPR inclusions are a valuable pathological marker to predict the *C9ORF72* mutation but are of uncertain pathogenic significance.

NATURAL HISTORIES IN HEREDITARY DEMENTIAS: ANATOMICAL VULNERABILITIES AND PROTEIN SPREAD

B. Ghetti[1]
[1]*Pathology and Laboratory Medicine, Indiana University School of Medicine, Indianapolis, USA*

Neuropathologic analysis of multiple individuals from a single kindred may provide a powerful way to investigate the natural history of hereditary diseases, characterized by cognitive decline and dementia. The study can be even more fruitful if pre-mortem imaging studies are combined with post-mortem neuropathology.
Correlating imaging with neuropathology data provides essential information for defining which areas of the brain are affected in the course of degeneration. If neuropathologic analyses can be carried out in the early stages of disease, even before onset of symptoms, the combination of imaging and neuropathology may give insights about pathogenesis.
We have studied hereditary dementias associated with prionopathies and tauopathies. Studied individuals, affected by Gerstmann Sträussler Scheinker disease (GSS) or by hereditary tauopathies, belong to multiple generations of kindreds followed for decades. We illustrate the salient points of disease spread and abnormal protein deposition in patients at different stages of illness. In GSS, the first foci of prion protein amyloid are found in the cerebellum; in hereditary tauopathies, the frontal cortex shows the earliest presence of tau in nerve cells.
Identifying earliest vulnerability in anatomical areas facilitates the formulation of hypotheses related to pathways of protein spread. Spreading of pathologic proteins may be inferred on the basis of anatomical protein distribution and synaptic connectivity in the involved brain regions. The analysis of protein spread becomes complex when more than one protein aggregates in brain. One protein may be central in determining aggregation of the second one as in the case of GSS.

ADPD5-1879
MECHANISM AND THERAPY IN ALS/FTD AND BEYOND

D. Cleveland[1]
[1]*Ludwig Institute, Univ. of California at San Diego, La Jolla, USA*

The genes whose expression cause human neurodegenerative disease are widely expressed, producing damage not only within the most vulnerable neurons but also within their partner neurons and glia. This is certainly true for Amyotrophic Lateral Sclerosis (ALS), some instances of which are caused by mutation in the ubiquitously expressed superoxide dismutase (SOD1). Despite absence of consensus on the mechanism(s) of toxicity, slowed disease progression has been achieved by a clinically feasible infusion into the nervous system of antisense oligonucleotides (ASOs) that direct RNase H-dependent destruction of SOD1 mRNA within the nervous system.

The most frequent genetic cause of ALS and the second most common dementia (frontal temporal dementia) is hexanucleotide expansion in a non-coding region of the *C9orf72* gene. Sense and antisense strand repeat-containing RNAs have been found to accumulate in nuclear RNA foci, the hallmark feature of repeat expansion RNA-mediated toxicity. ASOs have been developed that selectively target sense strand repeat-containing RNAs and reduce sense-oriented foci without affecting overall *C9orf72* expression. These findings establish ASO-mediated degradation of repeat-containing RNAs as an attractive therapeutic approach.

Huntington's disease is caused by toxicity from CAG-repeat expansions in the widely expressed Huntington gene. ASO infusion to catalyze rapid degradation of huntingtin mRNA mediates partial, sustained reversal of disease that persists much longer than the mRNA knockdown. These findings establish transient ASO-mediated silencing as a feasible therapy for Huntington's disease.

Overall, ASO infusion into the nervous system is widely applicable for therapy in neurodegenerative diseases, with trials ongoing in spinal muscular atrophy and myotonic dystrophy and expected to initiate shortly in ALS, ALS/FTD and Huntington's disease. Alpha-synuclein, APP, presenilin, and tau are attractive targets for extending this approach to Parkinson's and Alzheimer's diseases.

FUNCTIONAL CONNECTIVITY AND IMPAIRED RECOGNITION OF FAMILIAR FACES IN ALZHEIMER'S DISEASE

E. Salmon[1], S. Kurth[1], M.A. Bahri[1], E. Moise[1], C. Bastin[1]
[1]Cyclotron Research Centre, University of Liege, LIEGE, Belgium

1.Objectives: Studies have reported that patients with Alzheimer's disease (AD) experience difficulties recognizing their own faces in recent photographs. Two case reports of late-stage AD reported that this loss of self-face recognition was temporally graded: photographs from the remote past were recognized more easily than recent photographs. Neuroimaging studies in healthy adults have related own face recognition abilities to a bilateral fronto-temporo-parieto-occipital network, involved in core, extended face perception and self-systems.
2.Methods: In this study, behavioral experiments and fMRI experiment were conducted to compare moderate AD patients with healthy older participants in a recognition task involving self and familiar faces from different decades of the participants' life. Variable performance allowed us to examine correlations between scores and resting-state fMRI in order to link behavioral data to cerebral connectivity. Critical regions of interest involved in familiar face perception and self-system were selected for seed to voxel analyses.
3.Results: Moderate AD patients had difficulties recognizing themselves in photographs taken at recent periods of their life (65 years and over), suggesting a temporally graded loss of self-face recognition. fMRI results showed that the higher the connectivity between the dorsomedial-prefrontal cortex (DMPFC) and the right superior-frontal gyrus, the lower the self- and familiar-face recognition scores in moderate AD patients.
4.Conclusions: DMPFC is part of face perception and self-system while previous studies have related the superior frontal region to control processes rather than face recognition processes. Impaired face recognition in AD appears to be related to functional dedifferentiation between brain networks.

[4]Therapeutic Strategic Unit Aging, Sanofi, Chilly-Mazarin Cedex, France

Objectives: Magnetic resonance imaging (MRI) combined with intra-cerebro-ventricular administration of Gadolinium (Gd-DOTA) contrast agents can be used to detect individual amyloid plaques in transgenic live mice (ICV-Gd-staining protocol [1]). Our objective was to implement an automated protocol to segment amyloid plaques from MRI in order to facilitate the estimation of amyloid load during preclinical therapeutic evaluation.

Methods: Three-D Gradient-echo MR images (resolution: 29x29x117µm^3) were recorded on 14 APP/PS1 transgenic mice after ICV-Gd-staining, a protocol based on the use of a clinically approved MR contrast agent [1]. SPM mouse [2] and "amyloid mouse" templates were used to automatically segment amyloid plaques. After imaging, mice were sacrificed and amyloid plaques were detected from histological sections.

Results: Gd-staining allowed plaque detection by MRI (Figure-top). SPM mouse was able to create probability maps with segmented amyloid plaques and can be used to quantify amyloid plaques on a longitudinal way from MRI (Figure-bottom). Plaques from segmented MR images were registered to amyloid plaques detected by histology.

Conclusion: Here, we show that amyloid plaques can be detected by in vivo MRI with a very high in-plane resolution (29µm) and segmented automatically. The protocol presented here can be used as a rapid and reliable reference method for anti-amyloid drug development trials.

HIPPOCAMPAL TEXTURE PREDICTS AD CONVERSION IN AMYLOID POSITIVE MILD COGNITIVELY IMPAIRED SUBJECTS

M. Nielsen[1], C. Igel[2], L. Sørensen[2]
[1]Biomediq A/S, Biomediq A/S, Copenhagen Ø, Denmark
[2]Computer Science, University of Copenhagen, Copenhagen Ø, Denmark

Objectives

We investigate whether hippocampal texture predicts conversion from mild cognitive impairment (MCI) to Alzheimer's disease (AD) in amyloid positive subjects.

Methods

The study dataset consisted of 98 MCI subjects (23 12-month converters, 46 24-month converters) from the Alzheimer's Disease Neuroimaging Initiative with a cerebrospinal fluid amyloid beta 1 to 42 peptide concentration below 192 pg/ml [1]. Hippocampal volume and hippocampal texture [2] were computed from each subject's structural magnetic resonance imaging (MRI) scan. Both MRI biomarkers were based on a segmentation of the hippocampi obtained using cross-sectional FreeSurfer (v.5.1.0, default parameters). Hippocampal volume was divided by the intra-cranial volume. Each biomarker was entered into a separate logistic regression model with age as covariate.

Results

MCI-to-AD conversion performance was quantified using the area under the receiver operating characteristic curve, and p-values were obtained using a DeLong test (see the table).

	12 month conversion	24 month conversion
Texture	0.701 ($p < 0.001$)	0.654 ($p = 0.005$)
Volume	0.648 ($p = 0.033$)	0.595 ($p = 0.099$)

Conclusions

Hippocampal texture predicts conversion to AD in amyloid positive MCI subjects. Interestingly, the commonly applied hippocampal volume does not predict a two year conversion. Hippocampal texture is a promising structural MRI biomarker for enrichment of AD trials using early AD and amyloid positive patients.

PROGRESSION OF WHITE MATTER DEGENERATION IN EARLY PD: A MULTICENTER EVALUATION USING DIFFUSION TENSOR IMAGING
Y. Zhang[1], K. Wu[1], N. Schuff[1], P.P.M.I. Parkinson's Progression Marker Initiative[2]
[1]Center for Imaging of Neurodegenerative Diseases,
San Francisco VA Medical Center and University of California San Francisco, San Francisco, USA
[2]PPMI, Parkinson's Progression Marker Initiative,, USA
Objectives: This study aimed to identify the utility of MRI diffusion tensor imaging (DTI) in measuring abnormal white matter (WM) progression in patients enrolled in the Parkinson's progression marker initiative (PPMI). PPMI is an international, multicenter, longitudinal study assessing biochemical, clinical, and imaging biomarkers of PD progression.
Methods: 48 healthy controls (age=59.9±11) and 110 de-novo PD patients (age=60.3±9) had MRI-DTI scans at baseline and follow-up over 12.6±1 months. Image processing included an intra-subject registration of all time points and an inter-subjects registration to a brain atlas using DARTEL. Fractional anisotropy (FA) and WM probabilistic index were measured in 108 WM and 18 basal ganglia ROIs of each subject at each time point. Linear mixed-effect models between-group within-subject analyses were conducted to examine group differences in rates of FA.
Results: The Figure indicates regional pattern of significantly increased annual rates of FA reduction (FDR-adjusted $p<0.05$) in patients compared to controls. PD was associated with greater rates of FA reduction predominantly in the basal ganglia and the medial temproparietal regions, without significant differences between ipsilateral and contralateral hemispheres (corresponding to the body side of symptom at onset). Among these regions, substantia nigra yielded the highest rate of FA reduction (contralateral=3.8%/year, ipsilateral=3.7%/year) from baseline.
Conclusions: The results suggest that increased rates of WM degeneration are a

potential marker of PD progression.

Objective. To assess white matter (WM) tract damage in patients with atypical Alzheimer's disease, including early age-of-onset AD, logopenic variant of primary progressive aphasia (lvPPA) and posterior cortical atrophy (PCA) using diffusion tensor (DT) MRI, and to identify similarities and differences across the AD spectrum.
Methods. WM tract damage and cortical atrophy were assessed in 28 EOAD, 12 lvPPA and 13 PCA patients relative to age- and sex-matched healthy subjects. Conjunction and interaction analyses were used to define overlapping and syndrome-specific patterns of brain damage.
Results. EOAD, lvPPA and PCA patients shared a common pattern of WM damage involving the body of the corpus callosum, fornix, and main anterior-posterior pathways, and cortical atrophy of the left temporo-parietal regions and precuneus. EOAD patients had also a specific damage to the genu and splenium of the corpus callosum, and parahippocampal tract bilaterally. In all AD patients, particularly in the two focal forms (lvPPA and PCA), WM damage was more severe and widely distributed than expected on the basis of cortical atrophy.
Discussion. In atypical AD clinical phenotypes, the distribution of WM damage exceeds cortical atrophy and may reflect the dissemination of pathology through structural connections from atrophic to unaffected cortical regions. WM degeneration may be an early marker of AD pathology in EOAD and focal AD forms.

DECREASED DEFAULT AND VENTRAL ATTENTION NETWORK CONNECTIVITY MEDIATE THE AMNESTIC EFFECTS OF SCOPOLAMINE ADMINISTRATION

J.P. Chhatwal[1], A.P. Schultz[1], B. Boot[2], S. Wigman[2], R.A. Sperling[2]
[1]Neurology, Massachusetts General Hospital / Harvard Medical School, Boston, USA
[2]Neurology,
Massachusetts General Hospital / Brigham and Women's Hospital / Harvard Medical School, Boston, USA

Objective: Disrupted cholinergic neurotransmission plays a key role in AD-related mnemonic deficits. Here we use functional connectivity MRI (fcMRI) to study cholinergic modulation of distributed neural networks following scopolamine administration. We determine the pattern of changing connectivity following anticholinergic challenge, and assess whether particular networks may mediate scopolamine-induced amnestic effects.
Methods: A double-blind, crossover design was used to assess cognitive function and connectivity across 10 cortical networks in 34 cognitively-normal elderly participants receiving placebo or scopolamine (0.2mg IV) on two separate visits.
Results: Scopolamine induced significant deficits in several cognitive tasks, most notably the delayed recall portion of the Selective Reminding Task (SRT-DR). Drug-induced changes in connectivity were observed in 4 of 10 cortical networks, with the largest decreases seen in two cognitive networks: the Default (DN) and Ventral Attention Networks (VAN; both $p < 0.001$, cohen's $d > 1$). Alterations in DN and VAN connectivity were highly predictive of subsequent memory performance, and mediation analysis demonstrated DN and VAN connectivity fully mediated the effect of scopolamine on SRT-DR performance.
Interpretation: Scopolamine administration led to significantly altered connectivity in a subset of cognitive networks, without changing connectivity in visual and motor networks. In particular, the DN and VAN were highly sensitive to cholinergic modulation, and decreased connectivity in these networks demonstrated full statistical mediation of scopolamine-induced deficits in the SRT-DR. These results highlight the importance of DN and VAN connectivity to memory, as well as the potential of fcMRI as a tool to better understand drug induced changes in cognition.

ADPD5-0252
INTRACEREBRAL INJECTION OF PREFORMED SYNTHETIC TAU FIBRILS INITIATES WIDESPREAD TAUOPATHY AS WELL AS NEURONAL LOSS IN THE BRAINS OF TAU TRANSGENIC MICE

D. Moechars[1], E. Peeraer[1], A. Bottelbergs[1], K. Brunden[2], J. Trojanowski[2], V. Lee[2], J. Kemp[1]
[1]Neuroscience, Janssen Research & Development, Beerse, Belgium
[2]Dept. of Pathology and Laboratory,
Ctr. for Neurodegenerative Dis. Research Inst. on Aging Univ. of Pennsylvania Sch. o f Med, Philadelphia, USA

Neurofibrillary tangles (NFTs) composed of hyperphosphorylated fibrillized tau are found in numerous tauopathies including Alzheimer's Disease (AD). Increasing evidence suggests that tau pathology can be transmitted from cell-to-cell; however, the mechanisms involved in the initiation of tau fibrillization and spreading of disease linked to progression of tau pathology are poorly understood.
Intracerebral injections of preformed synthetic tau fibrils (PFFs) into the hippocampus or frontal cortex of young tau transgenic (Tg) mice expressing mutant human P301L tau induces tau hyperphosphorylation and aggregation around the site of injection, as well as a time-dependent propagation of tau pathology to interconnected brain areas distant from the injection site. Both the injection site and the nature of the seed affect the distribution and characteristics of the resulting tau pathology. Furthermore, we show that injection of tau PFFs into the hippocampus induces selective loss of CA1 neurons.
Together, our data confirm previous studies on the seeded induction and the spreading of tau pathology in a different tau Tg mouse model and reveals for the first time neuronal loss after intracerebral injection of tau PFFs in tau Tg mouse brain. These results further validate the utility of the tau seeding model in studying disease transmission, and provide a more complete in vivo tauopathy model with associated neurodegeneration which can be used to investigate the mechanisms involved in tau aggregation and spreading, as well as aid in the search for disease modifying treatments for AD and related tauopathies.

THE UNFOLDED PROTEIN RESPONSE: AN EARLY FACTOR IN TAU PATHOLOGY

W. Scheper[1], J.M. Van der Harg[2], A. Nölle[1], J.J.M. Hoozemans[3]
[1]Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands
[2]Genome Analysis, Academic Medical Center, Amsterdam, Netherlands
[3]Pathology, VU University Medical Center, Amsterdam, Netherlands

1. Objectives

The unfolded protein response (UPR) is a homeostatic stress response that is strategically positioned in the endoplasmic reticulum to sense and transduce signals from metabolic and inflammatory pathways. Our previous work shows activation of the UPR in the brain of tauopathy patients in neurons containing early stage tau pathology. In this study we investigate the mechanistic connection between the UPR and tau.

2. Methods

Post-mortem brain tissue, animal and cell models to modulate and analyse UPR signaling and tau phosphorylation and aggregation.

3. Results

UPR activation leads to tau phosphorylation, which is initially a reversible event involving the PERK pathway of the UPR. This is illustrated by our data that demonstrate that the UPR is also connected with physiological and reversible tau phosphorylation during metabolic stress in cell and animal models. Our data show that dysfunction of the autophagy/lysosomal system contributes to the persistence of tau phosphorylation and the initiation of tau aggregation.

4. Conclusions

We propose that phosphorylation of tau is part of the adaptive UPR. Our data are in accordance with a model where early in AD pathogenesis the adaptive UPR is activated in response to cellular stress, with tau phosphorylation as part of this response. Inability to restore homeostasis, for example by dysfunction of the autophagy/lysosomal system, ultimately leads to the formation of neurofibrillary tangles and neuronal loss. The functional involvement of the UPR in the earliest phases of tau pathology may provide an interesting window of opportunity by intervention in specific UPR signaling pathways.

CRITICAL ROLE OF TAU ACETYLATION IN MEDIATING TAU AGGREGATION AND SYNAPTIC TOXICITY

L. Gan[1], S. Min[1], T. Tracy[1], X. Chen[1], P. Sohn[1], C. Wang[1]
[1]Department of Neurology, Gladstone Institutes UCSF, San Francisco, USA

Background

Neurodegenerative tauopathies are characterized by pathogenic accumulation of tau. How pathogenic tau accumulates and induces neurodegeneration remains largely unknown. Tau is extensively modified post-translationally. Emerging evidence from our lab and others demonstrated that tau is acetylated by acetyltransferases p300/CBP at various lysine residues and that aberrant tau acetylation is elevated in all tauopathies. We hypothesize that tau acetylation plays a critical role in tau accumulation and tau-mediated neurodegeneration.

Methods

High performance liquid chromatography–electrospray tandem mass spectrometry was used to identify the acetyllysines in the soluble lysates from AD brains. We also developed monoclonal and polyclonal antibodies against specific acetyllysines on tau. The effects of acetylated-tau on tau accumulation and neuronal circuitry in vivo were examined in transgenic mice or in hippocampus using AAV-mediated transduction, followed by behavioral, electrophysiological, biochemical and pathological analyses.

Results and Conclusions

Several acetyllysine sites on tau were identified in AD brains, including ac-K174 and ac-K274. Compared with mice expressing wildtype human tau, mice expressing tau mutants that mimic tau acetylation exhibited elevated tau accumulation, most likely via blocking tau clearance mechanisms. Acetylation of tau at specific lysine residues also led to enhanced tau oligomerization. Moreover, acetyl-mimic tau is mis-sorted to somatodendritic compartments, leading to impaired long-term potentiation and cognitive deficits. Notably, reducing tau acetylation with small molecule inhibitors protected against tau-mediated deficits in tauopathy mouse models, providing proof-of-principle that inhibitors of tau acetylation represent promising new therapeutic strategies.

Symposium 41: TAU BIOLOGY AND DISEASE MECHANISMS 1

ADPD5-1629
FAMILIAL TAUOPATHIES
Z. Wszolek[1]
[1]*Neurology, Mayo Clinic, Jacksonville, USA*
Tauopathies are characterized by the pathologic accumulation of hyperphosphorylated, insoluble tau protein (Tau), which forms neurofibrillary tangles in the brain. Tau binds axonal microtubules, promotes their assembly, and stabilizes the cytoskeleton. Microtubule-associated protein tau gene complex (*MAPT*) located on chromosome 17 encodes Tau. *MAPT* consists of a non-coding exon followed by 14 coding exons. Alternative splicing leads to six major transcripts observed in the human brain and tau isoforms that contain either three or four 18-amino acid imperfect repeats (3R-tau and 4R-tau). In normal adult human brains, 3R-tau and 4R-tau are equally expressed. The 3R-tau/4R-tau ratio is altered in taupathies. Some taupathies such as Pick's disease contain predominantly hyperphosphorylated 3R-tau. 4R tauopathies include progressive supranuclear palsy, corticobasal degeneration, age-related medial temporal lobe tauopathy, globular glial tauopathies, and argyrophilic grain disease. In Alzheimer's disease, the neurofibrillary pathology is composed of approximately equal amounts of hyperphosphorylated 3R-tau and 4R-tau,
Most tauopathies are sporadic. However, more than 40 different mutations have been identified in frontotemporal dementia and parkinsonism linked to chromosome 17 (FTDP-17) due to *MAPT* mutations. In FTDP-17 due to *MAPT* mutations, tau pathology can be of 3R or 4R type. Clinical presentation and pathological characteristics differ widely.
Mutations in the leucine-rich repeat kinase 2 gene (*LRRK2*) on chromosome 12 usually presents as a synucleinopathy; however, *LRRK2* G2019S and *LRRK2* R1441C mutation carriers can present with taupathies and PSP-like symptoms. Currently, our Mayo Udall Center concentrates on the identification of other genetic forms of tauopathies, and their clinical, pathological, and genetic characterizations.

MISSORTING OF TAU IN DEGENERATING NEURONS: Abeta, TAU, SPASTIN, AND MICROTUBULE BREAKDOWN

E.M. Mandelkow[1], H. Zempel[1], J. Luedtke[1], E. Mandelkow[1]
[1]DZNE Bonn, DZNE, Bonn, Germany

Objectives

We are interested in mechanisms by which exposure of neurons to Abeta causes pathological effects on the level of tau and microtubules observed in AD, such as missorting of tau into the somadendritic compartment, destabilization of microtubules, and synapse decay.

Methods

Primary neurons from mature wildtype and Tau knockout mice were exposed to A-beta oligomers. Changes in the Tau/microtubule system were observed by confocal microscopy and staining with antibodies against components of the microtubule cytoskeleton.

Results

Microtubule breakdown occurs in Abeta-exposed dendrites invaded by Tau. This process is mediated by spastin, a microtubule-severing enzyme. Spastin is recruited to microtubules modified by polyglutamylation through TTLL6 (Tubulin-Tyrosine-Ligase-Like-6 enzyme). Photoconversion of Dendra2-labeled Tau reveals that missorted Tau is newly synthesized and not derived from axons. The toxic effects of A-beta are reversible and involve the activitation of the kinase MARK. In absence of Tau (TauKO neurons), microtubules and synapses are resistant to A-beta induced toxicity because mislocalization of TTLL6 and polyglutamylation of microtubules are prevented, end there is no recruitment of spastin nor microtubule breakdown. Reintroduction of Tau re-establishes A-beta induced toxicity in TauKO neurons.

Conclusions

Abeta oligomers can activate a cascade leading to breakdown of microtubules in dendrites and thus impairing intraneuronal traffic. The results point to the importance of posttranslational modifications of microtubules and the role of microtubule-severing enzymes such as spastin. These Abeta-induced effects depend on the presence of Tau and thus can be suppressed by reducing tau.

Objectives

To compare effects of Tau mutation A152T (related to PSP, with mutation outside the MT-binding domain) with pro-aggregant mutation DeltaK280 (related to FTDP, mutation within MT-binding domain) in vitro and in transgenic mouse models in order to understand different pathological features.

Methods

Analysis of Tau mutants by biochemical and biophysical methods (microtubule binding and Tau aggregation assays, electron and AFM microscopy). Generation of transgenic mice, analysis of histopathology and behavior, electrophysiology of acute and organotypic slices.

Results

Comparison of MT binding and Tau aggregation shows that interaction of Tau-A152T with MT is weakened, aggregation into filaments is decreased, but there is pronounced increase of soluble Tau oligomers in Tau-A152T. This is remarkable considering that residue152 is far from the repeat domain, the basis of MT binding and Tau aggregation.

Transgenic mice overexpressing Tau-A152T under the Thy-1 promoter show characteristic features of tau pathology (hyperphosphorylation, aggregation, missorting, neuronal loss). Signs of inflammation are pronounced (microgliosis, astrocytosis), cognitive decline sets in comparatively late (see abstract Sydow et al.).

Organotypic slices of TauA152T expressing mice reveal presence of Tau both in pre- and postsynaptic compartments, in contrast to normal Tau. There is increased epileptiform activity and excitotoxicity, correlating with an increase of extracellular glutamate. Calcium levels are strongly increased after membrane depolarization with KCl. All of these are unique features not observed in slices from proaggregant mice (see abstract Krüger et al.).

Conclusions

Tau-A152T reduces Tau-MT interaction and filamentous Tau aggregation but shifts the balance towards oligomers. Even though the mutation is far from the domain regulating microtubule interactions and aggregation, there is pronounced Alzheimer-like pathology, coupled with excitotoxicity, and a remarkable degree of inflammation.

Objectives:
To investigate the relationship between cerebrovascular disease and amyloid deposition including multiple forms of β-amyloid (Aβ) in MCI and AD.
Methods:
CSF-Aβ38, CSF-Aβ40 and CSF-Aβ42 were determined and the Aβ42/Aβ40-ratio calculated in 267 healthy elderly controls (M/F:102/162; mean age 72.9 years), 359 MCI subjects (M/F:179/178; mean age 70.7 years) and 20 AD subjects (M/F:5/15; mean age 72.9) were analyzed including. A composite score of [18F]flutametamol uptake (PET) was available for a subpopulation (n=350).White Matter Hyperintensities (WMH) on MRI FLAIR-images, graded using Fazekas and AWMRC-scales, were used as proxy for cerebrovascular disease.
Results:
In MCI patients, the total Fazekas score, continuous and dichotomized using cut-off 4, and the total ARWMC score were negatively associated with CSF-Aβ38, CSF-Aβ40, and CSF-Aβ42, but not with the Aβ42/Aβ40-ratio. In healthy controls, there was no association between WMH and CSF-biomarkers or the Abeta42/Abeta40 ratio (Table 1). The composite score from [18F]flutametamol PET was not associated with WMH in any of the groups.
Conclusions:
We found that in MCI, cerebrovascular disease present as white matter hyperintensities was associated only with lower levels of CSF-Aβ38, CSF-Aβ40, and CSF-Aβ42, while the Aβ42/Aβ40 ratio was unaffected. This suggests that subcortical cerebrovascular disease is related to a general decrease in the production of Aβ, rather than AD specific aggregation of Aβ42, which was supported by the amyloid PET imaging data.

Table 1. Beta- and p-values from linear regression models that tested associations between white matter lesions on MRI as a measure of cerebrovascular disease as independent variable, and CSF-biomarkers and PET composite scores as dependent variables. Significant ($p<0.05$) associations are marked with an asterix (*).

Background: Early onset Alzheimer's disease and early onset frontotemporal dementia have been largely studied, while little attention was paid to early onset subcortical vascular cognitive impairment (EOSVCI). The aim of this study was to evaluate the differences between EOSVCI and late onset SVCI (LOSVCI) in terms of small vessel disease burden, amyloid burden, brain atrophy pattern, and cognitive dysfunction.
Methods: We prospectively recruited 137 patients from a single referral center. Patients were divided into EOSVCI (n=30, onset age <65 years) and LOSVCI (n=107, onset age ≥ 65 years). All patients underwent brain MRI, PiB-PET and detailed neuropsychological testing. Cortical thickness and volume of subcortical structures were analyzed.
Results: The educational level or severity of cognitive impairment did not differ between EOSVCI and LOSVCI patients. History of stroke and obesity were more prevalent in EOSVCI patients. EOSVCI patients tend to have higher number of lacune and had lower PiB-retention-ratio than LOSVCI patients. Atrophy in temporal and occipital cortex, amygdala, and hippocampus were more severe in LOSVCI, while pallidal atrophy was more severe in EOSVCI. The neuropsychological test showed that frontal-executive dysfunction was more prominant in EOSVCI patients while memory dyfunction was more prominent in LOSVCI patients.
Conclusions: EOSVCI patients had more vascular related factors while LOSVCI patients exhibited more Alzheimer's disease related characteristics. This suggests that cognitive dysfunction in LOSVCI is partially driven by aging related factors such as amyloid burden, whereas in EOSVCI, more extensive amount of vascular factors are necessary to reach the same stage of cognitive impairment.

Cerebrovascular accumulation of the amyloid ß-protein (Aß), a condition known as cerebral amyloid angiopathy (CAA), is an important driver of vascular cognitive impairment and dementia (VCID) and is a common comorbidity of patients with Alzheimer's disease (AD). In addition to its prevalence in AD, several related familial CAA disorders result from specific mutations that reside within the Aß peptide sequence of the Aß precursor protein including the Dutch-type (E22Q) and Iowa-type (D23N) mutations. Presently, there are no reliable biomarkers or effective therapies specifically for CAA and VCID. These deficiencies are complicated by a poor understanding of the unique structural attributes of cerebral vascular amyloid and their distinctive features and processes compared to parenchymal plaque amyloid. Previous studies suggest that differences exist between cerebrovascular amyloid and parenchymal plaque amyloid. Here we show that CAA mutant forms of Aß more readily adopt a anti-parallel fibril structure in contrast to wild-type Aß42 that largely assembles into parallel fibril structures commonly found in parenchymal plaques. In vitro, CAA mutant amyloid fibril seeds promote wild-type Aß peptide assembly. Similarly, in transgenic mice CAA mutant vascular amyloid deposits dramatically promote the assembly and co-deposition of wild-type Aß on cerebral vessels. Further, isolated CAA mutant amyloid seeds were found to drive anti-parallel fibrillar assembly of wild-type Aß. These findings suggest that CAA deposits exhibit an anti-parallel fibril structure that can serve as a template to enhance wild-type Aß assembly into similar anti-parallel structures.

VASCULAR COGNITIVE IMPAIRMENT
R. Schmidt[1]
[1]*Clinical Division of Neurogeriatrics,*
Medical University Graz Department of Neurology, Graz, Austria
Vascular brain abnormalities influence the evolution of clinical Alzheimer´s disease (AD). The existence of pure vascular dementia is considered to be exceptional and there has been a shift in nomenclature to vascular cognitive impairment. New guidelines for the diagnosis of vascular cognitive impairment (VCI) represent an important step in the definition of this clinical entity. However, these guidelines still remain vague in the definition of "vascular" brain lesions causing cognitive decline, because longitudinal correlative imaging studies are still scarce. I will explore which abnormalities are likely to contribute to VCI based on a proven vascular etiology, fast progression and their incidence or progression being related to cognitive decline. Among focal changes visible on standard MRI these features apply for coalescent white matter changes. The evidence for lacunes and microbleeds is much less convincing. Microstructural alterations in normal appearing brain tissue which can be detected by new MRI techniques such as magnetization transfer imaging (MTI), diffusion tensor imaging (DTI) and high resolution MR appear to better correlate with cognitive decline, but the etiology of these changes and their histopathological correlates is still incompletely understood as is their evolution over time. New multimodal image processing such as voxel-based lesion-symptom mapping (VLSM) or combinations of DTI and voxel-based analysis will allow to allocate the lesion patterns that show the greatest covariance with clinical outcome. Such data and more longitudinal correlative data on lacunes and microbleeds will increase our pathophysiologic understanding of the vascular component in dementia including the interplay with primary degenerative processes and will lead to refinement of current VCI criteria

APOE AND CEREBROVASCULATURE IN ALZHEIMER'S DISEASE
G. Bu[1]
[1]*Department of Neuroscience, Mayo Clinic, Jacksonville, USA*
While amyloid-β (Aβ) is a key pathogenic molecule in AD, epidemiological studies have shown that several well-established risk factors for AD including diabetes, atherosclerosis, stroke, and hypertension all have a vascular component that reduces cerebral perfusion. Therefore, disturbance of cerebrovascular system is likely a major contributor to AD pathogenesis. Among the three human apolipoprotein E (apoE) isoforms (E2, E3 and E4), *APOE4* is the strongest genetic risk factor for late-onset AD and cerebral amyloid angiopathy (CAA). The most consistent finding that differentiates apoE4 from apoE3 is their respective roles in brain Aβ clearance, where apoE4 is either less efficient or inhibitory compared to apoE3. To address the differential functions of apoE isoforms, we compared cerebral blood flow, behaviors and Aβ metabolism among human *APOE* isoform (E2, E3 and E4)-targeted replacement (TR) mice at young and old ages. We found that cerebral blood flow and memory performance are reduced, while endogenous Aβ levels are elevated, in aged *APOE4*-TR mice compared to *APOE3*-TR mice. Brain glucose metabolism was also compromised in aged *APOE4*-TR mice. To specifically address the function of a major apoE and Aβ receptor LRP1 in cerebrovasculature, we generated conditional knockout mice deleting *Lrp1* in vascular mural cells (smLRP1-KO), which include smooth muscle cells and pericytes. We found that cerebral blood flow and vessel functions are significantly impaired in smLRP1-KO mice. Our results demonstrate that the presence of *APOE4* or an absence of apoE receptor LRP1 leads to cerebrovascular defects, which compromise Aβ clearance machinery resulting in Aβ accumulation in the brain. The resulting Aβ aggregates further exacerbate cerebrovascular dysfunction in AD.

[4]Inserm UMR 1167 - Institut Pasteur de Lille, Université de Lille, Lille, France

Background
Some studies show a decrease in the prevalence of dementia. This could be due to a decrease in cerebrovascular pathology that may magnify the effect of Alzheimer pathology. The aim of this study was to evaluate the progression of the prevalence of vascular risk factors(VRF) in patients admitted in a memory center diagnosed with Alzheimer's disease(AD), vascular dementia(VD) or both (mixed dementia[MD]).
Methods
All consecutive patients were prospectively included. We compared the prevalence of VRF (hypertension, diabetes mellitus and hypercholesterolemia) and the diagnostic distribution across three 5-year periods: 1995-1999(P1), 2000-2004(P2), 2005-2009(P3). We used statistical tests such as anova and X^2 for simple comparison, and Poisson regression for multivariate analysis.
Results
We included 3428 patients (P1=1067, P2=1275, P3=1086). The prevalence of VRF increased in each period (hypertension: P1=33.4%, P2=50.5%, P3=63.0%; diabetes: P1=10.1%, P2=15.8%, P3=19.1%; hypercholesterolemia: P1=unreliable, P2=22.4%, P3=41%). The mean dementia onset age significantly increased (P1=69.6, P2=71.6, P3=71.9 years). The diagnostic distribution evolved with a larger number of MD at the expense of AD (AD: P1=59.9%, P2=41.9%, P3=29.1%; MD: P1=25.1%, P2=43.0%, P3=53.9%). Mean MMSE score at inclusion did not change significantly (P1=19.4, P2=20.1, P3=19.9).
Conclusion
In patients with dementia, the prevalence of VRF increased with time, contrary to what is observed in the general population except for diabetes mellitus, as well as the proportion of mixed dementia, while the age at onset was delayed. These findings support the role of cerebrovascular pathology in dementia and highlight the necessity for better VRF management to prevent or delay dementia.

WHERE AND WHEN TO TARGET PATHOGENIC SYNUCLEIN VARIANTS FOR THERAPEUTIC PURPOSES IN PRECLINICAL MODELS?

M. Xilouri[1], O. Riess[2], L. Stefanis[1,3]
[1]Biomedical Research Foundation of the Academy of Athens
[2]University of Tubingen
[3]University of Athens Medical School

Background: A variety of precilinal models based on overexpression or transmission of alpha-synuclein (AS) in the nervous system are now available, although their relevance to human synucleinopathies remains questionable. In parallel, therapeutic strategies to combat the generation of aberrant AS species or their detrimental effects are being developed. A case in point is the enhancement of Chaperone-Mediated Autophagy (CMA) through overexpression of its rate-limiting step Lamp-2a, which achieves the double effect of minimizing aberrant AS species and mitigating their detrimental effects on lysosomes (Xilouri et al., 2013). A major challenge lies in the selection of the timing and site of application of such strategies in a progressive synucleinopathy model, so as to most closely mimic a possible intervention in a clinical trial.

Objective: To evaluate the timing and site of intervention of enhancement of CMA in a progressive synucleinopathy model.

Methods: We are using human AS BAC Tg rats, which develop widespread alpha-synucleinopathy and dopaminergic neurodegeneration (Nuber et al., 2013). We are injecting them at various time points and at various sites with Adeno Associated Virus (AAV) expressing Lamp-2a (Xilouri et al., 2013). We are evaluating Lamp-2a expression and effects on AS species and indices of neurodegeneration.

Results: Fractionated Western immunoblotting shows widespread accumulation of oligomeric alpha-synuclein in various brain areas of hAS BAC Tg rats, including hippocampus and cortex. Injections of Lamp-2a AAV have been performed in striatum and nigra and effects on AS species and dopaminergic neurodegeneration will be evaluated.

Conclusions: Our study represents an example of a therepautic intervention in a synucleinopathy animal model that addresses the issues of timing and site of intervention. Similar strategies undertaken by others will be discussed.

This work was supported by ARISTEIA (GSRT), SINERGASIA (GSRT) and MULTISYN (EU FP7) grants, as well as the NEURASYNC ITN (EU FP7) to LS.

ADPD5-1344
ENHANCING GBA1 ACTIVITY AS A THERAPEUTIC STRATEGY IN LEWY BODY DISEASES

S.P. Sardi[1], S.H. Cheng[1], L.S. Shihabuddin[1]
[1]Genzyme, a Sanofi Company, 49 New York Avenue, Framingham, MA 01701, USA

Gaucher disease, the most common lysosomal storage disease, is caused by a recessively inherited deficiency in glucocerebrosidase and subsequent accumulation of toxic lipid substrates. Heterozygous mutations in the lysosomal glucocerebrosidase gene (GBA1) have recently been recognized as the highest genetic risk factor for the development of ?-synuclein aggregation disorders (“synucleinopathies”), including Parkinson’s disease (PD) and dementia with Lewy bodies (DLB). Despite the wealth of experimental, clinical and genetic evidence that supports the association between mutant genotypes and synucleinopathy risk, the precise mechanisms by which GBA1 mutations lead to PD and DLB remain unclear. Decreased glucocerebrosidase activity has been demonstrated to promote ?-synuclein misprocessing. Furthermore, aberrant ?-synuclein species have been reported to downregulate glucocerebrosidase activity, which further contributes to disease progression. We will summarize the recent findings that highlight the complexity of this pathogenetic link and how several pathways that connect glucocerebrosidase insufficiency with ?-synuclein misprocessing have emerged as potential therapeutic targets. From a translational perspective, we will discuss how glucocerebrosidase augmentation has been explored for the treatment of GBA1-related synucleinopathies, and potentially, for non-GBA1-associated neurodegenerative diseases. In summary, the link between GBA1 and synucleinopathies has become the paradigm of how the study of a rare lysosomal disease can transform the understanding of the etiopathology, and hopefully the treatment, of a more prevalent and multifactorial disorder.

[5]Neuroscience, Ottawa Hospital Research Institute, Ottawa, Canada

Objectives: We have created a new animal model of complex genetic susceptibility informed by dementia, parkinsonism and other alpha-synuclein-associated diseases of the human brain: the SYNERGY mouse (Synucleinopathy related to Gaucher's and Lewy body dementia). These animals carry three distinct susceptibility traits at two loci (SNCA, GBA1); each trait is strongly linked to dementia and parkinsonism.

Methods: The SYNERGY mouse was generated by crossing a PAC1-hSNCA^{A53T} line, which carries 148Kb of the human SNCA locus [Kuo et al., 2010], with Gba1^{D409V} knock-in mice [Xu et al., 2003]. SYNERGY mice thus combine: (1) SNCA gene multiplication (i.e., four copies); (2) A53T point mutations in all SNCA alleles; (3) absence of murine Snca; and (4) two Gba1^{D409V} knock-in mutations.

Results: We observe significant motor, cognitive and olfactory deficits in SYNERGY mice compared to wild-type control animals at 3 to 4 months of age; biochemically, we detect altered glycolipid profiles and aggregates of alpha-synuclein in select brain areas of 10 week-old mice. Assessment of age-dependent progression for these early proteomic, lipidomic and microscopic changes as well as of behavioural deficits is currently ongoing.

Conclusions: We posit that SYNERGY mice represent the etiologically most relevant model for Lewy body dementia created to date. We are hopeful that our bi-genic animals will advance preclinical research by permitting the study of multi-systems changes that underlie SNCA-associated neurodegeneration in humans, and by serving as a platform for target validation and drug screening in the future.

Symposium 49: UPDATE ON DLB: CLINICAL AND PRE-CLINICAL STUDIES (PART 2)

ADPD5-1587
RIPK3 AS A POSSIBLE THERAPEUTIC TARGET FOR GAUCHER DISEASE AND OTHER NEURODEGENERATIVE DISEASES
A.H. Futerman[1]
[1]*Biological Chemistry, Weizmann Institute of Science, Rehovot, Israel*
Gaucher disease (GD), an inherited metabolic disorder caused by mutations in the glucocerebrosidase (*GBA*) gene, is the most common lysosomal storage disease (LSD). Heterozygous mutations in *GBA* are a major risk factor for Parkinson's disease (PD). GD is divided into three clinical sub–types based on the absence (type 1) or presence (types 2 and 3) of neurological signs. Type 1 GD was the first lysosomal disease for which enzyme therapy became available, and although infusions of recombinant glucocerebrosidase (GCase) ameliorate the systemic effects of GD, lack of efficacy for the neurological manifestations, along with the significant expense and inconvenience of enzyme therapy for patients, renders the search for alternative or complementary therapies paramount. Glucosylceramide (GlcCer) and glucosylsphingosine accumulation in the brain leads to massive neuronal loss in neuronopathic GD (nGD) patients and in nGD mouse models. However, the mode of neuronal death is not known. Here, I will present data showing that modulating the receptor–interacting protein kinase 3 (Ripk3) pathway markedly improves neurological and visceral disease in a mouse model of GD. Importantly, *Ripk3* deficiency dramatically improved the clinical course of GD mice with increased survival, motor coordination and salutary effects on cerebral as well as hepatic injury. The relevance of these findings to PD will be discussed.

ADPD5-1882
LONGITUDINAL PD BIOMARKER STUDIES: DENOPA AND PPMI
B. Mollenhauer[1]
[1]*Department of Neurology and Neuropathology, Paracelsus-Elena-Klinik and University Medical Center, Kassel, Germany*
Objectives: To demonstrate first longitudinal data on one single- [De No Parkinson's disease (PD): DeNoPa] and one multicenter biomarker study (Parkinson Progression Marker Initiative of the Michael J Fox Foundation; PPMI) for progression biomarkers as outcome measures for clinical trials
Methods: clinical measures (motor scales, non-motor symptoms, cognitive tests, sleep),volumetric imaging [magnetic resonance imaging (MRI)] and blood/cerebrospinal fluid (CSF) biomarkers have been investigated in two longitudinal cohorts on de novo PD and healthy controls.
Results: 159 patients and 110 healthy controls have been recruited in the DeNoPa study and followed after 24 months. A multimodal panel of clinical, functional and imaging measures significantly reflect the progression of the disease in DeNoPa.While non-motor symptoms progress (MDS-UPDRS 1 and Scopa AUT), sleep deteriorates (ESS) and volumetric imaging of grey-matter and hippocampal area decrease significantly, the CSF parameters remain relatively stable (α-synuclein) or increase slighlty (β-amyloid 1-42, total tau protein, neurofilaments) from baseline to the first follow-up period in comparison of patients and controls. This propoed progression panel needs validation by continuing follow-up and in independent, larger cohorts, such as PPMI. For PPMI 24 sites in the USA and Europe recruited 232 de novo PD patients and 196 healthy controls. Follow-up assessments including clinical data, MRI, dopamine transporter imaging, CSF and blood sampling are done every 6 months.
Conclusion: A multimodal panel of progression marker can serve as outcome measure for clinical trials in de novo PD. More accurate biomarkers in biological fluids for the progression of PD need to be established.

Symposium 49: UPDATE ON DLB: CLINICAL AND PRE-CLINICAL STUDIES (PART 2)

ADPD5-1994
VARIANTS IN SYNUCLEIN GENES UNDERLYING A DLB PHENOTYPE

I. Guella[1], *M. Farrer*[1]
[1]*Centre for Applied Neurogenetics, University of British Columbia, Vancouver, Canada*

The relationship between Parkinson disease (PD), PD with dementia (PDD) and dementia with Lewy bodies (clinically DLB or diffuse Lewy body disease (DLBD) at autopsy) is long debated. Although PD is primarily considered a motor disorder cognitive impairment is often present at diagnosis, and only ~15% of patients remain cognitively intact in the long term. Alpha-synuclein is a major constituent of Lewy bodies and Lewy neuritic pathology, and although the regional and quantitative burden differs, PD, PDD, and DLB may represent a disease continuum. Alpha-synuclein was first implicated in pathogenesis when *SNCA* point mutations and locus multiplications were identified in familial parkinsonism with dementia. In world-wide populations *SNCA* genetic variability remains the most reproducible risk factor for idiopathic PD, and the synuclein gene family has been implicated in DLB/DLBD. However, the precise variant(s) driving those associations have yet to be elucidated. The relationship between genetic variability, gene and protein expression is contentious, while the physiologic and pathologic roles of alpha-synuclein, and their relationship, remain enigmatic. Hence, comprehensive analysis of the *SNCA* locus is ongoing in four cohorts: 1) families with *SNCA* and *SNCB* mutations; 2) the Progressive Parkinson's Markers Initiative *de novo* cohort, focused on biomarker measurement of protein in plasma and cerebrospinal fluid; 3) the Movement Disorders Society PD-Mild Cognitive Impairment cohort, focused on the classification and progression of cognitive decline in advancing PD; 4) studies in brain bank series focusing on Lewy neuropathology, protein and gene expression. A brief summary and synthesis of interim findings will be presented.

Symposium 52: CLINICAL TRIALS PODIUM DISCUSSION - IS THERE A WAY TO INCREASE THE CHANCE OF SUCCESS IN PHASE 3?

ADPD5-2313
DESIGNING CLINICAL TRIALS IN AD

P. Scheltens[1]
[1]*Department of Neurology and Alzheimer Centre, VU University Medical Center, Netherlands*

Recent failures of large size Phase III randomized clinical trials (RCT) in mild to moderate stages of Alzheimer's disease (AD), or even prodromal AD, comparing placebo to drugs interfering with the amyloid cascade are raising serious concerns about the likelihood of success for the ongoing RCTs in similar populations. Patients currently under study have either dementia or MCI, using the modified NINCDS criteria or the Dubois criteria with ages usually ranging from 55 to 90. The relative weight of the underlying pathology is different in younger vs older patients: younger patients will show predominantly amyloid pathology, have a different disease course and atrophy pattern, whereas the older patients will have variable levels of tau hyperphosphorylation, small vessel disease and Lewy Body pathology. The plan of analysis should compare the clinical efficacy in younger vs older subjects, with the hypothesis that the effect size will be higher in younger patients using therapy directed against amyloid. In future studies, proof-of-concept could be attempted in Phase II by enrolling younger (age 50-70 year) subjects with predominantly familial early onset AD, like in the API trial in PS1 carriers, whereas Phase III should require proof of amyloid pathology with low CSF Aβ42 levels, correcting for APOE status,using the best available laboratories to process the samples or using a single reference laboratory, or use a positive amyloid PET scan judged centrally as entry criterion. . However, studies show that having amyloid per se does not predict progression. This may jeopardize the power of the study to detect a difference. An enrichment strategy to increase the likelihood clinical progression, as well as decrease heterogeneity, could consist of including APOE4 carriers only, or include patients with relatively high tau values in CSF, or requiring the presence of a certain amount of bilateral hippocampal atrophy at baseline, or using a randomised start design by documenting clinical or atrophy progression in a run-in period of 6 months and randomizing those with progression only. Coexisting pathology may decrease the chance of success of a therapy directed at amyloid pathology. Presence of concomitant Lewy Body pathology could be ruled out by requiring DAT-SPECT scans at entry, as a proxy for the yet absent reliable alpha-synuclein marker in CSF or serum, or by ruling out clinical features such as visual hallucinations, motor rigidity, or fluctuations of cognition. Since structural MRIs are now done on all patients at screening, the relative amount of white matter lesions could be quantified using a structured method, allowing sub-analysis for low vs relatively high amount of vascular co-morbidity. Patients with the lowest levels of vascular and Lewy body pathology and the highest levels of amyloid pathology would be expected to show the highest clinical response to anti-amyloid therapy. The current designs and primary endpoints are modeled on the ChEI symptomatic trials: fixed time end-points (18 months), dual cognitive and global or functional outcomes. Statistically significant differences between treatment arms for these outcomes at 18 months determine the fate of the

drugs being tested. We argue that this will be not be easily achieved in an analysis putting together all the patients diagnosed as “probable AD” ages 55 to 90 considering the heterogeneity of the underlying age-associated pathology. Futhermore, even if such a difference was demonstrated, the clinical relevance of such a finding will be questioned by regulators, third part payers and future users. Clinically meaningful endpoints such as delay of progression from very mild to moderate dementia, operationally defined as CDR 0.5, progressing to CDR 1 or 2, should be added on the primary plan of analysis. In addition, I argue for the development of more meaningful IADL scales that tap into the activities of the younger patients as defined above, and that are more sensitive to change than the current available scales (Sikkes et al 2009). Considering involving patient panels in the design of future trials and asking them what they consider is important, may beneficial as well. Delaying progression will be even more meaningful in future studies enrolling patients with “prodromal AD”, based on the revised NINCDS-ADRDA criteria (Dubois et al 2007), where (1) placebo can be used until dementia is diagnosed, (2) the underlying pathology may be more amenable to arrest of progression, (3) delaying further cognitive decline, emergence of functional decline or dementia will offer high face validity. We cannot use the RCT design of short-term symptomatic drugs when dealing with longer term disease modification. Innovative plans of analysis are required for the ongoing studies, and the shift to prodromal AD for current and future RCTs. In short we argue to rethink the design of RCT in AD and put more focus on including as homogeneous as possible populations in Phase II, use the prodromal AD criteria, and shift the current emphasis on cognitive outcomes in short-term studies to prevention of global and functional decline in longer Phase III studies. A constant dialogue is necessary between patients, clinicians, pharmaceutical sponsors and regulators in order to move this field forward.

Symposium 52: CLINICAL TRIALS PODIUM DISCUSSION - IS THERE A WAY TO INCREASE THE CHANCE OF SUCCESS IN PHASE 3?

ADPD5-2319
THE FUTURE FOR ALZHEIMER CLINICAL TRIALS

L.S. Schneider[1]
[1]*Alzheimer Disease Research Center, Keck School of Medicine of USC, Los Angeles, USA*

Despite marked advances in knowledge, biomarkers, and drug discovery, phase 2 and 3 Alzheimer-related clinical trials methods have remained relatively stagnant, although some advances have been made. We review trials methods that mostly showed lack of efficacy, at best, modest efficacy; discuss ongoing trials' inclusion criteria, targets, focus, designs, and outcomes. Then we estimate the likelihood for success based on prior evidence.

Current trials include mild/moderate AD, prodromal or MCI due to AD, preclinical AD, secondary prevention, at-risk, and primary prevention trials. Many include features such as biomarkers for sample enrichment intended to increase likelihood for Alzheimer pathology. Outcomes, however, continue to be basic cognitive and functional assessments; although some modifications include executive function tests, computerized administration, and 'composite' batteries derived from scales used in observation cohort studies; biomarkers are exploratory. Compared to earlier prevention trials, current prevention trials use evolved selection criteria, potentially interesting outcomes and no doubt will offer new lessons.

Predicting expectations or designing trials that may increase likelihood for success is an uncertain endeavor as it requires predicting or exploiting advances in knowledge, targets and drugs. A few changes in methods are probable that involve changing management, infrastructure, preparation, recruitment methods, medication/therapy delivery, and regulatory oversight. There will be very few clinic visits, little direct fact-to-face testing, and physicians may not need to be involved. Assessments will be brief, frequent, active and passive, rely on sensors, biosensors, holograms, and virtual systems to assess pharmacokinetics, cognitive and functional behaviors, and health effectiveness. Conducting trials will become faster, cheaper, and ecologically valid. Scenarios for Alzheimer clinical trials of the future utilizing these approaches will be described. Whether these changes increase the chances for success remains to be determined.

[4]INM-4, Forschungszentrum Jülich, Jülich, Germany

1. Objectives:
Strong evidence exists for a central role of amyloid-beta (Abeta) oligomers in the pathogenesis of Alzheimer's disease (AD). The potency to eliminate Abeta oligomers is one of the most desirable criteria for the selection of agents for drug development. Starting from the lead compound 'D3", we set out to identify derivatives with increased efficacy in Abeta oligomer elimination.
2. Methods
We have designed an assay for the quantitative determination of interference with Abeta aggregate size distribution (QIAD). It is a fast, reliable and robust in vitro assay that is able to quantify the Abeta oligomer eliminating potential of any compound. We characterized D3 derivatives with QIAD and with other in vitro assays for their Abeta oligomer eliminating efficacy and binding affinities to Abeta species. Moreover, the most promising derivatives were also characterized in various animal models.
3. Results
D3 and its derivatives specifically eliminated Abeta oligomers and converted them into non-amyloidogenic, non-fibrilar and non-toxic species. We show that next to plaque load and inflammation reduction, oral application of the compounds slowed down neurodegeneration and improved cognitive performance in several transgenic AD mouse models. We demonstrate the predictive power of the QIAD assay for in vivo efficacy by comparing QIAD outcomes of several therapeutically interesting compounds with their treatment effects in animal models.
4. Conclusions
Some D3 derivatives show superior properties in vitro und in vivo. The relation between Abeta oligomer elimination efficacy and in vivo outcome underlines the role of Abeta oligomers in AD pathogenesis.

[5]Drug Safety, Merck Research Laboratories, Kenilworth, USA

Alzheimer's disease (AD) patients need disease modifying therapies that slow progression or delay onset of AD. The amyloid hypothesis proposes a critical pathological role for toxic β-amyloid (Aβ)-containing oligomers and plaques. Inhibition of the aspartyl protease β-secretase (BACE1) may be a robust strategy for testing the amyloid hypothesis because BACE1 is required for Aβ synthesis. MK-8931 is a structurally novel, non-peptidic, BACE inhibitor that was discovered through the intensive use of structure-based drug design and in vivo screening for CSF Aβ lowering in rodents. Here we describe the pharmacological and pharmacokinetic characterization of MK-8931 across multiple preclinical species. MK-8931 is a potent inhibitor of the human BACE1 enzyme with excellent selectivity over other human aspartyl proteases. MK-8931 potently inhibits amyloid precursor protein processing in cells. Acute oral administration of MK-8931 to rats dose- and time-dependently reduces plasma, CSF and brain Aβ40. Acute oral administration to cynomolgus monkeys robust lowers CSF and cortical Aβ40. MK-8931 has moderate to high bioavailability, a moderate $T_{1/2}$ in all species, and good brain penetration in rats and monkeys. The compound does not inhibit or induce the major human CYP450 enzymes and is a weak inhibitor of the hERG channel. Pharmacodynamic and pharmacokinetic modeling based on preclinical data was used to estimate the exposure required for 75% reduction of CSF Aβ in humans. Phase 1 studies have shown that MK-8931 potently and effectively lowers CSF Aβ peptides in humans and MK-8931 has progressed to Phase 3 clinical trials in mild-moderate and prodromal Alzheimer’s disease.

Alzheimer's disease is characterized pathologically by an abundance of extracellular neuritic plaques composed primarily of the amyloid β peptide variant (Abeta42). In the majority of familial AD (FAD) cases, e.g. those harboring mutations in presenilin 1 (PS1), there is a relative increase in the levels Abeta42 compared to Abeta40. We previously reported the characterization of a series of aminothiazole-bridged aromates referred to as aryl aminothiazole gamma-secretase modulators or AGSMs (Kounnas et al. 2010 Neuron 67:769-780) and showed their potential for use in the treatment of FAD (Wagner et al. 2012 Arch. Neurol . 69:1255-1258). Here we describe a series of GSMs with improved physicochemical properties compared to AGSMs. Specific heterocycle replacements of the phenyl rings in AGSMs provided potent molecules with improved aqueous solubilities. A number of these soluble gamma-secretase modulators (SGSMs) potently lowered Abeta42 levels without inhibiting proteolysis of Notch or causing accumulation of amyloid precursor protein carboxy-terminal fragments (APP-CTFs), even at concentrations approximately 1000-fold over their IC_{50}'s for reducing Abeta42 levels. The effects of one potent SGSM on Abeta peptide production were verified by MALDI-TOF mass spectrometry, showing enhanced production of a number of carboxy-truncated Abeta species. This SGSM also inhibited Abeta42 peptide production in a highly purified reconstituted gamma-secretase *in vitro* assay system and retained the ability to modulate gamma-secretase-mediated proteolysis in a stably-transfected cell culture model over-expressing a human PS1 mutation validating the potential for use in FAD.

ADPD5-0821
TOWARDS TREATMENT OF AMYLOID TOXICITY IN DEMENTIA
K. Beyreuther[1]
[1]*University of Heidelberg, Network Aging Research (NAR), Heidelberg, Germany*
The correlation between the total amount of fibrillar aggregates and cognitive decline depends not only on the quantity of the amyloid protein deposited but also on the number of synapses to be destroyed. Indeed, patient with Alzheimer's disease (AD) exhibiting similar level of clinical severity, higher levels of education are associated with more severe disease related changes of ß-amyloid PET or CSF Aß42 levels suggesting that amyloid toxicity may be the same in patients with matched clinical severity but gross differences in AD pathology. Pre-fibrillary Aß species rather than elongated amyloid fibrils are likely to represent the primary pathogenic agents simply because the former provide on their surfaces more chemical groups than the latter, such as hydrophobic side chains and unbound hydrogen bonds that would not be accessible within amyloid. The origine of the toxicity of the oligomers may arise from inappropriate interaction in trans with the folding of cellular and extracellular structures including proteins, lipid membranes and nucleic acids. Therefore, prevention and treatment of protein misfolding disorders needs to address aggregation and misfolding in cis and trans by decreasing the concentration and disrupting the formation of these toxic species. This can be achieved, as we have shown as first, with Aß-analogues that selectively bind to the native state of the peptide that suppress nucleation and proliferation of toxic pre-amyloid species, by antibodies to reduce the level of highly trans-aggregation prone species (such as Aß oligomers), and by stimulating clearance by proteolytic degradation.

ADPD5-0594

NATURALLY OCCURRING AUTOANTIBODIES AGAINST BETA-AMYLOID OLIGOMERS RESCUES MEMORY DEFICITS IN TRANSGENIC MICE WITH ALZHEIMER'S DISEASE

R. Liu[1], X. Xie[1], T. Wang[1], S. Wang[1]
[1]National Key Laboratory of Biochemical Engineering,
Institute of Process Engineering Chinese Academy of Sciences, Beijing, China

Objectives: Previous reports showed that naturally occurring autoantibodies, intravenous immunoglobulin (IVIG), had the benefits in patients with moderate-stage AD who carried an APOE ε4 allele. However, the mechanism by which IVIG played a role in patients remained unclear. Here, we investigated the properties of the antibodies in IVIG in vitro and in vivo.

Methods: Naturally occurring autoantibodies against amyloid-β oligomers (nAbs-Aβo) were purified from IVIG by Aβ oligomer or Cibacron blue affinity chromatography. The effect of nAbs-Aβo on Aβ aggregation and cytotoxicity were analyzed by thioflavin T fluorescence and MTT assay, respectively. The antibodies were injected intraperitoneally to the APPswe/PS1dE9 transgenic mice and the spatial memory and cognition were assessed by morris water maze test and novel object recognition.

Results: nAbs-Aβo purified by both affinity chromatography specifically recognized the Aβ oligomers, inhibited Aβ42 aggregation and attenuated Aβ42-induced cytotoxicity in SH-SY5Y neuroblastoma cells. nAbs-Aβo significantly improved the spatial memory and cognition, reduced the soluble Aβ and oligomers levels. Moreover, nAbs-Aβo reduced the production of pro-inflammatory cytokines, such as TNF-α and IL-6 in AD mice.

Conclusions: Our findings suggested that nAbs-Aβo may have therapeutic potential for AD mice and patients by inhibiting neurotoxicity of Aβ oligomers, and decreasing Aβ levels and pro-inflammatory cytokine production.

[4]Molecular Microbiology and Biotechnology, Tel Aviv University, Tel Aviv, Israel

Protein misfolding that produces assemblies of toxic and transmissible aggregates is a central feature of the pathobiology of neurodegenerative diseases. A serendipitous discovery that direct exposure to filamentous bacteriophage mediates reductions of both amyloid-beta and tau deposits in brains of transgenic mouse models of Alzheimer's disease led to a search for the mechanism. We have isolated and characterized a fragment of the capsid protein responsible for the amyloid targeting activities of the phage, and we show that an immunoglobulin fusion of this General Amyloid Interaction Motif (GAIM), called NPT088, recapitulates the efficacy of the phage both in vitro and in transgenic models of Alzheimer's disease, tauopathy, and Parkinson's disease following chronic systemic administration. Assays for amyloid fiber remodeling, fiber assembly inhibition, and neuroprotection from cytotoxic oligomers together suggest that this GAIM mediates these activities by potently preventing edge-to-edge beta strand aggregation. NPT088 represents a novel, potent, and specific therapeutic candidate for reducing pathologic misfolded protein assemblies that are central players in neurodegenerative diseases.

Alzheimer's disease (AD) clinical trials typically employ an array of outcome measures in order to capture the high dimensionality of dementia. These outcomes are traditionally analysed separately, resulting in much useful clinical information being lost. For this reason, new analytical methods to recognize treatment responses, using techniques that better embrace the high dimensionality of the dementia syndrome, might prove useful.

This study aimed to ascertain the viability of detecting treatment signals using network analysis, a well-established set of techniques employed in a wide range of applications (e.g. ecology to stock markets) but to date little used in dementia clinical trials. Our specific objectives were to evaluate the feasibility and performance of analysing changes in the degree of network connectivity in recent clinical trials of Souvenaid®, a medical nutritional drink for the dietary management of mild AD. Souvenir I and Souvenir II trials both showed significantly more connectivity in the treatment group compared to the placebo, with the difference being evident as early as 12 weeks. The increased connectivity in the Souvenir I and II studies suggest a more widespread treatment effect than when the measures are analysed individually. In this way, the network analysis approach allows overall treatment change to be demonstrated. By considering each treatment arm in a clinical trial as a network, the information from all outcome measures employed in the trial can be evaluated. Further work on translating this into clinically recognizable treatment effects is ongoing.

Symposium 21: TRANSLATIONAL STRATEGIES 2: NUTRITION, TAU TARGETS

ADPD5-2325
SOUVENAID: A NUTRITIONAL INTERVENTION DESIGNED TO ENHANCE SYNAPSE FORMATION IN EARLY ALZHEIMER'S DISEASE
D. Wilkinson
Synapse loss and synaptic dysfunction are established features of the neuropathological processes involved in the early stages of Alzheimer's disease (AD). This early involvement of synapses is very likely the neuropathological substrate for the early symptoms. Indeed, synapse loss has been shown to be the closest pathological correlate of memory dysfunction. Consequently, synapse loss and membrane-related pathology provide viable targets for intervention in AD. Studies have shown that blood levels of key nutrients, essential for the formation and turnover of synapses are lower in patients with AD. This includes uridine, docosahexaenoic acid, eicosapentaenoic acid, choline, phospholipids, in combinations with certain vitamins and cofactors such as folic acid, vitamins B12, B6, C, E, and selenium. Furthermore lower brain and CSF levels of these nutrients have been demonstrated in subjects with AD.
The specific nutrient combination Souvenaid, was developed to provide the key nutrients required for synapse formation and membrane-related pathology in order to ameliorate synapse dysfunction and loss in AD.
This talk will focus on the rationale and preclinical evidence behind the hypothesis, that providing nutritional precursors and cofactors will act together to support membrane formation, and the broad clinical study program investigating the potential of this nutrient combination in AD.

ADPD5-1901
TRANSLATING THE BIOLOGY OF AGING TO NOVEL THERAPEUTICS FOR NEURODEGENERATIVE DISEASE

H. Fillit[1], A. Carmen[2], P. Dacks[2], R. Lane[1], D. Shineman[1]
[1]Medical and Scientific Affairs, Alzheimers Drug Discovery Foundation, New York, USA
[2]Aging and Alzheimers Program, Alzheimers Drug Discovery Foundation, New York, USA

Aging is clearly the leading risk factor for sporadic Alzheimers disease. While research on the biology of aging has progressed rapidly in the past decades, translating this knowledge to develop a better understanding of how aging and age-related diseases might ultimately cause neuronal dysfunction and death in Alzheimers has not been extensively explored. Age-related pathobiological mechanisms can also link lifestyle and other risk factors to cognitive aging and Alzheimers with implications for prevention. Applying knowledge from the biology of aging to neurodegeneration creates opportunities for new drugs to prevent and treat Alzheimers disease. Here, we will provide an overview of drug discovery and development for Alzheimers based on our understanding of the biology of aging as it relates to neurodegeneration.

GENE THERAPY APPROACHES TO TAUOPATHY
D. Morgan[1], M.N. Gordon[1], D.C. Lee[2]
[1]Byrd Alzheimer's Institute, University of South Florida, Tampa FL 33613, USA
[2]Byrd Alzheimer's Institute & Coll. of Pharmacy, University of South Florida, Tampa FL 33613, USA
Arginase-1 converts arginine to ornithine and subsequently polyamines, such as spermidine and spermine. It also can deplete arginine, reducing the production of nitric oxide. In cultured C3H cells overexpressing human tau, increased arginase1 expression led to decreased tau, decreased phosphotau, decreased nitrated tau and reduced mTOR, implying increased autophagy. Adding excess arginine to these cells increased tau, phospho-tau and elevated mTOR, implying reduced autophagy. When added to in vitro tau aggregation assays, spermidine and spermine inhibited tau aggregation at physiological concentrations. These results suggest that increased arginase1 expression may benefit the tau phenotype. 4 mo old Tg4510 mice were injected bilaterally with arginase1-AAV9 into the hippocampi and tissues were collected at 8 mo of age. Histological analysis of one hemisphere indicated successful increases in arginase expression. They also revealed significant 40% reductions in phospho-tau, Gallyas silver staining and reduced atrophy of the hippocampus. Western analysis of SDS soluble fractions found decreased levels of 50-60kD phospho-tau isoforms and nitrated tau plus 130-180kD multimers of total tau, phospho-tau and nitrated tau. Kinases GSK-3B, p38MAPK, CDK-5 (but not casein kinase) were reduced by the treatment. Inflammatory cytokines IL-1B, IL-12, and INF-gamma were reduced to nontransgenic levels. Proteins known to inhibit autophagy were also reduced, suggesting increased autophagy. These results suggest that gene therapy using arginase1 may have therapeutic potential for tauopathies.

ADPD5-1562
THE LEUKOTRIENES PATHWAY IN TAUOPATHY
D. Pratico[1], P. Giannopoulos[1], J. Chu[1], M. Sperow[1]
[1]Pharmacology, Temple University School of Medicine, Philadelphia, USA
Tauopathies are diseases characterized by an accumulation of pathological tau protein leading to progressive neurodegeneration. Current drug interventions for these diseases are limited to the treatment of symptoms without directly affecting tau pathology or the resultant neuronal dysfunction, underscoring the need for development of tau-targeted therapeutics.
The 5-lipoxygenase is an enzyme widely expressed in the central nervous system and the source of pro-inflammatory lipids called leukotrienes (LTs). Recent evidence suggests that pharmacological or genetic modulation of their levels directly influences neurodegenerative processes and improve cognition.
However, no data are available as to whether leukotriene pathway is elevated in human tauopathy, or if it directly influences tau pathology in a relevant model of the disease. In this study we provide the first evidence that the leukotrienes pathway is up-regulated in human tauopathy (i.e, Progressive supranuclear palsy) and in transgenic tau mice. Furthermore, we demonstrate that leukotrienes play a functional role in the development of tau pathologic phenotype since their pharmacological suppression in transgenic tau mice results in memory improvement, rescue of synaptic integrity and dysfunction and reduction of tau pathology via a cdk5-dependent mechanism.
Our results establish leukotrienes as a key player in the development of the entire spectrum of tau pathology phenotype, and a novel viable therapeutic target for the pharmacological treatment of human tauopathy.

TAU ANTIBODY EFFECTOR FUNCTION STATUS DETERMINES INFLAMMATORY RESPONSES IN TARGETING PROPAGATION OF TAU PATHOLOGY

G. Ayalon[1], S. Lee[1], C. Le Pichon[1], O. Adolfsson[2], M. Pihlgren[2], J. Atwal[1], A. Pfeifer[2], R. Watts[1], K. Scearce Levie[1], A. Muhs[2]
[1]Neuroscience, Genentech Inc., South San Francisco, USA
[2]Neuroscience, AC Immune, Lausanne, Switzerland

Immunotherapy to neurodegenerative diseases has been demonstrated to hold promise in preclinical models and in clinical trials. However, despite exquisite target specificity, antibodies harbor the risk of aggravating neuroinflammation in an already chronically inflamed brain. We hypothesized that antibody effector function might be both beneficial in slowing the spreading of tau, yet have the potential to cause neural toxicity by stimulating gliosis. Anti-Tau with full effector function may promote microglia engulfment and clearance of extracellular toxic protein, while also inducing FcgR-mediated microglial activation that could have deleterious effects on neurons. We therefore tested, in a tauopathy mouse model, whether effector function is required for efficacy. Tau-P301L transgenic mice were dosed with full-effector or effectorless antibodies targeting S409 phospho-tau for 3 months. Both reduced tau pathology relative to control-treated mice, measured by IHC and WB. In primary cultures, both antibodies rescued neurons from extracellular tau-mediated toxicity independent of effector function. In cultured microglia effector function enhanced tau uptake, however also induced release of proinflammatory cytokines. Effectorless antibodies prevented both tau uptake and activation by microglia. In neuron-microglia co-cultures only the effectorless antibody rescued neurons. We show that effector function is not required for efficacy in vivo, and propose that effector function status may determine antibody mechanism-of-action. Furthermore, we suggest that effectorless antibodies are potentially safer. We conclude that engineering Tau antibodies to have attenuated effector function may mitigate potential deleterious inflammatory consequences of antibody treatment, while still preserving the ability to limit the spread of toxic proteins in vivo.

ADPD5-1903
TARGETING THE P75 NEUROTROPHIN RECEPTOR FOR ALZHEIMER'S THERAPEUTICS: BASIC MECHANISMS THROUGH PHASE 1
F.M. Longo[1]
[1]*Neurology and Neurological Sciences, Stanford University, Palo Alto, USA*
The p75 neurotrophin receptor ($p75^{NTR}$) is linked to signaling networks promoting synaptic dysfunction and degeneration in AD. Its expression occurs in neuronal populations undergoing degeneration, including cortical, hippocampal, basal forebrain, raphe, and locus coeruleus neurons and is increased in AD and mouse AD models. In its predominant signaling state, $p75^{NTR}$ promotes degenerative signaling and knockout studies demonstrate that it enables Aβ-induced degeneration *in vitro* and *in vivo*. We have developed small molecule $p75^{NTR}$ ligands that inhibit its degenerative signaling and prevent Aβ-oligomer induced neurite and synaptic degeneration. *In vitro* studies demonstrate inhibition of Aβ-induced: GSK3β, cdk5, p38 and c-Jun activation; tau phosphorylation and missorting; compromised AKT and CREB function; RhoA/cofilin activation; FYN activation/NR2B phosphorylation; and inhibition of LTP. *In vivo* studies employing oral administration in $APP^{Lond/Swe}$ mice demonstrate $p75^{NTR}$ target engagement, inhibition of tau phosphorylation and misfolding, inhibition of neurite and spine degeneration (including late-stage reversal of degeneration), inhibition of microglial activation; and improved performance in multiple behavioral tests, with no effects on Aβ levels. Inhibition of neuronal degeneration in Tg2576 and Ts65Dn mice, along with reversal in wild type mice of age-related cholinergic neurite atrophy, indicate that mechanisms extend beyond a single transgenic mouse model. $APP^{Lond/Swe}$ mouse micro-PET and autoradiography studies with a TSPO PET ligand revealed $p75^{NTR}$ ligand-mediated inhibition of elevated signaling consistent with inhibition of microglial activation. Phase 1 safety and PK studies with a derivative of the prototype $p75^{NTR}$ ligand have been successfully completed and Phase 2a-enabling studies are underway. [3]Research, FORUM, Watertown, USA
While anti-amyloid therapies in Alzheimer's disease (AD) hold great promise, such treatments may only slow functional decline. Therefore additional therapies are needed that will help to restore lost function. We discuss the current understanding of the mechanism of action of alpha7 nicotinic acetylcholine receptor (alpha 7) agonists, therapies that may restore cognitive function. We will compare clinical efficacy data for encenicline, an alpha 7 partial agonist currently in phase 3 development for AD and cognitive impairment in schizophrenia, with preclinical data. We will propose a model of how alpha 7 agonists may affect neuronal networks and enhance cognition. Encenicline activates alpha 7 receptors at concentrations below the Ki in the presence of acetylcholine, a phenomenon we term priming. alpha 7 agonists affect hippocampal neuronal networks involved in cognition at priming concentrations through enhancing GABAergic inhibitory post-synaptic currents, long-term potentiation (LTP), and theta synchrony. Independent pharmacokinetic (PK) studies and pharmacodynamics-pharmacokinetic modeling confirmed that plasma concentrations capable of increasing theta rhythm power *in vivo* corresponded to priming concentrations *in vitro* and to active concentrations in preclinical models of cognition. These data extend the concept of priming activity at alpha 7 receptors into neuronal systems at the circuit level. At priming concentrations, these data with encenicline analogs are consistent with the important role for increased GABAergic tone, mediated by interneurons, in the generation of theta synchrony and its concomitant role in memory.

THE GALANTAMINE PRODRUG, MEMOGAIN®, REVERSES DEFICITS IN HIPPOCAMPAL NEUROGENESIS AND MIGRATION FOLLOWING CHOLINERGIC DENERVATION.

J. Van Kampen[1], A. Maelicke[2]
[1]Biomedical Science, University of Prince Edward Island, Charlottetown, Canada
[2]Managing Director Europe, Neurodyn Life Science Inc., Mainz, Germany

Loss of basal forebrain cholinergic innervation of the hippocampus and severe neuronal loss within the hippocampal CA1 region are early hallmarks of Alzheimer's disease (AD), and are strongly correlated with cognitive status. This loss of cholinergic innervation is a key factor underlying alterations in hippocampal neurogenesis, which are also characteristic of AD. We have previously reported the effects of various cholinergic compounds on hippocampal neurogenesis indicating that acetylcholine serves as a potent neurogenic regulator.

Memogain® (GLN 1062) is an inactive galantamine pro-drug with 15 fold higher brain availability than galantamine. It is designed to provide improved blood brain barrier penetration, greater potency, and fewer side effects than the cholinesterase inhibitors currently used for the treatment of AD. Galantamine is unique among the cholinesterase inhibitors in that it also has allosteric actions at α-7 nicotinic receptors, linked to both disease-modifying and cognitive enhancing effects.

The immunotoxin, 192IgG saporin (SAP), used to induce selective basal forebrain cholinergic cell loss, resulted in a pronounced loss of basal forebrain cholinergic neurons and hippocampal ChAT fiber density. SAP-lesioned animals also displayed significant reductions in hippocampal neuroprogenitor populations, reduced cell proliferation, and disrupted neuronal migration, when compared to sham-operated control animals, as well as significant impairments in spatial working memory. By contrast, animals treated with Memogain® displayed a restoration of hippocampal cell proliferation, increased neuronal cell counts, normalized neuronal migration, and improvements in cognitive function. Thus, the beneficial effects of Memogain® may extend beyond acute cognitive enhancement, to include disease modification through support of hippocampal neurogenesis.

ROLE OF CREB IN AMYLOID-BETA-INDUCED BDNF DOWN-REGULATION

M. Fahnestock[1], E. Rosa[2]

[1]Psychiatry & Behavioural Neurosciences, McMaster University, Hamilton, Canada

[2]McMaster Integrative Neuroscience Discovery & Study (MiNDS) Graduate Program, McMaster University, Hamilton, Canada

Objectives: Accumulation of amyloid-β (Aβ) peptide results in loss of brain-derived neurotrophic factor (BDNF), loss of functional synapses and subsequent neurodegeneration and memory loss. Previous work has demonstrated that Aβ decreases activity-induced BDNF expression by regulating CREB phosphorylation, which occurs via both activation of GSK3β and inactivation of PKA. However, the mechanism by which Aβ reduces basal levels of BDNF remains unclear.

Methods: Differentiated, unstimulated human neuroblastoma (SH-SY5Y) cells were treated with 5μM oligomeric Aβ prior to quantification of BDNF and CREB mRNA via qRT-PCR. Phosphorylated and total CREB protein levels were analyzed in both the cytoplasmic and nuclear fractions. Lastly, the GSK3β inhibitor CT99021 or the PKA activator forskolin were added to SH-SY5Y cells with or without Aβ treatment to determine if activating CREB by either mechanism could protect against Aβ-induced loss of basal BDNF expression.

Results: CREB mRNA was reduced in Aβ-treated cells compared to controls. Phosphorylated and total CREB proteins were decreased in both the cytoplasm and nucleus of Aβ-treated cells. However, neither pCREB129 nor pCREB133 levels were altered relative to total CREB levels. Although CT99021 did not protect cells against Aβ-induced BDNF down-regulation, forskolin increased pCREB133 levels and prevented Aβ-induced BDNF down-regulation.

Conclusions: Aβ down-regulates basal levels of BDNF in the absence of cell stimulation. This is a consequence of Aβ-induced CREB transcriptional down-regulation rather than changes in CREB phosphorylation. Aβ reduces basal BDNF expression and activity-induced BDNF expression by different mechanisms. However, pCREB133 protects against both basal and activity-induced BDNF down-regulation following Aβ treatment.

Symposium 23: TRANSLATIONAL STRATEGIES 3: CHOLINERGIC TARGETS, STEM CELLS AND GROWTH FACTORS

ADPD5-0993
POTENTIAL STEM CELL THERAPY FOR AD AND PD
Y.H. Suh[1]
[1]*President, Korea Brain Reserch Institute (KBRI), Daegu, Korea*
Recent studies of stem cell show its therapeutic potential for neurodegenerative disorders. The aim of the present study was to elucidate the preventive and therapeutic potential of stem cells for AD and PD. Among stem cells, autologous human adipose-derived stem cells (hASCs) elicit no immune rejection responses, tumorigenesis, or ethical problems.
Here, we used hASCs and examined whether intravenously or intracerebrally transplanted hASCs could have therapeutic and preventive effects in AD mouse model (Tg2576). We first report that intravenously or intracerebrally transplanted hASCs significantly rescues memory deficit and neuropathology in the brains of Tg mice by up-regulating IL-10 and VEGF and by elevating synaptic and dendritic stability. More importantly, our findings that transplanted hASCs prevent or delay the onset and progression of the disease strongly suggest that the simple, convenient and safe intravenous injection of hASCs can be very useful in both the prevention and treatment of AD.
Parkinson's disease (PD) is caused by the progressive degeneration of dopaminergic neurons and is characterized by cytoplasmic inclusions known as lewy bodies in the substantia nigra. Recently, treatment of PD using stem cells has been in the spotlight. In many studies, it has been described that the structural and functional alteration of mitochondria were associated with neurodegenerative diseases including PD. Therefore, we investigated the effects of intra-venous injection of hASCs on mitochondrial functions in PD mouse model induced by 6-hydroxydopamine (6-OHDA). Intravenous injection of hASCs greatly improved behavior and mitochondrial dysfunction in PD mice model.

DEFICIENT NEUROGENESIS PLAYS A ROLE IN COGNITIVE IMPAIRMENTS IN ALZHEIMER'S DISEASE

O. Lazarov[1]

[1]*Anatomy and Cell Biology, University of Illinois at Chicago, Chicago, USA*

Objectives (1) Examine whether adult neurogenesis plays a role in learning and memory impairments and cognitive deficits. (2) Determine whether deficient neurogenesis can induce cognitive deficits in Alzheimer's disease (3) Determine whether loss of gamma-secretase function in neural progenitor cells induces cognitive deficits.

Methods For objective 1,2 we temporally depleted neurogenesis by conditional nestin-regulated expression of δ-HSV-TK in neural progenitor cells in the brain of mice harboring FAD-linked APPswe/PS1-delta-E9. For objective 3 expression of presenilin-1 in hippocampal neural progenitor cells was downregulated by lentiviral vectors expressing shRNA for the targeting of presenilin-1.

Results (1) Depletion of neurogenesis was manifested by a dramatic decrease in the number of new neurons in the subgranular layer of the dentate gyrus of the hippocampus. (2) Depletion of neurogenesis induced and enhanced deficits in contextual memory, pattern separation, novelty recognition and spatial memory in the FAD mice. (3) Downregulation of presenilin-1 in hippocampal neural progenitor cells induces learning and memory deficits in adult mice. New neurons expressing downregulated presenilin-1 levels exhibit reduced dendritic branching and reduced number of dendritic spines. (4) Presenilin-1 regulates adult neurogenesis via beta-catenin and notch signaling.

Conclusions These experiments provide, for the first time, (1) Evidence that impairments in neurogenesis promote cognitive deficits in Alzheimer's disease (2) A novel mechanism underlying learning and memory deficits in Alzheimer's disease. Enhancing neurogenesis may attenuate or prevent learning and memory impairments characterizing the disease.

ADPD5-1927
TREATMENT OF ALZHEIMER DISEASE; THE PATHWAY TO 2025

B. Winblad[1]
[1]*NVS Center for Alzheimer Research, Karolinska Institutet, Huddinge, Sweden*

In 2012, the World Health Organization presented a report where Alzheimer Disease (AD) and other dementias should be regarded as a global public health priority. A similar policy declaration has been presented by the European Union and USA. The main reason for these policy declarations is the awareness of trends that sometimes are described as a "time-bomb". In 2010, the number of people affected by dementia worldwide was estimated to 36 million, with an estimated cost of approx 600 bUSD. The prevalence of dementia is expected to reach 115 million in 2050, with an equivalent cost increase.

The progressive nature of dementia influences the whole life situation for families during several years-decades and so far, no cure or highly significant symptom relieving treatment is available. Increased understanding of the pathophysiology of AD has given us new therapeutic targets, and by using new biomarkers possibilities to diagnose patients earlier.

The last drug to enter the market place was in 2002. Since then, many products in different development phases have failed. Why? Wrong molecules, inappropriate animal models, inappropriate proof-of-concept studies, heterogeneous patient groups, too advanced disease, non-relevant outcome measures, intercenter variability in increasingly globalised multi-centre trials?

Our hope for the future is not only to give the patient an early symptomatic relief but that new therapies could potentially slow or even halt the progression of the disease. Increased global collaboration between academia, industry and regulatory authorities is a vital step for a successful drug development.

We have good hope that until 2025, ongoing studies directed towards beta-amyloid and/or tau metabolism have proven effective and are on the market.

A 52-WEEK PILOT STUDY TARGETING ABETA WITH PBT2: NEUROIMAGING RESULTS

V.L. Villemagne[1], C.C. Rowe[1], K.J. Barnham[2], R. Cherny[2], M. Woodward[3], S. Pejoska[1], G. Jones[1], R. Tanzi[4], C.L. Masters[2]

[2]The Florey Institute, University of Melbourne, Melbourne, Australia
[3]Aged Care &. Residential Services, Austin Health, Melbourne, Australia
[4]Aging and Gen. Research Unit, Massachusetts General Hospital, Boston, USA

Objectives The trial aimed to explore putative imaging markers to help inform future clinical trial design of PBT2 in Alzheimer's disease (AD).

Methods We conducted a 52-week, double-blind, randomized, placebo-controlled trial involving 42 patients with mild AD (71.1±9.2 years, MMSE 24.2±2.5) with a baseline ^{11}C-PiB-SUVR ≥1.7. Participants received either PBT2 (250mg/day) or placebo for 52 weeks. Primary outcome measure was Aβ burden as measured by ^{11}C-PiB-PET at baseline and 12 months. Participants also underwent periodic neuropsychological evaluation, FDG-PET and MRI scans.

Results PBT2 was well tolerated. At baseline, there were no significant between-group differences in age, gender, ApoE, hippocampal volume, PiB or FDG SUVR. Baseline ^{11}C-PiB-SUVR ranged between 1.73 and 3.31 (median 2.5). Despite PBT2-treated patients showing a significant decrease in Aβ burden at 12 months (-2.5%, p=0.048) post-hoc, this was accompanied by a similar decrease in the placebo group (-3.1%, p=0.06), yielding no significant between-group differences. Similarly, no significant between-group differences were found on cognition, FDG or MRI volumetrics, though a trend towards a slower rate of hippocampal atrophy on PBT2-treated patients (p=0.09) was observed. When analyzed separately, PBT2-treated participants with baseline >SUVR 2.5 (n=11) showed significant reductions in PiB-SUVR (p=0.002) while those with <SUVR 2.5 (n=14) did not (p=0.6), and while the between-groups differences became more pronounced, they did not reach statistical significance.

Conclusions There were no between-group differences in Aβ burden in PBT2 treated and untreated mild AD patients, despite a significant reduction in Aβ in the PBT2-treated patients, especially in those with a baseline PiB-SUVR ≥2.5.

[10]Neuroscience, Pfizer Inc, Collegeville, USA
[11]Neuroscience, Janssen Research and Development Johnson and Johnson, Fremont, USA

Objective: Amyloid-Related Imaging Abnormalities with edema/effusion (ARIA-E) are observed with anti-amyloid therapies in Alzheimer's disease (AD). This study evaluated whether ARIA-E was associated with specific biomarker patterns.
Methods: Bapineuzumab, an anti-amyloid-β therapy, was evaluated in separate trials for *APOE*4 carriers and non-carriers with mild-moderate AD. Subsets underwent PET, CSF, or volumetric MRI assessments.
Results: 223, 558, and 1398 subjects underwent PET, CSF, and vMRI assessments, and 22, 64, and 134, respectively, developed ARIA-E. No differences in baseline brain PET amyloid signal (GCA SUVr) or vMRI measures (WBV, VV, HCV) were observed between ARIA-E and non-ARIA-E subjects. No differences in baseline CSF Aβ42, Aβ40, t-tau, or p-tau were observed, except Aβ42 in *APOE*4 non-carrier ARIA-E vs non-ARIA-E (bapineuzumab/placebo p=0.026/0.012). Bapineuzumab-treated subjects with ARIA-E showed greater reduction at week 71 in GCA SUVr and greater VBSI and HBSI vs non-ARIA-E (all comparisons PET: p<0.001-0.059; VBSI/HBSI: p<0.001). Greater CSF p-tau reduction at week 71 was observed in ARIA-E subjects (all comparisons p<0.001-0.096). Greater t-tau reduction was seen for ARIA-E vs non-ARIA-E (*APOE*4 carriers: bapineuzumab/placebo p=0.022/0.018; non-carriers placebo: p=0.054). No differences in changes at week 71 were observed in CSF Aβ42 or Aβ40, except for decreased Aβ40 in ARIA-E *APOE*4 carriers vs non-ARIA-E (bapineuzumab/placebo p= 0.042/0.089). **Conclusion:** Except for PET amyloid signal and CSF Aβ42 in *APOE*4 non-carriers, baseline biomarkers do not predict risk for developing ARIA-E. Longitudinal changes in several biomarkers were significantly

associated with ARIA-E. These data support the hypothesis that ARIA-E may be related to Aβ efflux from the brain.

[7]Clinical Pharmacology, Janssen Research & Development, Titusville, USA
[8]Neuroscience Development, Janssen Research & Development, Beerse, Belgium

Objectives
Reduction of Aβ production by inhibition of BACE1 has been proposed as a promising treatment in Alzheimer's Disease. JNJ-54861911 is a novel oral BACE inhibitor. We report plasma and CSF Aβ reductions in phase 1 clinical trial, investigating target engagement.
Methods
Healthy participants, aged 55 to 85, were randomized (JNJ-54861911/placebo) in a single dose (1-150mg) and subsequent multiple ascending 14-day dose (5-90mg) trial, to assess safety, tolerability, plasma and CSF (36h catheterization) pharmacokinetics (PK) and pharmacodynamics (PD) including Aβ (Aβ1-37, 1-38, 1-40 and 1-42), sAPPα and sAPPβ. To account for inter-subject variability of baseline Aβ and sAPP levels, reductions were expressed as % of predose.
Results
After single dose, plasma Aβ reached maximal reduction after 3-4 hours, while CSF Abeta started declining only after 6-8 hours post-dose. Aβ reductions persisted long after compound levels declined. This resulted in sustained Aβ reductions, up to 95%, after 14 days of dosing. The changes observed for all 4 Aβ peptides were dose-dependent and similar, but Aβ1-40 (most prevalent in plasma and CSF) had the best assay characteristics. sAPPβ peptides reduced in parallel, while sAPPα increased up to 2-3 fold. These effects appear to be independent of baseline factors (e.g. Aβ or APOE genotype).
Conclusions
JNJ-54861911 is a potent, brain-penetrant BACE inhibitor, achieving up to 95% Aβ reduction with once daily oral dosing. Aβ reduction outlasted plasma/CSF PK, leading to sustained PD activity. It is plausible that plasma and CSF Aβ reductions are driven by peripheral and central activity, respectively.

Symposium 26: AMYLOID-REDUCING THERAPIES IN ALZHEIMER'S DISEASE

ADPD5-0966

RANDOMIZED, DOUBLE-BLIND, PHASE 1B STUDY OF BIIB037, AN ANTI-AMYLOID BETA MONOCLONAL ANTIBODY, IN PATIENTS WITH PRODROMAL OR MILD ALZHEIMER'S DISEASE

J. Sevigny[1], P. Chiao[1], L. Williams[1], X. Miao[1], J. O'Gorman[1]
[1]Clinical Developement, Biogen Idec, Cambridge, USA

Objectives: BIIB037 is a fully human monoclonal antibody selective for aggregated forms of amyloid beta-peptide being investigated as a disease-modifying treatment for Alzheimer's disease (AD). Results of an interim analysis of a Phase 1b study evaluating safety, tolerability, pharmacokinetics, and pharmacodynamics of BIIB037 in patients with prodromal or mild AD will be presented.
Methods: This is a multicenter, randomized, double-blind, placebo-controlled, multiple-dose study of BIIB037. Patients were 50–90 years of age, positive for amyloid beta deposition as assessed by florbetapir (^{18}F-AV-45) positron emission tomography (PET) scan, and met clinical criteria for prodromal AD or mild AD. During the double-blind, placebo-controlled phase, patients received BIIB037 or placebo by intravenous infusion once every 4 weeks for 52 weeks. In a staggered, parallel-group design, patients were randomized to 1 of 5 treatment arms and stratified by APOE epsilon 4 status (carrier or non-carrier). The primary endpoints were safety and tolerability. Secondary endpoints included BIIB037 pharmacokinetics and change from baseline to Week 26 in brain amyloid plaque burden as measured by PET imaging.
Results: A total of 126 patients were randomized. Incidence of adverse events, serious adverse events, and amyloid-related imaging abnormalities (ARIA) will be presented. Quantitative analysis of ^{18}F-AV-45 PET imaging will assess the effect of BIIB037 on cerebral amyloid plaque content.
Conclusions: These data will provide information on the safety and tolerability of BIIB037. The effectiveness of BIIB037 in reducing amyloid plaque burden will be addressed.

Symposium 29: ER STRESS, SIGMA-1 RECEPTORS AND GPCRS AS THERAPEUTIC TARGETS IN CNS DISEASE

ADPD5-1916
ABETA 42 OLIGOMER BINDING TO NEURONAL SIGMA-2/PGRMC1 RECEPTORS IS DISPLACED BY DRUG CANDIDATES THAT IMPROVE COGNITIVE DEFICITS

S.M. Catalano[1], N.J. Izzo[1], C. Rehak[1], K. Mozzoni[1], C. Silky[1], G. Look[1], G. Rishton[1], H. Safferstein[1], M. Windisch[2], T. Spires-Jones[3]
[1]Development, Cognition Therapeutics Inc., Pittsburgh, USA
[2]Development, NeuroScios, Graz, Austria
[3]Center for Cognitive and Neural Systems and Euan MacDonald Centre for Motorneu rone Disease, The University of Edinburgh, Edinburgh, United Kingdom

Objectives: We have discovered novel therapeutic antagonists of a receptor not previously associated with AD (sigma-2/PGRMC1) capable of blocking Abeta oligomer toxic effects on synapses in vitro and cognitive deficits in vivo. We sought to define the role of this receptor in mediating Abeta oligomer-induced deficits.
Methods: Knockdown of sigma-2/PGRMC1 (progesterone receptor membrane component 1) protein expression in vitro using siRNA results in a highly correlated reduction in binding of exogenous Abeta oligomers to neurons of more than 90%. Expression of sigma-2/PGRMC1 protein is upregulated in vitro by treatment with Abeta oligomers, and is dysregulated in Alzheimer's disease patients' brain compared to age-matched, normal individuals. Specific, high affinity small molecule receptor antagonists can displace synthetic Abeta oligomer binding to synaptic puncta in vitro and displace endogenous human AD patient oligomers from brain tissue sections in a dose-dependent manner. These receptor antagonists prevent and reverse the effects of Abeta oligomers on membrane trafficking and synapse loss in vitro and cognitive deficits in AD mouse models.
Results: These findings suggest sigma-2/PGRMC1 receptors mediate saturable oligomer binding to synaptic puncta on neurons and that brain penetrant, small molecules can displace endogenous and synthetic oligomers and improve cognitive deficits in AD models.
Conclusions: We propose that sigma-2/PGRMC1 is a key mediator of the pathological effects of Abeta oligomers in AD and is a tractable target for small molecule disease-modifying therapeutics. These receptor antagonists represent promising disease modifying drug candidates that will be studied in planned clinical trials.

Symposium 29: ER STRESS, SIGMA-1 RECEPTORS AND GPCRS AS THERAPEUTIC TARGETS IN CNS DISEASE

ADPD5-1598
TARGETING THE SIGMA-1 PROTEIN FOR NEUROPROTECTION IN ALZHEIMER'S DISEASE

T. Maurice[1]
[1]*University of Montpellier 2, INSERM U. 710, Montpellier cedex 5, France*

The sigma-1 receptor (S1R) is a ligand-operated molecular chaperone expressed in the brain and localized on endoplasmic reticulum (ER), mitochondria and plasma membranes. Its activation modulates IP_3 receptor-dependent Ca^{2+} mobilizations, facilitates the activation of ER stress sensor proteins and kinase pathways. Under chronic activation, it is also involved in recomposition of lipid domains on the plasma membrane, which are highly functionalized domains. Interestingly, the chaperone can be directly activated (or inactivated) by several classes of natural and synthetic ligands, explaining its historic misunderstanding as a classical membrane receptor. Ligands modulating the S1R ligands have been shown to be potent neuromodulatory and protective drugs in different neurodegenerative insults and apthologies (stroke, Alzheimer's disease (AD), Parkinson's disease, amyotrophic lateral sclerosis…). We examine the involement of the S1R in Ad pathology and validate selective or non-selective S1R agonists as neuroprotective agents. First, we analyzed the impact of S1R invalidation (using S1R KO mice) on the vulnerability to AD pathology. Two main AD models were used, a nontransgenic model by direct icv injection of oligomeric amyloid-b (Ab) protein fragments [25-35] (Ab_{25-35}) in mice and transgenic animals overexpressing $hAPP_{Swe}$ or $hAPP_{SweInd}$. We observed that AD toxicity is significantly amplified in S1R KO mice injected with Ab_{25-35} and in S1R KO x $hAPP_m$ lines. Second, we showed the protective potency of S1R agonists and mixed muscarinic/S1R ligands in AD models. The pathology was analyzed in terms of ER and oxidative stress, inflammation, mitochondrial damage, cell loss, memory deficits, increased APP processing and Tau hyperphosphorylation. We therefore confirmed the role of endogenous neuroprotection system in neurodegenerative processes and identified S1R agonists as potent neuroprotective and putatively disease-modifying agents.

Symposium 29: ER STRESS, SIGMA-1 RECEPTORS AND GPCRS AS THERAPEUTIC TARGETS IN CNS DISEASE

ADPD5-0875
CELLULAR STRESS SIGNALING AT THE MITOCHONDRION-ER-NUCLEUS AXIS: ROLES OF THE SIGMA-1 RECEPTOR CHAPERONE

T. Su[1]
[1]*Cellular Pathobiology Section, IRP NIDA NIH, Baltimore, USA*

The sigma-1 receptor (Sig-1R) is ligand-operated endoplasmic reticulum (ER) chaperone that resides specifically at the ER-mitochondrion interface referred to as the MAM (**M**itochondrion **A**ssociated ER **M**embrane). At the MAM, Sig-1Rs serve to (1) chaperone the IP3 receptor type 3 to maintain proper Ca2+ signaling from the ER into mitochondria to ensure sustenance of sufficient bioenergetics; (2) attenuate free radical generation at the ER for proper ER-mitochondrion-plasma membrane signaling that is essential for dendritic spine formation; (3) chaperone the ER stress sensor IRE1 to ensure proper transmission of stress signaling in the mitochondrion-ER-nucleus axis to enhance cellular survival at the genomic level. Interestingly, in addition to those actions at the MAM, Sig-1R agonists like psycho-stimulant cocaine or certain neurosteroids can cause the Sig-1R to dissociate from their cognate co-chaperone BiP at the MAM and translocate the Sig-1R thereby to the plasma membrane to interact with other receptors, ion channels, or kinases to trigger a plethora of pharmacological responses. The Sig-1R agonists can also cause Sig-1Rs to translocate to the nucleus and extracellular space. We are in the process of understanding the complete underpinning mechanism of the dynamic action of this molecular chaperone Sig-1R as it has been implicated in diseases like Alzheimer's, Parkinson's, ALS/FTLD, HIV-associated neuro-dementia, and addiction, and may thus provide new therapeutic avenues for those diseases.

POSSIBLE ROLES OF CALCIUM STORES IN THE INITIATION OF AD
M. Segal[1], G. Grigoryan[1], E.T.A.Y. Aloni[1], G. Biella[2], D. Albany[2], G. Forloni[2]
[1]Neurobiology, Weizmann Inst, Rehovot, Israel
[2]Neuroscience, Mario Negri Inst, Milan, Italy
Objectives: Early life stress has been shown to affect adult brain and behavior, and to accelerate the development of mental disorders. In our earlier studies we found that release of calcium from stores is altered by stress, to affect the ability to undergo long term potentiation (LTP) of reactivity to stimulation. We have now tested the hypothesis that juvenile stress (JS) contributes to the development of deficits in neuronal plasticity in the triple-transgenic mouse model for Alzheimer's disease (3xTgAD) by interacting with regulation of calcium stores. Methods: We studied LTP in 3, 6 and 8 month-old 3xTgAD and wt mice. Juvenile animals were exposed to three stressors; restrain, forced swim and elevated platform. EPSPs were recorded in stratum radiatum of CA1 region of hippocampal slices. Results: Adult 3xTgAD mice exhibited significant deficits in LTP compared with wt mice. LTP in 3xTgAD control and stressed mice was rescued by pre-exposure to 0.2 μM ryanodine, in an age-dependent manner. Acting at a beta adrenergic receptor, isoproterenol (Iso) converted STP to LTP. This was mediated by activation of calcium stores, and was suppressed by JS, especially in the 3xTgAD slices. Biochemically, 3xTgAD express a reduced level of Sirtuin-1, a deacetylase involved in synaptic plasticity. Furthermore, stressed mice have altered ratio of Aβ42/40. Conclusions: These and more recent results highlight the intricate relations among calcium stores, ryanodine receptors, stress and catecholamines in the regulation of cognitive decline associated with AD, adding new dimensions to the plethora of factors that lead to the disease.

Symposium 29: ER STRESS, SIGMA-1 RECEPTORS AND GPCRS AS THERAPEUTIC TARGETS IN CNS DISEASE

ADPD5-0215
PRESENILINS, NEURONAL STORE OPERATED CALCIUM ENTRY AND SYNAPTIC LOSS IN ALZHEIMER´S DISEASE

I. Bezprozvanny[1]
[1]*Physiology, University of Texas Southwestern Medical Center, Dallas, USA*

Background. Mutations in presenilins result in familial Alzheimer's disease (FAD). These mutations affect gamma-secretase function of presenilins and influence Ab42/Ab40 ratio. Our previous studies suggested that FAD mutations also affect endoplasmic reticulum (ER) calcium (Ca^{2+}) function of presenilins and result in ER Ca^{2+} overload (Tu at al, 2006. Cell 126, 981-993; Zhang at al. 2010. J Neurosci 30, 8566-8580). However, mechanistic connection between ER Ca^{2+} signaling dysregulation and synaptic loss in AD has not been previously established.
Methods. Perform studies of Ca^{2+} signaling and synaptic loss in hippocampal neurons from presenilin 1 (PS1) M146V knockin (KI) model of FAD. Our approach is centered on measurements of synaptic Ca^{2+} signals and analysis of postsynaptic spine shapes in wild type and PS1-M146V KI neurons.
Results: We discovered that PS1-M146V KI neurons compensate for ER calcium overload by downregulating STIM2 protein, a master regulator of neuronal store operated calcium entry pathway (nSOC). We further demonstrated that similar downregulation of STIM2 occurs as a result of normal aging process. In experiments with STIM2 conditional knockout mice we demonstrate that knockout of STIM2 results in destabilization of mushroom spines in hippocampal neurons. We further demonstrate that overexpression of STIM2 results in rescue of mushroom spine deficiency in PS1-M146V KI hippocampal neurons. We determined that synaptic CaMKII acts downstream of nSOC in spines.
Conclusions. We concluded that (1) STIM2-nSOC-CaMKII pathway is essential for long-term maintenance of mushroom spines; (2) function of this pathway is compromised in aging and AD neurons due to downregulation of STIM2.

Symposium 34: TRANSLATIONAL STRATEGIES 4: Gsk3BETA , Tau Targets (2)

ADPD5-2245
POTENTIAL FOR TAU ISOFORM-SPECIFIC ANTIBODIES FOR PASSIVE IMMUNOTHERAPY IN TAUOPATHIES

B. Hapuarachchi[1], R. De Silva[1], T. Warner[1], J. Staddon[2], M. Roberts[2]
[1]Dept of Molecular Neuroscience, Institute of Neurology, London, United Kingdom
[2]EKC Mosquito Way, Eisai Ltd, Hatfield, United Kingdom

Introduction: From Braak staging in Alzheimer's disease, it is now recognised that tau pathology spreads along anatomically connected pathways with progression of disease. The agent of this "prion-like" aggregation and trans-synaptic spread are pathological conformers of tau that are released by cells, endocytosed by neighbouring healthy neurons and in turn convert normal tau in a cascade-like fashion. Studies have shown the potential therapeutic benefit of targeting this extracellular tau with specific antibodies.
Objective: RD3 and RD4 antibodies that target regions in the microtubule-binding repeat domain of tau that are crucial for aggregation were investigated to demonstrate their efficacy in preventing pathological tau uptake and aggregation in a cell-based model.
Methods: Sequences encoding the wild-type, deltaK280 (Δ) and P301L/V337M (LM) double mutant tau repeat region were cloned into pEGFP-N1 and pDsRed-monomer-N1. SH-SY5Y neuroblastoma cells were co-transfected with mutant and WT tau constructs. After 48 hours, fixed cells were analysed by fluorescence resonance energy transfer (FRET) using both acceptor photo bleaching microscopy and a fluorescence plate reader with fixed excitation/emission windows.
Results: Strongest FRET signals in cells co-expressing the Δ and LM mutants were observed. Pre-incubation of the cells with AD brain homogenate further increased the signal. This was progressively abolished with pre-incubation of the brain homogenate with increasing concentrations of RD3 antibody with a more modest efficacy of the RD4 antibody.
Conclusions: The well-characterized RD3 antibody appears to be effective in preventing the cellular uptake and seeding of tau aggregation. These findings suggest that RD3 could be developed for passive immunotherapy.

TAU VACCINE AADVAC1 - THE ROAD TO PHASE II CLINICAL TRIALS

M. Novak[1], E. Kontsekova[1], N. Zilka[1], B. Kovacech[1], P. Novak[1], R. Skrabana[1]
[1]Neuroscience, Axon Neuroscience, Bratislava, Slovakia

The microscopic changes that underlie the syndrome of Alzheimer's disease (AD) dementia are accumulation of pathological amyloid-β and tau proteins, accompanied by synaptic and neuronal loss and neuroinflammation. The progress and spreading of neurofibrillary tau pathology through the brain correlates with the cognitive symptoms, neuronal loss and atrophy observed in AD. We have analyzed the building blocks of tau pathology and identified the most toxic species, which were used to develop transgenic animal models that faithfully replicated human neurofibrillary pathology. We have developed an active and passive vaccine against neurofibrillary pathology. These vaccines are phosphorylation-independent, instead targeting a conformational epitope found in all stages of human Alzheimer's disease, and throughout the AD tau proteome, both on early and late pathological tau species.

The vaccines reduced the neurobehavioral impairment of transgenic animals, and reduced the number of neurofibrillary tangles and the total amount of insoluble tau protein in their brains, also eliminating tau hyperphosphorylation at multiple AD-related tau epitopes.

The active vaccine AADvac1 was tested in GLP toxicology and safety pharmacology studies, displaying an excellent safety profile.

AADvac1 was applied in a clinical phase 1 trial (EudraCT 2012-003916-29) to 30 patients with mild to moderate AD. The safety and immunogenicity results are presented.

An 18-month follow-up study (EudraCT 2013-004499-36) studies these patients further.

ADAMANT, a phase II 24-month randomized, blinded, placebo-controlled safety/efficacy study of AADvac1, will assess long-term safety of AADvac1 and its impact on patient cognition, function and biomarkers. The study begins in Q2 2015.

[2]Neurology, NYU Langone Medical Center, New York City, USA

Immunomodulation holds promise as a treatment for AD but current attempts only address one aspect of the pathology: either amyloid β (Aβ) or the hyperphosphorylated tau (ptau) protein. We developed a novel immunomodulatory approach using a pBri peptide. We tested this approach in APP/PS1, 3xTg and TgSwDI AD models and have documented pBri as an immunogen reduces: amyloid plaques, vascular amyloid deposits and neurofibrillary tangles. Using pBri we have developed monoclonal antibodies (mAbs).

MAbs were obtained from pBri inoculations of BALBc mice. Positive hybridomas were selected by their shared reactivity against Aβ, PHF and PrP^{Res}. The best mAbs were characterized by blots, surface plasmon resonance (SPR) and histology in AD tissue. One such mAb is being tested in 3xTg mice with both tau and Aβ related pathology. These mAbs on tissue sections specifically immunolabel AD tissue. On Western blots these mAbs detect purified paired helical filament preparations, aggregated/oligomeric Aβ and PrP^{Res}, extracted from CJD brain tissue. SPR shows high affinity binding to oligomeric/aggregated Aβ, with no binding to monomeric Aβ. One of these mAbs is being tested therapeutically in 3xTg mice.

We have developed a novel immunization procedure which we have used to produce monoclonal antibodies (mAbs) that recognize multiple pathological proteins. We are characterizing these mAbs which give selective immunolabeling in AD tissue and on Western blots to pathological conformers. We believe that immunotherapy that specifically targets the most toxic, oligomeric forms of Aβ and ptau, has a greater chance of success clinically with much less risk of toxicity.

TAU REDUCTION PREVENTS ABETA-INDUCED AXONAL TRANSPORT DEFICITS BY BLOCKING ACTIVATION OF GLYCOGEN SYNTHASE KINASE 3 BETA

K.A. Vossel[1], J.C. Xu[1], V. Fomenko[1], T. Miyamoto[1], E. Suberbielle[1], J.A. Knox[1], K. Ho[1], D.H. Kim[1], G. Yu[1], L. Mucke[1]
[1]Gladstone Institute of Neurological Disease, The J. David Gladstone Institutes, San Francisco, USA

Objectives: Determine mechanisms by which tau enables Aβ-induced deficits of axonal transport.

Methods: We prepared primary hippocampal neuronal cultures from *Tau*$^{+/+}$, *Tau*$^{+/-}$, and *Tau*$^{-/-}$ mice, with or without expression of familial Alzheimer's disease-linked forms of human amyloid precursor protein (hAPP). We treated cultures with a γ-secretase modulator and used tau ablation, tau knockdown, and tau reconstitution to investigate mechanisms of Aβ/tau-dependent deficits in axonal transport of mitochondria. Axonal mitochondrial motility was quantified by transfecting cultures with a mito-RFP plasmid, fluorescence microscopy, and kymograph analysis in ImageJ.

Results: We demonstrate deficits in anterograde axonal transport of mitochondria in primary neurons from transgenic mice expressing hAPP. We show that these deficits depend on $A\beta_{1-42}$ production and are prevented by partial tau reduction or tau ablation. Expression of mutant tau constructs in *Tau*$^{-/-}$ neurons and knockdown of endogenous tau revealed that the copathogenic effects of tau do not depend on its microtubule binding, interactions with Fyn, or potential roles in neuronal development. Inhibition of neuronal activity, NMDA receptor function, or GSK3β activity or expression abolished Aβ-induced transport deficits. Tau ablation prevented Aβ-induced GSK3β activation.

Conclusions: Tau allows Aβ oligomers to inhibit axonal transport of mitochondria through activation of GSK3β, possibly by facilitating aberrant neuronal activity. Our findings suggest a role for tau in Aβ-induced neuronal dysfunction that is independent of microtubule binding and upstream of GSK3β activation. Our tau-reconstitution assay provides a new approach to dissecting mechanisms underlying Aβ- and tau-dependent neuronal deficits, including the intriguing mediator role that GSK3β has in this process.

DP-C016, AN INNOVATIVE MULTIVALENT VACCINE TARGETING HYPER-PHOSPHORYLATED TAU

E. Zanelli[1], C. D'Abramo[2], P. Davies[2]
[1]Research and Development, Déclion Pharmaceuticals Inc., Boxford, USA
[2]Litwin-Zucker Research Center for the Study of Alzheimer's Disease, Feinstein Institute for Medical Research, Manhasset, USA

Objectives: Effective vaccines to treat tauopathies will need to specifically eliminate abnormally hyper-phosphorylated tau proteins while causing neither encephalopathy nor microhemorrhage. Declensional peptides, defined as amino acid copolymers [glatiramer acetate (Copaxone™; Teva) with antigen specificity, constitute a new class of immunomodulators which can achieve this goal.
Methods: We design cationic peptides with high alanine content and incorporating more than one amino acid at a given position, capable of inducing an immune response against multiple antigenic variants, while driving antigen-presenting cells into an anti-inflammatory phenotype. DP-C016 declensional peptides target multiple phosphorylation sites in the C-terminal region of tau. We have tested these compounds in monocyte activation and human T-cell proliferation assays, and immunogenicity studies in mice.
Results: We have identified DP-C016.11 as a prototype compound: it activates a monocyte cell line and induces the acute release of the anti-inflammatory T_H2 chemokine CCL22; it induces the proliferation of a significant proportion of naïve CD4+, but very little CD8+, T-lymphocytes in a 6-day assay using CFSE-labeled PBMCs isolated from healthy donors; it is a very strong T_H2 immunogen in mice even without adjuvant. Antibodies induced by DP-C016.11 cross-react against PHFs isolated from autopsy brain tissue from AD patients and stain, by immunohistology, neuritic elements and NFTs in the hippocampus CA1 field of the same patients.
Conclusions: DP-C016 peptides combine a broad immunogenicity against multiple phosphorylation sites of tau, in the absence of strong adjuvant, with anti-inflammatory, neuroprotective properties. We are currently testing DP-C016 peptides in tau-transgenic, JNPL3 mice.

GSK-3 INTERACTS WITH LYSOSOME NETWORKING AND CONTRIBUTES TO NEURODEGENERATION

L. Avrahami[1], R. Paz[1], H. Eldar-Finkelman[1]
[1]Human Molecular Genetics & Biochemistry, Tel Aviv University, Tel-Aviv, Israel

Glycogen synthase kinase-3 (GSK-3) has been recently implicated in the etiological mechanisms of neurodegenerative disorders including Alzheimer's disease (AD). Inhibition of GSK-3 produces multiple therapeutic benefits in AD animal models including the ability to reduce amyloid-β deposition (Aβ), a major pathological hallmark of AD. This raises the possibility that GSK-3 interacts with pathways responsible for cellular clearance.

Lysosomes are acidic organelles responsible for clearance of damaged and obsolete proteins and organelles. Deficiency in lysosomal function is found in human pathogenesis and has been recently implicated in enhance build-up of Ab deposits and reduced cognitive performance in the context of AD. Agents that repair defects in lysosomal function are thus considered a potential therapeutic intervention.

In a recent work we identified the lysosome as a GSK-3 target. We showed that hyperactive GSK-3 impairs lysosomal acidification and that inhibition of GSK-3 restores lysosomal acidification, reduces Ab loads, and improves cognitive performance in an AD mouse model, the 5XFAD mice. Further research using AD-like cell cultures or primary hippocampal neurons indicated that GSK-3 suppresses autophagic flux by impairing lysosomal acidification. In addition, GSK-3 interplay with mammalian target of rapamycin (mTOR) inhibits autophagy and regulates de-novo lysosome biogenesis. We suggest that the therapeutic activity achieved with GSK-3 inhibitors is mediated via enhanced lysosomal acidification thus accelerating degradation of Aβ deposits. GSK-3 inhibitors may be used as a potential therapy targeting lysosomes.

APOE INCREASES RISK FOR DEMENTIA WITH LEWY BODIES: INDEPENDENT EFFECT OR CONTAMINATION OF ALZHEIMER-RELATED PATHOLOGY?

L. Parkkinen[1], H. Haytural[1], C. Joachim[1], E. Watts[1], M. Esiri[1], O. Ansorge[1]
[1]Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom

Objectives: ApoE was recently found to be the strongest genetic risk factor for dementia with Lewy bodies (DLB) in a large multi-national study but it remains unclear whether this association was merely detected due to contamination of DLB patients with frequent concomitant Alzheimer disease (AD)–type pathology. Here, we examine whether the ApoE epsilon (e) 4 risk allele influences the burden of cortical Lewy bodies in DLB brains and whether the ApoE protein and mRNA levels are increased independent of AD-type pathology.
Methods: The ApoE allele frequencies and Lewy and Alzheimer-related pathologies were examined in 290 autopsied subjects; part of the largest prospective study of dementia and aging in UK (OPTIMA).These subjects were further stratified into four groups: pure DLB (n=30); DLB with AD pathology (n=39); pure AD (n=139) and controls (n=82). In addition, we examined ApoE protein and mRNA levels in cingulate, entorhinal and occipital cortex in 20 subjects of each group (10 e4 carriers vs. 10 non-e4 carriers).
Results: The ApoE genotype distribution was significantly different between study groups (Chi-square, $p<0.001$), highest e4 allele frequency seen in DLB-AD group (51%). Apo e4 carriers also showed higher cortical Lewy body densities in compared to non-ε4 carriers in a model adjusted for age, gender and AD-type pathology. The protein and mRNA levels of ApoE were increased in brain regions with prominent Lewy body pathology.
Conclusions: Our results suggest that ApoE e4 allele may contribute to dementing synucleinopathies via increased cortical Lewy body burden and not mechanisms related to amyloid processing.

APOE4 TARGETED PHARMACOLOGICAL AND IMMUNOLOGICAL THERAPY OF ALZHEIMER'S DISEASE

D.M. Michaelson[1]
[1]*Neurobiology, Tel Aviv University, Tel Aviv, Israel*

Brain pathology of Alzheimer's diseases (AD) and the genetics of autosomal dominant familial AD have been the "lamp posts" for looking for AD therapeutic targets. Although this approach still remains valid, none of the compounds tested to date have produced clinically meaningful results. This calls for developing complementary therapeutic approaches and AD targets. The allele ε4 of apolipoprotein E4 (APOE-ε4), which is the most prevalent genetic risk factor for sporadic AD and is expressed in more than half of the patients, presents such an AD therapeutic target. .

The pathological effects of the protein apoE4 which is coded by the allele APOE-ε4 can be due to loss of a structural feature which the "good", AD benign allele, apoE3 possesses and/or to gain of structural features and functions specific to apoE4. The contribution of the gain of structural effects of apoE4 will be presently assessed by investigation of the extent to which the pathological effects of apoE4 can be counteracted by i.c.v. injection of anti-apoE4 mAbs whereas the possible role of loss of structure related mechanisms will be assessed by measurements of the extent to which correction of the impaired lipidation of apoE4 utilizing either the RXR-agonist Bexarotene or by direct activators of the apoE lipidating protein ABCA1, can reverse its pathological effects. The results obtained utilizing naïve apoE4 and apoE3 targeted replacement mice suggest that the pathological effects of apoE4 are mediated by both loss and gain of structural features and that apoE4 directed therapy should thus target both mechanisms.

[2]Cell Research and Immunology, Tel Aviv University, Tel-Aviv, Israel

Introduction: Recent findings suggest that key pathological effects of apoE4, the most prevalent Alzheimer's disease (AD) genetic risk factor, are associated with gain-of-toxic function mechanisms.

Objective: This study examined the extent to which anti-apoE4 mAbs can counteract the cognitive and pathological effects apoE4 in targeted-replacement (TR) mice.

Results: The anti-apoE4 mAbs were injected i.p to TR mice, which express either apoE4 or its AD benign isoform apoE3, via a preventive paradigm (10 weekly injections, starting at the age of 4 weeks) and a treatment paradigm (3 weekly injections, at the age of 4 months).

Examination of naïve 4 months old apoE4 mice revealed distinct hippocampal pathologies. Of these, the apoE4-driven accumulation of hyperphosphorylated tau and the decreased apoER2 levels were abolished by the injection of anti-apoE4 mAbs in both the preventive and treatment paradigms. In contrast, the apoE4 accumulation of Aβ was not affected by either treatment. Behavioral studies revealed that the anti-apoE4 mAbs counteract the cognitive deficits of the apoE4 mice. These effects were associated with the accumulation of IgG in the brain and its co-localization with apoE4.

Conclusion: Peripherally injected Anti-apoE4 mAbs penetrate the brain and counteract key pathological effects of apoE4 in TR mice. This suggests a novel therapeutic approach for treatment of apoE4 carriers in AD and in other acute and chronic diseases.

Objectives: To examine, using a cross-sectional design, the genetic influence of ApoE gene polymorphisms on hippocampal volume in a large AD, Mild Cognitive Impairment (MCI) and normal ageing dataset (n=1781), as well as a multicentre study of 14-year old healthy adolescents (n=1387).

Methods: A linear mixed model regression was used to compare automated Freesurfer derived hippocampal volumes between ApoE groups in AD patients, MCI, cognitively normal (CN), and non-demented individuals. Further ApoE comparisons were also made in MCI ε4 carriers that converted to a future AD diagnosis (MCI-converters) compared to those that remained clinically stable over follow-up, and CN individuals stratified by amyloid positivity.

Results: Hippocampal volumes were significantly smaller in ε4 carrier AD patients and MCI subjects. A similar effect of the ε4 allele was found in MCI subjects that progressed to AD at follow up and cognitively normal (CN) individuals who met the criteria for amyloid positivity as assessed by positron emission tomography (PET). In

contrast, volumes of ε2 carriers from healthy and non-demented groups were found to be comparatively larger than the AD group. No evidence of an ApoE genotype effect on hippocampal volume was established in non-demented and CN individuals and young healthy adolescents.
Conclusions: Our results show that hippocampal volumes are most affected in AD patients and subjects with either prodromal or pre-clinical stages of disease possessing the ε4 allele, whereas no such effect is present in older and young healthy groups of individuals.

DIFFERENTIAL BINDING OF ABETA43 TO APOLIPOPROTEIN E ISOFORMS MAY AFFECT ITS CLEARANCE ACROSS THE BLOOD-BRAIN BARRIER

H.B. Kuiperij[1], E.A.L.M. Biemans[1], R.M.W. de Waal[2], M.M. Verbeek[1]
[1]Departments of Neurology and Laboratory Medicine, Radboud University Medical Centre, Nijmegen, Netherlands
[2]Department of Pathology, Radboud University Medical Centre, Nijmegen, Netherlands

Background: A range of Abeta peptides that vary in length have been found in the human brain with Abeta40 and Abeta42 being the most studied. However, recently the Abeta43 peptide was found to be more abundant than previously thought and might play a role in AD development. Interestingly, it has been described that Abeta43 does not accumulate in CAA. We hypothesize this is due to an altered blood-brain barrier clearance compared to shorter Abeta peptides. Several studies indicate that interaction with apolipoprotein E (ApoE) is important for clearance of Abeta.
Objectives: To gain more insight in the mechanism of cerebral Abeta clearance, by studying the interaction of Abeta peptides with ApoE isoforms.
Methods: Interaction of ApoE isoforms with Abeta peptides is analyzed using SDS-PAGE and native PAGE plus Western Blotting. The interaction between peptide (complexes) and cerebrovascular cells is determined using viability assays.
Results: Preliminary results indicate that Abeta43 is more toxic towards cerebrovascular cells than other Abeta peptides. Results based on immunoblot quantification show that lipidation of ApoE strongly affects its interaction with Abeta. Furthermore, the binding affinity of this interaction is dependent on the Abeta isoform, with Abeta40 and Abeta42 showing much stronger interaction with ApoE2/E3 than Abeta43.
Conclusions: Our results indicate that the Abeta43 peptide shows increased toxicity towards cerebrovascular cells and decreased binding affinity for ApoE compared to other Abeta peptides. Since Abeta43 is not associated with CAA our results suggest that its decreased interaction with ApoE may affect its clearance efficacy across the blood-brain barrier.

Objectives: The apolipoprotein Eε4 (ApoEε4) allele is the strongest genetic risk factor for developing sporadic Alzheimer's Disease (AD). However, the mechanisms underlying the pathogenic nature of ApoE4 are not well understood. In this study, we test the hypothesis that ApoE is essential for maintenance of brain phospholipid homeostasis and that the ApoE4 isoform is dysfunctional in this process. **Methods:** We performed phospholipid analysis using high pressure liquid chromatogram (HPLC) with suppressed conductivity in human and mouse brain samples, as well as primary neurons expressing ApoE4 alleles. We also developed a haploinsufficiency mouse model of PIP_2 degrading enzyme, the phosphoinositol phosphatase synaptojanin 1 (synj1) with ApoE4 background for further studies. **Results:** We have found that the levels of phosphoinositol biphosphate (PIP_2) are reduced in postmortem human brain tissues of ApoE4 carriers, as well as in ApoE4 knock-in (KI) mouse brains. We found similar changes in primary neurons expressing ApoE4 alleles compared to neurons expressing the ApoE3 allele. These changes are secondary to increased expression of synaptojanin 1 (synj1) in ApoE4 carriers. Further studies indicate that ApoE4 which behaves like ApoE null conditions, fails to degrade synj1 mRNA efficiently unlike ApoE3 does, partially due to differential expression levels of miR155. These data suggest a loss-of-function of ApoE4 genotype in regulating PIP_2 homeostasis. Most importantly, genetic reduction of synj1 in ApoE4 KI mouse models restores PIP_2 levels, and rescues AD-related cognitive deficits. **Conclusions:** Together, our findings uncover a novel mechanism that links ApoE4-related lipid changes to the pathogenic nature of ApoE4 in AD.

Symposium 44: TAU IMUNOTHERAPY

ADPD5-1781
TAU IMMUNOTHERAPY
E.M. Sigurdsson[1]
[1]*Neuroscience and Physiology and Psychiatry,*
New York University School of Medicine, New York, USA
In recent years, tau immunotherapy has advanced from proof-of-concept studies (Sigurdsson, EM, NIH R01AG020197, 2001; Asuni AA et al, J Neurosci, 27, 2007), which have now been confirmed and extended by us and others. Phase 1 clinical trials on active tau immunizations are being conducted, with several passive tau antibody trials likely to be initiated in the near future for Alzheimer's disease and other tauopathies. Because tau pathology correlates better with the degree of dementia than amyloid-β (Aβ) pathology, greater clinical efficacy may be achieved by clearing tau- than Aβ aggregates in the later stages of the disease, when cognitive impairments become evident.
Substantial insight has now been obtained regarding which epitopes to target, mechanism of action, and potential toxicity but much remains to be clarified. All of these factors likely depend on the model/disease or stage of pathology and the immunogen/antibody. Interestingly, tau antibodies interact with the protein both extra and intracellularly but the importance of each site for tau clearance is not well defined. Some antibodies are readily taken up into neurons whereas others are not. It can be argued that extracellular clearance may be safer but less efficacious than intraneuronal clearance and/or sequestration to prevent secretion and further spread of tau pathology.
Development of therapeutic tau antibodies has led to antibody-derived imaging probes, which are more specific than the dye-based compounds that are already in clinical trials. Such specificity may give valuable information on pathological tau epitope profile, which could then guide the selection of therapeutic antibodies for maximal efficacy and safety.
Hopefully, tau immunotherapy will be effective in clinical trials, and further advanced by mechanistic clarification in experimental models with insights from biomarkers and postmortem analyses of clinical subjects.

EFFECTS AND MECHANISMS OF ANTI-TAU ANTIBODIES IN TAUOPATHIES

K. Yanamandra[1], H. Jiang[1], T.E. Mahan[1], S.E. Maloney[2], D.I. Wozniak[2], M.I. Diamond[3], D.M. Holtzman[1]
[1]Neurology, Washington University, St. Louis, USA
[2]Psychiatry, Washington University, St. Louis, USA
[3]Neurology and Neurotherapeutics, University of Texas Southwestern Medical Center, Dallas, USA

Objective
We previously found a strong reduction in tau pathology, insoluble tau, and improved cognitive performance in P301S tau transgenic mice following intracerebroventricular infusion of the anti-tau antibody HJ8.5. We evaluated the effects of HJ8.5 in the same model of tauopathy following intraperitoneal administration.
Methods
Six-month old P301S mice received one of two dose levels of HJ8.5 through intraperitoneal injection for 3 months. Following treatment, we performed immunostaining for p-tau, anatomical and biochemical analysis, and behavioral tests.
Results
Both 10 mg/kg and 50 mg/kg treatment with HJ8.5 significantly reduced the loss of cortical and hippocampal tissue volumes compared to control treated mice. Mice treated with HJ8.5 showed a very strong decrease in detergent-insoluble human tau as well as reduced phospho-tau staining in the hippocampal CA1 cellular layer. Both doses of HJ8.5 reduced thio-S positive tau aggregates in the piriform cortex and amygdala, and mice treated with HJ8.5 at 50 mg/kg showed significantly improved sensorimotor performance on both the inverted screen and ledge tests compared to vehicle treated mice. In BV2-microglial cells, we observed significantly higher uptake of P301S tau aggregates in the presence of HJ8.5. In addition, HJ8.5 treatment resulted in a large dose dependent increase of tau in the plasma.
Interpretation
Systemically administered anti-tau antibody HJ8.5 significantly decreased insoluble tau and brain atrophy. It also improved motor function in a mouse model of tauopathy. These data indicate that passive immunization targeting tau should be strongly considered as a therapeutic strategy for tauopathies.

Tau pathology (tauopathy) is a neuropathological hallmark in Alzheimer's disease (AD) and chronic traumatic encephalopathy (CTE) associated with traumatic brain injury (TBI). Since tau pathologies, as detected by commonly known antibodies or methods, are not obvious acutely after TBI, whether tauopathy is an end result or early driver of TBI pathology is unclear, although TBI is a potential risk factor for AD. We have previously shown that Pin1-catalyzed *cis-trans* isomerization of tau and APP after proline-directed phosphorylation is a unique signaling mechanism protecting against tau and Abeta pathologies in Alzheimer's disease (AD). To visualize Pin1-catalyzed post-phopshorylation conformational regulation, we have developed novel peptide chemistry that allow the generation of *cis* and *trans*-specific polyclonal antibodies, and use them to raise antibodies specific for isomers of phosphorylated tau (p-tau) (Cell 149: 232-244). Using these cis and trans conformation-specific antibodies, we have shown that *trans* p-tau is the physiological form that promotes microtubule assembly, whereas the *cis* form is the previously unrecognized early pathogenic pretangle tau conformation that not only loses its normal function, but also gains toxic function, leading to tauopathy in AD. We have now further generated *cis* and *trans*-specific p-tau monoclonal antibodies and identified *cis* p-tau as an early central mediator of brain injury after TBI that is effectively stopped by antibody in vitro and in vivo. These insights uncover a novel disease mechanism in TBI and its connection with AD, and suggest a potentially exciting new immunotherapy for treating TBI, CTE and AD.

TAU SPREAD AND IMMUNOTHERAPY TARGETING ITS AMINO-TERMINAL DOMAIN

K. Iqbal[1], *F. Liu*[1]
[1]*Neurochemistry,*
New York State Institute for Basic Research in Developmental Disabilities,
Staten Island NY, USA

Objectives: A key lesion of Alzheimer disease (AD) and related tauopathies is the accumulation of abnormally hyperphosphorylated tau (ptau) which forms neurofibrillary tangles. Unlike normal tau which interacts with tubulin and promotes its assembly into microtubules, the AD P-tau sequesters normal tau, disrupts microtubules and serves as a template for its prion-like aggregation and spread.
Methods: These previous studies of ours led us to attempt tau immunotherapy employing antibodies to N-terminal projection domain of tau which we would expect to be accessible in the AD P-tau/N-tau aggregates. For immunotherapy we employed mouse mAb 43D to tau_{6-18}, and 77E9 to $tau_{184-195}$, and as control, mouse IgG.
Results: Intraperitoneal administration of 100 micrograms 43D IgG/injection/week for 4 weeks in 14-17-month-old 3xTg-AD mice at moderate to severe stage of tau and Abeta pathologies showed a significant decrease in tau hyperphosphorylated at Ser199, Ser202/Thr205, Ser262/356 and Ser396/404, and a trend for reduction in Abeta pathology, and significant improvement in reference memory by Morris Water Maze task. Identical treatment with mAb 77E9 to $tau_{184-195}$ also significantly reduced the levels of hyperphosphorylated taus and showed a trend to reduce Abeta pathology as above found with mAb 43D, but could not improve the reference memory of the treated animals.
Conclusions: These studies show (1) that passive immunization targeting N-terminal projection domain of tau can effectively clear the hyperphosphorylated protein and possibly reduce Abeta pathology and (2) that targeting tau_{6-18} is potentially an especially promising strategy for the treatment of AD and other tauopathies.

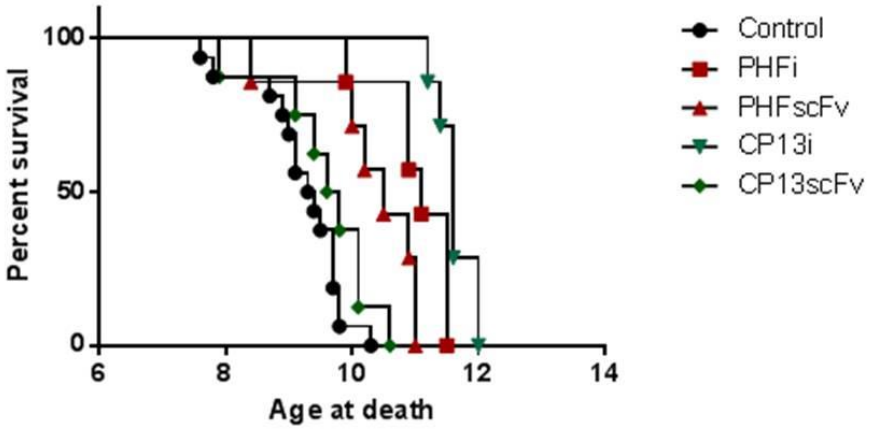
Objectives: Cellular inclusions of hyperphosphorylated tau are a hallmark of tauopathies, which are neurodegenerative disorders that include Alzheimer's disease (AD). Active and passive immunization against hyperphosphorylated tau has been shown to attenuate phenotypes in model mice. We developed new monoclonal antibodies to hyperphosphorylated tau and sought high therapeutic efficacy for future clinical use.
Methods: Using more than 20 antibodies, we investigated which sites on tau are phosphorylated early and highly in the tauopathy mouse models tau609 and tau784. These mice display tau hyperphosphorylation, synapse loss, memory impairment at 6 months, and tangle formation and neuronal loss at 15 months. We generated mouse monoclonal antibodies to selected epitopes and examined their effects on memory and tau pathology in aged tau609 and tau784 mice by the Morris water maze and by histological and biochemical analyses.
Results: Immunohistochemical screening revealed that pSer413 is expressed early and highly. Monoclonal antibodies to pSer413 and to pSer396 (control) were generated. These antibodies specifically recognized pathological tau in AD brains but not normal tau in control brains according to Western blots. Representative anti-pSer413 and anti-pSer396 antibodies were injected intraperitoneally into 10-11- or 14-month-old mice once a week at 0.1 or 1 mg/shot 5 times. The anti-pSer413 antibody significantly improved memory, while the anti-pSer396 antibodies showed less effect. The cognitive improvement paralleled a reduction in the levels of tau hyperphosphorylation, tau oligomer accumulation, synapse loss, tangle formation, and neuronal loss.
Conclusions: These results indicate that pSer413 is a promising target in the treatment of tauopathy.

Symposium 44: TAU IMUNOTHERAPY

ADPD5-0270
TARGETING INTRA VS EXTRACELLULAR TAU BY RECOMBINANT ANTIBODIES
Y. Levites[1], O. Sinyavskaya[1], A.M. Rosario[1], P.E. Cruz[1], J. Lewis[1], T.E. Golde[1]
[1]Neuroscience, University of Florida College of Medicine, Gainesville, USA
Objectives
The mechanisms underlying the abnormal phosphorylation and accumulation of tau in AD remain unclear, but one of the possibilities is that it might be due to conformational changes in tau in the diseased brain. Anti-tau immunotherapy has recently emerged as a promising approach to target tau, but many mechanistic questions regarding the optimal form of anti-tau immunotherapy remain. We hypothesize that anti-tau immunotherapy may be optimized by targeting both intracellular and extracellular pools of tau and that specific binding of hyperphosphorylated tau by single chain variable fragments (scFv) or by intracellularly expressed intrabodies will prevent its toxicity and formation of neurofibrillary tangles.
Methods
We cloned scFvs from two monoclonal anti-phospho-Tau antibodies (PHF and CP13) and generated stable intracellular anti-Ptau scFvs (intrabodies), as well as scFvs, directed into the secretory pathway. Then we expressed these intrabodies and scFvs in the brains of newborn transgenic rTg4510 mice and in spinal cords of homozygous JNPL p301L mice. Effects on pathology and life expectancy were assessed at three and 12 month of age, respectively
Results
Analysis of three month old rTg4510 brains revealed that both intrabodies and scFvs attenuated tau pathology relative to PBS-injected controls with CP13i being the most effective. Similarly, CP13i as well as PHFi significantly prolonged life expectancy of homozygous JNPL P301L mice (Fig).
Conclusions
These studies suggest that targeting phosphorylated tau in the intracellular vs. extracellular compartment is feasible therapeutic approach against tauopathy in animal models, whereas antibody effector functions are not required.



Expression of intracellular single chain fragments against phosphorylated Tau prolongs life expectancy in homozygous JNPL P301Lmice following intraspinal delivery of AAV expressing PHF scFv, PHF intrabody, CP13 scFv, and CP13 intrabody.

PD-61-W3 (SYNUCLERE™) IS A NOVEL SMALL MOLECULE AND CLINICAL CANDIDATE FOR TREATMENT OF ALPHA-SYNUCLEIN AGGREGATE ACCUMULATION IN PARKINSON'S DISEASE AND OTHER SYNUCLEINOPATHIES

L.A. Esposito[1], K.L. Hanson[1], J. Cummings[1], M.C. Yadon[1], T.A. Chong[1], T. Lake[1], Q. Hu[1], J. Cam[1], A.D. Snow[1]
[1]Neuroscience, ProteoTech Inc., Kirkland, USA

PD-61-W3 (Synuclere™) is a novel small molecule that prevents alpha-synuclein aggregation at substiochiometric proportions and rapidly remodels, reduces and detoxifies pre-formed alpha-synuclein aggregates, a central pathogenic component in Parkinson's disease (PD) and other synucleinopathies. PD-61-W3 efficacy was tested in independent studies using PD-relevant Thy-1 human wild-type alpha-synuclein transgenic mice (Line 61). These animal model studies demonstrated that PD-61-W3 is well-tolerated in vivo and that PD-61-W3 targets brain alpha-synuclein accumulation, as demonstrated by marked reduction in alpha-synuclein aggregate load in substangia nigra, cortex and hippocampus following 3-months of subcutaneous (s.c.) treatment in younger mice (45-90% reduction) or 6-months of i.p. treatment in older mice (79-91% reduction). Western blot analysis of brain extracts showed that PD-61-W3 significantly reduced alpha-synuclein oligomers by ~72%. Reduced alpha-synuclein aggregates in PD-61-W3-treated transgenic mice were accompanied by improved motor performance on the challenging beam traversal and pole tests. Importantly, PD-61-W3 exhibited good CNS drug properties including: micromolar exposure in brain, plasma and CSF following a single s.c. injection in mice at a therapeutic dose level; no significant off-target binding to a panel of brain receptors, transporters or ion channels; no significant CYP450 inhibition; and good chemical stability. Furthermore, PD-61-W3 was non-mutagenic in the Ames test. These studies support the advancement of PD-61-W3 into human clinical trials as a disease-modifying small molecule drug for the treatment of alpha-synuclein aggregation in Parkinson's disease and other synucleinopathies.

NATIVE ALPHA-SYNUCLEIN MULTIMERS ARE DESTABILIZED BY PD-LINKED POINT MUTATIONS; THEIR COMPLETE ABOLITION BY MUTATING THE REPEAT MOTIFS CAUSES ACUTE NEUROTOXICITY

U. Dettmer[1], *A.J. Newman*[1], *T. Bartels*[1], *D. Selkoe*[1]
[1]*Neurology, Brigham and Women's Hospital/Harvard Medical School, Boston, USA*

There is growing evidence that alpha-synuclein (aS) can occur normally in alpha-helix-rich tetramers and related physiological low-n assemblies (collectively, aS multimers).
Combining data from cultured cells, mouse brains and patient-derived iPSC neurons and using two independent assays, in vivo crosslinking and fluorescent protein complementation, we have obtained highly consistent evidence that all known familial PD-linked aS missense mutations destabilize native aS multimers.
In particular, mutations G51D and E46K strongly reduced tetramer:monomer ratios, and this effect was amplified by stepwise introduction of E46K-like mutations (KTKEGV becomes KTKKGV) into additional aS repeat motifs. When we sought to abolish the physiological propensity of aS to multimerize by introducing deletion mutations, we unexpectedly found that aS multimerization still occurred in each of fourteen sequential 10-amino acid deletion-mutants, suggesting compensatory effects among the 6 highly conserved (KTKEGV) and up to 3 additional aS repeats. We therefore introduced selected mutations into all relevant repeats and found that certain mutations repeated in-register across these motifs completely abolished aS multimerization. Thus, the altered repeat motifs KLKEGV, KTKKGV, KTKEIV or KTKEGW did not support multimer formation, suggesting the importance of certain charged and small residues for normal self-interaction. Expression in human neuroblastoma cells showed that all multimer-abolishing (but no neutral) mutants induced neurotoxic effects (see abstract by von Saucken *et al.*). Moreover, all multimer-abolishing mutants were enriched in PBS-insoluble fractions of the cells and showed pathological aggregation in biochemical and confocal microscopy assays. We hypothesize that the neurotoxicity from multimer-to-monomer conversion recapitulates early events in the pathogenesis of synucleinopathies.

ENHANCED ALPHA-SYNUCLEIN INDUCED DOPAMINERGIC NEURODEGENERATION IN G2019S-BAC TRANSGENIC RATS
J.P. Lima Daher[1], *A.B. West*[1]
[1]*Neurology, University of Alabama at Birmingham, Birmingham, USA*
Objectives: The leucine-rich repeat kinase 2 (LRRK2) gene is associated with a form of parkinsonism that is indistinguishable from idiopathic Parkinson's disease (PD). We previously reported LRRK2-knockout rats as resistant to dopaminergic neurodegeneration elicited by overexpression of human α-synuclein, and such resistance correlated with reduced pro-inflammatory myeloid cells recruited to the midbrain. Recently, we characterized novel G2019S-BAC transgenic rats and found robust expression of LRRK2 in the substantia nigra. Here, we aim to test whether G2019S-LRRK2 expression in rats enhances α-synuclein induced dopaminergic neurodegeneration and inflammatory responses.
Methods: 10-12 weeks-old G2019S-LRRK2 rats and littermate controls negative for the BAC transgene were injected with recombinant adeno-associated virus 2/1 (rAAV2/1)-α-synuclein vector into the right substantia nigra pars compacta (SNpc). Unbiased stereological analysis was subsequently performed to estimate the total number of dopaminergic neurons and proinflammatory myeloid cells in these animals.
Results: We observed that G2019S-LRRK2 expression resulted in enhanced dopaminergic neurodegeneration elicited by rAAV2- α-synuclein mediated neurodegeneration. Pro-inflammatory cells recruited to the substantia nigra were enhanced in G2019S-LRRK2 rats and correlated well with neurodegeneration.
Conclusions: These data show that, similar to some mouse transgenic models of PD, G20129S-LRRK2 exacerbates α-synuclein-linked neurodegeneration. The relatively short timeline of the model (4 weeks) makes this model ideal to test novel neuroprotective therapies.

Amyloid beta (Aβ) and hyper-phosphorylated tau (ptau) are the proteins undergoing misfolding in Alzheimer's disease (AD). Recent studies have shown that brain homogenates rich in amyloid aggregates are able to seed the misfolding and aggregation of amyloidogenic proteins inducing an earlier onset of the disease in mouse models of AD. Prion diseases are able to be transmitted by the inoculation of the misfolded prion protein noted in cattle affected by bovine spongiform encephalopathy. The infectious agent can be propagated from cattle to human beings. In the case of AD, it has been reported that Aβ aggregates and neurofibrillary tangles (NFTs) are present in the brain of several non-human mammals, including **a**ged monkeys, bears, dogs, and cheetahs. We have analyzed the hippocampus, temporal cortex, and thalamus in more than 60 cows ranging from 13 to 23 years old. After a complete histopathological analysis, we could observe many of the typical hallmarks detected in human AD brains, including Aβ and tau aggregates. Cow amyloid deposits are reactive against human anti-Aβ antibody and thioflavin-S. The morphological characteristics of these deposits are remarkably similar to human aggregates. When the cattle brains were stained with anti-ptau antibody and silver-stained, they displayed NFT-like structures in the cortical area. These results could have a huge repercussion in public health since AD has been shown to be transmissible under certain circumstances. We are currently investigating whether cattle tissue containing Aβ aggregates and/or NFTs are able to seed amyloid misfolding and aggregation**,** similarly delineated in prion diseases**.**

GLYCATION DISRUPTS PROTEOSTASIS AND PROMOTES NEURODEGENERATIVE ALTERATIONS IN SYNUCLEINOPATHIES

T. Outeiro[1]
[1]*Department of Neurodegeneration and Restorative Research, University Medical Center Goettingen, Göttingen, Germany*

α-synuclein (aSyn) aggregation in Lewy bodies is a pathological hallmark of Parkinson's disease (PD) and other synucleinopathies. Glycation, an age-dependent protein modification, is present in Lewy bodies. Here, we investigated the effect of the natural glycating agent methylglyoxal on aSyn biology and found that glycation increased aSyn aggregation and toxicity. Notably, striatal injection of methylglyoxal in mice caused neuronal loss. Genetic and pharmacological manipulation of methylglyoxal increased aSyn-dependent toxicity in human LUHMES cells and in PD patient-derived iPSCs, and decreased motor performance and survival in aSyn transgenic flies. Furthermore, glycated aSyn impaired synaptic transmission in rat hippocampal slices. Methylglyoxal promoted aSyn oligomerization by affecting its N-terminal structure and impairing lipid-binding ability. Glycation disrupted proteostasis, reducing aSyn turnover, aggregation, and release, likely the mechanistic link underlying the phenotypes observed. In total, our study uncovers glycation as a novel player in synucleinopathies, opening novel avenues for the design of therapeutic strategies.

ADPD5-0222
ALDEHYDE DEHYDROGENASE 1 DEFINES AND PROTECTS A SUBPOPULATION OF NIGROSTRIATAL DOPAMINERGIC NEURONS IN PD
H. Cai[1], G. Liu[1], J. Yu[1], J. Ding[1]
[1]Neurogenetics, National Institute on Aging, Bethesda, USA
There exist subpopulations of dopaminergic (DA) neurons in *substantia nigra pars compacta* (SNpc) that display differential vulnerabilities in Parkinson's disease (PD). The underlying molecular mechanism is unknown. Rodent SNpc DA neurons can be divided into two subpopulations based on the expression of aldehyde dehydrogenase 1 (ALDH1A1). Here we show in PD-related alpha-synuclein transgenic mice that DA neurodegeneration mainly occurred in the dorsomedial ALDH1A1-negative subpopulation, which was also prone to cytotoxic alpha-synuclein aggregation. Notably, ALDH1A1 also exhibited a conserved topographic expression pattern in human SNpc. Studies with postmortem PD brains revealed a severe reduction of ALDH1A1 expression and neurodegeneration in the ventral ALDH1A1-positive subpopulations. ALDH1A1 expression was also suppressed in alpha-synuclein transgenic mice. Genetic inhibition of *Aldh1a1* exacerbated alpha-synuclein-induced DA neurodegeneration and alpha-synuclein aggregation, whereas overexpression of *ALDH1A1* was protective. Furthermore, ALDH1A1 appeared to specifically protect against alpha-synuclein-mediated DA neurodegeneration. *Aldh1a1*-null and control DA neurons showed comparable sensitivity to 1-methyl-4-phenylpyridinium (MPP+), glutamate, or camptothecin-induced cell death, while overexpression of *ALDH1A1* did not rescue alpha-synuclein-induced loss of cortical neurons. Together, our findings suggest ALDH1A1 plays an important role in protecting subpopulations of SNpc DA neurons through preventing the accumulation of dopamine aldehyde intermediates and formation of cytotoxic alpha-synuclein oligomers.

DEEP BRAIN STIMULATION AS A SYMPTOMATIC TREATMENT OF MEMORY IMPAIRMENT IN ALZHEIMER DISEASE : FEASIBILITY STUDY AND LONG TERM OUTCOME

D. Fontaine[1], A. Deudon[2], J. Darcourt[3], P. Robert[2]
[1]Neurosurgery, Centre Hospitalier Universitaire de Nice, Nice, France
[2]Centre Memoire de Ressources et de Recherche,
Centre Hospitalier Universitaire de Nice, Nice, France
[3]Nuclear Medicine, Centre Hospitalier Universitaire de Nice, Nice, France

Recent studies have suggested that neuronal circuits involved in memory can be modulated by deep brain stimulation (DBS) and that this propriety might be used to slow the cognitive decline of Alzheimer Disease (AD) patients.
We conducted a prospective study whose objective was to evaluate the feasibility and safety of DBS in AD patients. Inclusion criteria were: adult patients under 70 years old, with AD diagnosed for less than 2 years, with Mini Mental Status (MMSE) between 20 and 24 and predominant impairment of episodic memory. The fornix was stimulated bilaterally by electrodes implanted stereotactically in the hypothalamus (3V, 130 Hz). Clinical, biological, neuropsychological and imaging evaluation was conducted 3 months before and 6, 12, 24 and 36 months after surgery.
During the one year- inclusion period, 108 patients with recently diagnosed AD and episodic memory impairment were screened in a specialized consultation. Only 8 patients fulfilled all the inclusion criteria, 4 accepted to be included but only one was finally operated and followed for 3.5 years. The stimulation was perfectly tolerated. The memory scores (MMSE, ADAS-Cog, Grober & Buschke) were stabilized compared to baseline during 2 years of continuous stimulation, and slightly worsened after 3 years. 18FDG PET scan showed an increase of the mesial temporal lobes metabolism compared to baseline, sustained at long term.
This pilot study brings additional data about the safety of fornix DBS in the hypothalamus in AD patients. Clinical and functional imaging data suggest that the fornix DBS effect might be maintained over time.

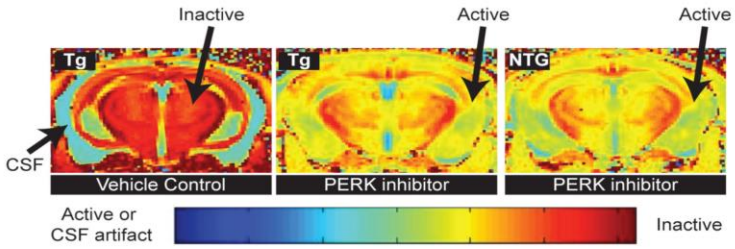
PERK INHIBITION REVERSES STRUCTURAL AND FUNCTIONAL ABNORMALITIES IN TAU TRANSGENIC MICE.
M. Shelby[1], A. Ingram[1], C. Poole[1], M. Bell[1], M. Vandsburger[2], D. Powell[3], J. Abisambra[1]
[1]Sanders-Brown Center on Aging, University of Kentucky, Lexington, USA
[2]Cardiovascular Research Center, University of Kentucky, Lexington, USA
[3]MRI and Spectroscopy Center, University of Kentucky, Lexington, USA
A major challenge in tauopathy research is the lack of effective therapeutic strategies. We recently established that the most toxic form of tau chronically activates the endoplasmic reticulum (ER) stress sensor PERK. Under conditions of ER stress, PERK inhibits RNA translation. If sustained, as it occurs in tauopathies, extended shut down of protein synthesis weakens and kills neurons and other tau-bearing cells. We inhibited PERK with a novel compound, GSK2606414, in the rTg4510 tau transgenic mouse model. Mice were treated from 6 to 9 months of age, which is after abundant tau pathology, extensive brain atrophy, and significant neuronal dysfunction appear (5.5 months). Every month during the treatment course, we measured neuronal function and brain volume by adapting an innovative imaging technique called MEMRI (manganese-enhanced MRI). At the end of treatment, we performed cognitive testing and quantified changes in tau pathology.
The drug effectively inhibited PERK in the tau transgenic mice. In addition, drug-treated tau mice showed virtually complete recovery of brain 1) structure and 2) function, 3) significant cognitive improvements, and 4) dramatically reduced soluble tau levels. Meanwhile, pathological tau deposits remained the same as vehicle-treated transgenic controls.
These data suggest that PERK is a potent therapeutic target for tauopathies. A major advantage of our strategy is rooted on the **therapeutic** paradigm of our study. Therefore, PERK inhibition could positively impact early and late stage tauopathic patients. Future efforts aim to develop safe and effective PERK inhibitors for the clinic.



Representative MEMRI images after 3 months of treatment with PERK inhibitor. Warm colors indicate no or reduced activity, while cold colors (blue and green) represent abundant activity; due to compromise of the blood-brain barrier and dramatic brain atrophy, manganese leaks into the CSF and shows positive in the MEMRI images of tau transgenic mice treated with vehicle. PERK inhibitor-treated transgenic mice showed virtually complete recovery of MEMRI signal compared to non-transgenic controls (NTG).

ADPD5-0919
TRICYCLIC ANTIDEPRESSANTS REDUCE ALPHA-SYNUCLEIN ACCUMULATION IN TWO ANIMAL MODELS OF SYNUCLEINOPATHY

T. Collier[1], C. Justman[2], K. Luk[3], S. Celano[1], T. Ramnarine[1], J. Trojanowski[3], V. Lee[3], C. Sortwell[1], P. Lansbury[2], K. Paumier[1]
[1]Translational Science & Molecular Medicine, Michigan State University, Grand Rapids, USA
[2]Medical School, Harvard, Cambridge, USA
[3]Perelman School of Medicine, University of Pennsylvania, Philadelphia, USA

Objectives. We previously demonstrated that tricyclic antidepressants, including amitriptyline (AMI), delay need for dopaminergic therapy in an early cohort of Parkinson's disease (PD) patients (Paumier et al., 2012), suggesting they may have disease-modifying properties. Recently, the tricyclic drug nortriptyline (NOR) was found to reduce alpha-synuclein (alpha-syn) aggregation in *in vitro* aggregation assays (unpublished data). These findings prompted us to examine the effects of tricyclics on alpha-syn accumulation in two distinct animal models of synucleinopathy.
Methods. 1) We conducted a dose response study in a human wild-type alpha-syn overexpression mouse model driven by the PDGF promoter. Four-month-old mice were injected (i.p.) with 0.5, 5.0 or 25 mg/kg NOR daily for 30 days. 2) We investigated whether AMI or NOR reduced accumulation of alpha-syn in a rat model produced by injections of pre-formed fibrillar (PFF) alpha-syn (Luk et al., 2012). PFF alpha-syn (8µg/4µl) was injected unilaterally into striatum. Daily injections with saline/tricyclics began 2 weeks prior to and continued for 8 weeks following PFF injections (AMI 5 or 15mg/kg; NOR 5 or 20mg/kg).
Results. NOR significantly reduces human alpha-syn accumulation in a dose-dependent manner within both the cortex and hippocampus of transgenic mice. In the rat PFF model, both AMI and NOR reduce the accumulation of alpha-syn in a dose dependent manner; however, NOR was significantly more potent than both doses of AMI.
Conclusions. Reduction of alpha-syn accumulation by tricyclic drugs supports the view that in addition to their antidepressant properties these drugs hold potential as a disease-modifying therapeutic for PD.

COMBINED GENETIC TREATMENT IN A TOXIN-INDUCED MOUSE MODEL OF MULTIPLE SYSTEM ATROPHY IMPROVED MOTOR FUNCTIONS

D. Offen[1], T. Ben-Zur[1], Y. Barhum[1], C. Benkler[1]
[1]Felsenstein Medical Research Center, Tel Aviv University, Petach-Tikva, Israel

Background: Multiple System Atrophy (MSA) is a sporadic neurodegenerative disorder found in 4 people per 100,000 individuals with a mean survival of 7-9 years after the diagnosis. The clinical features of MSA include autonomic failures combined with Parkinsonism (MSA-P subtype) in 80% of cases, or cerebellar ataxia (MSA-C subtype) in 20% of cases. Pathologically, MSA is characterized by glial cytoplasmic inclusions (GCIs), gliosis, and striatonigral and olivo-pontocerebellar degeneration. Studies in animal models of MSA and MSA patients have identified several factors that may contribute to the neurodegeneration, such as inflammation, oxidative stress, and mitochondrial dysfunction. These factors are assumed to be linked to alterations in glutamate homeostasis, as observed in the CSF of MSA patients. To examine whether changes in glutamate homeostasis impacts the disease, we used 3-nitropropionic acid (3-NP) to generate a mouse model of striatonigral degeneration in order to evaluate the therapeutic effect of a mixture of three genes (*Nrf2, EAAT2, GDH2*) involved in glutamate homeostasis and oxidative stress.

Results: Following intrastriatal injection of 3-NP in C57 black mice we observed amphetamine and apomorphine induced ipsilateral rotations as well as contralateral motor deficiency. Mice that were injected intrastrataly with a mixture of *Nrf2, EAAT2* and *GDH2* prior to 3-NP injections, showed improvement in motor function and in apomorphine induced ipsilateral rotations, but not in amphetamine induced ipsilateral rotations.

Conclusions: Our findings suggest that the our novel genetic treatment combining *Nrf2, EAAT2* and *GDH2* genes, protects striatal cells from excitotoxicity. These results may provide a novel potential therapeutic approach for MSA.

SEXUAL DICHOTOMY ALZHEIMER'S DISEASE: NOVEL INSIGHTS AND FUTURE INTERVENTIONS BASED ON ADNP

I. Gozes[1], N. Amram[1], G. Hacohen-Kleiman[1], E. Giladi[1], A. Malishkevich[1]
[1]Human Molecular Genetics and Biochemistry, Tel Aviv University, Tel-Aviv, Israel

Activity-dependent neuroprotective protein (ADNP), essential for brain formation, mutated in autism in men and the only protein reduced in Alzheimer's disease (AD) patient serum, is regulating tauopathy, which is shared by autistic and AD patients. Thus, $ADNP^{+/-}$ mice exhibit tauopathy, age-driven neurodegeneration and behavioral deficits.

Objectives: 1] Is there a sexual difference in ADNP expression, associated with differential AD prevalence?

2] Are the sex-specific ADNP gene targets?

Methods: $ADNP^{+/+}$ mice were compared to $ADNP^{+/-}$ mice behaviorally and gene expression was analyzed by quantitative real time PCR.

Results: Our most recent findings identified sexual dichotomy in hippocampal ADNP expression in men and mice (with a significantly higher ADNP expression in males compared to females) and different behavioral impairments in ADNP-deficient male compared to female mice. Furthermore, the hippocampal transcript content for apolipoprotein E (the major risk gene for AD) was doubled in female compared to male mice, and further doubled in the $ADNP^{+/-}$ females, suggesting differential association with AD in females, also taking into consideration that AD is more prevalent in women.

Conclusions: The identification of sexual dichotomy in the hippocampal expression of ADNP and downstream regulation of apolipoprotein E, coupled with our recent identification of a precise target for ADNP/NAP (davunetide) neuroprotection[1] provides for rational drug development.

Symposium 53: OTHER TREATMENT STRATEGIES

ADPD5-0319
ULTRASOUND AS A THERAPEUTIC AVENUE IN ALZHEIMER'S DISEASE
G. Leinenga[1], R. Nisbet[1], J. Götz[1]
[1]Clem Jones Centre for Ageing Dementia Research (CJCADR), Queensland Brain Institute The University of Queensland, Brisbane, Australia
BACKGROUND. Alzheimer's disease (AD) and related disorders are characterized by the presence of oligomeric forms of peptides and proteins that eventually aggregate into intra- and extracellular deposits (Ittner & Götz, Nature Rev Neurosci 2011). Levels of these molecules are elevated because of their increased production and/or impaired removal, with recent therapeutic strategies targeting both processes.
METHODS. In our study we aimed to determine whether a transient opening of the blood-brain barrier (BBB) together with the delivery of therapeutic antibodies would assist in the clearance of these molecules. Only one method has been demonstrated to open the BBB non-invasively and repeatedly: non-thermal focused ultrasound coupled with the intravenous injection of microbubbles, widely used ultrasound contrast agents. This is the method we used because it allows for a transient opening of the BBB in the absence of tissue damage, as demonstrated in many experimental species, including rhesus macaques (McDonnald et al., Cancer Res 2012).
RESULTS. We applied focused ultrasound to transgenic mouse models with a pronounced AD pathology and found that this resulted in a significant improvement biochemically, histologically and behaviourally, without causing any tissue damage. We will present mechanistic insight that has been generated in different cohorts of mice.
CONCLUSIONS. Our study highlights the potential of focused ultrasound as a viable therapeutic approach for AD, and possibly other diseases involving protein aggregation, such as frontotemporal dementia and motor neuron disease.

[2]CCNH, UFABC, São Bernardo do Campo, Brazil

Objectives: Cannabinoids have demonstrated in recent studies a important role in the physiopathological development of neurodegenerative diseases such as Alzheimer's Disease. However, it is still very controversial the influence of an endogenous cannabinoid, anandamide, in Alzheimer's Disease as well as it is unknown its influence on tau protein phosphorylation . Thus. the aim of this study was to evaluate the effect of anandamide on cell death and tau phosphorylation in differentiated and non-differentiated neuronal-cells.
Methods: Neuroblastoma cells SH-SY5Y were cultivated for seven days in **24 wells plates with** Dulbecco's Modified Eagle Medium **with bovine fetal serum (SFB 15%**) and differentiated cells have retinoic acid 100uM added to **the medium (SFB 1%**) in the days 1, 4 and 7. **Also in day 7,** anandamide was added at the concentrations: 0,1 uM, 1uM e 10uM **and cell viability test or protein extraction was performed 24 hours after the administration**. Cell viability was evaluated by Tripan blue exclusion test. Protein quantification was performed using Western Blotting technique
Results: Anandamide at concentrations 1,0 uM and 3,0 uM promoted significative cell death, but only on non-differentiated cells, differentiated cells showed no alterations. Quantitative values were analyzed by one-way ANOVA (Duncan's post-test, $p<0.05$). Preliminary data of Western blotting analysis revealed a tendency of increasing strongly tau phosphorylation levels in both cells types, although different concentrations have promoted distinct effects in differentiated cells compared to non-differentiated.
Conclusions: Anandamide promoted cell death and probably increases phosphorylation.

Abstract

In Morocco, genes predisposing individuals to Alzheimer disease AD and predicting disease incidence remain elusive and prevent health care professionals from identifying AD in its early stages, with the goal of slowing down the progression. The purpose of the present study is to:

- Evaluate the genetic contribution of mutations in in the presenilin-1 (PS1) and presenilin-2 (PS2) genes to familial early-onset AD cases (FAD) and sporadic late-onset AD cases;
- Elucidate the critical role of GAPDH in the blood of FAD cases carrying presenilin mutations and its interaction with Aβ amyloid.

A higher level of atrophy reflects a decrease in neuropsychological performance. We identified 1 novel frameshift mutation in the PS1 gene and 2 novel frameshift mutations in the PS2 gene. The activity of GAPDH in FAD cases, was significantly decreased as compared to sporadic cases and healthy controls. The expression of GAPDH in blood samples from Mutant tau transgenic mice and FAD cases was decreased as compared to sporadic cases and healthy controls. The Dot blotting examination showed an incresead Aβ accumulation in the blood samples from FAD cases.EM examination showed an increase in amyloid fibrils both in the blood and brain samples. Our mutational analysis report a correlation between clinical symptoms and genetic factors in our cases and suggesting that these mutations increase the risk for developing AD. Our proteomic analysis, report the involvement of GAPDH in AD that may influence the pathogenesis of AD.

ADPD5-0349
NOSOLOGICAL DIFFERENTIATION OF MIXED DEMENTIA (PET-CSF STUDY)
V. Lobzin[1]
[1]*nervous diseases, Military-medical academy n.a. S.M. Kirov, St-Petersburg, Russia*
“Mixeddementia” (MD) is defined as a combination of Alzheimer's disease (AD) andvascular dementia (VaD). According to various studies it’s frequency ranges in15-25%. But pathological, clinical and instrumental studies recently showeddata of much more higher frequency of MD: about 80-95%.
We examined257 patients aged 64,8±8,2 years with various cognitive impairment. In 85patients were diagnosed both vascular and neurodegenerative cognitiveimpairment at the stage of mild cognitive impairment or dementia. In 148patients were investigated levels of Aβ-42 amyloid and total tau-protein in cerebrospinalfluid. 38 patients underwent positron emission imaging with 18-FDG to evaluatecerebral metabolic changes.
In MD Aβ-42level was significantly reduced (195,7±105,5 pg/ml) as compared to patientswith VaD and AD. The concentration of tau was higher (1239,3±582,0 pg/ml)compared with AD patients (677,6±444,0 pg/ml) and VaD (460,9±151,4 pg/ml). Suchdifferences can be due to mutual potentiation of neurodegeneration andcerebrovascular damage. There was significant decrease in glucose metabolismin the temporo-parietal regions and hyppocampus in MD and in AD. In 16 of 18patients with VaD (not at the stage of MCI) specific AD hypometabolic pattern wasobserved, but in a less extent.
Cerebrovascular damage is a significant riskfactor for the progression of neurodegeneration. Pathophysiological mechanismsof AD development, such as amyloidogenesis and tauopathy determine progressionof ischemic brain damage. It can be assumed that the majority of vascular andneurodegenerative cognitive disorders are inherently mixed and this probabilityis even more higher at the stage of dementia.

[7]Dept. Surgical Sciences Anesthesiology & Intensive Care Medicine, University Hospital Uppsala University, Uppsala, Sweden

Diabetes and hypertension are the key co-morbidity factors in several neurodegenerative diseases and could precipitate Alzheimer's Disease (AD) pathophysiology in human populations. Thus, a possibility exists that amyloid beta peptide (AbP) infusion in diabetic and hypertensive rats may induce greater AD pathology than in normal animals. Since these co-morbidity factors are associated with severe oxidative stress, we investigated effects of a potent anti-oxidant H-290/51 in AD pathology associated with hypertensive diabetic (HYDB) rats.

Rats were made hypertensive by 1 kidney 1 Clip (1K1C) method and after 4 weeks administered streptozotocine (60 mg/kg, i.p. for 3 days) to develop clinical symptoms of HYDB. AD like pathology was produced by AbP infusion (50 ng/10 µl, i.c.v. for 4 weeks) in healthy and HYDB rats. Blood-brain barrier (BBB) breakdown, brain edema and neuronal injuries and oxidative stress parameters were investigated. We found that HYDB rats after AbP infusion showed 6 to 12 fold increase in oxidative parameters and exacerbated BBB breakdown to proteins, edema formation and neuronal damages as compared to AbP infusion in healthy animals. TiO2-naowired H-290/51 administered (50 mg/kg, i.v. daily for 2 weeks after AbP infusion) resulted in marked neuroprotection and reducing in oxidative stress parameters. These observations are the first to point out that AD pathology worsens in HYDB cases and nanodelivery of antioxidants may have profound therapeutic value in clinics, not reported earlier.

PROTEIN AGGREGATION VERSUS TOXICITY: DEVELOPING DROSOPHILA MODELS TO STUDY AMYLOID-BETA PATHOLOGY

R.F. Sowade[1], *T.R. Jahn*[1]
[1]*Proteostasis in Neurodegenerative Disease,*
German Cancer Research Center (DKFZ), Heidelberg, Germany

A major hallmark of Alzheimer's disease (AD) is the aggregation of the Amyloid-beta (A-beta) peptide. Until now the exact role of these aggregates in AD pathology is not understood, as the amount of aggregated A-beta poorly correlates with disease severity. This raises the question how aggregation and toxicity are linked. Interestingly, A-beta aggregates do not appear randomly during disease progression but spread throughout the brain in a stereotypical manner. How exactly this spreading occurs is still under debate but recent data suggest a prion-like seeding mechanism. In our lab, we are developing *Drosophila in vivo* models that mimic this spreading phenotype. We expressed several A-beta constructs in the *Drosophila* brain and observed differences in their toxicity that did not necessarily correlate with the amount of aggregated A-beta. Hence, our constructs are suitable to examine the relationship between aggregation and toxicity. By simultaneously expressing a slow- and a fast-aggregating A-beta species in the same fly brain, we are analyzing whether there is a crosstalk between the two variants. We hypothesize that A-beta variants with distinct aggregation capacities will influence each other's aggregation kinetics, which might affect the speed of A-beta deposition and thereby alter toxicity levels. This would speak in favor of a "seeding-mechanism". As a read-out we apply various methods to detect parallel changes in toxicity and aggregate formation. Using these novel in vivo models, we can gain new insights into how A-beta pathology spreads throughout the brain and how A-beta aggregation and toxicity are linked to each other.

MUTATIONS AND MODIFICATIONS IN THE METAL-BINDING DOMAIN OF ABETA AFFECT ITS ZINC-INDUCED INTERACTION WITH DNA
V. Mitkevich[1], S. Khmeleva[2], A. Makarov[1], S. Radko[2]
[1]Laboratory of conformational polymorphism of proteins in health and desease, Engelhardt institute of molecular biology RAS, Moscow, Russia
[2]Group of transcriptional analysis, Orekhovich institute of biomedical chemistry, Moscow, Russia
Objectives: Post-translational modifications and/or point mutations in the metal-binding domain (MBD) alter the ability of Abeta to form neurotoxic oligomers. The objective of this work was to evaluate the role of mutations and modifications in zinc-induced interaction of MBD with naturally occurring polyanions, using synthetic single- and double-stranded DNA as a model.
Methods: Surface plasmon resonance biosensing; set of synthetics peptides representing MBD of Abeta natural variants associated with Alzheimer's disease.
Results: (1) Acetylation of the N-terminus amino group and the H6R substitution ("English" mutation) results in a decrease of Zn-induced binding of MBD to DNA. This agrees with the known involvement of the N-terminal amino group and histidine 6 in the formation of Zn-induced dimers of the metal-binding domain. (2) Phosphorylation of serine 8, known to enhance the ability of the metal-binding domain to oligomerize in the presence of zinc ions, and the D7N substitution ("Tottory" mutation) increase the ability of MBD to bind to DNA. (3) In contrast to other bivalent metal ions (Cu, Mg, Ca, Ni, Mn) zinc is a necessary molecular factor for the interaction of MBD with DNA for all peptide variants studied.
Conclusions: (1) MBD is the Zn-dependent DNA binding site of Abeta. (2) The ability of MBD to bind to DNA depends on the peptide oligomerization state. (3) The D7N substitution presumably enhances zinc-induced oligomerization of MBD. (4) Natural polyanions presented in the cerebral spinal fluid can modulate Zn-induced aggregation of Abeta.

ADPD5-0451

THE METAL-BINDING DOMAIN 1-16 OF ABETA COMPRISING ISOMERIZED ASPARTATE 7 IS THE MINIMAL AGGREGATION SEED

S. Kozin[1], A. Kulikova[1], I. Petrushanko[1], V. Polshakov[1], A. Makarov[1]
[1]Structure-function analysis of biopolymers,
Engelhardt institute of molecular biology RAS, Moscow, Russia

Objectives: to determine influence of the isomerization of Aspartate 7, the most abundant spontaneous aging-related chemical modification of Abeta, on amyloidogenic, neurotoxic, structural and aggregation properties of the soluble Abeta species corresponding to the metal-binding domain 1-16.

Methods: transgenic mice model of Alzheimer's disease, histology, neuronal cell cultures, solution NMR spectroscopy, molecular modelling, surface plasmon resonance biosensing.

Resuts: (1) intracerebral injections of synthetic metal-binding domain of Abeta comprising the isomerized Asp7 (isoAbeta16) increase the amyloid burden in transgenic mice; (2) isoAbeta16 is not toxic for neuronal cells; (3) isoAbeta16 forms zinc-induced heterodimers with the intact Abeta16; (4) the primary zinc recognition site 11-14 controls formation of the zinc-bound homo- and hetero-dimers involving isoAbeta16; (5) zinc ions trigger aggregation of isoAbeta16; (6) NMR data reveal structural similarity between zinc-bound dimers of isoAbeta16 and the H6R mutant of Abeta16 (H6RAbeta16); (7) 3D model of the isoAbeta16 zinc-bound dimer structure has been built using solution structure of the zinc-bound dimer of H6RAbeta16 as a template.

Conclusions: (1) soluble isoAbeta16 appears to be the minimal molecular agent triggering aggregation of the endogenous Abeta in vivo; (2) possible molecular basis of the isoAbeta16 amyloidogenicity is related to its ability to form zinc-induced aggregation seeds; (3) blocking the 11-14 site of Abeta responsible for the formation of seeds is a potential anti-aggregation strategy for the therapy of Alzheimer's disease.

Supported by the Russian Scientific Foundation grant No.14-24-00100.

ADPD5-0476
AGGREGATION IN ALZHEIMER'S DISEASE AND PD IS CONTROLLED BY MONOMER RECONFIGURATION
L.J. Lapidus[1], S. Acharya[1], B. Ahmad[1]
[1]Physics and Astronomy, Michigan State University, East Lansing, USA
Objectives: We have developed a model of the first step of aggregation, the formation of a dimer, that is kinetically controlled by the reconfiguration of the monomer. When reconfiguration is rapid there is not enough time for two monomers to make stabilizing interactions and form an oligomer. When reconfiguration slows down to the rate of bimolecular diffusion, then stabilizing interactions can be made. We have investigated this hypothesis with measurements of alpha-synuclein and the Alzheimer's peptide.
Methods: To measure reconfiguration we use the method of Trp-Cys contact quenching. One tryptophan and one cysteine are mutated into the sequence. The lifetime of the tryptophan triplet state depends on the likelihood of making a close contact with the cysteine on the same chain and the intramolecular diffusion coefficient, which then yield the rate of reconfiguration.
Results: We find that the reconfiguration rate is highly correlated with conditions that accelerate aggregation (e.g. temperature, pH, mutation). We also find that various small molecule aggregation inhibitors increase the rate of reconfiguration to keep the proteins from forming oligomers.
Conclusions: These experiments give a new view on why these proteins are so prone to aggregation and how therapeutics may be assayed.

QIAD ASSAY FOR QUANTITATING A COMPOUND'S EFFICACY IN A-BETA OLIGOMER REMOVAL

O. Brener[1], L. Gremer[1], L. Nagel-Steger[1], D. Willbold[1]
[1]ICS-6, Forschungszentrum Jülich, Jülich, Germany

1. Objectives:
Strong evidence exists for a central role of amyloid-beta oligomers in the pathogenesis of Alzheimer's disease (AD). The potency to eliminate A-beta oligomers is, from the current point of view, one of the most desirable criteria for the selection of agents as lead compounds for drug development towards AD treatment. Any screening for oligomer eliminating compounds requires a well characterized target. Therefore, new methods for the preparation, purification and quantification of specific A-beta oligomers, which are representative for the toxic oligomers involved in AD pathogenesis, are urgently needed in AD drug development.
2. Methods
We have designed an assay for the quantitative determination of interference with A-beta aggregate size distribution (QIAD). It is a fast, reliable and robust *in vitro* assay that is able to quantify the A-beta oligomer eliminating potential of any chemical compound.
3. Results
The predictive power of the assay for *in vivo* efficacy is demonstrated by comparing QIAD outcomes of several therapeutically interesting compounds with their treatment effects in animal models and clinical studies.
4. Conclusions
The hereby described A-beta-QIAD assay for analysis of agent-induced A-beta oligomer elimination allows comprehensive and reliable *in vitro* screening of drug candidates for maximum efficacy in the elimination of cytotoxic A-beta oligomers. The quantitative nature of the assay allows comparison between various drug candidates. Furthermore, the observed relation between A-beta oligomer elimination and *in vivo* results strengthens the role of Aβ oligomers in AD pathology.

ADPD5-0555
THE ROLE OF ABETA INTERMEDIATES DURING INDUCED ABETA AGGREGATION
N. Katzmarski[1], C. Abou-Ajram[2], B. Nuscher[2], M. Prinz[3], C. Haass[2], M. Meyer-Luehmann[1]
[1]Neurology, University of Freiburg, Freiburg, Germany
[2]Adolf Butenandt Institute Biochemistry, Ludwig-Maximilians-University Munich, Munich, Germany
[3]Neuropathology, University of Freiburg, Freiburg, Germany
Objectives
The accumulation of Amyloid-beta leading to the formation of plaque deposits in Alzheimer's disease (AD) is a nucleation-dependent polymerization process. The fibrillogenesis from Abeta monomers occurs through the stepwise formation of oligomers to protofibrils and to finally fibrils. Previous studies have shown that intracerebral injection of Abeta-containing brain homogenate induced Abeta plaque deposition in APP transgenic mice. However, the role of Abeta intermediates during this induced amyloid plaque formation remains elusive.
Methods:
To identify critical factors that are required for the induction of Abeta plaque formation in vivo, we injected APP transgenic mice with 1) either Abeta-containing brain homogenate from APP transgenic mice or with brain homogenate immunodepleted for 2) Abeta and 3) Abeta intermediates. Furthermore, we immunized those intracerebrally injected APP transgenic mice with an antibody against Abeta intermediates. The $Abeta^{+}$ area was defined as seeding area and quantified by immunohistochemical staining.

Results:
Postmortem analysis at different time points revealed that mice injected with brain homogenate depleted for Abeta intermediates showed less seeded plaques when compared to control mice. Passive immunization with an antibody against Abeta intermediates showed similar results, although induced Abeta deposition was still evident.
Conclusion:
Our results suggest that intermediate forms of Abeta are important for the early and rapid plaque formation, but the lack of intermediates in the brain homogenate *per se* doesn't completely prevent the formation of plaques. We conclude that monomeric species of Abeta are sufficient for the initiation of plaque formation and postulate that Abeta intermediates are not the real culprit.

ADPD5-0574

PROTECTIVE EFFECT OF NMDA RECEPTOR ANTAGONIST MK-801 AGAINST SMALL BETA-AMYLOID(1-42) OLIGOMER-INDUCED NEURONAL DEATH

S. Jankeviciute[1], R. Morkuniene[1], P. Cizas[1], R. Petrolis[1], A. Krisciukaitis[1], V. Borutaite[1]

[1]Institute of Neurosciences, Lithuanian University of Health Sciences, Kaunas, Lithuania

Soluble beta amyloid (Aβ) forms – one of the most important and critical factors in the pathogenesis of Alzheimer's disease, particularly $A\beta_{1-42}$ oligomers. However, the molecular mechanism how $A\beta_{1-42}$ oligomers trigger neurotoxic cascades are not fully elucidated.

The aim of this study was to investigate the toxic effects of small $A\beta_{1-42}$ oligomers on neurons and glia cells in primary neuronal/glial cerebellar granule cell cultures (CGC) and pure microglia cultures, evaluating whether these neurotoxic effects caused by $A\beta_{1-42}$ oligomer are sensitive to NMDA receptor antagonist MK-801.

Membrane potential of cells was monitored using fluorescent dye DiBAC4(3). The viability of cells was assessed using a fluorescent microscopy, changes in glutamate concentration were measured by the fluorimetric method.

We found that during 0.5-1h incubation small $A\beta_{1-42}$ oligomers caused depolarization of neurons and microglia membranes and MK-801 protected only the microglia cells from $A\beta_{1-42}$-induced membrane depolarization. The effect of MK-801 was also seen in pure microglia cultures. Measuring glutamate level in CGC culture medium we found that during 0,5-4h incubation $A\beta_{1-42}$ oligomers increased glutamate level and this was prevented by MK-801. In pure microglial cultures, $A\beta_{1-42}$ oligomers did not cause release of glutamate into medium. We found that MK-801 preserved neuronal viability and protected CGC from $A\beta_{1-42}$-induced neurotoxicity during 24h incubation.

In conclusion, $A\beta_{1-42}$ oligomers induced rapid and NMDA receptor–dependent microglial plasma membrane depolarization **and rapid** NMDA receptor–independent neuronal depolarization and NMDA receptor–dependent release of glutamate in CGC cultures leading to excitotoxic neuronal death.

FIBRILLIZATION OF THE MIXTURES OF AMYLOID BETA 1-40 AND 1-42

J. Krishtal[1], *M. Friedemann*[1], *V. Tõugu*[1], *P. Palumaa*[1]
[1]*Gene Technology, Tallinn University of Technology, Tallinn, Estonia*

Objectives
Ratio of Amyloid-beta (Abeta) 42 and 40 in the peptide mixture and agitation conditions are important determinants of the fibrillization kinetics *in vitro*. Our aim was the quantitative determination of the effects of these factors.
Methods
Abeta aggregation was monitored by Thioflavin T fluorescence intensity in a fluorimetric cell equipped with a magnetic stirrer.
Results
Under quiescent conditions carefully defibrillized Abeta solutions were stable for several days, whereas in agitated solutions the fibrillization was completed in less than 2 hours. Agitation was crucial in the initial exponential phase of the process, fibrillization rate of Abeta40 and Abeta 40/42 mixtures, but not that of Abeta 42 were enhanced by agitation also in the elongation phase. Kinetic parameters of the fibrillization depend on the ratio of Abeta 40/42 ratio in the mixture. Adding 10% of Abeta42 to Abeta40 shortened the lag period almost to the level observed with pure Abeta42. Importantly, 10 and 50% Abeta42 did not increased the fibrillization rate that started to increase only when Abeta42 content was 90%.
Conclusions
Fibrillization of Abeta 40 and 42 peptides and their mixtures is triggered by agitation most likely by secondary nucleation mechanism. In the agitated solutions both peptides demonstrated similar fibrillization kinetics, lag period for Abeta 42 was twofold shorter and fibril growth rate twofold faster than that of Abeta 40. The different amyloidogenity of the peptides most likely arise from different ability to form fibrillar seeds and grow under “quiescent” conditions and different stability of their aggregates *in vivo*.

ANALYSIS OF GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE (GAPDH) CONTRIBUTION TO ALZHEIMER NEUROPATHOLOGY USING 2ND GENERATION MODEL MICE

S. Hashimoto[1], T. Saito[1], S. Tsubuki[1], T.C. Saido[1]
[1]BRAIN SCIENCE INSTITUTE, RIKEN Insitute, Saitama, Japan

Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) has been known to serve as a key enzyme in the glycolytic pathway. Besides, recent evidence suggests that accumulation of s-nitrosylated GAPDH in the nucleus initiates induction of apoptosis. Aggregates consisting of GAPDH have been detected in Alzheimer's disease (AD) brains although the mechanism(s) by which GAPDH affects the progression of AD pathology have remained elusive. In order to examine the contribution of GAPDH to AD pathology, we inspected the expression levels and patterns of GAPDH in a newly established AD model mice. In this novel mouse model, the Ab sequence of the murine APP gene has been humanized, and the Swedish (KM670/671NL), the Arctic (E693G) and the Beyreuther/Iberian (I716F) mutations have been introduced by knock-in strategy (APP^{NL-GF} mice) (Saito et.al., Nat. Neurosci., 2014). In the present study, we investigated the expression profile of GAPDH in APP^{NL-GF} mice by immunohistochemistry. 3 month old mice carrying premature amyloid plaques in hippocampus and cortex showed a modest GAPDH expression compared to age-matched wild-type controls. 7 month old mice carrying a larger number of cored plaques exhibited apparent plaques-like staining of GAPDH near some of the amyloid plaques in hippocampus and cortex. These results suggest that GAPDH plaques appear near mature amyloid plaques. Consistently, we observed similar GAPDH plaques in the hippocampus of AD brains. Further investigation of the mechanism(s) by which GAPDH accumulates in AD model mice may lead to elucidation of the link between GAPDH accumulation and subsequent pathological events such as tauopathy and neurodegeneration.

[2]Vienne, IC2MP - UMR CNRS 7285, Poitiers, France

Objectives: Alzheimer's disease (AD) is notably characterized by senile plaques, oxidative stress and inflammation. Polyphenols, such as stilbenoïds, have antioxidant effects and interact with amyloid peptides. These properties could rescue biological impairments observed in experimental AD models. The objectives were to determinate the potential neuroprotective role of *trans*-epsilon-viniferin, isolated from grape cane extracts using new technology (Patent WO2010063980), by studying anti-inflammatory action and anti-aggregating effects on $Abeta_{1-42}$ *in vitro* and *in vivo* AD models.

Methodology: Cellular model of AD was murine primary cultures of neurons and astrocytes treated by aggregated $Abeta_{1-42}$ and IL-1beta. Anti-inflammatory action was studied by quantifying cytokine levels with X-MAP® Luminex assay. Anti-aggregating and disaggregating effects on $Abeta_{1-42}$ were studied *in vitro* by scanning electron microscopy. Animal model of AD was APPswePS1dE9 mice, which received an intraperitoneal injection of viniferin every week between 3 and 6 months or 6 and 12 months to study respectively putative its preventive or curative effects. Anti-inflammatory action and effects on amyloid load were respectively studied by quantifying levels of cytokines by ELISA and immunofluorescence.

Results: We demonstrated that viniferin inhibited inflammation in cellular model of AD and $A\beta_{1-42}$ aggregation process with a superior efficacy than resveratrol and even induced disaggregation of aggregated peptide. In APPswePS1dE9 mice, we confirmed that viniferin go through the blood barrier. Analysis of neuroprotective effects are in progress.

Conclusion: These results promote us to investigate other viniferin's analogs, in large study.

THE N-TERMINAL REGION OF AMYLOID? CONTROLS THE AGGREGATION RATE AND FIBRIL STABILITY AT LOW PH THROUGH A GAIN OF FUNCTION MECHANISM

K. Brännström[1], A. Öhman[2], L. Nilsson[3], M. Phil[1], L. Sandblad[4], A. Olofsson[1]
[1]Medical chemistry, Umeå University, Umeå, Sweden
[2]Department of Pharmacology and Clinical Neuroscience, Umeå University, Umeå, Sweden
[3]Department of Chemistry, Umeå University, Umeå, Sweden
[4]Department of Molecular Biology, Umeå University, Umeå, Sweden

Alzheimer's disease is linked to a pathological polymerization of the endogenous amyloid β-peptide (Aβ) that ultimately forms amyloid plaques within the human brain. We used surface plasmon resonance (SPR) to measure the kinetic properties of Aβ fibril formation under different conditions during the polymerization process. For all polymerization processes, a critical concentration of free monomers, as defined by the dissociation equilibrium constant (K(D)), is required for the buildup of the polymer, for example, amyloid fibrils. At concentrations below the K(D), polymerization cannot occur. However, the K(D) for Aβ has previously been shown to be several orders of magnitude higher than the concentrations found in the cerebrospinal and interstitial fluids of the human brain, and the mechanism by which Aβ amyloid forms in vivo has been a matter of debate. Using SPR, we found that the K(D) of Aβ dramatically decreases as a result of lowering the pH. Importantly, this effect enables Aβ to polymerize within a picomolar concentration range that is close to the physiological Aβ concentration within the human brain. The stabilizing effect is dynamic, fully reversible, and notably pronounced within the pH range found within the endosomal and lysosomal pathways. Through sequential truncation, we show that the N-terminal region of Aβ contributes to the enhanced fibrillar stability due to a gain of function mechanism at low pH. Our results present a possible route for amyloid formation at very low Aβ concentrations and raise the question of whether amyloid formation in vivo is restricted to a low pH environment.

ADPD5-0724

A YEAST MODEL SHOWING SYNERGISTIC TOXICITY BETWEEN ABETA42 AND TAU.

K. Vandermeeren[1], M. Verduyckt[1], H. Vignaud[2], T. Bynens[1], P. Letard[2], T. Wilms[1], C. Coun[1], J. Rosseels[1], E. Swinnen[1], C. Cullin[2], J. Winderickx[1]

[1]Functional Biology, KU Leuven, Leuven, Belgium

[2]Institut de Biochimie et Génétique Cellulaires, Université Bordeaux 2 Victor Segalen, Bordeaux, France

The molecular basis behind Alzheimer's disease is inadequately understood. We have developed a humanized yeast model that shows a clear synergistic toxicity between Abeta42 and Tau. In this model, coexpression of Abeta42 and Tau leads to increased oxidative stress and cellular necrosis. Furthermore, Tau becomes hyperphosphorylated on pathologically relevant epitopes when coexpressed with Abeta42. We identified *MDS1*, the yeast orthologue of human GSK-3beta as a major regulator of this process. Not only is this hyperphosphorylation reduced in a *mds1* deletion strain, the synergistic toxicity observed in wild type strains is significantly decreased, providing evidence for the importance of Tau hyperphosphorylation in the disease progression. However, additional toxicity is still observed in *mds1* deletion strains, meaning at least one other factor is left to be discovered. Furthermore, the growth defect was even more pronounced when Abeta42 was coexpressed with FTDP-17 Tau mutants known to be more aggregation-prone. Finally, we studied a number of deletion strains in which the toxicity of Abeta42 is strongly increased. Upon coexpression with Tau, cellular growth of these mutants fell to nearly zero, showing that our model provides a screenable phenotype that can be a valuable tool in the search for disease modulators. In addition, we performed a synthetic genetic array (SGA) with the genome wide collection of yeast deletion strains and a collection of compromised alleles of essential genes (DAmP library). This revealed a significantly reduced toxicity when *TUB4*, encoding gamma-tubulin essential for microtubule nucleation in both yeast and mammalian cells, was knocked-down (DAmP library).

[2]CNRS UMR 5293 -, Institut des Maladies Neurodégénératives, Universitè de Bordeaux, France

[3]International PhD Program in Translational Biomedicine, University of Catania, Catania, Italy

[4]Department of Drug Sciences, University of Catania, Catania, Italy

Objectives: Amyloid-beta oligomers (Abeta-o) are key intermediates in Alzeimer's disease-related synaptic dysfunction. Our aim is to assess the therapeutic potential of a new trehalose-conjugated peptide by probing its ability to 1) hinder Abeta aggregation 2) hold back the synaptic targeting of Abeta-o 3) decrease the neuro-toxicity of Abeta-o, and 4) improve the cognitive deficit due to the accumulation of Abeta-o.

Methods: We have conjugated a trehalose moiety to the LPFFD pentapeptide, to give the Ac-LPFFD-Th. The ability of Ac-LPFFD-Th to bind monomeric Abeta has been investigated by means of NMR, ESI-MS analyses of proteolysis experiments, and Thioflavine-T. The impact of Ac-LPFFD-Th on the assembly of Aβo has been assessed by western-blot analysis. The ability of Ac-LPFFD-Th to neutralize the binding of toxic Abeta-o to synapses and to reduce Abeta-o-induced toxicity has been investigated using cultured rat cortical neurons and subcellular fractionation. We are checking *in vivo* the impact of Ac-LPFFD-Th on the Abeta-o-induced cognitive decline by using the Y-maze spontaneous discrimination task in mice. Abeta-o or Abeta-o+Ac-LPFFD-th will be injected intracerebroventricularly 14 days before the cognitive performance evaluation.

Results: We have characterized the Abeta sequence involved in the molecular recognition with Ac-LPFFD-Th. We have obtained evidences that Ac-LPFFD-Th modify the aggregative features of Abeta-o, reduces the Abeta-o binding to synapse and protects neurons from toxic insults. We also expect that the Ac-LPFFD-Th treatment in rodents will reduce the cognitive impairment induced by Abeta-o.

Conclusions: Based on our findings Ac-LPFFD-Th is a promising candidate for the treatment and prevention of AD.

The aggregation and accumulation of the beta amyloid (Aβ) protein in the brain is known to be one of the major contributors to neurodegeneration and cognitive decline in AD. Enhancing the removal of Aβ aggregates has been suggested as one approach to preventing neuronal toxicity. Intracellular clearance pathways such as autophagy play a vital role in maintaining cellular homeostasis and survival by removing damaged organelles or aggregated proteins, including Aβ aggregates. However, the cellular mechanisms underlying autophagy mediated Aβ clearance and protection against toxicity is poorly understood. I have developed a yeast cell model expressing Aβ tagged with green fluorescent protein (GFP-Aβ) to help provide insight into its aggregation, toxicity and intracellular clearance pathways that regulate Aβ accumulation.

In yeast, I showed that aggregated Aβ can be selectively targeted for degradation in the cell and enhancing the autophagy-lysosomal activity reduced Aβ accumulation and toxicity. To understand the mechanisms underlying autophagy mediated protection against Aβ, I recently undertook a screening analysis of Aβ expression and toxicity in a gene knock-out autophagy mutant library in yeast. Findings from the study indicated an important role for Hsp70/40 chaperone mediated pathways in the clearance of Aβ aggregates and protection against toxicity. We are currently investigating the protective role of these chaperones in modulating aggregation, Aβ42 clearance and alleviating toxicity using overexpression systems. In addition to its use as a biological screen to dissect disease-relevant pathways, these yeast cell based systems are also ideally suited for high-throughput combinatorial screening techniques for novel drug discovery in AD.

Soluble beta-amyloid (Abeta) oligomers account for the decline in synaptic plasticity and loss of memory associated with dementia and therefore represent an early diagnostic and therapeutic target for the treatment of Alzheimer's disease (AD). In order to elucidate the mechanisms of peptide misfolding in the early stages of AD pathogenesis, it is important to develop sensitive and specific assays to identify and monitor key molecular triggers and biological markers before the development of clinical symptoms. In this work we have investigated the early events of Abeta peptide aggregation using high resolution mass spectrometry and have identified key molecular changes associated with Abeta peptide oligomerisation. Analytical dissection of the molecular events associated with peptide aggregation has enabled us to design and develop a new type of anti-Abeta antibodies (neo-epitope), which specifically target molecular triggers appearing during the initial, early stages of peptide oligomerisation. Screening of AD transgenic mice and human post-mortem AD brain samples, using a combination of antibody targeted and quantitative mass spectrometry revealed that these molecular changes in Abeta peptide are highly relevant *in vivo*. Our findings show that the use of neo-epitope antibodies offers a novel analytical tool for the identification of early molecular seeds of Abeta oligomers. Here we reveal crucial information not only for understanding and targeting Abeta peptide aggregation, but also for monitoring the pathological associated changes in levels of Abeta found in human biofluids.

1. Objectives: Neurodegenerative disorders affect an ever increasing number of people in aging societies. In many of these diseases, protein misfolding and aggregation is involved. Therefore, the development of new methods to detect, understand and prevent pathological protein aggregation processes is essential. In our approach, tailored nanoparticles are used as organizational platform and transport vehicle to combine different functional units. These are intended to cooperate synergistically, so that they perform peptide recognition, beta-sheet breakage and peptide cleavage.
2. Methods: Surfactant-free, monodisperse nanoparticles are fabricated by laser ablation in saline solution and conjugated to different self-synthesized ligands. Biophysical assays such as ThioflavinT-staining (beta-sheet content), circular dichroism (secondary structure), density gradient centrifugation and ELISA (oligomerization) reveal the influence of the new materials on Abeta-aggregation.
3. Results: Immobilization of various functional units on gold has a profound influence on colloidal stability kinetics. It was found that different ligand modifications require specific ligand to nanoparticle ratios to secure an overall positive or negative net charge. Most stable conjugates were tested in biophysical experiments, showing that nanoparticles functionalized with an Abeta-selector interact with the model protein and inhibit its aggregation, whereas non-functionalized nanoparticles do not affect protein aggregation.
4. Conclusions: The inhibitory influence of stable, mono-functionalized gold nanoparticle conjugates on Abeta-aggregation was shown. Next, we will synthesize bi-functional nanoparticles carrying an additional beta-sheet breaking unit.

ROLE OF REDOX SIGNALING EVENTS IN PROTEIN MISFOLDING DISEASES
Z.A. Stapper[1], A.G. Barata[2], T.P. PD Dr. Dick[2], T.R. Dr. Jahn[1]
[1]CHS Research Group Proteostasis in Neurodegenerative Disease, German Cancer Research Center (DKFZ), Heidelberg, Germany
[2]Division of Redox Regulation, German Cancer Research Center (DKFZ), Heidelberg, Germany
There is accumulating evidence that Alzheimer´s disease (AD) pathogenesis correlates with mitochondrial damage and increased oxidative stress due to the overproduction of reactive oxygen species (ROS) and an imbalance in anti-oxidative defenses. AD pathology is firmly associated with oxidative stress endproducts which can be found at the endpoint of AD pathology, in brains of AD patients. However, it is still not well characterized whether oxidative stress is the cause or consequence of AD pathology or whether ROS act as signaling molecules in the onset and progression of AD.
We are using novel genetically encoded fluorescence-labeled redox sensors which are fused to redox proteins specific for real-time-imaging of glutathione redox potential or H_2O_2. This powerful tool allows the quantitative measurement of redox changes in specific cellular compartments *in vivo.* We have introduced them into our *in vivo Drosophila* model of Amyloid-beta (Abeta) aggregation to gain novel insights into the role of oxidative stress in the onset and progression of AD. With the tools we can follow redox changes in real-time and in parallel to Abeta aggregation and neurodegeneration. The establishment of dual-expression *Drosophila* models, further allows the expression of different Abeta variants (non-toxic/toxic) and the redox sensors in neurons or glia cells, to explore neuron-glia communication. Interestingly, preliminary data show that changes in oxidized glutathione levels in neurons parallel, but not in glia cells, correlate with the deposition of toxic Abeta42 species. The major challenge will be to unravel the direct molecular mechanisms of ROS signaling in neurodegeneration and AD pathogenesis.

APP-INDUCED NEURODEGENERATION IS ABETA-INDEPENDENT AND MEDIATED BY THE UNFOLDED PROTEIN RESPONSE

N. Cheng[1], S. Jiao[1], L. Bai[1], L. Belluscio[1]
[1]Developmental Neural Plasticity Section,
National Institute of Neurological Disorders and Stroke, Bethesda, USA

Objective:
Accumulation of amyloid-β (Aβ) peptide is a hallmark of Alzheimer's disease (AD) and thought to be the cause of neurodegeneration. However, some animal models produce widespread Aβ deposits but no clear neuronal loss questioning this Aβ hypothesis. We sought to determine the underlying mechanism for olfactory loss associated with AD.

Methods:
We utilized a previously developed an in vivo mouse model that reveals amyloid precursor protein (APP) induced apoptosis is cell-autonomous in olfactory sensory neurons (OSNs). Together with additional transgenic lines and a combination of molecular and biochemical assays we analyzed the basis of OSN neurodegeneration.

Results:
Here we show, in 2 distinct transgenic models that APP-induced apoptosis of OSNs occurs early and is independent of Aβ, highlighting the presence of other pathogenic mechanisms. We further demonstrate that APP-induced apoptosis is dependent on the Unfolded Protein Response (UPR) and that blocking the activity of protein kinase R-like endoplasmic reticulum kinase (PERK) can rescue both anatomical and behavioral phenotypes, thus revealing a key regulatory function.

Conclusions:
These findings support olfactory disruption as an early indicator of AD and present a mechanistic basis for the associated olfactory loss that may prove to be an effective therapeutic target.

ADPD5-0982
LET-7C DECREASED ABETA PRODUCTION VIA ACTIVATION OF BACE2
X. Sun[1], H. Liu[1]
[1]Qilu hospital, Qilu Hospital of Shandong University, Jinan, China
Alzheimer's disease(AD) is the most common form of dementia. Nearly all Down syndrome(DS) patients develop AD neuropathology including neuritic plaques and neurofibrillary tangles after 40 years of age. It was believed that some genes on chromosome 21 contributed to the AD pathogenesis in DS patients. miRNAs are regulatory RNAs playing vital roles in physiology and pathology conditions. To study the contribution of miRNAs in AD pathogenesis in DS, we used low density array to screen for differential expression of miRNAs between DS and normal cells. The taqman based array identified 42 differential miRNAs. Our data showed let-7c was increased in DS cells and brain tissues. Let-7c decreased Abeta production, but had no effect on APP or BACE1 expression. Nevertheless, let-7c increased the C99 cleavage within Abeta domain. Further study showed let-7c increased BACE2 expression via activation of BACE2 gene transcription. And this activation depended on Ago1/2 complex. Our study here demonstrated that let-7c, as an activating miRNA, can decrease Abeta production via activation of BACE2.

Objectives

Amyloid-beta (Abeta) oligomers have been identified in Alzheimer's disease (AD) brain, but no general consensus has yet been reached as to which are the most significant in AD pathogenesis. This study addresses the following questions related to brain-derived Abeta oligomers: 1) are there distinct subtypes of Abeta oligomers based on quaternary structural motifs; 2) what is the most abundant type of Abeta oligomer produced and how does it affect neurological function?

Methods

We classified brain–derived Abeta assemblies into amyloid-related Abeta oligomers (AmAbetaO's) and non-AmAbetaO's based on their spatial, temporal, and structural relationships to fibrils. We quantified the relative levels of AmAbetaO's and non-AmAbetaO's in Tg2576 and rTg9191amyloid precursor protein (APP) transgenic mice. Using rTg9191 mice, which predominantly produce AmAbetaO's, we examined the effects of AmAbetaO's on cognitive function.

Results

AmAbetaO's, immunoreactive to OC antibodies recognizing in-register parallel beta-sheet structure, appear plaque-dependently and represent the most abundant soluble assemblies in both Tg2576 and rTg9191 mice. AmAbetaO's are concentrated in the vicinity of dense-core plaques and largely overlap with plaque-associated neuropathology. Non-AmAbetaO's, recognized by A11 antibodies, emerge before plaque formation. In contrast, Abeta*56, a memory-impairing non-AmAbetaO's that is produced at low levels, is distributed throughout the cortex. AmAbetaO's do not impair cognition in rTg9191 mice.

Conclusions

Our results highlight spatial distribution as a key factor determining the role of distinct Abeta assemblies on cognition. In the APP transgenic mice studied here, AmAbetaO's, despite being the most abundant soluble Abeta assemblies, are rendered innocuous because of their effective containment within plaques.

[6]Edith Cowan University, School of Medical Sciences, Perth, Australia

Objective: We have previously reported that a novel 15mer peptide, isolated via phage display screening, targeted Aβ and attenuated its neurotoxicity. Here, we aimed to generate and biochemically characterise analogues of this peptide with improved stability.

Methods: The stable peptide analogue (15MS.A.) underwent the following analysis: stability in brain homogenate, ability to inhibit Aβ aggregates and attenuate neurotoxicity, ability to bind monomeric, oligomeric and fibrillar Aβ using co-immunoprecpitation or Surface Plasmon Resonance analysis; staining for Aβ plaques on brain tissue from transgenic mice and analysis in plasma and brain homogenate following i.v. injection of tritiated (^{3}H) peptide into to mice.

Results: We found that 15M S.A. retained the activity and potency of the parent peptide and demonstrated improved proteolytic resistance *in vitro* and reduced the formation of soluble Aβ42 oligomers. The 15M S.A. candidate directly interacted with oligomeric Aβ42, with an affinity in the low μM range. Furthermore, this peptide bound fibrillar Aβ42 and also stained plaques *ex vivo* in brain tissue from AD model mice. Following i.v. administration, plasma concentrations of ^{3}H peptide decreased with time, as expected, however the peptide was detected in brain homogenate with levels remaining stable over time. Further validation, particularly the ability of the peptide to bind Aβ aggregates *in vivo* is required.

Conclusion: Given its multifaceted ability to target monomeric and aggregated Aβ42 species, this candidate holds potential for novel preclinical AD imaging and therapeutic strategies.

[2]Chemistry, The University of Melbourne, Melbourne, Australia
[3]Florey Institute of Neuroscience, The University of Melbourne, Melbourne, Australia

The key protein causing Alzheimer's disease (AD) is called amyloid beta (Aβ). This protein can acquire a destructive nature to brain neurons and it is unclear why this occurs in a subset of the aging population. Therefore, to better understand what makes this protein neurotoxic, we hypothesise that its toxicity is correlated with binding to the lipid components of the plasma membrane. Further, we have identified the specific amino acids, glutamine (Q), at position 15 and lysine (K) at positions 16 and 28 in Aβ that may have a critical role in mediating the binding to lipid membranes. We will present data showing the biophysical, cell binding and cell toxicity properties of the mutated Aβ peptides. **Methods:** To study Aβ binding to lipid membrane surfaces, giant unilamellar vesicles will be prepared and treated with the Aβ peptides and the extent of binding will be quantitated. ThT aggregation assays will be performed. Primary cortical neuronal cultures will be used for cell toxicity and cell binding studies. **Results:** All three mutant peptides have 1) diminished neurotoxic activity while the Q15A mutant peptide was not toxic at all 2) diminished levels of peptide binding to cells in culture 3) decreased rate of aggregation and fibril formation. **Conclusion:** By understanding the role of these key residues within the Aβ peptide sequence in mediating cell binding and toxicity, this will assist us in future design of therapeutic drugs for the treatment of AD.

[4]Clinical Neurochemistry Laboratory Department of Neuroscience and Physiology, Sahlgrenska University Hospital, Sydney, Sweden

Objective: Apart from ageing; brain injury and brain inflammation are believed to be important risk factors to trigger Alzheimer disease (AD) pathology. We have studied the role of lysozyme in AD. Lysozyme is a protein of the innate immune system, and is secreted from microglia and astrocytes during inflammatory conditions.
Methods: Lysozyme levels were quantified in cerebrospinal fluid from Alzheimer patients and immunohistochemistry of lysozyme and amyloid plaques were performed in brain sections of sporadic AD patients. Aβ aggregation was investigated using ThT, cell viability was detected using XTT, cellular uptake of Aβ was studied by flow cytometer and binding of Aβ and lysozyme was examined using fluorescence resonance energy transfer.
Results: We have found increased levels of lysozyme in Alzheimer patients' cerebrospinal fluid and sizable deposits of lysozymes in Aβ plaques in the brain of sporadic Alzheimer patients. Pathological importance of lysozyme in AD was revealed by *in-vitro* toxicity studies, where lysozyme prevents Aβ aggregation and rescues neuroblastoma cells from Aβ toxicity. Lysozyme binds to monomers of $A\beta_{(1-42,1-40,1-38)}$ and this binding inhibits neuronal uptake of Aβ.
Conclusions: These results indicate that increased levels of lysozyme could be a preventive stress response during AD that eventually gets overwhelmed by the AD pathology development. Understanding of details about Aβ uptake inhibition and internalization mechanisms by lysozyme will give insights about how to stop intracellular Aβ accumulation and subsequent disease progression, a path breaking mechanism in AD. The study will further enlighten the therapeutic potential of lysozyme to halt AD pathology.

01b. Protein Misfolding & Aggregation: Abeta

ADPD5-1083
MODIFIERS OF AMYLOID-BETA TOXICITY IN ALZHEIMER'S DISEASE
M. Azhar[1], *S. Ott*[1]
[1]*Genetics, University of Cambridge, Cambridge, United Kingdom*
.
Objectives
Processing of Amyloid precursor protein leads to production of two reservoirs of Aβ: a secreted pool and non-secreted cytoplasmic pool. Secreted Aβ contributes to extracellular plaques but despite various studies, the role of cytoplasmic Aβ in AD pathogenesis remains unclear. In this study, we hypothesise that cytoplasmic Aβ contributes to the toxicity of secreted Aβ through specific transmembrane interactions in our fly model of AD.
Methods
Our preliminary experiments show that expression of aggregation prone form of extracellular Aβ leads to a reduction in longevity, locomotor deficits and deposition of plaques while that of cytoplasmic Aβ, on the other hand, is non-toxic. Interestingly, the co-expression of cytoplasmic Aβ enhances the plaque deposition and toxicity of extracellular Aβ. To investigate how extracellular and cytoplasmic Aβ may interact we undertook an RNAi modifier screen of 115 candidate genes in *Drosophila*. We measured the increase in longevity caused by RNAi in flies expressing extracellular and cytoplasmic Aβ. Only those RNAi constructs that did not also cause increased longevity in control flies (those expressing only extracellular Aβ and those not expressing Aβ) were retained.
Results
Thirteen genes are found to specifically rescue the combined toxicity of cytoplasmic with extracellular Aβ. The longevity data is also supported by brain histology, gene and protein expression measurements. Presently, we are further investigating these genes in mammalian cell culture.
Conclusions
Our results suggest a synergistic interaction between two pools of Aβ and highlight the importance of transmembrane Aβ interactions in AD pathology
.

MODULATION OF ENDOPLASMATIC RETICULUM-MITOCHONDRIA CONTACT SITES DECREASES INTRACELLULAR AMYLOID BETA-PEPTIDE LEVELS

N. Leal[1], C. Moreira Pinho[1], B. Wiehager[1], B. Schreiner[1], H. Karlström[1], M. Ankarcrona[1]

[1]Center for Alzheimer Research, Karolinska Institutet, Stockholm, Sweden

Objectives The metabolism of glucose, calcium, lipids and cholesterol is controlled in the contact points formed between ER and mitochondria. Interestingly, all these important cellular processes are impaired in Alzheimer's disease. Here, we show that modulation of ER-mitochondria contacts by knock-down of the tethering protein Mitofusin2 (Mfn2) decreases the intracellular levels of amyloid beta-peptide (Abeta).

Methods HEK293 cells overexpressing mutated amyloid precursor protein were transfected with siRNA to knock-down Mfn2. Decreased Mfn2 expression was confirmed by Western Blot. ELISA was used to detect intra- and extracellular levels of Abeta 1-40/1-42. Alamar Blue assay was used to assess cell viability.

Results Knock-down of Mfn2 was successfully performed and did not affect cell viability during a 48 h period. In cells treated with Mfn2 siRNA decreased intracellular levels of both Abeta 1-40 and Abeta1-42 were detected. However, the levels of secreted Abeta were not affected.

Conclusions APP and gamma-secretase complexes are present in the ER-mitochondria interface and interestingly we have recently shown that Abeta is indeed generated in these contact points (Schreiner et al 2014 JAD *DOI10.3233/JAD-132543*). Here we clearly show that intracellular Abeta levels are regulated by ER-mitochondria interplay, while secreted Abeta levels are not affected. This may be interpreted as Abeta is produced at different subcellular sites and that the pool produced in ER-mitochondria contact points normally accumulates intracellularly. In our future work we will test the hypothesis that modulation of ER-mitochondria interplay affects formation of autophagosomes and intracellular production/transport/deposition of Abeta.

OLIGOMER MIMICKING STANDARD PROTEIN FOR MULTIMER DETECTION SYSTEM

S.C. Kim[1], S.H. Jung[1], S. Kang[2], S.S. An[1], S. Kim[3]
[1]BioNano, Gachon University, Seongnam-si Gyounggi-do, Korea
[2]CEO, PeopleBio Inc., Seoul-si, Korea
[3]Department of Neurology, Seoul National University Bundang Hospital, Seongnam-si Gyounggi-do, Korea

Objectives
Protein misfolding-related diseases or proteinopathies are becoming significant in age-related diseases, such as Alzheimer's disease, Parkinson's disease. Several commercial kits were developed and used to detect their respective oligomer proteins in diseases which are mentioned above. Due to their nature of aggregation, these proteins tend to aggregate and oligomerize often, making the standardization of the measurement in trouble. Hence, it was difficult to quantify these aggregating proteins without expansive devices or kits in a reasonable time frame.
Methods
Standard Amyloid beta 42 (Aβ42) protein was constructed by attaching various fragment peptides of Aβ42 protein onto carrier proteins. The carrier protein would have no immunological relations with anti-Aβ protein antibodies. Three types of standard proteins were constructed for amyloid beta peptides, which was a biomarker for Alzheimer's disease. The artificial standard proteins were characterized by ELISA, SDS-PAGE and western blot.
Results
Oligomer Mimicking Standard Proteins were well detected based on the sequence of the Aβ42 peptide and specific antibodies against N- or C-termini. Oligomer Mimicking Standards Proteins can be applied to MDS as controls and references. Further studies are in progress to construct the correlations between Aβ42 Oligomer Mimicking Standard Proteins. Optimization, stabilization, and features of Artificial Standard Proteins are also in the works. Standard proteins for other protein-aggregating diseases are being developed.
Conclusions
These standard proteins could be efficiently applied as standard references in the Multimer Detection System, which was developed for differentiating oligomers in various proteins aggregating disease.

NEURONAL TOXICITY OF AMYLOID-BETA OLIGOMERS

J.H. Birnbaum[1], R.M. Nitsch[2], C. Tackenberg[2]
[1]Division of Psychiatry Research and Graduate Program of the Zurich Neuroscience Center, University of Zurich, Schlieren, Switzerland
[2]Division of Psychiatry Research, University of Zurich, Schlieren, Switzerland

Objectives:

Aggregation of the amyloid-beta peptide (Aβ), especially into oligomeric forms, is considered to trigger the pathology of Alzheimer‘s disease (AD) by causing synaptic loss and neurodegeneration. In order to gain a deeper insight into their neurotoxic properties, we characterized synthetic and recombinant (wild-type and E693G mutated (Arctic mutation)) Aβ oligomer species (ADDLs) and their effects on cell survival, formation of reactive oxygen species (ROS) and tau phosphorylation in neuronal cultures.

Methods:

Aβ oligomers were routinely characterized by western blot and silver staining. Binding of oligomers to hippocampal neurons was assessed by immunocytochemistry and confocal imaging. We further investigated generation of ROS after Aβ oligomer treatment using the CellRox dye. The viability of neurons was assessed by LDH assay. Changes in the phosphorylation state of virally overexpressed human tau were examined by western blot.

Results:

We show that the preparations of synthetic and recombinant Aβ oligomers lead to a distinct oligomer composition. These exhibited differential abilities to bind to the surface of neurons and displayed differences in neuronal toxicity. Further, synthetic Aβ oligomers were able to induce tau phosphorylation and ROS formation in neurons.

Conclusions / Outlook:

Aβ oligomers induce AD-typic neuronal phenotypes e.g. oxidative stress and hyperphosphorylated tau. However, although oligomer preparations were highly reproducible according to SDS-PAGE and western blot, we observed high variations within individual experiments. Therefore, we will further characterize the structural properties of our oligomeric Aβ preparations. Moreover, we will investigate the interplay of tau phosphorylation, oxidative stress and neuronal cell death.

[2]Department of Medical Biosciences, Umea University, Umeå, Sweden
Selective targeting of oligomeric assembles using specific antibodies provides promising therapeutic and diagnostic opportunities for protein misfolding diseases. Unfortunately, the molecular properties associated with oligomer-specific antibodies are not well understood, and this limits targeted design and development. In this work we demonstrate a generic method that enables the design and optimization of oligomer-specific antibodies. The method takes a two-step approach. The first step discriminates between oligomers and fibrils and is accomplished through identification of cryptic epitopes exclusively buried within the structure of the fibrillar form. The second step discriminates between monomers and oligomers based on differences in avidity. We show inhere that a simple bivalent mode of interaction, as within e. g. the IgG isotype, can increase the binding strength of the antibody up to 1500 times compared to its monovalent counterpart. We expose how the ability to bind oligomers is affected by the monovalent affinity and the turnover rate of the binding and, importantly, also how oligomer specificity is only valid within a specific concentration range. We provide an example of the method by creating and characterizing a spectrum of different monoclonal antibodies against both the A beta peptide and alpha-synuclein that are associated with Alzheimer's and Parkinson's diseases, respectively. The approach is however generic, does not require identification of oligomer-specific architectures, and is, in essence, applicable to all polypeptides that form oligomeric and fibrillar assemblies.

EFFECT OF ALOE VERA ON LIFE SPAN, MOTOR ACTIVITY, AND OXIDATIVE STRESS PARAMETERS IN THE BRAIN OF DROSOPHILA MODEL OF ALZHEIMER'S DISEASE

S. Singh[1], S. Srivastav[1], A. Yadav[1], S. Srikirhsna[1]
[1]Biochemistry Faculty of Science, Banaras Hindu University, Varanasi, India

Objectives- The present study was conducted to test the neuroprotective effect of *Aloe vera* extract in *Drosophila* AD model.
Methods- Genetic cross was set by using UAS/GAL4 system to get *Drosophila* model of Aβ, expressing amyloid-β ($A\beta_{42}$) specifically in eye and neuronal tissues under the control of UAS promoter. *Aloe vera* Liquid extract (5, 10, 15 and 20ml/L of *Drosophila* food) was orally administered to Aβ-driven flies. Polyphenolic and flavonoid content in Aloe vera extract was determined by HPLC.The memory-enhancing effects of the *Aloe vera* extract were studied by means of Climbing and Longevity assay. Also, the antioxidant activity in *Drosophila* head was assessed using superoxide dismutase (SOD), catalase (CAT), Malondialdehyde (MDA), and protein carbonyl assays.
Results- Eye specific expression of human $A\beta_{42}$ resulted in absolute degeneration of eye ommatidial structures that progress with age. This ommatidial neurodegeneration phenotype was rescued significantly by the treatment with Aloe vera extract. Better rescue was found at concentration of 15ml/L. Similarly *elavGal4* driven Aβ flies showing improved climbing ability and increased longevity. Significantly increase in SOD and CAT level was observed in *Aloe vera* treated flies whereas MDA and protein carbonyl content was significantly reduced.
Conclusions- Our results suggest that the *Aloe vera* extract ameliorates amyloid beta (1–42)-induced spatial memory impairment by attenuation of the oxidative stress in AD model of *Drosophila. Aloe vera* showed a dose dependent significant delay in the loss of activity pattern, reduction in the oxidative stress and apoptosis, and increase in the life span of AD flies.

THE PERMANENT OXIDATION OF ABETA-MET35 MODULATES THE PEPTIDE'S AGGREGATION AND INCREMENTS ITS TOXICITY IN VIVO

A.N. Minniti[1], N.C. Inestrosa[1], R. Aldunate[2]
[1]Biologia Celular y Molecular,
Biological Sciences Faculty. Pontificia Universidad Catolica de Chile, Santiago, Chile
[2]Escuela de Biotecnología, Universidad Santo Tomás, Santiago, Chile

Objectives: To examine the role of Abeta-peptide Met^{35} redox state on its aggregation and toxicity *in vivo,* using a *C. elegans* model of the human amyloidogenic disease Inclusion Body Myositis.

Methods: We used transgenic strains that express the Abeta-peptide intracellularly in muscle cells and, to maintain the peptide´s Met^{35} permanently oxidized, we introduced a deletion of the methionine sulfoxide reductase A-1 gene (*msra-1*). The enzyme MSRA-1 repairs oxidized methionines in proteins.

Results: In the case of a constitutive Abeta transgenic strain, we found that in the absence of MSRA-1, the number of amyloid aggregates decreases while the oligomeric Abeta species increase. These results correlate with increased synaptic dysfunction and misslocalization of the nicotinic acetylcholine receptor ACR-16. In an inducible Abeta strain, which allows us to analyze Abeta toxicity in its early phase of aggregation, the absence of MSRA-1 causes paralysis delay indicating decreased toxicity in these initial stages.

Conclusion: Our approach aims at modulating the oxidation of Abeta Met^{35} *in vivo* and analyzing its aggregation and toxicity, which we measured as changes in locomotor behavior, and neuromuscular junction function and structure. Understanding the process of Abeta aggregation and toxicity related to Met^{35} redox state will contribute to elucidate its role in amyloidogenic diseases. Our results suggest that therapies that boost the activity of the Msr system could have a beneficial effect in managing amyloidogenic diseases at their early stages.

[5]Structural Biochemistry (ICS-6), Research Center Juelich, Juelich, Germany

One of the most important targets in Alzheimer's Disease (AD) therapy is still the proteolytic fragment of the amyloid precursor protein, called amyloid beta peptide. This fragment is marked by its high tendency to self-associate. The self-assembly, which finally leads to the formation of amyloid fibrils, has to proceed via an unknown number of intermediate structures, among which a more potent therapeutic target than the fibril is suspected. OBJECTIVES: The objective was to identify and characterize possible early, distinct assemblies of the amyloid beta peptide in solution regarding size, shape and fraction.
METHODS: Sedimentation velocity centrifugation has been complemented by small angle neutron scattering experiments, atomic force microscopy, and CD-spectroscopy.
RESULTS: By sedimentation velocity centrifugation a small number of s-value species could be reliably detected corresponding to monomers, dodecamers and octadecamers of the amyloid beta peptide, thus corroborating the assumption, that certain assembly states possess a higher probability than others. The observed oligomeric species possessed globular shape, increased beta sheet content in comparison to the mostly random coil structure of the monomer, were negative for thioflavin T staining, and exhibited a stronger cytotoxicity than amyloid fibrils at the same mg/ml concentrations.
CONCLUSIONS: Our study of small Abeta peptide assemblies present in solution during the lag phase of amyloid formation provided size-, as well as shape information and relative fractions of distinct oligomeric species and thus adds to the characterization of a possible new target for AD therapy. The collected quantitative data further allow designing a model for the self-assembly process.

LABEL-FREE SINGLE PARTICLE CHARACTERIZATION OF A-BETA OLIGOMERS IN SOLUTION

M. Mayer[1], *E.C. Yusko*[1]
[1]*Biomedical Engineering, University of Michigan, Ann Arbor, USA*

This work determines the size of individual amyloid-beta oligomers in solution without chemical labels by taking advantage of resistive-pulse sensing when single amyloid-beta particles move through the molecular-scale volumes in lipid bilayer-coated nanopores. By measuring the magniture of resistive pulses due to translocation of individual amyloid-beta oligomers, protofibrils, or fibers, this method makes it possible to account for the large heterogeneity of amyloid-beta aggregate sizes and shapes. We propose that this emerging single-molecule technology may help to elucidate the pathological role of various amyloid oligomers in amyloid-associated diseases by characterizing the dynamic distributions in size and shape of these oligomers with high resolution.

PRE-PLAQUE AMYLOID AGGREGATION IN BRAIN WITH ALZHEIMER'S DISEASE PATHOGENESIS

O. Klementieva[1], K. Willen[1], A. Sroka[1], S. Linse[2], A. Engdahl[3], P. Uvdal[3], G. Gouras[1]
[1]Department of Experimental Medical Science, Lund University, Lund, Sweden
[2]Department of Biochemistry and Structural Biology, Lund University, Lund, Sweden
[3], MAX VI, Lund, Sweden

Objective: To determine the native conformation(s) of beta-amyloid (Abeta) in normal brain and to examine how these conformations change in brain early in the course of Alzheimer's disease (AD) pathogenesis. Prior studies attempting to analyse early Abeta conformations in brain have relied on methods that can alter the conformation of Abeta and/or require fixation. To visualize secondary structure of proteins in their natural state we use label free synchrotron based Fourier transform infrared microspectroscopy (FTIRM) on unprocessed brain sections and primary neurons of AD transgenic mice.

Methods: FTIRM, confocal immunofluorescence microscopy and nondenaturing Western blot are used to analyse Abeta in brains and primary neurons of wild type and AD transgenic mice (Tg19959 with Swedish & Indiana APP mutations) at different ages or time in culture, respectively.

Results: Comparisons of the FTIRM spectral intensity of the alpha and beta bands support that 1. Abeta in the brains of AD transgenic mice starts to aggregate before plaques can be found, and 2. this Abeta starts to aggregate within neurons. In contrast, beta-aggregation is not apparent in wild type mouse brains or primary neurons. Abeta in brain and cells runs as a high molecular weight complex on native gels.

Conclusions: Our data support that localized beta-aggregation precedes amyloid plaque formation in brains of AD transgenic mice and within primary neurons of AD transgenic but not wild type mice. These results further support the growing awareness that misfolded intraneuronal Abeta can be a key pathogenic species involved in causing synapse dysfunction in AD.

[4]Section of Pharmacology Department of Internal Medicine and Centre of Excellence for Biomedical Research (CEBR), University of Genoa, Genoa, Italy
[5]Institute for Macromolecular Studies ISMAC, CNR, Milan, Italy

Objectives: to determine which is the ratio in the mixture of AβpE3-42 and Aβ1-42, where AβpE3-42 has the major influence on the aggregation kinetics, secondary structure, morphology and toxicity of Aβ1-42.
Methods: We characterized the cell toxicity by analysis of the intracellular calcium dysregulation; aggregation kinetics by turbidity assay; conformation by Circular Dichroism; morphology by TEM and AFM; secondary structure of single oligomer by NanoIR.
Results: The different mixtures and peptides alone were differently effective in inducing free Ca^{2+} increase in the exposed cells, but the mixture with 5% of AβpE3-42 showed the higher increase. The 5% mixture showed fast aggregation kinetic, similar to that of AβpE3-42 alone, the aggregation kinetics for the other mixtures were inversely proportional to the amount of pEpeptide. The Nano IR spectroscopy revealed that the 5% mixture has an oligomeric population with a prevailing β-sheet conformation and some oligomers with unordered secondary structure, that are not found neither in full length, nor in AβpE3-42. Morphological analysis was in agreement with the previous data. The 5% mixture has a morphology characterized by globular aggregates with more segmented and unstructured fibers, so it is different from the AβpE3-42, Aβ1-42 and from the other mixtures
Conclusions: here we showed that AβpE3-42 has an active role in the formation of pathological oligomers and revealed its maximum effective when it is present at 5% in the amyloid beta mixture.

ALZHEIMER'S DISEASE -CAUSING PROLINE SUBSTITUTIONS LEAD TO PRESENILIN 1 AGGREGATION, DEPOSITION AND ATTENUATED FUNCTION

T. Ben-Gedalya[1], L. Moll[1], M. Bejerano-Sagie[1], E. Cohen[1]
[1]Biochemistry, Hadassah-Hebrow University Medical Center, Jerusalem, Israel

Objectives: PXXP proline substitutions in the sequence of presenilin 1 lead to familial Alzhiemer disease (AD). Cyclophilin folding chaperone recognition of presenilin 1 is affected in these mutations. We studied the cellular and biochemical consequences of presenilin 1 misfolding brought about by cyclophilin inhibition. **Methods:** cell biological and biochemical assays were utilized to observe misfolding, aggregation and accumulation of presenilin 1 as a result of PXXP mutations or cyclophilin inhibition. Gamma secretase activity assays were preformed to measure presenilin 1 function. **Results:** Similarly, to their key role in the folding of the prion protein, cyclophilin activity is critically required for the correct folding and functionality of PS1. Inhibition of cyclophilin activity results in PS1 misfolding aggregation and deposition in the endoplasmic reticulum quality control compartment- the ERQC. Correspondingly, the substitution of proline 264 or 267 abolishes a cyclophilin recognition site essential for the proper maturation of PS1 leading to its aggregation. The loss of PS1 function reduces gamma secretase activity, modulates the ratio between the aggregative prone amyloid beta 42 product to 40 and impairs mitochondrial distribution and function initiating the pathological process that underlies familial AD.
Conclusions: Our discoveries point at the cyclophilin family of folding chaperones as a novel linker between toxic protein aggregation, the aging process and neurodegenerative diseases and suggest the elevation of cyclophilin activity as a potential target for therapeutic intervention.

[3]Neuroradiology Department, University Hospital of Coimbra, Coimbra, Portugal
[4]Neurology Department, Hospital of Braga, Braga, Portugal
[5]Neurology Department, Faculty of Medicine and University Hospital of Coimbra, Coimbra, Portugal

Objectives: To investigate the presence of the pathogenic *C9orf72* repeat expansion in patients with the clinical diagnosis of Alzheimer Disease (AD) or mild cognitive impairment (MCI) not having an imaging and/or a cerebrospinal fluid biomarkers profile compatible with the disease.
Methods: Sixty two patients assisted in the Dementia outpatient clinic of Coimbra University Hospital having a brain imaging and/or CSF profile not typical of AD were included in the study. 15 patients with the clinical diagnosis of AD and 47 MCI were studied for the presence of *C9orf72* expansion.
Results: Three patients (*age* 58 to *81 years*) harboring the *C9orf72* G_4C_2 repeat expansion have been identified (4,8%), all of them with the clinical diagnosis of amnestic mild cognitive impairment based on their neuropsychological assessment. Two *cases were* initially *selected* because they presented atypical CSF levels of $A\beta_{1-42}$, T-tau, and P-tau_{181P}, whereas the remaining one had shown a negative PiB-PET imaging. The MRI scan revealed asymmetrical hippocampal atrophy in all cases, more pronounced in the left mesial temporal lobe. All patients had rapid progressive course to dementia within 12 months.
Conclusions: This study suggest that, albeit rare, *C9orf72* G_4C_2 expansion can be detected in clinical MCI patients. Therefore, our data underscore the utility of testing this particular mutation in clinical diagnosed AD or MCI patients with an asymmetrical pattern of hippocampal atrophy and in patients who presented atypical AD biomarkers profile. This procedure will correct misclassified FTLD cases with direct implications in genetic counseling of both patients and family members.

USING GENETICS, BIOMARKER AND MENDELIAN RANDOMIZATION TO IDENTIFY COMMON PATHWAYS AND GENES IMPLICATED ON ALZHEIMER'S AND PARKINSON'S DISEASE

C. Cruchaga[1]
[1]*Psychiatry., Washington University, St. Louis, USA*

Latest genetic studies suggest that there is some genetic overlap between Alzheimer's disease (AD) and Parkinson disease (PD). Similarly, recent studies also supports CSF Aβ and tau levels are potential biomarkers for not only AD but also PD. However it is not clear whether the difference in the CSF Aβ and tau levels is a cause or an effect of the disease. In this project we will use the ADNI, the PPMI, and Washington University genetic and biomarker data to identify common biomarkers and genetic risk factors for AD and PD.

Alzheimer's disease (AD) and Parkinson disease (PD) share common genes, pathways and biochemical biomarkers. A relative large proportion of PD cases also have memory problems. We also hypothesize that AD-related genes and pathways may explain the memory problems in those individuals.

In this project we will use the CSF Aβ, tau and α-synuclein levels together with the genetic information (used as instrumental variable) to perform mendelian randomization studies and determine whether the CSF Aβ, tau and α-synuclein levels are true endophenotypes for PD. Second, we will to use the CSF Aβ, tau and α-synuclein for genetic studies to identify additional variants associated with CSF protein levels and risk for AD and PD. Third, in this proposal, we plan to use genetic data (both rare and common variants) as well as biomarker levels to identify common genes and pathways between AD and PD.

We will present the results at the meeting.

CEREBROSPINAL FLUID BETA AMYLOID1–42 LEVELS IN THE DIFFERENTIAL DIAGNOSIS OF ALZHEIMER'S DISEASE – SYSTEMATIC REVIEW AND META-ANALYSIS

H. Kim[1], S. Kim[1], H. Han[2]
[1]Neurology, Hanyang University, Seoul, Korea
[2]Neurology, Myongii Hospital, Ilsan, Korea

ObjectivesThe purpose of this study was to carry out systematic review of the literature and meta-analysis to evaluate the diagnostic utility of cerebrospinal fluid Ab_{1-42} as a biomarker for differentiating Alzheimer's disease (AD) from non-AD dementia.
METHODS Design Systematicliterature review was used to evaluate the effectiveness of the Ab for the diagnosis of Alzheimer's disease. The Scottish Intercollegiate Guidelines Network (SIGN) tool was used by two evaluators to evaluate independently the quality of the 17 studies.**Data sources** The literature review covered from October 27, 1946, to October 22, 2013, and searched eight domestic databases including Korea Med and international databases including Ovid-MEDLINE, EMBASE, and Cochrane Library.**Data Extraction and Synthesis**Primary criteria for inclusion were valid studies on (i) patients with mild cognitive impairmentwith confirmed or suspected AD and non-AD dementia, and (ii) assessment of Ab_{1-42} levels using appropriate comparative tests.**Results** total of 17 studies were identified in which levels of CSF Ab_{1-42} were assessed. Meta-analysis was performed on eleven robust studies that compared confirmed AD with healthy individuals, 10 studies that compared AD with non-AD dementias, and 5 studies that compared a-MCI with na-MCI subjects. Overall, the CSF $Ab_{1–42}$ levels were reduced in patients with AD patients compared to healthy controls or non-AD dementia. The effectiveness of this test was evaluated for diagnostic accuracy (pooled sensitivity, 0.80 (95% CI 0.78–0.82); pooled specificity, 0.76 (95% CI 0.74–0.78).**Conclusions** Reduced CSF $Ab_{1–42}$ levels are of potential utility in the differential diagnosis of AD versus non-AD dementias and healthy controls.

EFFECT OF METAL CHELATORS ON THE AGGREGATION OF AMYLOID ? PEPTIDES IN THE PRESENCE OF METAL IONS

S. Emadi[1], F. Tahmasebinia[1]
[1]Biological Sciences, Institute for Advanced Studies in Basic Sciences, Zanjan, Iran

Redox-active metal ions, copper and iron, can bind to β-amyloid (Aβ) peptides in the brain of patients with Alzheimer's disease, and they have been implicated in Alzheimer's disease, as their dyshomeostasis and imbalance may induce aggregation of amyloidogenic peptide. In this work, first, we examined the formation of all types of Aβ40 and Aβ42 aggregates (oligomers, fibrils, and amorphous aggregates) in the presence of the added metal ions, iron and copper, by using fluorescence spectroscopy and atomic force microscopy. Copper and iron differentially altered the morphology of amyloid aggregates. The morphology is crucial for Aβ neurotoxicity and Alzheimer's disease progression. It has been proposed that Aβ oligomers are the most toxic species of Aβ and play a pivotal role in Alzheimer's disease pathogenesis. We have found that iron ions are involved in fibril formation and copper ions induce the formation of amorphous aggregates and oligomers and prevent the formation of fibrillary aggregates. Since metal chelation has been proposed as a therapy for Alzheimer's disease on the basis that it may prevent Aβ aggregation, we also investigated the metal chelating ability of two chelators, ethylenediaminetetraacetic acid and clioquinol (5-chloro-7-iodo-8-hydroxyquinoline), to bind these metal ions and the effects of them on metal-triggered amyloid-β aggregation. Our results showed that both clioquinol and ethylenediaminetetraacetic suppressed the iron ion-induced fibrillization and the copper ion-induced oligomerization of Aβ40 and Aβ42. They also induced changes in the morphology of Aβ aggregates.

ADPD5-1938
MOLECULAR INTERACTIONS OF GLYCODENDRIMERS IN ALZHEIMER´S DISEASE
D. Appelhans[1], O. Klementiva[2], E. Aso[3], I. Ferrer[3], J. Cladera[4]
[1]Bioactive and Responsive Polymers, Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany
[2]Department of Experimental Medical Science, Lund University, Lund, Sweden
[3]Institute of Neuropathology, IDIBELL-University Hospital Bellvitge, Barcelona, Spain
[4]Department of Biochemistry and Molecular Biology, Universitat Auto`noma de Barcelona, Barcelona, Spain
Objectives:
H-bond active glycodendrimers are presented as potential Anti-Alzheimer agent in-vitro and in-vivo. To examine Anti-Alzheimer effect of glycodendrimers in vitro and in vivo focusing on the molecular interactions against various amyloidogenic peptides ($A\beta_{1-28}$, $A\beta_{1-40}$, $A\beta_{1-42}$, and human AD brain extracted Aβ).
Methods:
Behavioral evaluation of AD transgenic mice treated with glycodendrimers, Confocal immunofluorescence microscopy, cell viability assay, fluorescence measurements, TEM, Western blot are used to analyze Abeta in cultured cells, in brains and primary neurons of wild type and AD transgenic mice.
Results:
Glycodendrimers are suited to modulate fibril formation of various amyloidogenic peptides and are partly able to reduce the toxicity of Alzheimer's disease brain extracts in human neuroblastoma cells. For in-vivo study both cationic and neutral glycodendrimers are capable to cross blood-brain-barrier and to modify the aggregation state of β-amyloid burden in APP/PS1 mice (*Biomacromolecules* **2011**, *12*, 3903; *New J. Chem.* **2012**, *36*, 350; *Biomacromolecules* **2013**, *14*, 3570). Recent progress is that partial substitution of maltose with histidine significantly increased the ability of PPI maltose dendrimers to cross the BBB and improves cognitive performance in APP/PS1 transgenic mice as a model of cerebral β-amyloidosis with similarities to familial AD.
Conclusions:
Cationic glycodendrimers do not outline the promising in-vivo properties as determined by neutral glycodendrimers. Next efforts are directed to integrate promising biologically active units in neutral glycodendrimers to understand a mechanism of glycodendrimer´s action as anti-Alzheimer agent under in-vivo.

MEMBRANE TOXICITY OF ABETA BY PORE FORMING MECHANISMS: INHIBITION BY A NOVEL PENTAPEPTIDE

C. Peters[1], E. Fernández-Pérez[1], D. Bascuñán[1], M.P. Espinoza[1], C. Opazo[2], L.G. Aguayo[1]

[1]Physiology Department, University of Concepcion, Concepcion, Chile

[2]Oxidation Biol. Lab., University of Melbourne, Melbourne, Australia

Objectives

Several studies suggest that beta amyloid (Abeta) fragments produced in the brain by enzymatic processing can generate toxic effects similar to those of $Abeta_{42}$. Here, we used fragments derived from different regions of Abeta with the aim of determining the role of each region on neurotoxicity. Moreover, we identified a neuroprotective pentapeptide having the sequence of the glycine zipper region of the C-terminal of Abeta ($G_{33}LMVG_{37}$).

Methods

In order to evaluate the neuroprotective pentapeptide and the toxicity of $Abeta_{1-28}$ (N-terminal region), $Abeta_{25-35}$ (central region) and $Abeta_{17-42}$ (C-terminal region), we performed patch clamp, immunofluorescence, western blot, FRET, electronic microscopy, calcium imaging and viability assays.

Conclusion

We conclude that Abeta fragments produced toxic effects similar to those observed with $Abeta_{42}$. The results suggest that the center region of Abeta (25-35) is important for membrane perforation and intracellular calcium increase; the N-terminal region (1-28) contributes to the increase in intracellular calcium, but not in the membrane perforation, likely by interacting with other calcium effectors; and the C-terminal region containing the fragment produced by the α-secretase (17-42) induced mitochondrial toxicity, but not membrane perforation and calcium increase, supporting the idea of less toxicity in the non-amyloidogenic pathway.

The effects of GLMVG could be explained by a direct interaction between Abeta and this pentapeptide, which prevents the synaptotoxic effects associated with Abeta that are initiated at the plasma membrane. These results provide a novel rationale for drug development against Alzheimer´s disease.

CONNECTIVITY ANALYSIS IN ALZHEIMER'S DISEASE (AD) BY INTERREGIONAL CORRELATION COMBINING [11C] PIB AND [18F] FDG PET

F. Reesink[1], M. Koole[2], B.M. De Jong[1], P.P. De Deyn[1], R.A. Dierckx[2]
[1]Neurology, University Medical Center Groningen (UMCG), Groningen, Netherlands
[2]Nuclear Medicine and Molecular Imaging,
University Medical Center Groningen (UMCG), Groningen, Netherlands

Objectives: to determine whether [^{18}F] FDG PET brain pattern correlates with [^{11}C] PIB uptake in AD specific brain region using a SPM (Statistical Parametric Mapping) based network analysis.
Methods: Combined [^{11}C] PIB and [^{18}F] FDG PET patterns data of 15 patients: 3 controls, 8 probable Alzheimer's disease and 4 possible Alzheimer's disease. We used Frontal Cortex and Precuneus as 'seed region' defining [11C]-PIB uptake normalized to cerebellum (CBL) as covariate for a multiple regression analysis of the corresponding [^{18}F] FDG PET data.
Results: PIB uptake in Precuneus (Figure 1) and Frontal Cortex (Figure 2) showed negative correlation with FDG uptake in the parietal cortex (Significance level uncorrected P= 0.005, Extend threshold = 50 voxels).
Conclusions: For specific brain regions PET PIB biomarker for amyloid load correlates with PET FDG biomarker representing brain glucose metabolism. The area of negative correlation is in the parietal cortex. Combined [^{11}C] PIB and [^{18}F] FDG PET scanning needs to be extended to confirm this negative correlation and investigate other functional networks of neurodegeneration.

Figure 1: Area of correlation PIB and FDG PET with Precuneus as 'seed region'

CORTICAL AND CEREBELLAR A-BETA OLIGOMERS AND A-BETA DEPOSITIONS IN NORMAL CONTROLS AND ALZHEIMER PATIENTS

C. Bouras[1], A. Savioz[1], E. Kovari[1], G. Gold[2], E. Giacobini[2]
[1]Psychiatry, HUG, Geneva, Switzerland
[2]Internal Medicine Rehabilitation and Geriatrics, HUG, Geneva, Switzerland

Objectives: presence (Western blots), the regional distribution and the co-localisation (immunohistochemistry) of ß-amyloid and oligomer-deposits were studied in cerebral and cerebellar cortex in controls and in Alzheimer's disease patients.
Methods: 69 cases (43-104 years old) were studied by immunohistochemistry using anti-Aß (4G8), anti-oligomer (NU-1 monoclonal antibody) and anti-tau (AT8) antibodies in the hippocampus and the temporal, frontal, occipital neocortex. Moreover, oligomers were examined with Western blots in the temporal cortex (TC) and in the cerebellum of 21 aged-matched cases (11 controls, 10 AD).
Results: A parallel evolution and a similar localization of oligomer deposits with Aß deposition were observed in all studied area. Co-localisation of amyloid deposition and oligomers was observed in the senile plaques. On Western blots all signals detected with the NU-1 antibody against the Aß-amyloid oligomers were present in all cases (controls and AD) in the cortex and in the cerebellum, despite the total absence of plaques in the TC of 6 controls and one «tau only AD», as well as in all cases in the cerebellum. Only the 48 kDa band, corresponding to a dodecamer in the TC and the cerebellum and was significantly increased in the AD patients and was statistically associated with the severity of plaque deposition of the TC.
Conclusions: Aß oligomers are globally present in the human brain aging and the dodecamer (48 kDa) is statistically associated with the severity of plaques. Aß-amyloid and oligomer deposition parallels in all cases in neocortical areas including hippocampal formation.

ADPD5-2142

THE RELATIONSHIP BETWEEN AMYLOID ANGIOPATHY AND CEREBRAL MICROBLEEDS IN A TWO YEARS AUTOPSY COHORT

E. Kovari[1], *G. Gold*[2], *C. Bouras*[1]
[1]*Psychiatry, HUG, Geneva, Switzerland*
[2]*Internal Medicine Rehabilitation and Geriatrics, HUG, Geneva, Switzerland*

1. Objectives

Cerebral microbleeds (CMB) are hemosiderin-containing macrophages around small vessels on histological examination. The physiopathology of CMBs is largely debated. Several authors report an association with hypertensive encephalopathy in basal ganglia CMB and more associated with amyloid angiopathy (CAA) in superficial, lobar lesions. The goal of our study was to examine the frequency of CMB in different brain regions and the relationship between CAA and CMB with histological and immunhistological methods in a non-selected autopsy population.

2. Methods

Four regions: the frontal, parietal, occipital cortex with the adjacent white matter and basal ganglia of 88 cases of consecutive autopsies with authorisation for research were examined. CMBs were identified on haematoxylin-eosin-stained histological slides, CAA using antibody anti-amyloid.

3. Results

CMBs were present in at least one region in 95.5 % of cases and CAA was observed in 46.6 % of this series. CMB were more frequent in the parietal and frontal lobe followed by the occipital region and basal ganglia. In contrast, CAA was most frequent in the occipital lobe. No statistical correlation was found between the two lesions. In lobar localisation, amyloid of the vessels was present in the cerebral cortex, in contrast to microbleeds, which were mainly in subcortical localisation and both affected different type of arteries.

4. Conclusions

CMB are frequent lesions in postmortem examination and are not associated with CAA, and affects different anatomical subregions and vessel type.

THE CO-EXISTENCE OF AN EQUAL AMOUNT OF ALZHEIMER'S AMYLOID-B 40 AND 42 FORMS STRUCTURALLY STABLE AND TOXIC OLIGOMERS THROUGH A DISTINCT PATHWAY

Y.J. Chang[1], Y.R. Chen[1]
[1]Chemical Biology, Genomics Research Center, Taipei, Taiwan

Fibrillar amyloid-β (Aβ) is the major constituent of senile plaques in the brain of patients with Alzheimer's disease (AD). Aβ is a short peptide generated from amyloid precursor protein with two main isoforms, Aβ40 and Aβ42, with the latter having two additional hydrophobic residues at the C-terminus. The two isoforms have distinct characteristics, in which Aβ42 plays a more pathogenic role. Some early-onset familial AD cases possess an elevated Aβ42/Aβ40 level, and biochemical studies show the two species interact with each other. Therefore, understanding structural conversion in the aggregation of mixed Aβ isoforms is essential for elucidating AD pathogenesis. Here, we systematically examined the differences among Aβ42, Aβ40, and various Aβ42/Aβ40 mixtures by monitoring the fibrillization kinetics, epitope changes, assembly, morphology, and induced cytotoxicity. We found the minor Aβ species in different mixing ratios modulated the major aggregation pathway. Size-exclusion chromatography, circular dichroism spectroscopy, and photo-crosslinking assay showed that soluble Aβ42 oligomers were stabilized after Aβ40 addition, and the equimolar Aβ42/Aβ40 mixture rapidly formed spherical oligomers. These oligomers were the most toxic among those examined as evidenced by neurite degeneration and neuronal toxicity. However, these oligomers were not responsible for intracellular calcium elevation. Overall, our results demonstrated that differently mixed Aβ species repartitioned oligomer intermediates on the major aggregation pathway. Furthermore, the equimolar mixture rapidly formed structurally stable and the most toxic oligomers. These results provided information on the potential pathological mechanisms underlying the elevated Aβ42/Aβ40 ratio in familial AD patients and in the local environment of sporadic AD brains.

GENETIC VARIANT OF AMYLOID BETA A2T MUTANT SLOW DOWN THE FIBRIL FORMATION AND REDUCE CELL CYTOTOXICITY

T. Lin[1], Y. Chen[1]
[1]Genome Research Center, Academia Sinica, Taipei, Taiwan

Alzheimer's disease (AD) is the most common dementia in the world. Dementia describes significant loss of certain mental functions such as memory, attention, and abstract thinking. The primary neuropathologic hallmark in AD is amyloid plaques. Plaque formation results from increased production or decreased clearance of amyloid beta peptide, which is generated by proteolytic cleavage of the amyloid precursor protein (APP). Genetic mutations reside in APP gene result in familial AD that cause early-onset. Most APP mutations are found in and around abeta region. Previous study showed that the mutations located in N-terminus of abeta, such as the English (H6R) and Tottori (D7N) mutations, would promote fibril formation and increase cell toxicity. However, A673T mutant (A2T in abeta numbering) located in abeta N-terminus close to the beta-secretase cleavage site not only affect the production of abeta but also showed low-prevalence incidence of AD compared to the normal controls. In this study, we used several aggregation and toxicity assays to elucidate the differences reside in wile type, A2T mutant, and A2V mutants. We found that fibril formation in A2T mutantsignificantly retarded and induced less neurotoxicity. The results suggest that N-terminus mutation on abeta could alter its aggregation and toxicity property even though it is not included in the current abeta oligomer and fibril structural models. Further investigation on the involving residues at the N-terminal region is undergoing.

NITRATION OF Y10 IN AB1-42 HAS SIGNIFICANT EFFECTS ON ITS AGGREGATION

J. Zhao[1], Z. Gao[1], H. Li[1]
[1]School of Chemistry and Chemical Engineering,
Huazhong University of Science & Technology, Wuhan, China

Alzheimer's diease（AD）is a neurodegenerative disease that is characterized by the deposition of A β_{1-42}.What's more， oxidative /nitrative stress is always detected in patients brain. So，in this way， A β_{1-42} is easy to be nitrated. We used synthetic nitrated peptide to study the effects of nitration of Y10 of A β_{1-42}.We used thioflavin-T（ThT）binding assay and transmission electron microscopy （TEM）to test the aggregation of nitrated A β_{1-42}. We found that nitration of Y10 of A β_{1-42} has significant effects on its aggregation. It can reduce the aggregation of A β_{1-42}. As we know，the formation of oligomers of A β_{1-42} was believed to play a crucial role in AD.These results may suggest that nitration of A β_{1-42} can reduce the toxicity of A β_{1-42} .Our founding may lead a detailed understanding of the function of A β_{1-42} and be helpful in curing AD.

HEPARAN SULFATE IN NEUROPATHOLOGY IN AMYLOID-BETA PRECURSOR PROTEIN TRANSGENIC MICE

C. Jendresen[1], H. Cui[2], X. Zhang[3], I. Vlodavsky[4], L. Nilsson[1], J.P. Li[2]
[1]Department of Pharmacology, University of Oslo and Oslo University Hospital, Oslo, Norway
[2]Department of Medical Biochemistry and Microbiology, University of Uppsala, Uppsala, Sweden
[3]Department of Neuroscience, University of Uppsala, Uppsala, Sweden
[4]Cancer and Vascular Biology Research Center Rappaport, Technion, Haifa, Israel

Objectives:
Heparan sulfate (HS) co-localize with amyloid-beta (Aβ) deposits in Alzheimer's disease (AD) brain and in Aβ precursor protein (AβPP) transgenic mice. HSPGs are widely expressed in extracellular matrices and at cell surfaces, but their pathogenic role in AD is unclear. Our aim was to test if HS participates in Aβ-pathogenesis *in vivo* relating to immune-based mechanisms.
Methods:
Heparanase degrades HS, the glycosaminoglycan side-chains of HSPGs. We compared neuropathology in 15-months-old transgenic mice overexpressing both human heparanase and human AβPP with the Swedish mutation (tgHpa*Swe, n=17) and AβPP single-transgenic mice (tgSwe, n=17). Brains were examined with Congo red and Aβ- and HS-immunohistochemistry. For AβPP-processing, Aβ and sAβPPβ levels were measured in 2.5-months-old mice by ELISAs and western blots. Finally, we investigated the effect of heparin on $Aβ_{1-42}$-aggregation in an *in vitro* Thioflavin T assay.
Results:
The double-transgenic tgHpa*Swe mice had significantly lower amyloid burden (p_{x-42}-burden (p_{1-42}-aggregation *in vitro* (p_{x-40}, and $Aβ_{x-42}$ in 2.5-months-old mice did not differ. Preliminary data of the influence of a peripheral inflammatory stimulus will also be presented.
Conclusions:
HS contributes to amyloid deposition in tgSwe mice by increasing Aβ fibril formation, since the HS-like glycosaminoglycan, heparin, increased $Aβ_{1-42}$ aggregation *in vitro* and heparanase-induced fragmentation of HS led to reduced amyloid burden *in vivo*. Heparanase overexpression did not directly alter AβPP processing in young tgHpa*Swe mice.

PORTABLE AMYLOID AGGREGATION ASSAYS
D. Barrettino[1], R. Nitsch[2]
[1]Department of Technology and Innovation (DTI),
University of Applied Sciences of Southern Switzerland (SUPSI), Manno, Switzerland
[2]Division of Psychiatry Research, University of Zurich, Zurich, Switzerland
This paper presents the design of portable amyloid aggregation assays for sorting amyloid-beta (Abeta) aggregates by size using nanochannels and then measuring the concentrations of the different Abeta aggregation stages using nanoreactors. In addition, this portable device not only will keep the sample of cerebrospinal fluid (CSF) at a controlled temperature after the extraction, but also will allow to study the correlation between the different Abeta aggregation stages and their cytotoxicity.
First, the CSF sample will be injected into the sampling section. Most of the fluid will be sent to the storage reservoir for the cytotoxicity tests, but a small fraction will be injected into the analytical system. Then, in the sample preparation section, the CSF will be processed to avoid further Abeta aggregation (e.g., by chemical cross-linking), thus ensuring the biological relevance of the analysis. After the injection of the reagents needed to avoid further aggregation, the sample will go through several loops, thus ensuring complete mixing with the reagents. Finally, in the detection/separation section, the sample will go through a series of reservoirs separated by arrays of nanochannels of different widths and heights (from 10nm to 200nm), thus sorting the Abeta aggregates of the CSF sample according to their sizes. Once the sorting is performed, the concentrations of the different Abeta aggregation states will be quantified in each reservoir by nanoreactors, which consist of antibody-functionalized vesicles containing enzymes that can specifically bind to the Abeta aggregates and then can be captured by a surface immobilized primary antibody (IgG).

CLINICAL FEATURES OF ALZHEIMER'S DISEASE WITH LEWY BODIES

E.J. Chung[1], G.M. Babulal[2], C.M. Roe[2], S.E. Monsell[3], N. Cairns[2], J.C. Morris[2]
[1]Neurology, Inje University Paik Hospital, Busan, Korea
[2]Neurology,
Knight Alzheimer's Disease Research Center Washington University School of Medicine, St. Louis, USA
[3]Neurology, National Alzheimer's Coordinating Center University of Washington, Seattle, USA

Objectives. Among those with Alzheimer's disease (AD), we examined the clinical differences between individuals with and without Lewy body (LB) pathology.
Methods. A total of 531 participants who met neuropathologic criteria for 'high' and 'intermediate' "likelihood" of AD according to the National Institute on Aging-Ronald Reagan Institute guidelines were included. All participants underwent a clinical assessment within two years of death. Chi-square and t-test were used for unadjusted analyses and general linear models were used for adjusted analyses.
Results. Age at onset and age at death were lower among participants with LBs than without. Men more often had LBs. Participants with LBs more often had a demented parent and at least one *APOE* ε4 allele. After adjustment for age, gender, education, neuritic and diffuse plaques, and tangles, scores on the Geriatric Depression Scale (GDS), Neuropsychiatric Inventory Questionnaire (NPIQ), the Unified Parkinson's Disease Rating Scale (UPDRS) motor scale and Wechsler Adult Intelligence Scale-Revised Digit Symbol subtest were more severe for participants with LBs.
Conclusions. In AD, LBs presence related to a younger age at onset and death. Persons with LBs are more often male, have had a parent with a history of dementia and have at least one *APOE* ε4 allele. Participants with LBs have more depressive symptoms, neuropsychiatric symptoms, motor disturbances and slower visual-motor processing. Comorbid Lewy body pathology in AD results in a different clinical phenotype.

INTERLEUKIN-1 DRIVES PROTEIN AGGREGATION IN ALZHEIMER'S DISEASE AND PARKINSON'S DISEASE

S. Griffin[1], P. Parcon[1], R. Jones[1], J. Biedermann[1], L. Liu[1]
[1]Geriatrics, UAMS Reynolds Institute on Aging, Little Rock, USA

A growing body of evidence establishes neuroinflammation as central in the pathogenesis of both Alzheimer's (AD) and Parkinson's (PD). Here we show evidence that the pluripotent pro-inflammatory cytokine IL-1 regulates the synthesis and function of two of the major components of protein degradation and/or recycling.
Objective: To define and characterize the relationship between IL-1, Parkin, and NEDD8 in human AD and PD, an animal model, and human neuronal cell cultures.
Methods: Using immunohistochemistry and Immunofluorescence, we probed the intercellular localization of NEDD8 and Parkin in cell culture and human brain from AD, PD, and controls. We measured IL-1 and Parkin levels in an AD mouse model and measured Parkin levels in response to IL-1 in primary rat and human (NT2) neuronal cultures.
Results: In an animal model of AD, IL-1 and E3 ubiquitin ligase Parkin increased with age. Further, we showed that neuronal IL-1 treatment increases Parkin expression and mediates translocation of its activator NEDD8. Importantly, in human brain, NEDD8 immunoreactivity is absent in the nucleus and Parkin is aggregated and increased in both AD and PD compared to that in age-matched controls.
Conclusions: Our results are consistent with the idea that IL-1 is a driver of neddylation dysfunction and Parkin aggregation in AD and PD. Thus, we predict that early intervention to appropriately regulate IL-1 expression and activity would prevent or delay protein recycling dysfunctions in neurodegenerative disease, and may be generalized to all disorders characterized by glial activation and IL-1 overexpression. Supported by AG12411 and the Windgate Foundation.

[3]Occupational therapy, Bishoen, Suzu, Japan
[4]Neurology, Iou Hospital National Hospital Organization, Kanazawa, Japan
[5]Enviromental and Preventive Medicine, Kanazawa University, Kanazawa, Japan

Objectives
We aimed to determine whether the consumption of green tea, coffee, or black tea is associated with the incidence of dementia and mild cognitive impairment (MCI) in the general population.
Methods
We conducted a population-based prospective study with Japanese residents aged >60 years from Nakajima, Japan (the Nakajima Project). Participants received an evaluation of cognitive function and blood tests. The consumption of green tea, coffee, and black tea was also evaluated at baseline.
Results
Of 723 participants with normal cognitive function at a baseline survey (2007-2008), 490 completed the follow up survey in 2011-2013. The incidence of dementia during the follow-up period (mean ± SD: 4.9 ± 0.9 years) was 5.3%, and that of MCI was 13.1%. With regard to the incidence of dementia, multiple-adjusted odds ratio was 0.26 (95% CI: 0.06–1.06) for consuming green tea every day compared with those who did not consume green tea at all. Regarding the incidence of cognitive decline (dementia or MCI), multiple-adjusted odds ratio was 0.32 (95% CI: 0.16–0.64) among individuals who consumed green tea every day and 0.47 (95% CI: 0.25–0.86) among those who consumed green tea 1–6 days per week compared with individuals who did not consume green tea at all.
No association was found between coffee or black tea consumption and the incidence of dementia or MCI.
Conclusions
Higher green tea consumption was associated with lower incidence of cognitive decline (dementia or MCI), even after adjustment for possible confounding factors.

LOW DOSE CO-APPLICATION OF CELASTROL AND ARIMOCLOMOL INDUCES HEAT SHOCK PROTEINS IN DIFFERENTIATED HUMAN NEURONS: RELEVANCE TO NEURODEGENERATIVE DISEASE TREATMENT

I. Brown[1], *C. Deane*[1]
[1]*Centre for the Neurobiology of Stress, University of Toronto Scarborough, Toronto, Canada*

Neurodegenerative diseases such as Alzheimer's, Parkinson's, and Amyotrophic Lateral Sclerosis (ALS) have been termed 'protein misfolding disorders' that are characterized by the accumulation of aggregation-prone, misfolded proteins which trigger pathogenic cascades that lead to cell death in specific populations of neurons. Heat shock proteins (Hsps) are protein repair agents which can detect and repair misfolded proteins. Upregulation of Hsps has been suggested as a potential therapeutic strategy to combat neurodegenerative protein misfolding disorders. Celastrol induces Hsps by acting on heat shock transcription factor 1 (HSF1). Arimoclomol is a co-inducer of Hsps that potentiates their induction. *In vivo* administration of celastrol in a mouse model of Alzheimer's reduces a key neuropathological feature, namely aggregation of amyloid-beta protein, while *in vivo* administration of arimoclomol in a mouse model of ALS delays the time course of the disorder. Using differentiated SH-SY5Y human neuronal cells, we examined if co-application of celastrol and arimoclomol, at low dosages that do not affect cell viability or neuronal process morphology, triggered induction of Hsps in neurons that is greater than that obtained by their individual application. Low dosage co-application induced Hsps in the human neuronal cells whereas single application did not. Hence this may represent a promising strategy to upregulate a set of neuroprotective Hsps in the treatment of neurodegenerative diseases. Supported by grants from NSERC, Canada and a Canada Research Chair (Tier I) in Neuroscience to IRB.

ADPD5-0456

STRESS-INDUCED LOCALIZATION OF HSP70 HEAT SHOCK PROTEINS TO DISCRETE CYTOPLASMIC AND NUCLEAR STRUCTURES OF DIFFERENTIATED HUMAN NEURONS BY LIVING IMAGING AND FRAP

I. Brown[1], S. Shorbagi[1]

[1]Centre for the Neurobiology of Stress, University of Toronto Scarborough, Toronto, Canada

Heat shock proteins (Hsps) are protein repair agents that can detect and refold misfolded, aggregation-prone proteins that accumulate during neurodegenerative diseases, such as Alzheimer's, Parkinson's and ALS, triggering pathogenic cascades that result in cell death in specific populations of neurons. The localization of Hsps to particular cytoplasmic and nuclear sites was employed as an index to identify structures in differentiated human neuronal SH-SY5Y cells that are particularly sensitive to cellular stress and require the recruitment of Hsps to refold misfolded, aggregation-prone neuronal proteins. Live imaging, using spinning disk microscopy, revealed that YFP-tagged members of the Hsp70 multigene family rapidly localized to discrete neuronal cytoplasmic structures (centrioles) after cellular stress and also to particular elements of the nucleus (nuclear speckles, rich in RNA splicing factors, and the nucleolus). The cytoplasmic and nuclear structures that were targeted by the YFP-tagged HSPA6 (Hsp70B' protein) and HSPA1A (Hsp70-1 protein) were subjected to FRAP (Fluorescence Recovery After Photobleaching). The recovery kinetics, after laser induced photobleaching, demonstrated that the stress-induced recruitment of the Hsp70 proteins into specific cytoplasmic and nuclear structures of human neuronal cells was highly dynamic. Supported by grants from NSERC, Canada and a Canada Research Chair (Tier I) in Neuroscience to IRB.

DESIGN OF SPECIFIC DNA PRIMERS TO DETECT OF VARIABLE CLU GENOMIC LESIONS IN ALZHEIMER'S DISEASE

V.V. Giau[1], E. Bagyinszky[1], S.C. Kim[1], S. Kim[2], S.S.A. An[1]
[1]Department of Bionano Technology, Gachon University, Seongnam, Korea
[2]Department of Neurology, Seoul National University Bundang Hospital, Seongnam, Korea

Recently has been implicated polymorphisms on clusterin (CLU) gene is significantly associated with lipid metabolism, atherogenesis and Alzheimer's disease (AD). However, the influence of genetic variation has not been examined in Korean. So far, there were many techniques have been developed for genome-wide analysis of fusion genes, a more efficient method is desired. In this study, we have developed PCR primer pairs that target specific regions of previously sequenced genes from CLU gene. Primers were targeted to amplify 8 exons, and flanking region its genes which were optimized PCR analysis. This study comprised ten Alzheimer's disease (AD) patients, one Parkinson's disease (PD) patients and two transient global amnesia (TGA) patiens were selected for genotyping. We identified four nucleotide sequence polymorphisms (SNPs) in APOJ/CLU, by direct sequencing from PCR products. These include there (rs7982, rs2279590 and rs3216167) previously reported variants in the SNP database (dbSNP) established by NCBI and as well as one new (NEW1) or extremely low frequency mutations was found in more than one individual in LOAD subjects. Our study suggests that CLU variants may be an AD susceptibility factor in southern Korean population. Larger genetic studies in different ethnics and future metaanalysis are needed to clarify the relationship between the CLU gene and AD.

Objectives: Alzheimer's disease (AD) is the most common cause of dementia. Recently, many studies support the oligomer hypothesis that soluble amyloid β (Aβ) oligomers are primarily neurotoxic and affect synaptic plasticity. However, it is unclear whether production of Aβ oligomers would actually increase or not in AD. We examined the production of Aβ protein species in cultured cells expressing mutants of an amyloid precursor protein (APP) linked to Alzheimer's disease in order to determine the common biochemical abnormalities of Aβ formation in various FAD mutations. Methods: Flp-In 293 cells were transfected with wild-, Swedish-, Dutch- and London-type mutant APP, and cultured for two days. We measured the amount of Aβ1-40, Aβ1-42 and Aβ oligomer species in culture media with Western blotting and ELISA. We performed comparative analyses of the productive potencies of Aβ monomer and oligomers among cultured cells harboring wild-type and mutated APP genes. Results: The amounts of both Aβ1-42 and Aβ1-40 secreted from the cells with Swedish-type APP were about ten times more than those with wild-type APP. In London-type APP, the Aβ1-42/Aβ1-40 ratio was increased. Western blotting of culture media using 6E10 antibody showed an intense band of Aβ monomer in cells with wild-type and mutant APP. The amount of Aβ oligomers increased in all the cultured media of cells with the 3 different APP mutants, compared with that of cells with wild-type APP.
Conclusion: We propose that increase in the secretion of Aβ oligomers is the common biological abnormalities in various APP mutants related to FAD.

ENDOCYTIC DISTURBANCE DISRUPTS ABETA CLEARANCE IN ASTROCYTES WITHOUT AFFECTING ABETA UPTAKE.

N. Kimura[1], S. Okabayashi[2], F. Ono[2]
[1]Department of Alzheimer's Disease Research,
National Center for Geriatrics and Gerontology, Aichi, Japan
[2]Section of Research Support,
The Corporation for Production and Research of Laboratory Primates, Ibaraki, Japan

We previously showed that aging attenuates the interaction between dynein-dynactin complexes in cynomolgus monkey brain and that dynein dysfunction reproduces age-dependent endocytic pathology such as intracellular accumulation of abnormally enlarged endosomes and endosomal APP accumulation. On the other hand, it remains unclear whether such age-dependent endocytic disturbance also occurs in glial cells. Here, we show that intracellular accumulation of enlarged endosomes occurs even in astrocytes of aged monkey brains. Moreover, we found that Abeta accumulates in these enlarged endosomes. RNA interference studies demonstrated that dynein dysfunction reproduces astroglial endocytic pathology and disrupts Abeta clearance in astrocytes via endocytic disturbances without affectin its uptake. These findings suggest that endocytic disturbance can alter astroglial functions and also may be involved in age-dependent Abeta pathology.

ADPD5-0513

INTRABODY-BASED CONFORMATIONAL-SELECTIVE INTERFERENCE WITH Aß OLIGOMERS IN LIVING CELLS TO DISCOVER NEW SUBCELLULAR MECHANISMS OF ALZHEIMER'S DISEASE

G. Meli[1], A. Manca[1], N. Krako[1], C. Scopa[1], R. Scardigli[2], V. Fugnanesi[3], M. Morbin[3], P. Sarti[4], A. Cattaneo[5]

[4]Biochemistry, University La Sapienza, Rome, Italy
[5]EBRI-Roma, Scuola Normale Superiore, Pisa, Italy

Objectives

Aß oligomers (AßOs) are recognized as the most neurotoxic species in Alzheimer's Disease (AD) but they are still mysterious in terms of assembly, traffic and actions in living cells.

Recently, we established a new subcellularly-localized Conformational-Selective Interference (CSI) approach (Meli et al., Nat Comms 2014) by which we demonstrated that intracellular Aβ undergoes pathological oligomerization through critical conformations formed inside the endoplasmic reticulum (ER).

Here, we study the functional effects mediated by the ER-localized CSI on some AD-relevant subcellular alterations and mitochondrial disfunctions, in order to discover new subcellular mechanisms in AD pathogenesis.

Methods

The CSI approach is based on the expression of conformation-sensitive anti-AßOs antibody fragments as intracellular antibodies (intrabodies), targeted to the ER.

The ER-localized intrabody is expressed in some AD-relevant cell lines and in different primary cells derived from the AD mouse models, such as the neuronal stem cells (NSC) from adult brain subventricular zone (SVZ).

Subcellular and mitochondrial alterations are evaluated by morphological, bioenergetic and biochemical studies.

Results

Conformational-sensitive intrabodies targeted to the ER control the levels and the assembly state of intracellular and extracellular AßOs. This triggers a strong rescue of mitochondrial dysfunctions and bioenergetic deficits in CHO cell lines carrying fAD APP mutations. Ultrastructural changes on mitochondrial-ER junctions can be observed. Studies on primary cells are in progress.

Conclusions

The anti-AßOs intrabodies are unique tools to study the intracellular actions of AßOs; in this way we are deciphering new functional links ER-mitochondria and subcellular mechanisms relevant in the AD pathogenesis

ADPD5-0546

SEPT5 AND ITS POTENTIAL ROLE IN THE MOLECULAR PATHOGENESIS OF ALZHEIMER'S DISEASE

J.M. Marttinen[1], K.M.A. Kurkinen[1], H. Soininen[2], A. Haapasalo[1], M. Hiltunen[3]
[1]Institute of Clinical Medicine - Neurology, University of Eastern Finland, Kuopio, Finland
[2]Department of Neurology, Kuopio University Hospital, Kuopio, Finland
[3]Institute of Biomedicine, University of Eastern Finland, Kuopio, Finland

Objectives: Septins are a highly conserved family of guanosine triphosphate-binding proteins, which play a central role in the axonal transport and vesicle trafficking in the synapses. Particularly SEPT5 has been shown to interact with syntaxin-1 of the SNARE complex and regulate synaptic vesicle (SV) localization at the presynaptic terminal. Furthermore, SEPT5 interacts with SEPT8, which in turn has been suggested to impact SV recycling. Thus, SEPT5 is a potential target for further studies in the molecular pathogenesis of Alzheimer's disease (AD).
Methods: Here, we have investigated the possible alterations in SEPT5 mRNA expression and splicing in relation to the AD-related neurofibrillary pathology in the temporal cortex of human brain. Furthermore, we investigated whether the siRNA-mediated down-regulation of SEPT5 in human SH-SY5Y neuroblastoma cells impacts amyloid precursor protein (APP) processing and amyloid-β (Aβ) production.
Results: Our data suggest that the expression of SEPT5 is moderately decreased in relation to AD-related neurofibrillary pathology in the brain and that the down-regulation of SEPT5 reduces β-secretase (BACE1), soluble APPβ and Aβ levels *in vitro*.
Conclusions: Considering the known mechanistic functions and interactions of SEPT5, our results suggest that SEPT5 plays a role in the regulation of post-translational levels and activity of BACE1. Further characterizations of the potential role of SEPT5 in the early molecular pathogenesis of AD are currently undergoing.

ADPD5-0556

APP A673T MUTATION REDUCES NOT ONLY BETA-CLEAVAGE BUT ALSO GAMMA-CLEAVAGE OF APP IN CELLS

S. Funamoto[1], S. Ishihara[1], A. Kokawa[1], M. Nobuhara[1], Y. Ihara[1]
[1]Neuropathology, Doshisha University, Kyotanabe City, Japan

Objective: APP A673T mutation has been reported to protect against Alzheimer's disease and age-related cognitive disorders by reducing β-cleavage of APP (Jonsson et a., 2012). Although A673T reduces productions of sAPPβ and Aβ, it is unclear whether this mutation causes a concomitant reduction in C99 production leading to reduced Aβ level. The aim of this study is to examine main effects of A673T mutation on Aβ production.

Methods: (1) We expressed A673T APP in CHO cells to examine intracellular level of β-cleaved fragment of APP, C99. (2) We expressed A2T C99 (equivalent to A673T APP) in the cells to evaluate Aβ production. (3) We performed sucrose gradient centrifugation to visualize subcellular distribution of A2T C99 in the cells.

Results: (1) Although the level of sAPPβ in medium was significantly reduced, no concomitant reduction in intracellular C99 was observed in cells expressing A673T APP. (2) Aβ level from cells expressing A2T C99 was roughly 50% of those expressing WT C99. Cell free assay using microsomal fraction indicated that Aβ produced from A2T C99 was significantly reduced, compared to that from WT C99. (3) Sucrose gradient centrifugation revealed that A2T C99 was less associated with lipid raft, compared to WT C99.

Conclusion: APP A673T mutation causes an improper subcellular localization of C99, which alters Aβ production in cells.

CHARACTERIZATION OF AN ISOGENIC DISEASE MODEL OF ALZHEIMER'S DISEASE FROM HUMAN IPS CELL-DERIVED NEURONS

S. Lange[1], C. Carlson[1], J. Wang[1], N. Aoyama[1], K. Mangan[1], M. McLachlan[2], T. Burke[2], S. De Laura[3], A. Thompson[1], E. Jones[3], V. Ott[3]
[1]Applications & Support, Cellular Dynamics International, Madison, USA
[2]Research & Development, Cellular Dynamics International, Madison, USA
[3]Product Management, Cellular Dynamics International, Madison, USA

Objectives: Mutations in the gene encoding beta amyloid precursor protein (APP) have been linked with the progression of Alzheimer's Disease (AD). Leveraging our ability to produce previously inaccessible human neurons from iPS cells, we made biologically relevant AD disease models incorporating two APP mutations of interest as part of our Disease and Diversity Products that represent an array of both healthy and disease-specific backgrounds.
Methods: Using a TALEN-mediated SNP alteration, we introduced APP A673V or APP A673T gene mutations into a 'control' iPS cell line (01279.107) from an apparently normal healthy Caucasian male donor (no family history of neurological disorders). Cortical neurons were differentiated from these three unique isogenic iPS cell lines. Gene expression was analyzed by target- and disease-focused PCR arrays. Levels of AD-related biomarkers (i.e., sAPPα, Aβ 1-40, and Aβ 1-42) were quantified using various HTS-compatible assays (i.e., HTRF and AlphaLISA). The network-level activity of neurons from each background was evaluated on multi-electrode array (MEA).
Results: Here, we present data characterizing the gene expression and functionality of these neurons. Results from the HTS-compatible assays and MEA showed differences in functionality between the allele variants. Additionally, we present their individual responses to pharmacological modulation.
Conclusions: These data illustrate how human neurons derived from isogenic iPS cell lines provide a biologically relevant disease model that can be used to study AD in a dish.

DISTRIBUTION OF AMYLOID-BETA PROTEIN PRECURSOR AND SECRETASES IN CORTICAL SYNAPSES OF MICE: MODIFICATIONS IN EARLY ALZHEIMER'S DISEASE CONDITIONS.

P. Agostinho[1], A. Pliássova[1], J.P. Lopes[2], C. Lemos[2], C.R. Oliveira[1], R.A. Cunha[1]
[1]Center for Neuroscience and Cell Biology & Faculty of Medicine, University of Coimbra, Coimbra, Portugal
[2]Center for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal

Background and Objectives: An unbalanced proteolytic cleavage of amyloid-β precursor protein (APP) can result in an increased amyloid β peptide (Aβ) production and, consequently, in AD onset. Although it is widely accepted that synaptic Aβ metabolism is crucial for AD initial damage, the distribution of APP and secretases in different nerve terminals remains to be clarified. This study aims to investigate if the cortical synaptic levels of APP and of the secretases involved in APP proteolysis, BACE1 and ADAM10, are affected under AD conditions, using a mice model of AD.
Methods and Results Western blot analysis revealed that APP was located mainly in the pre-synaptic active zone (53.1 ± 5.5%) and in post-synaptic regions (37.1 ± 2.6%), ADAM10 was enriched in post-synaptic regions (61.3 ± 4.3%,), whereas BACE1 was concentrated in extra-synaptic zone (72.5 ± 4.9%). Immunocytochemistry analysis revealed that APP and BACE1 were present in glutamatergic and GABAergic nerve terminals and these proteins were co-localized in about 30% of these nerve terminals. Moreover, in mice intracerebroventricularly injected with $A\beta_{1-42}$ that displayed hippocampal-dependent memory deficits and a decrease in long-term potentiation, the levels of APP and ADAM10 increased by 30%, whereas the levels of BACE1 were significantly reduced.
Conclusions: The results provide the first comparative analysis of the synaptic and sub-synaptic distribution of APP and secretases in cortical brain regions of mice and show that, in early AD, there are compensatory mechanisms to avoid Aβ overload.

IDENTIFYING THE TOXIC ABETA OLIGOMERIC SPECIES BY CORRELATING NEUROTOXICITY AND ABETA BINDING TO NEURONS

M. Jana[1], R. Cappai[1], C.L.L. Pham[1], G. Ciccotosto[1]
[1]Pathology, The University of Melbourne, Melbourne, Australia

OBJECTIVES: Soluble Aβ oligomers (AβO) have been proposed as the key toxic Aβ species causing Alzheimer's disease (AD) brain pathology. The identity of the toxic oligomeric Aβ species remains unclear. We hypothesized that a specific AβO species binds to neurons inducing synaptic dysfunction and neuronal cell death. We identified the toxic AβO species that bound to neurons and correlated with neuronal death. The role of caspases in AβO-induced neurotoxicity was investigated as a possible mechanistic pathway of cell death. METHODS: Mouse (C57/BL6) primary cortical neurons (6 days in vitro) were treated with synthetic soluble Aβ40, Aβ42 and purified AβO (Aβ40; 1mer – 4mer prepared using PICUP technique) for up to 96 hours. Cell viability, Aβ binding to neurons and caspase (3, 6 and 8) levels were determined. RESULTS: Neurons treated with synthetic Aβ42 peptide caused neurotoxicity in a time dependent manner. This neurotoxicity significantly correlated with the presence of bound 3mer and 4mer AβO species. Treatment with purified AβO 4mer and 3mer oligomers were up to 50-fold more toxic than monomerised Aβ40 peptide. Soluble Aβ peptides induced cell death via caspase 3-dependent apoptotic pathway while the purified AβO induced cell death via non a caspase-dependent pathway. CONCLUSIONS: This study proposes that Aβ 4mer and 3mer are the most toxic of the lower molecular weight AβO species.

ADPD5-0656

BRILLIANT BLUE G DYE ATTENUATES ABETA OLIGOMER INDUCED NEUROTOXICITY BY DECREASING ABETA BINDING TO NEURONS

M. Jana[1], R. Cappai[1], G. Ciccotosto[1]
[1]Pathology, The University of Melbourne, Melbourne, Australia

OBJECTIVES: Brilliant blue G dye (BBG) is a primary component of the coomassie blue staining solution which is typically used for staining proteins on gels. But BBG has been shown to cross the brain blood barrier and act as a neuroprotective agent in various animal models including migraine, Huntington's disease, and Alzheimer's disease (AD). BBG has been shown to inhibit Beta Amyloid (Aβ) aggregation and its toxicity in cell culture models but the mechanism of how BBG in decreasing Aβ toxicity is unclear. Since Aβ oligomers (AβO) need to bind to neurons and cause significant neurotoxicity, we hypothesized that BBG attenuates AβO-induced neurotoxicity by decreasing Aβ binding to neurons. METHODS: Photo-induced cross-linking technique was used to generate and purify AβO (1mer-4mer). Mouse (C57/BL6) primary cortical neurons (6 days in vitro) were treated with purified AβO (with and without the presence of BBG) for up to 96 hours. Cell viability and Aβ binding to neurons were determined following treatments. RESULTS: AβO showed decreased neurotoxicity in the presence of BBG (at least 2 fold). This was accompanied with decreased AβO binding to neurons in the presence of BBG. CONCLUSIONS: This study showed that BBG attenuates AβO-induced neurotoxicity by decreasing AβO binding to neurons. Since BBG can enter the brain and inhibit Aβ binding and neurotoxicity, further studies are required to determine whether BBG has any therapeutic potential in treating AD.

BEXAROTENE AND ASTAXANTHIN MODULATE CHOLESTEROL AND AMYLOID-BETA METABOLISM IN AN IN VITRO MODEL OF THE BLOOD-BRAIN BARRIER

E. Fanaee-Danesh[1], M. Zandl[1], A. Chirackal Manavalan[1], A. kober[1], Y. sun[1], J. Pippal[1], U. Panzenböck[1]

[1]medical university of graz, Institute of Pathophysiology & Immunology, Graz, Austria

Using an *in vitro* model of the blood-brain barrier (BBB) we have shown that primary porcine brain capillary endothelial cells (pBCEC) express and release apoA-I that may assemble with cellular cholesterol to form HDL, a pathway that is enhanced by treatment with nuclear receptor agonists. These apo/lipoproteins may also interact with Aβ or its precursor protein (APP). Pharmacological modulation of cellular cholesterol metabolism could contribute to redirect APP synthesis and processing by cerebromicrovascular endothelial cells towards the beneficial, non-amyloidogenic pathway. This study aims to investigate the effects of a pharmacologic retinoid-X receptor (RXR) agonist, bexarotene, and PPAR-α agonist, astaxanthin, on pathways of APP processing, Aß production and transfer across the BBB, and on the (mechanisms of) formation and remodeling of HDL particles. Primary porcine (p)BCEC were incubated with bexarotene or astaxanthin. Protein and mRNA expression levels of apoA-I, apoJ, APP/Aβ, ABCA1, ABCG1 were measured. Furthermore, effects of bexarotene and astaxanthin on time-dependent [^{3}H]-cholesterol release from pBCEC were studied in the presence of apoA-I or HDL acceptor particles. Real-time PCR and immunoblotting analyses suggest a higher expression of both ABCA1, ABCG1 and APP and decreasing levels of Aβ oligomers. Cellular cholesterol efflux, the obligatory first step of reverse cholesterol transport, was enhanced after administration of [100 nM] bexarotene or [1 nM] and [10 nM] of astaxanthin with both acceptors. Our results, thus far, suggest that these two NR agonists exert beneficial effects on cholesterol and Aβ metabolism in cerebrovascular cells.

ADPD5-0691

INTRANEURONAL AMYLOID BETA OLIGOMERS CAUSE ABERRANT SPINE MORPHOLOGY AND DISRUPT AXONAL AND DENDRITIC TRAFFICKING INDEPENDENTLY OF TAU

T. Umeda[1], M. Silverman[2], H. Mori[1], T. Tomiyama[1]
[1]Department of Neuroscience, Osaka City University Graduate School of Medicine, Osaka, Japan
[2]Department of Biological Sciences and Department of Molecular Biology and Biochemis try, Simon Fraser University, Burnaby, Canada

Objectives:
Mounting evidence indicates that extracellular amyloid β (Aβ) oligomers cause synaptic dysfunction and that this toxicity requires tau in the dendrites. Meanwhile, it has been suggested that intraneuronal accumulation of Aβ proceeds extracellular Aβ, and is an early event in Alzheimer's disease. It remains unclear whether intraneuronal Aβ also contributes to synaptic alteration, and if so, whether the toxicity requires tau.
Methods:
To address these questions, mouse/rat primary neurons were transfected with human APP with or without the Osaka (E693delta) mutation which induces intracellular accumulation of Aβ oligomers. The morphology of dendritic spines, and axonal or dendritic transport of BDNF, mitochondria, and transferrin receptor (a marker of dendritic recycling endosomes) were evaluated. For comparison, the effect of extracelluar Aβ on dendritic spines was examined by adding Aβ into untransfected neurons at concentrations comparable to those in culture media of wild-type APP-transfectants. To study the necessity of tau, primary neurons from tau-deficient mice were also analyzed following to APP transfection.
Results:
Neurons expressing APP Osaka, but not wild-type APP, accumulated Aβ oligomers within cells. APP Osaka-transfectants showed reduced numbers of total and mushroom-type spines, but wild-type APP-transfectants and Aβ-added untransfectants did not. The flux values of BDNF, mitochondria, and the transferrin receptor transport in axons and dendrites were reduced only in APP Osaka-transfectants. Intracellular Aβ-induced aberrant spine morphology was observed even in tau-deficient neurons.
Conclusions:
Intraneuronal Aβ oligomers disrupted synaptic integrity independently of tau, and this toxicity was accompanied by an impairment of axonal and dendritic trafficking.

ADPD5-0788

DIMERIZATION OF APP IS PRIMARILY MEDIATED BY ITS E1-DOMAIN AND REGULATED BY THE ACIDIC REGION

S. Hoefgen[1], S.O. Dahms[1], I. Coburger[1], Y. Schaub[1], D. Roeser[1], M.E. Than[1]
[1]Protein Crystallography, Leibniz Institute for Age Research FLI Jena, Jena, Germany

Objectives

Alzheimer's disease (AD) is one of the most frequent dementias in the elderly population affecting more than 25 % of people in the age of 80 to 90 years. One key player in the generation of AD is the Amyloid Precursor Protein (APP). In addition to its role in Alzheimer's pathology many physiological functions, like stimulation of synaptogenesis and signal transduction in a receptor-like manner are discussed for APP. Dimerization of the protein has been described for APP and would influence most of its physiologic functions.

Methods

We studied the dimerization behaviour of the APP ectodomain by analysing the interaction of constructs comprising different parts of it employing a number of biochemical and biophysical methods like static light scattering, dynamic light scattering and analytical gelfiltration.

Results

We show that the dimerization of APP is primarily driven by the heparin induced dimerization of its E1 domain. Heparin induced dimerization has also been discussed for the E2 domain, but we see the concentration dependent self-dimerization of E2 and independent heparin binding, but no heparin induced dimerization here. Additionally, we show that the region in-between the two subdomains of APP influences the dimerization of E1 and with that of APP.

Conclusions

Our results led to a new model of APP dimerization that strongly depending on the cellular context features both, *cis*- and *trans*-dimers. This brings together a large number of previously mutually exclusive physiological functions and suggests that the trafficking of APP is essential for its dimerization and hence for its biology.

ADPD5-0793

IDENTIFYING THE MECHANISM OF DIFFERENTIAL PROCESSING OF AMYLOID PRECURSOR PROTEIN ISOFORMS

R.J. Andrew[1], K. Heesom[2], N.M. Hooper[1]
[1]Faculty of Medical and Human Sciences, University of Manchester, Manchester, United Kingdom
[2]Faculty of Medical and Veterinary Sciences, University of Bristol, Bristol, United Kingdom

Objectives
The expression profile of APP isoforms has been shown to change from the shorter APP695 isoform to the longer APP751/770 isoforms in the Alzheimer's disease (AD) brain. Amyloidogenic processing and Aβ production has been shown to vary between isoforms and we reported increased amyloidogenic processing and Aβ production from the APP695 isoform in neuronal cell lines (Belyaev et al, 2010). We sought to identify the molecular and cellular mechanisms underlying this differential processing of APP isoforms through studying their subcellular trafficking and interactome.
Methods
FLAG-tagged APP695 and APP751 isoform constructs were over-expressed in SH-SY5Y cells and their trafficking observed by fluorescence microscopy. Co-immunoprecipitation of APP isoforms was carried out and interacting proteins identified by mass spectrometry. Identified proteins were then targeted by siRNA knockdown and effects on APP processing observed by western blot and ELISA.
Results
A higher level of APP695 was observed in Rab11a positive endosomes, while a higher level of APP751 was observed in the trans-Golgi network and early endosomes. Several proteins appeared to interact differentially with the APP isoforms and affected APP processing to various extents including the APP interactor Fe65.
Conclusions
APP isoform interactomes show some significant variations and have identified several proteins potentially responsible for causing differences in isoform processing. Subtle differences were also observed in APP isoform trafficking, potentially affecting their processing through spatial separation from the proteases responsible for their cleavage.

School of Medicine. Pontificia Universidad Catolica de Chile, Santiago, Chile

Objectives: Niemann-Pick type C (NPC) is a neurodegenerative disease that presents amyloid beta (Abeta) accumulation in the brain. Previously, we showed that c-Abl is activated in NPC models. Additionally, c-Abl interacts and phosphorylates the amyloid precursor protein (APP), however the relevance of this interaction has not been defined yet.
Methods: We evaluated i) APP processing following Abeta, betaCTF and sAPPalpha levels by *Western Blot* in: a) WT and NPC CHO cells expressing APP_{Swe} and treated with Imatinib (c-Abl inhibitor) and b) NPC mice injected with Imatinib for 4 weeks and ii) the interaction between APP, c-Abl and beta-secretase (BACE1) by co-immunoprecipitation and FLIM techniques in NPC CHO cells expressing c-Abl-DsRed and APP-GFP. A mutant APPY682A-GFP was used to investigate whether the binding of c-Abl to APP is dependent on the Y^{682}ENPT motif.
Results: We found that NPC models showed increased levels of Abeta. Imatinib inhibited the amyloidogenic processing of APP reducing Abeta and betaCTF and increasing sAPPalpha levels. NPC cells showed an increase of APP-c-Abl interaction compared with WT cells. Imatinib or the APPY682A mutation inhibited APP-c-Abl interaction, but more importantly, Imatinib significantly reduced the APP-BACE1 interaction.
Conclusions: Our results suggest that c-Abl interacts with APP, through the Y^{682}ENPT motif and promotes APP cleavage by BACE1 favoring Abeta accumulation and contributing to the pathogenesis of NPC disease.

MITOCHONDRIAL BIOENERGETICS IS INVERSELY CORRELATED TO ER-MITOCHONDRIAL CONNECTIVITY IN ALZHEIMER DISEASE

M. Pera[1], D. Larrea[1], C. Guardia[2], E. Area-Gomez[2]
[1]Neurology, Columbia University Medical Center, New York City, USA
[2]Pathology, Columbia University Medical Center, New York City, USA

Perturbed mitochondrial function and altered mitodynamics have been described as possible triggers of neurodegeneration in Alzheimer disease (AD). However, while mitochondrial dysfunction is an undeniable early symptom of the disease, the pathogenesis of AD cannot be explained simply as a result of mitochondrial alterations; some other, currently-unknown, mechanism is likely at work.

We recently showed that presenilin 1 (PS1) and presenilin 2 (PS2), and γ–secretase activity itself, are present in mitochondrial-associated ER membranes (MAM), and that cells from AD patients with both the familial and sporadic forms of the disease have increased ER-mitochondrial connectivity and upregulated MAM function. For these reasons, we hypothesized that changes in MAM behavior might affect and perhaps regulate some mitochondrial activities. To explore this issue in the context of AD, we measured mitochondrial respiration in PS1/PS2 double knockout (DKO) mouse embryonic fibroblasts (MEFs), and found a profound decrease in OxPhos in these cells. In order to analyze the possibility that this phenotype was somehow related to the higher degree of ER-mitochondria apposition seen in AD-mutant cells, we measured mitochondrial respiration in mitofusin2-knockout MEFs (MFN2-KO) that have the opposite phenotype, namely, reduced ER-mitochondrial apposition and lower MAM activity. Remarkably, these cells showed a significant increase in OxPhos.

These data imply that there is a heretofore unappreciated inverse correlation between ER-mitochondrial apposition and mitochondrial bioenergetics, and provide new insight into the well-known defects in mitochondrial function in AD.

Amyloid-β (Aβ) peptides accumulate in cerebral capillaries indicating a central role of the blood-brain barrier (BBB) in the pathogenesis of Alzheimer's disease (AD). Although a close connection between apolipoprotein-, cholesterol- and Aβ metabolism is evident, the interconnecting mechanisms operating in brain capillary endothelial cells (BCEC) are poorly understood. Apolipoprotein (apo)J, also known as clusterin, is present in lipoprotein particles and regulates cholesterol and lipid metabolism of brain which is disturbed in AD. ApoJ expression is increased in AD brains and ApoJ binds, prevents fibrillization, and enhances endocytosis of Aβ. Our central study aim is to define the involvement of apoJ and cellular cholesterol homeostasis in amyloid precursor protein (APP) processing/Aβ metabolism at the BBB.

Primary porcine (p)BCEC are incubated in the presence and absence of plasma-derived apoJ and modulators of cholesterol metabolism prior to analyses of APP/Aβ and apoJ mRNA and protein expression levels. Aβ transport studies are aiming to elucidate the role of apoJ and the HMGCoA reductase inhibitor simvastatin in Aβ clearance across the BBB.

Thus far, we found an increase of both apoJ and full-length APP mRNA and protein in response to treatment of pBCEC with 5 µM simvastatin. Further, simvastatin reduced cell-associated Aβ oligomer levels, whereas extracellular Aβ peptides were increased. Addition of purified apoJ [2µg/ml] increased APP, whereas apoJ silencing decreased APP and Aβ oligomer protein levels.

Our results, so far, suggest an important role of cellular cholesterol homeostasis and apoJ in modulating APP/Aβmetabolism at the posttranslational level in cerebrovascular endothelial cells.

TRANSMEMBRANE INTERACTIONS IN APP STRUCTURE, FOLDING, AND PROCESSING BY GAMMA-SECRETASE

P. Kienlen-Campard[1], C. Marinangeli[1], M. Decock[1], B. Tasiaux[1], S.O. Smith[2], I. Dewachter[1], J.N. Octave[1], S.N. Constantinescu[3]

[2]Department of Biochemistry and Cell Biology, Stony Brook University, Stony Brook, USA
[3]LICR, de Duve Institute-Université catholique de Loucain, Brussels, Belgium

Objective

Understanding the molecular mechanisms controlling APP processing by gamma-secretase represents a challenging task in AD research. Transmembrane (TM) interactions appear to have a central role here, both by driving the assembly and activation of the gamma-secretase, and the docking/fitting of the substrate prior to cleavage. We identified key structural determinants (GxxxG and GxxxG-like motifs) in APP/Presenilins TM domains (TMDs) and analyzed their role in APP amyloidogenic processing and γ-secretase activity.

Methods

APP/PS1/PS2 constructs (including FAD mutants) were generated by site-directed mutagenesis. Assembly and activation of gamma-secretase was studied by non-denaturating electrophoresis, co-immunoprecipitations, and combined to results of in vitro gamma-secretase assays. APP transmembrane/juxtamembrane regions were analyzed by structural approaches (FTIR/NMR spectroscopy). APP processing was monitored by electrochemiluminescence assays (ECLIA).

Results

GxxxG motifs in APP TMD were initially found to control the association and orientation of APP homodimers. We showed here they control the alpha-helix/beta-sheet structure of inhibitory and cholesterol-binding regions, impacting on gamma-cleavage and Abeta release. Mutation of PS1 and PS2 TMD8 motifs either abolishes PS endoproteolysis and gamma-secretase activity, or increase it in the case of FAD mutant. Non-denaturating conditions indicated that GxxxG-like motifs in PS TMD8 are key determinants for the geometry of the mature gamma-secretase controlling the switch between physiological and pathological conformations.

Conclusion

Our data suggest that GxxxG-like motifs in APP and PS are crucial structural determinants for the physiological and pathological processing of APP. They control both the fitness of APP for gamma-cleavage and the conformation of the active gamma-secretase complex.

Our attention is focused on the study of a new model based on the red blood cell (RBC) and on its interaction with Aß. RBCs are highly deformable to assist blood flow in the microcirculation, and in this context NO was proposed to be a regulatory factor of RBC mechanical properties since inhibitors of endogenous NO synthesis induces decreased erythrocyte deformability. For this reasons abnormalities in RBCs could contribute to AD by obstructing oxygen delivery to brain causing hypoxia. In our work, firstly we will focus on the morphology and nano-properties of RBC's membrane (i.e. roughness) by AFM (i.e. Atomic force microscopy), following to soluble Aß peptides exposure at different times, in order to characterize specific alterations induced by Aß. Secondly, considering that RBC membrane contains, among blood elements, higher acetylcholinesterase (AChE) levels, we can assume that there is a mechanism similar to the one which occurs at the neuronal level leading to an increase of Aß toxicity mediated by the binding with erythrocytic AChE. Since mechanical properties of RBC membrane are regulated by a number of molecular components of signalling and/or regulatory pathways, of these, particular interest has been addressed toward protein band 3, protein kinase C isoenzymes (PKC), endothelial nitric oxide synthase (eNOS) and caspase 3, due to their possible roles in the modulation of erythrocyte morphology, deformability and metabolic functions.

Objectives: The Amyloid precursor protein (APP) plays a central role in Alzheimer's disease and has essential synapse promoting functions. Synaptogenic activity as well as cell adhesion properties of APP presumably depend on trans-cellular dimerization via its extracellular domain. Since neuronal APP is extensively processed by secretases, it raises the question if APP shedding affects its cell adhesion and synaptogenic properties.

Methods: We performed cell clustering assays in Schneider (S2) cells with shedding deficient APP mutants and with a dominant-negative form of Kuzbanian (Kuz^{DN}). Processing of the mutants was analyzed in mammalian HEK293 cells as well as the amount of full length APP at the cell surface by cell-surface biotinylation. We used HEK293 cells expressing APP or APP mutants co-cultured with primary cortical neurons to assay their capacity to induce presynaptic differentiation.

Results: We generated APP mutants with a significant reduction in $sAPP_{total}$ secretion, which showed significantly increased clustering in Schneider cells, similar to APP wt co-expressed with Kuz^{DN}. The mutants also showed a highly significant reduction in $sAPP_{total}$ secretion in mammalian HEK293 cells and an increase in cell surface levels of full length APP. The shedding deficient APP forms promoted presynaptic differentiation of contacting axons to a much higher extent than APP wt and Neuroligin1.

Conclusions: Inhibition of APP shedding strongly enhances its cell adhesion properties and its synaptogenic activity suggesting that synapse promoting function of APP is tightly regulated by alpha-secretase mediated processing, similar to other synaptic cell adhesion molecules.

Objectives: We have previously reported a neuroprotective activity of monomeric Aß$_{1-42}$, which was abrogated by inhibitors of insulin/IGF-1 receptor signaling (Giuffrida et al., J.Neurosci. 2009). Further investigation by our group has lead to the demonstration that Aß$_{1-42}$ monomers engage specifically type-I IGF receptors, thus promoting membrane translocation of Glut-3 and glucose uptake in primary neurons. We wanted to test the hypothesis that Aß$_{1-42}$ monomers could increase glucose uptake during neuronal activation.

Methods: Experiments were carried out in cultured cortical neurons stimulated KCl, and glucose consumption was assessed by either glucose meter or measuring the uptake of the fluorescent non-hydrolyzable glucose analogue NBDG. Causal relationship between Aß release during depolarization and glucose uptake was investigated by using a γ-secretase inhibitor or APP-null neurons. A set of experiments was carried out in CSF samples obtained from MCI and AD patients to obtain a source of native human Aß.

Results: Depolarization-induced glucose uptake was prevented by the addition of γ-secretase inhibitor IX, and it was re-established by exogenous Aß$_{1-42}$ monomers. In APP-null neuronal cultures, KCl-induced depolarization failed to enhance glucose uptake unless exogenous Aß$_{1-42}$ was added. Glucose uptake stimulated by high K^+ did not significantly differ between cultures incubated with MCI and AD CSF, although a trend to a reduction in AD-CSF treated cultures was seen. Addition of the anti-Aß 4G8 antibody (100 ng/50 µl CSF) significantly reduced glucose uptake at least in cultures treated with MCI CSF.

Conclusions: We conclude that Aß monomers are critical for neuronal glucose uptake under activation.

[3]Physiology & Experimental Medicine, Hospital for Sick Children, Toronto, Canada

Most Alzheimer's disease (AD) patients exhibit accumulation of amyloid-beta peptide (abeta) on leptomeningeal and cortical arterioles, or cerebral amyloid angiopathy (CAA) that is associated with impaired vascular reactivity and accelerated cognitive decline. Despite widespread recognition of the significance of vascular dysfunction in AD etiology and progression, much uncertainty still surrounds the mechanism underlying AD vascular injury. Studies to date have focused on abeta-induced damage to capillaries and CAA-associated arterioles, without examining effects across the entire vascular bed. Here, we studied the differential regulation of vascular function in both the feeding (arteriolar) and draining (venular) vessels in a transgenic AD mouse model that develops progressive CAA. Unexpectedly, we found that CAA correlated with degeneration of mural cells on the penetrating venules but not on the penetrating arterioles. Further pharmacological depletion of venular mural cells using SU6668, a platelet-derived growth factor receptor-antagonist, resulted in increased tortuosity of the venules but not arterioles, exacerbation of CAA in the penetrating arterioles, and further alterations of the microvascular network cerebral blood flow response to hypercapnia. Together, this work shows hitherto unrecognized structural alterations in penetrating venules, demonstrates their functional significance and sheds light on the complexity of the relationship between vascular network structure and function in AD.

Funding was supported in part by CIHR MOP#102467 (JM, BS), Partnership for Stroke Recovery (JM, BS), CIHR Fellowship (AL), and Cryptic Rite Charitable Foundation (JM).

EVIDENCE FOR A N-END RULE-MEDIATED PROTEASOMAL DEGRADATION OF SPECIFIC AICD SPECIES

M.T. Gersbacher[1], R.M. Nitsch[1], U. Konietzko[1]
[1]Division of Psychiatry Research, University of Zurich, Schlieren, Switzerland

Objectives
Previous studies have shown a variable position of gamma-secretase cleavage of APP, providing an explanation for the generation of Abeta and AICD species of different length. While evidence for different toxic potentials of specific Abeta species exists, little is known about the different AICD species. Thus, the objective of the present work is to better understand the regulation and function of different AICD species.
Methods
Naturally-occurring AICD species were expressed by the use of the Ubiquitin-fusion technique in HEK cells. Epoxomicin was used to monitor proteasomal degradation and protein levels were accessed by Western blotting. Formation of AFT-complexes was observed by confocal microscopy of transfected cells.
Results
We show that exchange of the N-terminal residues of AICD (APP(VML646LLR)) abolishes AICD localization to nuclear AFT-complexes. Inhibition of the proteasome revealed that AICD derived from APP(VML646LLR) undergoes faster degradation than its wildtype equivalent. Together, these results suggest that AICD is subject to the N-end rule of proteasomal degradation, which relates the identity of a substrate's N-terminal residue to its degradation rate. Expression of specific AICD species was used to show significantly lower steady state levels, but significantly higher proteasomal degradation of AICD51 than AICD50.
Conclusions
Our data suggest, in line with the N-end rule of proteasomal degradation, that different AICD species have different proteasomal degradation rates. Our results also imply that different Abeta species are inherently correlated with different AICD levels. A possible contribution of different AICD species to the pathology of familial AD cases will be evaluated in future experiments.

RHOMBOID-RELATED PROTEASE-4 PREVENTS THE AMYLOID PRECURSOR PROTEIN FROM AMYLOIDOGENIC PROCESSING

L. Munter[1], F. Oestereich[1], M. Hamzé[2], S. Paschkowsky[1]
[1]Pharmacology, McGill University, Montreal, Canada
[2]Biochemistry, Free University Berlin, Berlin, Germany

Objectives: Alzheimer disease is a complex disorder and multiple cellular processes contribute to it. Cell stress, endoplasmic reticulum-associated degradation (ERAD), and the unfolded protein response (UPR) have previously been reported to be involved in Alzheimer disease. ERAD is required to eliminate misfolded proteins from the endoplasmic reticulum (ER) and includes many chaperones and processing enzymes. Recently, rhomboid-related protease 4 (RHBDL4) was shown to be a member of ERAD-mediating protein machinery and to degrade model substrates. Rhomboid proteases are a family of intramembrane proteases and were to our knowledge never before studied in the context of Alzheimer disease. We investigated if RHBDL4 alters processing of the amyloid precursor protein (APP).
Methods: Analysis of APP processing in cell culture models by western blot, MALDI-MS, and ELISA.
Results: We discovered that RHBDL4 efficiently cleaves APP and depletes full-length APP levels by about 90%. N- and C-terminal APP fragments were detected in cell lysates indicating that APP is cleaved while residing in the ER. Amyloid-beta levels were drastically reduced by about 50% in cell culture supernatants. Thus, RHBDL4 activity bypasses APP from amyloidogenic processing. RHBDL4 also cleaves APLP1 and APLP2, but not BACE1. Preliminary data from human Alzheimer disease brains indicate an upregulation of RHBDL4 mRNA levels, which might be a consequence of overall increased ERAD processing.
Conclusion: Further investigations of this novel APP-degrading pathway is necessary to reveal the pathophysiological impact of RHBDL4 on Alzheimer disease.

ADPD5-1254

OVEREXPRESSION OF MAOB IN PRIMARY NEURONS INCREASES ABETA PRODUCTION AND THE GAMMA SECRETASE/MAOB INTERACTION

S. Schedin Weiss[1], S. Frykman[1], B. Winblad[1], L.O. Tjernberg[1]
[1]Neurobiology Care Sciences and Society, Karolinska Institutet, Huddinge, Sweden

Objectives

The neurotoxic amyloid β peptide (Aβ) is formed by proteolytic processing of the amyloid precursor protein (APP) by BACE1 followed by γ-secretase. Although γ-secretase is an attractive drug target for AD, its regulation is poorly understood. Clinical trials with γ-secretase inhibitors have shown adverse side effects, since the enzyme can process many substrates in addition to APP, including Notch. We have identified several γ-secretase associated proteins (GSAPs) that regulate Aβ production but don´t affect Notch processing to any great extent and then characterized their interaction with γ-secretase using co-immunoprecipitation and proximity ligation assay (PLA). We have selected some of the GSAPs, including monoamine oxidase B (MAOB) for further studies.

Methods

We have in our previous studies shown that overexpression of MAOB resulted in increased Aβ production. Here we have studied whether overexpression of MAOB in primary neurons affects its interaction with γ-secretase. We expressed SNAP-tagged MAOB in primary neurons, followed by conjugation to the SNAP-tag specific stain SNAP-Cell Oregon Green. We then performed *in situ* proximity ligation assay (PLA) on the cells to study the interaction between MAOB and γ-secretase. The results were visualized by confocal microscopy.

Results

Transfected cells were selected by the incorporation of SNAP-Cell Oregon Green. The PLA signals were clearly increased in the transfected cells, verifying that overexpression of MAOB in primary neurons can increase the interaction with presenilin 1.

Conclusion

The results strengthen our hypothesis that Aβ production increases in MAOB overexpressing cells as a result from an increased association with γ-secretase.

ADPD5-1288

FURTHER CHARACTERISATION OF THE CELLULAR INTERACTION OF ABETA ASSEMBLIES AND PRION PROTEIN

S.A. Purro[1], A.J. Nicoll[1], D. Walsh[2], J. Collinge[1]
[1]Dept Neurodegenerative disease, UCL Institute of Neurology - MRC Prion Unit, London, United Kingdom
[2]Laboratory for Neurodegenerative Research, Harvard Medical School, Boston, USA

One of the hallmarks in Alzheimer's disease is the aggregation of amyloid-Beta peptide into plaques. Although plaques can cause neurodegeneration, mounting evidence suggests that ABeta oligomers are a major cause for toxic effects on neurons. A subset of ABeta oligomers interact with cellular prion protein (PrP) triggering a signalling cascade that impairs synaptic plasticity. Recently, our group showed that ABeta oligomers with a nanotube structure bind to PrP in the nanomolar range and inhibit long term potentiation in a PrP-dependent manner.
Objectives: To dissect the interaction between PrP- ABeta oligomers and find ligands that can block this interaction.
Methods: Using an array of biochemical tools and cell biology techniques we examined the interaction between PrP- ABeta oligomers.
Results: Given that PrP is not the only protein that binds ABeta oligomers on the cell membrane, we firstly set out to find experimental conditions that allowed us to measure ABeta binding in a PrP-dependent way. Subsequently, we assayed a collection of ligands that could potentially block the interaction.
Conclusions: Shedding light on mechanisms of interaction between ABeta and PrP could open the way to find the right target in order to inhibit the synaptotoxic effects triggered by ABeta and PrP interaction.
This work was funded by UK MRC and UCL grants.

ACTIVITY-DEPENDENT ABETA OLIGOMERS PRODUCTION IMPAIRS SYNAPTIC FUNCTION AND DENDRITIC SPINE REARRANGEMENTS IN TG2576 MICE

A. Pignataro[1], V. Fontebasso[2], M. Ammassari-Teule[3], S. Middei[3]

In Alzheimer Disease (AD), accumulation of almyloid-ß (Aß) contributes to synaptic dysfunction, dendritic spines loss and neural networks destabilization. These early events selectively occur in brain regions important for memory such as hippocampus and parahippocampal cortices and associate with initial AD symptoms, including impaired consolidation of new memories. Synaptic activity regulates Aß production and release and the activity-regulated cytoskeletal-associated (Arc) protein is an important player in this process. However, whether activity-regulated Aß contributes to AD progression is currently unknown.

In the present study, we collect evidences suggesting that activity regulated Aß might have a deleterious effect on synaptic function in Tg2576 mice, a well-recognized model in which the expression of a familiar-AD mutation favors Aß production. Neuronal activity was achieved by training early symptomatic Tg2576 mice in Contextual Fear Conditioning (CFC), a memory task commonly associated with structural and functional reorganizations of synapses in specific memory-related neuronal circuits.

We demonstrate that in Tg2576 mice, CFC results in increased levels of Aß oligomers as compared to mice under control conditions. Interestingly, CFC associates with increased number of dendritic spines and enhanced synaptic function in the hippocampal CA1 region and in the Anterior Cingulate Cortex (ACC) of wild type but not Tg2576 mice. Furthermore, we prove that Arc fluctuations participate in the regulation of Aß levels in Tg2576 mice.

Together, these data suggest that activity-related Aß might impact on synaptic rearrangements required for consolidation of long-term memories and encourage modulation of Arc expression in therapies aimed to slow down AD progression.

ADPD5-1337

AMYLOID PRECURSOR PROTEIN (APP) PROCESSING IS ALTERED BY GOLGI-LOCALIZED-GAMMA-EAR-CONTAINING ARF-BINDING (GGA) PROTEIN ISOFORMS 1, 2 AND 3 VIA THE GGA-GAE DOMAIN INTERACTION WITH BACE1

C.A.F. von Arnim[1], A. Wahler[1], T. Schips[2], A. Serrano-Pozo[3], C. Proepper[4], T.M. Boeckers[4], A. Rück[5], T. Wirth[2], B.T. Hyman[3], K.M. Danzer[1], D.R. Thal[6], B. von Einem[1]

[5]Core facility Microscopy, Ulm University, Ulm, Germany
[6]Institute of Pathology, Ulm University, Ulm, Germany

Proteolytic processing of APP by BACE1 is the initial step in the production of amyloid beta (Abeta), which accumulates in senile plaques in Alzheimer's disease (AD). Essential for this cleavage is the transport and sorting of both proteins through endosomal/Golgi compartments. Golgi-localized gamma-ear-containing ARF-binding (GGA) proteins have striking cargo-sorting functions in these pathways. Recently, GGA1 and GGA3 were shown to interact with BACE1, to be expressed in neurons, and to be decreased in AD brain, whereas little is known about GGA2.

Since GGA1 impacts Abeta generation by confining APP to the Golgi and perinuclear compartments, we tested whether all three GGAs modulate BACE1 and APP transport and processing by overexpression and knock-down. As there are several potential binding sites, we addressed the question of which domain interacts directly with BACE1 by Co-Immunoprecipitation. To determine which GGA isoforms are most pathophysiologically relevant, we analyzed GGA levels in rat, and human postmortem brain tissue by in-situ hybridization, qPCR and Western blot.

We observed decreased levels of secreted APP alpha (sAPPalpha), sAPPbeta, and Abeta upon GGA overexpression, which could be reverted by knockdown. GGA-BACE1 co-immunoprecipitation was impaired upon GGA-GAE but not VHS domain deletion. Autoinhibition of the GGA1-VHS domain was irrelevant for BACE1 interaction. GGA1, 2, and 3 are differentially expressed and regulated in the brain.

Our data support a model in which all three GGAs contribute to endosomal/lysosomal transport of BACE1 and probably also APP via the GGA-GAE domain and might contribute to the development of AD pathology.

ADPD5-1356

HOMO- AND HETEROTYPIC DIMERIZATION OF APP, APLP1 AND APLP2 IS DIFFERENTLY REGULATED BY COPPER

N. Schmidt[1], F. Baumkötter[1], Y. Finger[1], V. Becker[1], A. Lauer[1], S. Kins[1]
[1]Division of Human Biology and Human Genetics, University of Kaiserslautern, Kaiserslautern, Germany

Objectives

APP and its mammalian homologs, APLP1 and APLP2, form homo- and heterotypic dimers, of which a minor fraction is stabilized by intermolecular disulfide bonds. Recently, we showed that copper promotes APP dimerization.

Methods

HEK293 cells were transiently transfected with APP/APLPs and incubated with increasing amounts of copper (0 – 250 µM), 4h prior analysis. APP/APLP interaction was analyzed by co-immunoprecipitation and in case of disulfide-bonded oligomers investigated under non-reducing conditions by gel mobility shift. To investigate the influence of copper treatment, cell viability and subcellular localization of APP/APLPs was analyzed by immunocytochemistry.

Results

Here we show that both, homotypic dimerization of APLP1 and APLP2, as well as heterodimerization of APP/APLP2 is promoted by increasing copper concentrations. In contrast, heterotypic interaction between APP and APLP1 is not influenced by copper, suggesting different interaction interfaces for homo- and heterotypic dimerization. Further, we show that APP family members form cysteine-bonded dimers that are strongly promoted by the addition af copper.

Conclusion

These data suggest that the influence of copper on the homotypic dimerization of APP/APLPs is mainly mediated by formation of stable intermolecular disulfide-bonded dimers. Differences in stability of covalently bond and non-covalently bond APP/APLP dimers suggest distinct pathophysiological functions.

ADPD5-1357

THE APP ADAPTOR PROTEINS FE65 AND FE65L1 ARE ESSENTIAL FOR LOCOMOTOR ACTIVITY, NMJ FORMATION AND LEARNING.

P. Strecker[1], M. Rust[2], S. Ludewig[3], S.Y. Guénette[4], C. Mehrfeld[1], M. Korte[3], S. Kins[1]
[1]Division of Human Biology and Human Genetics, Technical University of Kaiserslautern, Kaiserslautern, Germany
[2]Division of Neurobiology and Neurophysiology, Technical University of Kaiserslautern, Kaiserslautern, Germany
[3]Cell. Neurobiology Zoological Institute, Technical University of Braunschweig, Braunschweig, Germany
[4]Genetics and Aging Research Unit,
MassGeneral Institute for Neurodegenerative Disease, Charlestown MA, USA

Background
The Fe65-protein family, as the main intracellular interaction partner of the APP-family, plays a crucial role in proper positioning of neurons in the mouse brain. The Fe65/Fe65L1 dKO mice have phenotypes resembling those found in triple mutant mice lacking all APP family members. These data suggest a functional interplay between APP and Fe65 in brain development.
Methods
For analysis of Fe65/Fe65L1 KO mice we performed different immunohistochemical analyses and behavioral studies, such as grip strength measurements, balance beam, rota-rod, Morris Water Maze and fear conditioning followed by measurements of long term potentiation (LTP) and paired pulse facilitation.
Results
Here we report reduced grip strength and crucial impairments in locomotion for mice lacking the Fe65 and Fe65L1 proteins. Analysis of the neuromuscular junction (NMJ) formation in P5 pups and adult mice resulted in smaller pre- and post-synaptic areas and reduced apposition of the pre- and post-synapse, supporting deficits in the peripheral nervous system (PNS). Spatial learning analysis in the Morris Water Maze test and the fear conditioning test resulted in significant deficits in Fe65/Fe65L1 KO mice suggestive of hippocampal dysfunction. Further electrophysiological analyses revealed deficits in LTP in Fe65/Fe65L1 KO mice and impairments in paired pulse facilitation.
Conclusion
Fe65/Fe65L1 dKO mice resemble APP/APLP2 mutant mouse phenotypes with deficits in NMJ formation, locomotion and learning behavior suggesting that Fe65 protein family members are involved in APP/APLP synaptic signaling in the central nervous system (CNS) and in the PNS.

[4]Division of Psychiatry Research The Systems and cell biology of neurodegeneration, University of Zurich, Zurich, Switzerland

Alzheimer's disease (AD) is characterized by cerebral deposition of beta-amyloid peptides, which are generated from amyloid precursor protein (APP) by beta- and gamma-secretases. APP and the secretases are membrane associated, but whether membrane trafficking controls beta-amyloid levels is unclear. The objective of the study was to identify the specific trafficking mechanisms that regulate the production of beta-amyloid. Here, we performed an RNAi screen of all human Rab-GTPases,which regulate membrane trafficking, complemented with a Rab-GTPase-activating protein screen, and present a road map of the membrane-trafficking events regulating beta-amyloid production. We identify Rab11 and Rab3 as key players. We show that Rab11 controlled beta-secretase endosomal recycling to the plasma membrane and thus affected beta-amyloid production. Exome sequencing revealed a significant genetic association of Rab11A with late-onset AD, and network analysis identified Rab11A and Rab11B as components of the late-onset AD risk network, suggesting a causal link between Rab11 and AD. Our results reveal trafficking pathways that regulate beta-amyloid levels and show how systems biology approaches can unravel the molecular complexity underlying AD.

ADPD5-1396

DIFFERENT PROCESSING OF APP C-TERMINAL FRAGMENTS IN THE AMYLOIDOGENIC AND THE NON-AMYLOIDOGENIC PATHWAY

G. Siegel[1], L. Rajendran[1]

[1]Division of Psychiatry Research, University of Zurich, Schlieren, Switzerland

The amyloid precursor protein (APP) is processed in two main ways: In the amyloidogenic pathway APP is cleaved by beta- and gamma-secretase to produce A-beta peptides. In the non-amyloidogenic pathway the consecutive actions of alpha- and gamma-secretase give rise to the shorter p3 peptides. The C-terminus of both types of peptides is produced by gamma-secretase in different lengths. The most prominent variants end on position 40 and 42 of A-beta. While gamma-secretase appears to cleave the APP C-terminal fragments produced by alpha- and beta-secretase with comparable overall efficiency, we do not know whether there are differences in the abundance with which gamma-secretase produces 40 and 42 C-terminal ends from the respective substrates.

We observed an overproportional decrease of total 42-ending APP-derived peptides over 40-ending peptides when beta-secretase activity was downregulated in wildtype mouse primary neurons. The downregulation of alpha-secretase on the other hand shifted the total 42/40 peptide ratio in the opposite direction. These effects were not present when we analyzed specifically A-beta produced in the amyloidogenic pathway. Our data point to a higher 42/40 ratio in the beta-secretase pathway and suggest different processing of the different APP C-terminal fragments by the gamma-secretase complex in neurons.

ADPD5-1400

REGULATION OF NEURONAL FUNCTION BY APP NUCLEAR SIGNALING

S. Grinschgl[1], C. Tackenberg[1], T. Welt[1], S. Imobersteg[1], A. Trutzel[1], J. Birnbaum[1], R.M. Nitsch[1], U. Konietzko[1]

[1]Psychiatry Research, University of Zurich, Zurich, Switzerland

Objectives: The central molecule in the pathologic cascade leading to Alzheimer's disease (AD) is the transmembrane amyloid precursor protein (APP). APP processing liberates the APP intracellular domain (AICD), which subsequently localizes with its binding protein Fe65 and the histone acetylase Tip60 in multiple nuclear complexes. These AFT spots are localized to transcription factories, loci of gene expression. APP regulates several processes such as dendrite growth and spine morphology that might be mediated by AICD nuclear signaling.

Methods: We use lentiviral vectors to express AICD in hippocampal neurons to analyze the effects on dendrite complexity. Via Sindbisvirus we are expressing AICD in hippocampal slice cultures and analyze spine density with confocal microscopy. Further, we perform stereotaxic injections of lentivirus into the hippocampus to analyze AICD-induced effects on CA1 pyramidal and dentate gyrus granule cell morphology. Virus-mediated expression of AICD is also used to analyze candidate target genes via qRT-PCR.

Results: We demonstrate that lentiviral-mediated AICD expression significantly increases dendritic branching in hippocampal neurons *in vitro* compared to control-treatment. To identify the regulated genes responsible for this effect we are analyzing candidate genes discovered in qRT-PCR screens of APP/APLP2 knock-out mice.

Conclusions: We provide experimental evidence for AICD-mediated effects on neuronal morphology with respect to dendritic branching and spine density.

ADPD5-1415

POST-TRANSCRIPTIONAL REGULATION OF APP EXPRESSION BY NEURONAL HU PROTEINS

A. Fragkouli[1], *P. Koukouraki*[1], *E. Doxakis*[1]
[1]*BASIC RESEARCH CENTER,*
BIOMEDICAL RESEARCH FOUNDATION ACADEMY OF ATHENS, ATHENS, Greece

Amyloid-beta precursor protein (APP) is present in three main splice variants, the ubiquitous APP770 and APP751 and the neuronally enriched and less amyloidogenic APP695 (lacking exons 7 and 8). Hu (Human antigen) RNA-binding proteins - HUR and neuronal HU (nHU) HUB, HUC and HUD – are known to regulate alternative splicing events. Intriguingly, nHU are involved in cognitive processes and their levels, as well as those of APP695, are reduced in AD. We, thus, examined whether nHU are involved in splicing events generating APP695.

Methods: Protein and mRNA levels of Hu proteins and APP isoforms were determined by Western blot and RT-PCR, respectively, in lysates or RNA from various cell lines untreated, differentiated towards a neuronal phenotype or transfected with the appropriate plasmid constructs. Binding of nHU to *App* pre-mRNA was assessed by RNA-immunoprecipitation.

Results: We show that nHu expression correlates with APP695 expression in various cell lines and during neuronal differentiation. Moreover, over-expression of nHU results in a significant increase of APP695 mRNA and protein levels, whereas loss of endogenous HUC or HUD function leads to a significant decrease of APP695 levels. Consistently, we demonstrate that nHU interact with the endogenous *App* pre-mRNA. Finally, by co-transfecting artificial mini-gene constructs for APP exon 7 or exon 8 with plasmids expressing HUC or HUD, we identified the minimal flanking intronic sequences, necessary for APP exon 7 or 8 skipping by nHU.

Conclusion: Neuronal Hu proteins participate in the regulation of APP alternative splicing events leading to the generation of neuronal APP695.

ADPD5-1462

MODULATION OF BETA–AMYLOID/APP IN THE ENDOCYTIC PATHWAY

K. Willén[1], M. Faideau[2], G.K. Gouras[1]
[1]Department of Experimental Medical Science, Lund University, Lund, Sweden
[2]Cell Biology of Genetic Diseases, Telethon Institute of Genetics and Medicine, Pozzuoli, Italy

Objectives
Alzheimer's-linked beta-amyloid (Aβ) is generated at synapses and accumulates in endosomal vesicles near synapses with the onset of synaptic dysfunction in AD. Previous evidence has suggested that sorting via the multivesicular body (MVB) pathway is impaired by endosomal Aβ accumulation in cultured AD-transgenic primary neurons. Our aim is to investigate the trafficking and processing of APP and its cleavage products in the endocytic pathway with a focus on the role of ESCRT (endosomal sorting complex required for transport) -mediated sorting in intracellular Aβ accumulation.
Methods
Different steps in the endocytic pathway, including exocytosis, MVB formation, lysosome acidification and autophagy are modulated in neuroblastoma cells and primary mouse neurons. Aβ and other AD-related proteins as well as synaptic proteins are analysed using WB and immunofluorescence. Differences in the endocytic pathway between wt and AD-transgenic primary neurons and neurons treated with synthetic Aβ are also investigated.
Results
Inhibition of the ESCRT component VPS4A or inhibition of the vacuolar H+ ATPase in lysosomes, leads to intracellular accumulation and decreased secretion of Aβ in N2a cells and primary neurons. However, stimulating autophagy partially rescues the dnVPS4A induced increase of intracellular Aβ back to control levels. In contrast, we confirm that inhibition of VPS4A increases α-synuclein secretion without altering the total pool of intracellular α-synuclein.
Conclusions
We previously reported progressive intraneuronal Aβ accumulation and impaired Aβ secretion in AD-neurons with time in culture. This is mimicked by inhibition of VPS4A and is consistent with indications of MVB/lysosomal dysfunction in AD.

ADPD5-1470

SYNAPTOTAGMINS REGULATE BACE1-MEDIATED PROCESSING OF AMYLOID PRECURSOR PROTEIN AND ABETA GENERATION

V. Gautam[1], C. D'Avanzo[2], D. Kovacs[2]
[1]Department of Neurology,
MassGeneral Institute for Neurodegenerative DiseasesMassachusetts General Hospital Harvard Medical School, Charlestown, USA
[2]Department of Neurology,
MassGeneral Institute for Neurodegenerative Diseases Massachusetts General Hospital Harvard Medical School, Charlestown, USA

Objective: Accumulation of β-amyloid peptide is the major pathological hallmark of Alzheimer's disease. However, proteins regulating Aβ generation at the synapse have not been characterized. Here, we sought to identify proteins that interact with the APP and regulate Aβ generation at the synapse.
Methods: We used affinity chromatography-coupled mass spectrometry to identify the APP ectodomain-interacting proteins in mouse brain. Co-immunoprecipitation and GST pull-down assays were performed to test for protein interaction. Co-localization with APP was verified by different image-based methodologies. Overexpression and knockdown studies were used to analyze changes in APP metabolism and Aβ generation.
Results: We identified the synaptotagmin (Syt) family of proteins as novel APP-ectodomain interacting proteins. Our results have shown that Syt-1, -2 and -9 interact with APP both *in vitro* and *in vivo*. We further demonstrated that Syt interaction site lies between E1 and KPI domains of APP. Stable overexpression of Syt-1/Syt-9 with APP elevated APP-CTFs and sAPPβ, with ~3 fold increase in secreted Aβ levels. Using Syt-1 knockout PC12 cells and Syt-1 specific siRNA, we have observed a ~50% reduction in secreted Aβ generation and also a significant decrease in APP processing. In addition, lack of Syt-1 expression in PC12 cells also led to a significant reduction in secreted sAPPβ levels as compared to the wild-type PC12, strongly suggesting that Syt-1 modulates BACE1-mediated APP cleavage.
Conclusion: Our data here clearly identify Synaptotagmins as novel APP-interacting proteins that regulate BACE1-mediated APP processing and Aβ generation and thus may play an important role in AD pathogenesis.

ADPD5-1630

GENOME-WIDE SIRNA SCREENING IDENTIFIES NEW MODULATORS OF THE APP METABOLISM

J. Chapuis[1], B. Grenier-Boley[1], B. Deprez[2], P. Amouyel[1], P. Brodin[3], J.C. Lambert[1]
[1]INSERM U744, Institut Pasteur de Lille, Lille, France
[2]INSERM U761, Institut Pasteur de Lille, Lille, France
[3]Inserm 1019 - CNRS UMR 8204, Institut Pasteur de Lille, Lille, France

Objectives:

Even if numerous players of the APP metabolism have been characterized over the last 20 years, a large part of the actors of this metabolism are still unknown. It is expected that these actors could interfere with secretase activity but also with APP trafficking and/or degradation. To identify those modulators in taking into account these different levels of interactions, we developed a Genome-Wide siRNA screening using a High Content Screening (HCS) approach.

Methods:

A HEK293 cell line stably over-expressing a Tagged-fluorescent APP was transitory transfected in 384 wells plates with the human siGENOME siRNA library to silence every human gene. Each plate contained controls for both intra-plate validation (siRNA-PS1 and siRNA-APP) and inter-plate normalization (non-targeting siRNAs). Plates were read 72 hours after transfection using an automated confocal microscopy system (In Cell 6000) and fluorescence intensities were quantified using the COLUMBUS software. Modulators of the APP metabolism were selected among those exhibiting the strongest variation in terms of fluroscence intensity (the 2.5 % highest and lowest variations). From the selected, enrichment pathway analysis were performed using the Ingenuity database.

Results:

Data for 18,049 different genes were generated after our different control processes and we finally selected 820 hits showing strong impact on the APP metabolism. Pathway enrichment analysis identified canonical-pathways such as IGF-1 signaling (P=1.1E-05), Cholesterol Biosynthesis (P=1.5E-05) and JAK/Stat Signaling (P=2.2E05).

Conclusions:

Characterization of these modulators could be useful for our in-depth understanding of the APP metabolism and could be potentially linked to Alzheimer’s disease following subsequent analyses.

ADPD5-1734

DEREGULATION OF PROTEIN SYNTHESIS IN ALZHEIMER DISEASE

Z. Jaffal[1], D. Khamsing[1], A. Soltani[1], S. Lebrun[1], I. Fanget[1], D. Carrel[1], C. Desnos[1], F. Darchen[1]

[1]UMR 8250, Université ParisDescartes, Paris, France

Alzheimer's disease (AD) is the most common senile dementia. Cognitive deficits are widely believed to result from progressive synaptic dysfunction and neurodegeneration, most likely caused by soluble oligomers of the amyloid peptide (AβO). Synaptic plasticity (for instance long term potentiation (LTP)) that underlies memory, involves changes of synapse efficacy associated with a variation in number, size and morphology of dendritic spines. AbO induce dendritic spine shrinkage and inhibit synaptic plasticity. These effects are likely to account for the memory defects associated with AD, but the mechanism remains obscure.

Using a non radioactive technique known as surface sensing of translation, (SUNSET) and based on the detection of the incorporation of puromycin into nascent peptide chains, we have observed that protein synthesis increases in dendrites of cultured hippocampal neurons upon chemical LTP induction (Forskolin, BDNF, NMDA and dopamine). This effect is severely blocked by AbO (500 nM, 3h). Interestingly, we observed at lower doses (100 nM, 3h) an increase of mRNA translation in nonstimulated neurons. Similar results have been obtained using cultures of neurons from Tg2576 mice expressing a pathogenic mutant of APP.

These effects of AbO on mRNA translation (inhibitory at 500 nM and excitatory at 100 nM) are correlated with changes in the activity of mTOR. By using a pharmacological approach to characterise the signaling pathways, we observed that AbO at 100 nM affect mTOR by activating the BDNF receptor TrKB and the PI3-kinase/AKT pathway. However, AbO used at higher doses seem to impair RNA translation by inactivating the ERK pathway.

ADPD5-1750

PROTON MYO-INOSITOL COTRANSPORTER IS A NOVEL GAMMA-SECRETASE ASSOCIATED PROTEIN THAT REGULATES ABETA PRODUCTION WITHOUT AFFECTING NOTCH CLEAVAGE

L.O. Tjernberg[1], Y. Teranishi[2], M. Inoue[2], N.G. Yamamoto[2], T. Kihara[2], T. Ishikawa[2], S. Schedin Weiss[1], S. Frykman[1], B. Winblad[1]

[2]Drug Development Research Laboratories, Dainippon Sumitomo Pharma Co., Osaka, Japan

Objectives

The neurotoxic amyloid β peptide (Aβ) is formed by proteolytic processing of the amyloid precursor protein (APP) by BACE1 followed by γ-secretase. Although γ-secretase is an attractive drug target for AD, its regulation is poorly understood. γ-Secretase associated proteins (GSAPs) could be of importance for substrate selection and regulation of amyloid β-peptide production.

Methods

We used affinity purification of γ-secretase in combination with mass spectrometry to identify novel GSAPs in microsomal preparations from human brain. We studied their effect on Aβ production and Notch cleavage using siRNA mediated gene silencing as well as an overexpression approach. Three of the proteins that reduced the Aβ levels; Probable phospholipid-transporting ATPase IIA (ATP9A), BDNF/NT-3 growth factor receptor precursor (NTRK2), and Proton myo-inositol cotransporter (SLC2A13), were selected for further studies, including co-immunoprecipitation and proximity ligation assay (PLA).

Results

Of the three proteins, SLC2A13 showed the most selective effect on APP vs Notch processing, the highest increase of Aβ production after overexpression and the greatest extent of association with γ-secretase based on co-immunoprecipitation as well as PLA.

Conclusion

SLC2A13 was identified as a novel GSAP that regulates Aβ production without affecting Notch cleavage. Further investigations will be performed to investigate whether the association between SLC2A13 and γ-secretase can be targeted for pharmaceutical intervention of AD.

ADPD5-1754

O-GLCNACYLATION SELECTIVELY AFFECTS APP PROCESSING IN NEURON-LIKE CELLS

N. Koistinen[1], K.T. Jacobsen[1], Y. Stråål[1], K. Iverfeldt[1]
[1]Department of Neurochemistry, Stockholm University, Stockholm, Sweden

Objectives

Alpha-secretase processing of amyloid-beta precursor protein (APP) excludes the formation of the neurotoxic amyloid-beta (A-beta) peptide and generates a neuroprotective secreted fragment, sAPPalpha. We have previously shown that O-GlcNAcylation, a dynamic post-translational modification, stimulates alpha-secretase processing of APP, resulting in increased secretion of sAPPalpha concomitant with decreased A-beta formation. Further we investigated the mechanism behind the increased sAPPalpha secretion in response to PUGNAc, an inhibitor of the enzymatic removal of the GlcNAc moiety.

Methods

SH-SY5Y, SK-N-AS, HEK293, HeLa cells and rat primary neurons were cultured for 24 hours in the absence or presence of 50 µM PUGNAc. Cell lysates and conditioned medium were subject to western blot analysis with antibodies against APP. Co-immunoprecipitation assay was performed to analyze ADAM10-APP interactions. To analyze O-GlcNAcylation of proteins, O-GlcNAc immunoprecipitation or sWGA precipitation, followed by western blot using specific antibodies was performed as was click chemistry labeling of O-GlcNAcylated proteins.

Results

Our results show significant effects on sAPPalpha secretion in human neuroblastoma cell lines and rat primary neurons, but not in non-neuronal cells. In neuronal cells APP cell surface localization and its interaction with the alpha-secretase ADAM10 is enhanced.

Conclusions

O-GlcNAcylation-dependent APP alpha-secretase processing involves effects on APP trafficking, and ADAM10-APP interactions, and is most likely playing a specific role in neuronal cells.

ADPD5-1819

CELLULAR MECHANISMS OF LATE-ONSET ALZHEIMER'S DISEASE RISK GENES

R. Paolicelli[1], G. Siegel[1], L. Rajendran[1]
[1]Department of Psychiatry Research, University of Zurich, Zurich, Switzerland

Alzheimer's disease (AD) is a neurodegenerative disorder characterized by senile plaques, neurofibrillary tau tangles and overt neuronal loss. According to the onset of disease one can distinguish two types of AD: early-onset and late-onset. However, while an increased production of Ab is seen in early-onset AD, an impaired clearance has been postulated to be the major cause for late-onset AD. In addition, while the aberrant phosphorylation and aggregation of tau protein appears to be solely downstream of Ab accumulation in early-onset AD, in late-onset AD pathological tau might also be formed independently and thereby contribute to disease onset and progression via non- Ab triggered pathways. In the recent few years, genome-wide association studies have identified a long list of SNPs associated with late-onset AD, revealing a large set of genes (Alzgenes) that could confer suceptibility to the disease. **H**ere we tested the role of the Alzgenes in a neuronal context, specifically investigating their effect on the Ab 42/40 ratio, on the total Tau levels and the Tau phosphorylation. In addition, we explored the possibility that the Alzgenes could specifically modulate the function of microglia. Not significant effects were detected in the neuronal system with respect to Ab x-40 and Ab x-42 neither to total tau expression nor tau-phosphorylation at Thr231. However, some Alzgenes appear to have a role in modulating microglial phagocytic activity. This supports the hypothesis that -at least some- risk gene variants can act in late-onset AD as a susceptibility factor for impaired Ab removal.

[5]Department of Medical Biochemistry, Semmelweis University, Budapest, Hungary

The identification of early pathomechanism of Alzheimer's disease (AD) is in focus of interest for the discovery of potential markers for early diagnosis. Early synaptic dysfunction could be detected in AD transgenic mice models. The earliest detected clinical symptom of AD is the decrease in brain metabolism. It suggest early mitochondrial dysfunction as AD develops. In the present study we performed a brain synaptic and non-synaptic mitochondrial proteome analysis of the APP/PS1 double transgenic AD mouse model at 3, 6 and 9 month of age. Validation of correct separation of mitochondria was done by FACS, electron microscopy and Western Blot techniques. In parallel with proteomics studies we also recorded the functional changes in mitochondria via ROS metabolism and oxygen consumption. We investigated the mitochondrial protein changes with 2-D DIGE and mass spectrometry. We identified 45 mitochondrial protein changes, which reflects progressing effect of beta-amyloid on mitochondrial processes as glucose metabolism, oxidative stress and many others. Our data show, that beta-amyloid induced proteome changes in synaptic and non-synaptic mitochondria are different in all investigated ages. Proteome of synaptic mitochondria are more vulnerable than non-synaptic ones to Aβ insult particularly in early phase, when the mitochondrial functional parameters were still normal. Proteomics changes were in correspondence with ROS generation. We report here the first comprehensive, integrated mitochondrial protein-and-function data in correlation with Aβ progression in APP/PS1 mice. Our data are in good correspondence with *post mortem* human brain studies and also with mitochondrial protein data in AD obtained with biased strategy.

[2]Department of Anatomy, Eotvos Lorand University, Budapest, Hungary
[3]Department of Biophysics and Radiation Biology, Semmelweis University, Budapest, Hungary

Development of Alzheimer's diseases (AD) is a long process and the key for better treatment is to identify its earliest molecular mechanisms for reversing the AD development in time. It is generally accepted that beta-amyloid intracellular accumulation is associated with AD progression. The earliest detectable changes in the brains of AD patients are the decreased metabolism. Recently it has been uncovered that Presenilin-1 and -2, processing Amyloid Precursor Protein, is located predominantly in a special sub-compartment of the endoplasmic reticulum (ER) functionally connected to mitochondria (Mit), called mitochondria-associated ER membrane (MAM). MAM has a lipid raft-like profile, involved in phospholipid and cholesterol biosynthesis, in Ca^{2+} signaling and homeostasis, and in mitochondrial function and dynamics. According to MAM hypothesis of AD early development, presenilins maintain MAM function and ER-Mit crosstalk. The increased presenilin level in AD induces metabolic dysfunction, which is an early detectable alteration in AD. Thus, MAM dysfunction is probably an early AD marker. In the present study we isolated MAM from the brains of APP/PS1 mouse model of AD and performed MAM proteome analysis of the 3 months old APP/PS1 mouse model. In this early phase there are no behavioral changes in the animals, furthermore there are no extracellular amyloid plaque. We validated the MAM preparations with EM and WB techniques. We investigated the protein changes with 2D-DIGE and mass spectrometry. We report here the first comprehensive, unbiased molecular study on early beta-amyloid effect on MAM proteome, which may explain some molecular features of early AD.

ADPD5-1982

DISSECTING THE ROLE OF MICRORNAS AND THEIR THERAPEUTIC POTENTIAL IN ALZHEIMER'S DISEASE

A. Viegas[1], V. Carmona[1], C. Resende Oliveira[2], L. Pereira de Almeida[1], J.P. de Magalhães[3], A.L. Cardoso[1]

[3]Institute of Integrative Biology, University of Liverpool, Liverpool, United Kingdom

A pivotal role for microRNAs (miRNAs) has been proposed in ageing and neurodegeneration, since studies demonstrate that several miRNAs significantly change their expression during senescense. The identification of "molecular signatures", such as miRNA profiles, may lead to the development of new therapies for Alzheimer's disease (AD). Hence, this study aims to modulate the levels of selected miRNAs predicted to target proteins involved in AD.

Through bioinformatic tools, we have identified miRNAs with high affinity to 3'UTR-APP and 3'UTR-BACE1 and performed a biochemical validation of these binding sites, through luciferase assay, upon co-transfection of HT-22 cells with miRNA mimics. The results demonstrate that the selected miRNAs target APP and BACE1, since there was a decrease in luciferase activity in the presence of these mimics. Additionally, a decrease in APP and BACE1 mRNA levels was observed upon transfection of HT-22 and HEK-293 cells with lentiviral constructions containing the selected miRNAs sequences.

Regarding the results and that miR-31-5p targets both APP and BACE1, we have selected this miRNA to evaluate its therapeutic potential. Therefore, we developed a lentiviral platform able to modulate the levels of the miRNA in the brain of a triple-transgenic animal model of AD, through stereotaxic injection. Our preliminary results show that miR-31-5p must be able to decrease the levels of APP and BACE1 *in vivo*. Given the high conservation of miRNAs across species, it is likely that new significant insights in ageing process may arise and support new diagnostic and therapeutic avenues to treat ageing-related diseases, such as AD.

ADPD5-2088

A NEW PUTATIVE RECEPTOR TRIGGERING SAPPALPHA NEUROTROPHIC AND NEUROPROTECTIVE PROPERTIES

E. DORARD[1], S. Chasseigneaux[2], D. Rimet[3], T. Pillot[3], B. Allinquant[1]
[1]CPN, INSERM U894, Paris, France
[2]CPN, INSERM U894 and U1144, Paris, France
[3]S.A.S, SynAging, Nancy, France

Objectives

The amyloid precursor protein (APP) can be cleaved by the alpha-secretase which releases the soluble fragment called sAPPalpha. This fragment has neurotrophic and neuroprotective properties. However, the mechanisms underlying such properties are not yet elucidated. To this end, we focused our interest in membrane proteins interacting with sAPPalpha and susceptible to act as a receptor or co-receptor.

Methods

We isolated mouse brain membranes. After lysis, membrane extracts were incubated with the recombinant protein sAPPalpha-Fc. The proteins attached to sAPPalpha-Fc were isolated on protein A-sepharose beads. After elution, proteins were identified by MS/MS. We identified a protein, called R-sAPPalpha (for patent reasons). The involvement of R-sAPPalpha in the properties of the sAPPalpha has been validated using a siRNA approach in primary neurons.

Results

We showed that siRNAs against the R-sAPPalpha abolished sAPPalpha-induced axonal growth. Moreover, our data strongly suggest that the activation of cellular signaling pathways triggered by R-sAPPalpha might participate in the neuroprotective effects of the sAPPalpha against beta-amyloid oligomers.

Conclusions

Taken together, our data suggest that R-sAPPalpha could be a new therapeutic target for Alzheimer’s disease.

ALZHEIMER'S AMYLOID DEGRADATION BY SECRETED LYSOSOMAL ENZYMES

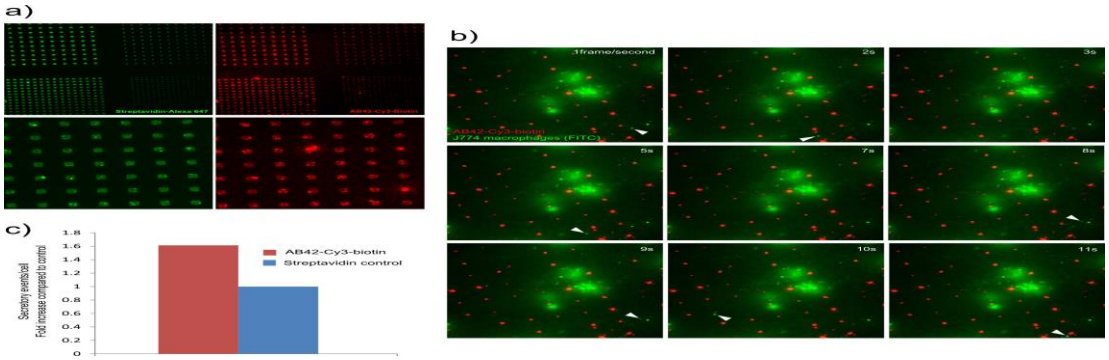
S. Sole-Domenech[1], D.L. Wakefield[2], E. Capetillo-Zarate[3], D.L. Cruz[3], B.A. Baird[2], F.R. Maxfield[3]

[1]Department of Experimental Medical Science, Lund University, Lund, Sweden
[2]Department of Chemistry and Chemical Biology, Cornell University, Ithaca, USA
[3]Department of Biochemistry, Weill Cornell Medical College, New York, USA

In Alzheimer's disease (AD), some brain regions associated with neurodegeneration present abundant amyloid-beta (Aβ) fibrillogenesis. It is unclear how microglia or macrophages in the brain can degrade Aβ fibrils (fAβ) and plaques that are significantly larger than these cells. A new mechanism is suggested by a study published by our lab in which it was found that macrophages could degrade large aggregates of LDL by creating an *extracellular,* acidic compartment that we called the 'lysosomal synapse" into which lysosomal contents are secreted (Haka et *al*. 2009).

To study the interaction of microglia and macrophages with fAβ, and in collaboration with the Cornell NanoScale Science & Technology Facility, we fabricate glass coverslips to present spatially defined, fluorescently labeled fAβ immobilized onto the surface (Fig.A). Cells, for which their lysosomes were labeled with FITC-dextran, are subsequently incubated on the fAβ-coated micro-pattern and imaged using TIRF microscopy, revealing rapid FITC flashes (white arrowheads in Fig.B) at the pattern surface which are indicative of lysosomal content release. As FITC exits the lysosomes, it undergoes fluorescence increase associated with the transition from the acidic lysosomal environment to the more alkaline pH of the extracellular environment. Measurements from a reduced number of samples indicate that macrophages incubated on fAβ-coated surfaces present higher secretory activity when compared to those exposed to streptavidin-coated surfaces (Fig.C).

These studies aim at exploring new ground for treatments based on the use of therapeutic agents to increase lysosomal activity, which could potentially lead to an enhancement in microglia fAβ lysosomal degradation.



ADPD5-2200

STUDY OF TRANSCRIPTIONNALLY ACTIVE/INACTIVE APP INTRACELLULAR DOMAIN (AICD) IN DIFFERENT CELL MODELS

R. Opsomer[1], C. Marinangeli[1], M. Decock[1], B. Tasiaux[1], I. Dewachter[1], J.N. Octave[1], P. Kienlen-Campard[1]

[1]Insitute of Neuroscience - pôle cellulaire et moléculaire - Alzheimer Dementia, Université Catholique de Louvain, Brussels, Belgium

Objective

APP has been extensively studied for its pathological role in AD, but its physiological role remains poorly understood. Several studies indicated that APP regulates gene expression via APP/AICD signaling, but neither the exact signaling mechanism nor the downstream targets have been unambiguously established. We analyzed AICD production, accumulation and transcriptional activity in engineered cell models expressing different APP/CTFs (C-Terminal Fragments).

Methods

Transcriptionally active AICD was monitored by transactivation assays in mouse embryonic fibroblast (MEFs) knock out for Presenilins (PS1 and PS2) and MEFs rescued by wild-type PS or familial Alzheimer disease (FAD) mutants.
HEK293 and CHO cell model were transfected wit APP/CTFs constructs and treated with alkalizing drug to assess AICD detection. Fractionation protocol was used in a neuronal cell model to analyze AICD in nucleus and its phosphorylation status.

Results

Transcriptional activity of AICD is different depending on APP in cleavage by PS-1 or PS-2 γ-secretase. Mutations in PS affect differently AICD production and its transcriptional activity when compared to wt PS. Alkalizing treatment of cells increase, as previoulsy shown, AICD detection preferentially produced from full length APP instead of exogenous CTFs. Fractionation of neuronal cells showed that AICD in nucleus is mainly not phosphorylated at Thr668.

Conclusion

Our data suggest that AICD release from PS1 or PS2 γ-secretase complexes display different transcriptional properties. Alkilizing treatment suggest that an AICD pool is degraded via endosomal/lysosomal pathway, irrelevant to transcriptional properties in physiological condition.

ADPD5-2233

ANALYZING CLEARANCE IN APP TRANSGENIC MICE WITH MID-DOMAIN AMYLOID BETA-ANTIBODIES

K. Henjum[1], C.B. Jendresen[1], R. Torp[2], T. Fladby[3], L. Nilsson[1]
[1]Department of Pharmacology, University of Oslo and Oslo University Hospital, Oslo, Norway
[2]Department of Anatomy, University of Oslo, Oslo, Norway
[3]Department of Neurology, Akershus University Hospital University of Oslo, Lørenskog, Norway

Objectives: The formation of amyloid plaques is a well-studied aspect of Alzheimer Disease (AD) pathogenesis, while mechanisms of amyloid-beta (Abeta) clearance are still fairly unknown. Although microglial/macrophage uptake and degradation of Abeta peptides has been demonstrated *in vitro*, its relevance *in vivo* remains controversial. New techniques and tools to examine Abeta clearance in brain is much needed.
Methods: A new mid-domain Abeta-antibody was characterized with dot-blot, epitope mapping and ELISA. Brain sections of tgArcSwe mice was used for immunofluorescent and immunogold staining at the light and ultrastructural microscopic level respectively. At the light microscopic level co-staining with microglial markers were done. ELISA was used for characterization of antibody binding epitope.
Results: We developed mid-domain antibodies as tools to better investigate degradation products of Abeta *in vitro* and transgenic models and AD. Antibodies were raised and purified against a 21-34 amino acid sequence in Abeta, but the binding domain was more limited. With the antibody we could detect Abeta-fragments and visualize amyloid beta-staining in brain microglia/macrophages at both the transmission EM data and at the light microscopic level.
Conclusions: Here we describe the *in vitro* characteristics of a new type of mid-domain Abeta-antibody that could become useful for further analysis of enzymatic Abeta-degradation and clearance *in vitro* and *in vivo*. Our data demonstrate uptake of Abeta occurring *in vivo* in transgenic mice, indicating a role of microglia/macrophages in Abeta-clearance.

ADPD5-2306

THERAPEUTIC EFFECT OF BERBERIS VULGARIS AND CALLUNA VULGARIS EXTRACTS ON LIPOPOLYSACCHARIDE (LPS)-INDUCED BRAIN INFLAMMATION

S. abdulmalek[1], A.L.A.A. Hegazy[2], S. Risk[3], D.O.A.A. Ghareeb[3]
[1]biochemistry, Faculty of Sciencce, Alexandria, Egypt
[2]medical laboratory technology, Allied Medical Science Faculty, Alexandria, Egypt
[3]biochemistry, Faculty of science, Alexandria, Egypt

Brain inflammation is important in aggravation of brain damage and causes neurodegenerative diseases that occur due to the formation reactive oxygen species and overexpress pro-inflammatory mediators of activated microglia. Lipopolysaccharide accounted as brain damage compound as it is induced injury in the rat brain. Both Berberis vulgaris L. and Calluna vulgaris L. have medicinal properties as they act as antioxidant and anti-inflammatory effects. Objective: The aim of the present study was to assess the mechanisms involved in the protective effect of B. vulgaris (Bv) and a C. vulgaris (Cv) extracts on LPS-induced brain inflammation and neurotoxicity. Methods: rats were orally administrated extracts (100 mg/kg/day) for three weeks and then intraperitoneally injected once with 4mg/kg LPS. Results: LPS administration significant increased brain lipid peroxidation (malondialdehyde level and xanthine oxidase activity) and decreased antioxidants status (superoxide-dismutase, reduced glutathione, glutathione-peroxidase, glutathione-S-transferase). Furthermore, oxidative stress stimulated the production of proinflammtory molecules. As a result, the brain acetylcholinestrase was activated that lead to brain glucose level diminished. Finally, β -amyloid plaques were formed as a result from low formation of (Aβ1-40) and insulin degrading enzyme activity and accumulation of (A β1-42) as a result of high expression levels of APP and β-secretase. we also show that production of β-amyloid plaques and neurodegenration are reduced by increasing the expressing of the NAD-dependent deacetylase SIRT1 in the brain. Conclusion: Our results suggest that the pre-treatment with extracts had the potential to suppress oxidative stress and pro-inflammatory cytokines and therefore prevent the neurotoxicity and amyloid plaques formation.

ADPD5-2327

MT5-MMP IS A NEW REGULATOR OF APP THAT PROMOTES AMYLOIDOSIS AND COGNITIVE DECLINE IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

S. Rivera[1], Y. Marchalant[1], A.A. Bonnet[1], N.N. Crouzin[1], A. Carrete[1], N. Py[1], A. Bernard[1], C. Bauer[2], E. Charrat[1], K. Moschke[3], M. Seiki[4], M. Vignes[5], S. Lichtenthaler[3,6], F. Checler[2], M. Khrestchatisky[1], K. Baranger[1]

[6]Munich Cluster for Systems Neurology (SyNergy), 80336 Munich, Germany

Objectives: Although membrane-type 5-matrix metalloproteinase (MT5-MMP) is a sheddase with emerging roles in brain pathophysiology, its implication in Alzheimer's disease (AD) remains elusive. Accordingly, we examined the impact of MT5-MMP invalidation in an experimental mouse model of AD.

Methods: We crossed the 5xFAD (Tg) mouse model of AD with MT5-MMP deficient mice (MT5-/-) to generate bigenic 5xFAD/MT5-MMP-/- mice (TgMT5-/-). We used molecular and cell biology techniques, as well as neuroanatomical assessment of amyloid lesions combined with LTP protocols and the 6-arm radial water maze.

Results: At early stages (4 months) of the pathology, the levels of amyloid beta peptide (Abeta) and its precursor the APP C-terminal fragment C99, where largely reduced in the brains of TgMT5-/-compared to Tg mice. Reduced amyloidosis in bigenic mice was concomitant with decreased glial reactivity and preservation of LTP and spatial learning, without changes in the activity of alpha-, beta-, and gamma-secretases. Beneficial effects of MT5-MMP invalidation were still present at 16 months of age in bigenic mice, which showed reduced amyloid burden and gliosis, and higher levels of synaptophysin. MT5-MMP expressed in HEKswe cells co-immunoprecipitated with APP, and significantly increased the levels of Abeta, C99 and a soluble APP fragment of 95 kDa (sAPP95). The latter was reduced in brain homogenates of TgMT5-/- mice, supporting the idea of in vivo APP processing by MT5-MMP.

Conclusions: MT5-MMP emerges as a new multimodal regulator of APP metabolism, whose invalidation limits the amyloidogenic processing of APP, and hence alleviates amyloid pathology and cognitive decline.

ADPD5-0433
ENGULFMENT ADAPTER PTB DOMAIN CONTAINING 1 (GULP1) IS A NOVEL TAU INTERACTING PROTEIN

A. Wahler[1], C. von Arnim[1]
[1]Experimental Neurology, University Ulm, Ulm, Germany

Alzheimer's disease (AD) is the leading cause of dementia worldwide and characterized by senile amyloid β (Aβ) plaques and neurofibrillary tangles composed of hyperphosphorylated tau. Our group identified GULP1 as novel APP adaptor protein that shuttles between cytosol and nucleus modulating transactivation together with LRP1. Fe65, a well characterized APP adaptor protein, has recently been identified as a tau interacting protein. We here addressed the question whether GULP1 interacts with tau as well.
Co-localization of overexpressed and endogenous GULP1 and tau was analyzed in different cell lines showing co-localization in perinuclear region. In addition, we investigated the impact of GULP1 overexpression and siRNA mediated knockdown on tau expression and phosphorylation. We could demonstrate that GULP1 overexpression, especially in SH-SY5Y cells, changed the subcellular localization of endogenous tau and led to a clear reduction of endogenous total tau expression levels in an expression level dependent manner. To study the interaction between GULP1 and tau, co-immunoprecipitation experiments of overexpressed and endogenous proteins were performed demonstrating that tau was co-precipitated upon GULP1-precipitation.
Here, we provide first evidence that GULP1 is a novel tau interacting protein regulating tau expression in a dose dependent manner. The protein may also have an impact on tau phosphorylation and can thereby regulate cellular re-organization and cytoskeletal dynamics. As GULP1 has already been shown to interact with APP, it may function as linker between APP and tau.

ABETA INTERACTS WITH CELLULAR PRION PROTEIN INDUCING NEURONAL MEMBRANE DAMAGE AND SYNAPTOTOXICITY

C. Peters[1], M.P. Espinoza[1], C. Opazo[2], L.G. Aguayo[1]
[1]Physiology, University of Concepcion, Chile, Chile
[2]Oxidation Biol Lab, University of Melbourne, Melbourne, Australia

Objetives: A major feature of Alzheimer's disease (AD) is the accumulation of β-Amyloid peptide (Abeta) in the brain. Recent studies have shown that Abeta oligomers interact with the cellular Prion protein (PrPc). Therefore, this interaction might be driving some of Abeta toxic effects at the neuronal membrane level. The aim of this study was to evaluate the functional consequences of this interaction.
Methods: In the present study, using a combination of electrophysiological recording, immunofluorescence, calcium imaging and Western blots techniques, we report that Abeta binds to PrPc in the neuronal membrane and plays a role on the toxic effects induced by Abeta. Phospholipase C-enzymatic cleavage of PrPc from the plasma membrane attenuated the association of Abeta to the neurons. Furthermore, an anti-PrP antibody (6D11) decreased the association of Abeta to hippocampal neurons with a concomitant reduction in Abeta and PrPc co-localization. Interestingly, this antibody blocked the increase in membrane conductance, intracellular calcium and synaptic deficit induced by Abeta.
Conclusions: The data indicate that PrPc plays a role on the membrane perforations produced by Abeta, the increase in calcium ions and the release of synaptic vesicles that subsequently leads to synaptic failure. Future studies blocking Abeta interaction with PrPc could be important for the discovery of new therapeutic strategies for AD.

Apolipoprotein E4 (*APOE4*) is a genetic risk factor for developing Alzheimer's disease (AD). Once AD manifests clinically, however, the effects of *APOE4* are less clear. Therefore, we investigated *APOE4* longitudinal effects on topographical changes in AD patient brain atrophy.

We prospectively recruited 35 patients with AD (19 *APOE4* carriers and 16 non-carriers), and 14 normal controls, then followed them for five years. We measured hippocampal deformities and cortical thickness. Hippocampal comparison between *APOE4* carriers and non-carriers with AD showed carriers had rapid changes in the head and body, while non-carriers had rapid changes in a small portion of the body. Cortical thickness comparison between *APOE4* carriers and non-carriers with AD dementia showed carriers had rapid thinning in the lateral frontal, temporal, and parietal regions, while no region showed more rapid cortical thinning in non-carriers than in carriers.

These findings underlined *APOE4* allele importance for designing and interpreting future treatment trials in patients with AD dementia.

Formation of inert mature amyloid fibrils constitutes a defense mechanism to clear the cellular toxicity of prefibrillar oligomers in pathological situations. Some genetic variants involved in this process predispose patients to heightened susceptibility to amyloid formation, such as of Apolipoprotein E (ApoE) in early onset Alzheimer's Disease. Amyloid structures can also serve physiological functions. Cells that produce so-called "functional amyloids" must therefore exploit specific mechanisms to avoid potential toxicity inherent in their formation.

To investigate the mechanisms of functional amyloidogenesis, we have combined cell biology methods, biochemistry and electron microscopy to analyze the amyloid formation by the premelanosome protein (PMEL) in mammalian pigment cells. Pigment cells have tuned their endosomes to assemble mature fibrils from the proteolytic fragments of PMEL using intraluminal vesicles (ILVs) as potential seeding platforms.

Using secreted ILVs, called exosomes, as reporters of endosomal processes, we show that exosomes and ILVs are associated with lipoparticles that are uniquely composed of Apolipoprotein E (ApoE). Within endosomes ApoE facilitates the loading of PMEL amyloidogenic fragments onto ILVs and regulates the formation of mature fibrils in melanocytic cell lines and pigment cells in vivo.

Our study establishes a paradigm for the mechanism by which ApoE regulates the assembly of mature amyloid fibrils under both benign and pathological conditions. The novel evidence that ApoE is a component of exosomes provides a breakthrough in the field of extracellular particles that might be exploited to reconsider the respective roles of each extracellular particle in amyloid associated pathologies.

IMPAIRED AUTOPHAGY IN APOE4 ASTROCYTES

S. Simonovitch[1], E. Schmukler[1], D. Frenkel[1], R. Pinkas-Kremarsk[1], D.M. Michaelson[1]
[1]Neurobiology, Tel Aviv University, Tel Aviv, Israel

Autophagy is the main cellular process involved in degradation pathways of organelles and damaged proteins. Recent studies suggest that Alzheimer disease (AD) is associated with activation of autophagy. Although it is not yet known whether autophagy plays a causative or protective role in AD, the prevailing view is that autophagy is first activated as a protective mechanism to remove cellular and protein debris but as the disease progresses, autophagy apparatus may become more clogged and dysfunctional. ApoE4 is the most prevalent genetic risk factor of AD, and affects more than half of the AD patient population. The mechanisms underlying the pathological affects of ApoE4 are not known.

Utilizing in-vitro and in-vivo models, the present study explores the possibility that autophagy plays a role in mediating the pathological effects of ApoE4. In vitro studies utilizing astrocytic cell lines prepared from ApoE3 and ApoE4 transgenic mice revealed that ApoE4 is associated with reduced levels of the microtubule-associated protein LC3-II and decreased levels of ubiquitin-binding scaffold protein p62. This suggest that ApoE4 can impairs autophagy and protein degredation. Additional studies revealed that the ApoE4 astrocytes are impaired in their ability to digest Amyloid-beta containing senile plaques in-situ suggesting that ApoE4 is associated with both biochemical and functional autophagy related impairments. Complementary studies utilizing ApoE3 and ApoE4 target replacement naïve mice revealed up regulation of p62 in hippocampal neurons of the ApoE4 mice.

Taken together these findings suggest that ApoE4 is associated with impaired autophagy, which may play role in exerting it's pathological affects.

ADPD5-1509

THE ROLE OF APOE IN REGULATING SYNAPSE FORMATION AND PLASTICITY

W.W. Poon[1], M.D. Torres[2], J.L. Davis[1], T.E. Lim[1], A.J. Rajic[1], M. Blurton-Jones[2]
[1]Institute for Memory Impairments and Neurological Disorders, University of California Irvine, Irvine, USA
[2]Neurobiology and Behavior, University of California Irvine, Irvine, USA

Objective. In the human population, there exist three possible apoE alleles, e2, e3, and e4. A single copy of the APOE ε4 allele increases the risk of developing AD by about threefold, whereas homozygosity for ε4 increases AD risk ~12 fold. Here, we utilized patient iPS cell-derived astrocytes to investigate how the APOE4 genotype confers AD risk.
Methods. We utilized iPS cell-derived astrocytes from an apoE knockout line, and also patient-derived ApoE3/3 and ApoE4/4 lines to determine how apoE regulates synapse formation and whether the APOE4 polymorphism differentially affects synapse formation when compared to APOE3. Astrocytes were co-cultured with neurons and synapse formation/plasticity *in vitro* was quantified.
Results. We found that apoE plays an important role in synapse formation *in vitro*. Furthermore, synapse formation was dependent on APOE genotype.
Conclusions. Our results suggest that ApoE modulates synaptic formation and plasticity and that APOE4 confers AD risk by differentially affecting synapse formation and synaptic plasticity when compared to APOE3.

ADPD5-1649

RISK SCORING FOR ALZHEIMER'S DISEASE IN INDIVIDUALS WITH FAMILY HISTORY

G. Novotni[1], A. Novotni[2], V. Aleksovski[1], D. Petrovska Cvetkovska[1]
[1]University Clinic of Neurology, Medical Faculty, Skopje, Macedonia
[2]University Clinic of Psychiatry, Medical Faculty, Skopje, Macedonia

Introduction: The insight in the ethiopathogenesis of Alzheimer's disease(AD) suggests a slowly developing neurodegenerative process that starts 10 to 20 years before the clinical manifestation. Preventing or slowing the process of neuronal damage would be the state of the art in neuroscience, but the fist step is to identify individuals at risk, diagnose AD in the preclinical stage, develop preventive strategies and start treatment in the early disease course.

Objectives: Developing a model for estimating a predictive risk score for AD in individuals with family history for AD and .

Material and Methods: A battery of biochemical test for identifying LPL deficiency, serological biomarkers(alfa 2 macroglobulin, homocystein, complement factor H, interleukin-6) , APO E genotyping and neuropsychological tests (Mini Mental State Examination-MMSE, Clinical Dementia Rating, and the novel Syndrome Kurz test) are performed in 50 individuals with family history for AD.

Results: The early stage ongoing research that our team is performing, gives optimistic insight in the first results by combining the presence of the examined serological biomarkers, the neuropsychological tests results and ApoE genotyping, we estimate the risk score for developing AD.

Conclusion: Till now a list of potential blood biomarkers has been suggested but none of them has shown to be sensitive, nor specific in accurate preclinical AD diagnosing. We believe that by combing these tests, a risk score for individuals with family history of AD would be estimated, so that a prospective approach and preventive strategies could be developed.

ADPD5-0377

NEW TOOLS TO STUDY THE INTRACELLULAR TRAFFICKING OF GAMMA-SECRETASE COMPLEXES USING FLUORESCENCE MICROSCOPY

X. Meckler[1], *F. Checler*[1]
[1]*UMR 7275 CNRS/Université Nice Sophia-Antipolis, IPMC, Valbonne, France*

Objectives: Gamma-secretase achieves the regulated intramembrane proteolysis of various substrates including APP, the cleavage of which leads to amyloid peptide production. The gamma-secretase protein complex is made of the four core-subunits presenilin (PS), nicastrin, APH1 and PEN2. With two PS variants (PS1 and PS2) and three APH1 variants (APH1aL, aS and b), the subunits combinations can potentially generate six different complexes. Our goal is to determine whether distinct gamma-secretase complexes traffic to similar or different cellular compartments and to identify the molecular motifs potentially involved in a specific targeting.
Methods: We generated different types of constructs to co-express specific combinations of gamma-secretase subunits and follow their intracellular trafficking using either bimolecular fluorescence complementation (BiFC) or more traditional fluorescent protein-tagging and fluorescence microscopy.
Results: We demonstrate that our constructs allow the formation of functional gamma-secretase complexes and their visualization. Using BiFC constructs, we detected PS1-containing complexes at the cell surface and in endosomes/lysosomes in addition to the endoplasmic reticulum (ER); however the majority of cells co-transfected with APH1b displayed only BiFC signal within the ER suggesting a higher retention of gamma-secretase complexes containing this variant.
Conclusions: Our new tools will be helpful to precisely characterize the successive steps of the subcellular trafficking of the different gamma-secretase complexes and to determine if distinct itineraries can be associated with a substrate specificity of particular gamma-secretase complexes.

ADPD5-0428

PROTEOGLYCAN NG2 IS SHED BY ALPHA SECRETASE; A PROCESS POTENTIALLY UNDERLYING THE ASSOCIATION BETWEEN LOWERED NG2 SHEDDING AND AMYLOID BETA 1-42 ACCUMULATION IN AD PATIENTS?

C. Orbjörn[1], L. Minthon[1], H. Toresson[1], M. Wennström[1]
[1]Clinical Sciences Malmö, Lund University, Malmö, Sweden

Objectives: The NG2-proteoglycan is implicated in important processes including cell-proliferation and cell-survival of its host cells and the shed version (sNG2) is known to regulate angiogenesis. We have previously shown decreased level of sNG2 positively correlating with amyloid beta (Aß) 1-42 levels in cerebrospinal fluid (CSF) from patients with Alzheimer's disease (AD). We have also demonstrated a direct impact of Aß1-42 on NG2 shedding and a decreased NG2 immunoreactivity in hippocampal tissue from AD patients. Here we investigate whether NG2 and the amyloid precursor protein (APP) are sensitive to the same protease activity.
Methods: NG2 expressing fibroblasts isolated from (n=8) healthy donors and (n=3) AD patients were exposed to α-secretase inhibitor TAP1-0, γ-secretase inhibitor DAPT or respective vehicle. Levels of sNG2, APPalpha and APPbeta in cell culture medium were measured using electrochemiluminescence (ECL) technology (Mesoscale Discovery).
Results: Levels of sNG2 and APPalpha decreased ($p<0.001$), whereas APPbeta levels increased, after exposure to TAP1-0 compared to vehicle ($p<0.001$). No impact on sNG2, APPalpha or APPbeta levels was detected after DAPT exposure. The sNG2 levels were strongly and positively associated with APPalpha levels, but not with APPbeta, regardless of stimuli exposure ($r>0.800$, $p<0.01$).
Conclusion: Our results suggest that sNG2 and the non-amyloidgenic APPalpha are generated by the same proteolytic pathway, which may underlie the disturbed NG2 shedding in relation to Aß1-42 accumulation seen in AD patients.

ADPD5-0473

METALLOPROTEASE MEPRIN BETA IS A NEW LINK TO SPORADIC ALZHEIMER´S DISEASE

C. Schönherr[1], J. Bien[1], S. Isbert[1], R. Wichert[2], J. Prox[2], H. Altmeppen[3], S. Kumar[4], J. Walter[4], S. Lichtenthaler[5], S. Weggen[6], M. Glatzel[3], C. Becker-Pauly[2], C.U. Pietrzik[1]
[1]Department of Molecular Neurodegeneration, Institute of Pathobiochemistry, Mainz, Germany
[2]Unit for Degradomics of the Protease Web, Institute of Biochemistry, Kiel, Germany
[3]Department of Neuropathology, Institute of Neuropathology, Hamburg, Germany
[4]Department of Neurology, Molecular Cell Biology, Bonn, Germany
[5]Department of Neuroproteomics,
German Center for Neurodegenerative Diseases (DZNE), Munich, Germany
[6]Molecular Neuropathology, Institute of Neuropathology, Düsseldorf, Germany

Objective
N-terminally truncated amyloid β (Aβ) peptides have been described in brains of sporadic AD patients. These peptides are generated independently of BACE-1, but can be attributed to the β-secretase activity of the metalloprotease meprin β. Aim of this work was to characterize the role of meprin β in APP processing and, even more, to study its importance concerning sporadic versus familial Alzheimer´s Disease (AD).
Methods
Immunoprecipitated Aβ species were separated with 8 M urea SDS-PAGE. Aggregation propensity of Aβ species was analysed using ThT-binding assay. Analysis of protein interactions was performed by applying co-immunoprecipitation or a split-GFP based complementation assay. Sections of paraffin-embedded samples of frontal isocortex of AD patients and non-demented control patients were stained with hematoxilin/eosin (HE) and a Bielschowsky staining kit.
Results
We could show that APP mutations, associated with familial AD (FAD), affect meprin β cleavage and that meprin β is not able to generate N-terminally truncated Aβ from the Swedish mutant APP. Furthermore, we could show that N-terminally truncation promotes Aβ aggregation and, even more, enhances the aggregation of non-truncated species. Our *in vitro* data demonstrates that APP and meprin β interaction occurs prior to endocytosis. Moreover, we revealed increased levels of soluble APPα (sAPPα) in meprin β knock-out mice. Most interestingly, we were able to detect increased levels of meprin β in sporadic AD versus control brains.
Conclusion
We propose that, besides BACE-1, meprin β is a novel candidate that can be linked to the generation of N-terminally truncated Aβ in sporadic AD.

ADPD5-0560

SERUM STARVATION INDUCES BACE1 PROCESSING AND SECRETION

A. Stavropoulos[1], O. Mavrofrydi[1], S. Efthimiopoulos[1]
[1]Biology, University of Athens, Athens, Greece

Objectives

β-secretase (BACE1) is a type 1 transmembrane protease implicated in Alzheimer's Disease (AD) pathogenesis. Cleavage of Amyloid Precursor Protein (APP), initiated by BACE1 and followed by γ-secretase, leads to the formation of toxic Aβ peptides. Increased levels of BACE1 have been detected in the CSF of AD patients compared to age-matched healthy controls indicating that neurodegenerative conditions induce proteolysis-dependent secretion of BACE1. The aim of this study is to examine the mechanism by which serum deprivation stimulates proteolysis-dependent secretion of BACE1.

Methods and Results

HEK293 cells were incubated in the presence or the absence of serum. We observed that serum-starvation stimulated proteolysis-dependent secretion of BACE1 and that ADAM10 and ADAM17 may be involved in BACE1 processing. This is unexpected since BACE1 is localized mainly in lipid rafts while ADAM10 is localized mainly in non-lipid raft domains. We hypothesized that serum deprivation results in alterations in the lipid composition of the membrane or the activation of signal transduction pathways both of which can alter the localization of ADAM10 and BACE1. In support, we obtained results indicating that extraction of membrane cholesterol following incubation with methyl β cyclodextrin potentiated the effect of serum deprivation.

Conclusions

Serum starvation induces proteolysis-dependent secretion of BACE1.

ADPD5-0651
THE RELATIONSHIP BETWEEN AGE-DEPENDENT ENDOCYTIC DISTURBANCE AND PRESENILIN-1

N. Ueda[1], K. Yanagisawa[1], N. Kimura[1]
[1]Department of Alzheimer's Disease Research,
National Center for Geriatrics Gerontology, Obu, Japan

Objectives
We previously showed that endocytic disturbance causes intraendosomal accumulation of β-amyloid precursor protein (APP) and Aβ. Therefore, endocytic disturbance may be involved in age-dependent AD pathology. Presenilin1 (PS1) is the catalytic core of gamma secretase complex that is required for Aβ cleavage. In this study, we investigated whether endocytic disturbance also affects PS1 level and localization.
Methods
Neuro2a cells were treated with siRNA against dynein heavy chain or lysosomal inhibitors to induce endocytic disturbance. We also examined various aged cynomolgus monkey brains for in vivo study.
Results
In contrast to APP, endocytic disturbance did not affect PS1 level or its subcellular distribution. Furthermore, co-immunoprecipitation analyses demonstrated that endocytic disturbance did not affect γ-secretase complex formation. In aged monkey brains, we confirmed that the level of PS1 unchanged in microsomal fraction, even though APP clearly accumulated as previously reported.
Conclusion
Age-dependent endocytic disturbance does not greatly affect PS1 level and its localization. These findings suggested that intracellular trafficking of PS1 would be different from APP.

ADPD5-0844

IDENTIFICATION AND VALIDATION OF NOVEL BACE1 SUBSTRATES IN VIVO

J. Wanngren[1], B. Dislich[1], A. Colombo[1], P.H. Kuhn[1], S. Lichtenthaler[1]
[1]German Center for Neurodegenerative Diseases (DZNE),
Technische Universität München, München, Germany

The protease BACE1 cleaves the amyloid precursor protein (APP) and is a key drug target in Alzheimer's disease. Several pharmaceutical companies have recently entered clinical trials with BACE1 inhibitor drug candidates. However, studies showed that BACE1-deficient mice display several neurological phenotypes. This raises the concern that possible mechanism-based side effects of BACE1 inhibition in patients may result from reduced cleavage of other BACE1 substrates. To fully evaluate the therapeutic potential of BACE1 inhibition, it is essential to understand how the function of other substrates is altered in BACE1-deficient mice and whether their loss of cleavage contributes to the phenotypes observed in these mice.

Objectives: To identify and characterize novel BACE1 substrates under physiological conditions in vivo by comparing WT and BACE1 knock-out mice brains.

Methods: BACE1 substrates were identified using a mass spectrometry based proteomic workflow with spike-in SILAC mice and validated using western blotting and immunofluorescence.

Results: 17 novel and previously known BACE1 substrates such as; APP, APLP2, CHL1 and Contactin-2 were identified. A subset of substrates including the classical axon guidance molecule EPHA4 was validated in an independent set of brains. We show that EPHA4 is shed by BACE1 from embryogenesis to adulthood, although acting as a minor sheddase. Further validation of other substrates and functional aspects are currently in progress.

Conclusions: The identified BACE1 substrates points to a role for BACE1 in establishment and maintenance of neuronal connectivity, since a majority of identified proteins are involved in neural outgrowth axonal guidance and synapse formation.

[5]Centre for Research into Neurodegenerative, University of Toronto, Toronto, Canada
[6]Molecular Cell Biology, European Molecular Biology Laboratory, Grenoble, France
[7]Structural Biology, European Molecular Biology Laboratory, Grenoble, France

Objective: γ-Secretase is a multi-subunit enzyme essential for processing a number of transmembrane proteins inclusing amyloid precursor protein (APP) and Notch. Although EM analysis of purified γ-secretase revealed a globular structure, higher resolution crystal structures for the complex or its components have not been elucidated. Such studies require large quantities of purified protein., Baculoviral expression is an approach to achieve such quantities... Previous studies have expressed multi-protein complexes by co-infecting cells with several viruses. With this approach, the logistical demands of maintaining known viral titres and establishing relative equal expression levels, renders large-scale complex production difficult. To circumvent these limitations, we used a baculoviral multi-gene vector (MulitBac) to generate γ-secretase.
Methods: Components of γ-secretase (PS1, APH1a, NCT and Pen-2) were cloned into pFBDM, MultiBac expression vector. Following integration into single baculovirus DNA, γ-secretase was expressed in insect cells. The complex was purified using affinity purification tags- octa-histidine and CBP on NCT and PEN-2 respectively.
Results: Expression of all components of γ-secretase was observed and the complex was active in processing APP and Notch (which was inhibited by γ-secretase inhibitors). Interactions between components were observed by co-immunoprecipitation studies. The complex was purified using His followed by CBP chromatography.
Conclusion: We have utilized the MultiBac expression system to successfully generate an active γ-secretase complex. This allows larger scale production and purification of the complex for further analysis. In conjunction with available automated multi-complex generation, this system allows the opportunity to generate γ-secretase variants with modified/mutated subunits in high throughput.

BACE1 REGULATES THE SURFACE LEVELS OF KV1.1/KV1.2 POTASSIUM CHANNELS

C. D'Avanzo[1], V. Gautam[1], S.H. Choi[1], R.E. Tanzi[1], D.M. Kovacs[1], D.Y. Kim[1]
[1]Genetics and Aging Research Unit MassGeneral Institute for Neurodegenerative Diseas e, Massachusetts General Hospital Harvard Medical School, Charlestown, USA

Objectives: BACE1 regulates various neuronal functions by cleaving multiple substrates. Recently, we found that BACE1 cleaves contactin-2, a GPI-anchored protein in neurons. Since contactin-2 regulates K_v1.1/1.2 trafficking in axonal compartments, we asked whether BACE1-mediated cleavage of contactin-2 leads to altered trafficking of K_v1.1/1.2.

Methods: To analyze surface levels of contactin-2/K_v1.1/K_v1.2, we performed surface biotinylation on brain slices from BACE1 KO and WT mice. Given the selective expression of K_v1.1 in hippocampal neurons and K_v1.2 in cortical neurons, we also used mouse primary cortical/hippocampal cultures treated with a BACE1 inhibitor. To explore axonal colocalization of contactin-2/K_v1.1/K_v1.2 in myelinated CNS neurons, we performed immunostaining in paraffin sections of optic nerve and hippocampus from BACE1 KO and WT mice.

Results: We found that surface contactin-2/K_v1.2 levels are elevated in cortical slices of BACE1 KO mice as compared to WT mice and in cultured cortical neurons treated with a BACE1 inhibitor. We also found increased K_v1.1/contactin-2 surface levels in hippocampal neurons treated with a BACE1 inhibitor. Abnormal localization of K_v1.1/K_v1.2 was observed in optic nerve axon bundles, while K_v1.1/K_v1.2 levels were found increased in the CA3 region of BACE1 KO mice as compared to WT mice.

Conclusions: Our findings show that BACE1 regulates surface levels of K_v1.1/1.2 possibly by cleaving contactin-2 in neurons. Our data also suggest that axonal localization of contactin-2/K_v1.1/K_v1.2 is disrupted in BACE1 KO neurons. This study will help elucidate non-amyloidogenic functions of BACE1 in neurons, important for developing BACE1 inhibitors as a safe therapeutic strategy for Alzheimer's disease.

ADPD5-0954

VALIDATION AND FUNCTIONAL ANALYSIS OF THE SEZ6 PROTEIN FAMILY - NOVEL SUBSTRATES OF THE ALZHEIMER PROTEASE BACE1.

M. Pigoni[1], P.H. Kuhn[1], J. Gunnersen[2], S.F. Lichtenthaler[1]
[1]Deutsches Zentrum für Neurodegenerative Erkrankungen, Technische Universität München, München, Germany
[2]Department of Anatomy and Neuroscience, University of Melbourne, Melbourne, Australia

In Alzheimer's disease, the amyloid beta (Abeta) peptides are considered the main neurotoxic species. Abeta peptides are generated through proteolytic processing of the transmembrane amyloid precursor protein (APP) by the key rate-limiting enzyme BACE1. Thus, BACE1 is a main drug target for the treatment of AD. Although much effort has been made in order to inhibit BACE1 activity and therefore reduce Abeta production, possible side effects resulting from its inhibition have not yet been clarified. These side effects may occur from the cleavage inhibition of other BACE1 substrates. Importantly, besides APP, BACE1 cleaves other substrates whose loss of processing has been linked to phenotypes observed in BACE1-deficient mice. We have recently identified novel BACE1 substrates, including the Seizure protein 6 (Sez6) family. This family is particularly interesting given its role in brain development and the similarity between the phenotype of Sez6 and BACE1-deficient mice. Objectives: To evaluate how the expression and function of Sez6 and Sez6L is altered in BACE1-deficient mice and whether their loss of cleavage contributes to the phenotypes observed in BACE1-deficient mice. Methods: Biochemical analysis of primary neurons and BACE1-deficient tissue. Results: We have validated Sez6 and Sez6L as main BACE1 substrates both in vitro and in vivo. Moreover, we are investigating the function of the Sez6 protein family and alterations that their loss of BACE1-cleavage may induce in neurons. Conclusions: Our work allows a better understanding of BACE1 function and may allow to predict potential side effects resulting from therapeutic BACE1 inhibition.

ADPD5-0971
UPREGULATED MAM FUNCTION IN ALZHEIMER DISEASE
D. Larrea[1], M. Pera[1], E. Area-Gomez[1], E. Schon[1]
[1]Neurology, Columbia University Medical Center, New York City, USA
Alzheimer disease (AD) is characterized by neuronal loss, especially in the cortex and hippocampus, accompanied by accumulation in the brain of extracellular neuritic plaques containing b-amyloid (Ab) and of intracellular neurofibrillary tangles consisting of hyperphosphorylated tau protein. AD patients also present with other features that have received less attention, including aberrant cholesterol, phospholipid, and calcium homeostasis, and altered mitochondrial function and dynamics.
Presenilin-1 (PS1), presenilin-2 (PS2), and g-secretase activity, which processes the amyloid precursor protein (APP) to generate Ab, are all located predominantly in a specialized subcompartment of the endoplasmic reticulum (ER) that is physically and biochemically connected to mitochondria, called mitochondria-associated ER membranes (MAM). MAM is involved in the regulation of cholesterol and phospholipid metabolism, calcium homeostasis, and in mitochondrial function and dynamics. Our work shows that MAM is lipid raft-like domain where Abeta is produced and that cells from AD patients have massively upregulated MAM activity and increased ER-mitochondrial connectivity, resulting in altered cholesterol, phospholipid and calcium homeostasis, and aberrant mitochondrial dynamics, which may help explain many of the biochemical and morphological features of the disease.
Based on these findings, we believe that MAM dysfunction and altered ER-mitochondrial connectivity are early causative events in the pathogenesis of AD.

ADPD5-1431

REGULATION OF BACE1 EXPRESSION BY TRANSLATION INITIATION FACTORS

D. Zacchetti[1], B. Bettegazzi[1], R. Baldini[1], F. Grohovaz[1]
[1]Neuroscience, San Raffaele Hospital, Milan, Italy

Objectives

BACE1 is the key enzyme in the production of the amyloid-beta (Abeta) peptides that are considered the cause of neuronal damage and death in Alzheimer's disease (AD). Changes in BACE1 expression/activity are a critical issue in disease progression and higher levels of BACE1 protein have been observed in the brain of AD patients. Previous work highlighted the complex regulation of BACE1 expression at the translational level and it has been proposed that translation initiation factors have a role in the modulation of BACE1 expression. We aim to investigate how translation initiation factors can affect the efficiency of BACE1 translation in neurons.

Methods

We employ primary neuronal cultures from the rat brain. We modulate the activity of translation factors by overexpression, by silencing and by modulating their phosphorylation. The expression of BACE1 is assessed by RT-PCR and Western blotting.

Results

We show that changes in the activity and expression of translation initiation factors can modulate the levels of BACE1 in neurons by acting at the level of the complexity of the BACE1 transcript leader. We also propose that neuronal-specific phosphorylation of translation factors could explain the difference in BACE1 translation efficiency between neurons and other cell types.

Conclusions

BACE1 translation in neurons can be under the control of translation initiation factors whose activity is regulated by the neuronal activity. A derangement of this control could underlie the pathological changes in BACE1 levels observed in AD.

IMPACT OF RTN3 DEFICIENCY IN MICE ON AMYLOID DEPOSITION AND TAU PHOSPHORYLATION

R. Yan[1], Q. Shi[1], Y. Ge[1], M. Sharoar[1], W. He[1], X. Hu[1]
[1]Neuroscoence, Cleveland Clinic Lerner Research Institute, Cleveland, USA

Reticulon 3 (RTN3) is a richly neuronal expressing member of reticulon/Nogo protein family. Previous studies showed that RTN/Nogo interacts with BACE1 and negatively regulates BACE1 activity. To what extent and how critical RTN3 deficiency affects BACE1 activity is an intriguing question. In this study, we aimed to address this question by utilizing generated RTN3-null mice. Mice with complete deficiency of RTN3 grow normally and have no obviously discernible phenotypes. Morphological analyses of RTN3-null mice showed no significant alterations in cellular structure, although RTN3 is recognized as a protein contributing to the shaping of tubular endoplasmic reticulum. However, RTN3 deficiency in Alzheimer's mouse models facilitates amyloid deposition, further supporting an *in vivo* role of RTN3 in the regulation of BACE1 activity. Further biochemical analysis revealed that RTN3 deficiency increased protein levels of BACE1 via posttranslational event. This elevation of BACE1 levels correlated with enhanced processing of amyloid precursor protein at the β-secretase site. More intriguingly, RTN3 deficiency in mice induces hyperphosphorylation of tau proteins in different age groups. Since it has been shown that RTN3 monomer is reduced in brains of Alzheimer's patients, our results suggest that long-lasting reduction of RTN3 levels in elderly will contribute to Alzheimer's pathogenesis by having adverse effects on BACE1 activity and tau phosphorylation.

ADPD5-2252
ACTIVITY-DEPENDENT AND GRADED BACE1 EXPRESSIN IN OLFACTORY EPITHELIUM IS MEDIATED BY RETINOIDS.
R. Butowt[1], H. Login[2], K. Wadowska[1], S. Bohm[2]
[1]Molecular Cell Genetics, Nicolaus Copernicus University, Bydgoszcz, Poland
[2]Molecular Biology, Umea University, Umea, Sweden
Whether and how neuronal activity can modulate amyloid precursor protein (APP) metabolism and beta-amyloid peptide accumulation remains poorly understood but may be of potential medical relevance. It has been previously shown that in certain brain areas the beta-secretase (BACE1), the enzyme obligatory for amyloidogenic processing of APP, is elevated when neuronal activity decreases. However the mechanism of this process is not well examined. Here, using different transgenic mice and olfactory pathway as a model system, we show that BACE1 expression is controlled by activity-dependent expression of retinoic acid (RA) degrading enzyme Cyp26B1. Both genes form counter gradients along dorsomedial-ventrolateral axis and inversely depend on neuronal activity. Overexpression of Cyp26B1 or presence of dominant negative RA receptor selectively inhibit BACE1 expression in olfactory sensory neurons. We conclude that stimulus dependent neuronal activity by controlling RA catabolic enzyme which potentially leads to formation of RA gradient, can control expression of downstream genes such as BACE1. This results improves an understanding how topographic axonal connectivity is established during olfactory sensory map formation in healthy context. It also suggest potential mechanism how retinoids and neuronal activity can affect APP processing and beta-amyloid accumulation in pathogenic scenario.

ADPD5-0840
ROLE OF TRANSTHYRETIN IN AMYLOID-BETA UPTAKE BY THE LIVER: IMPACT IN ALZHEIMERS DISEASE

M. Alemi[1], C. Gaiteiro[1], C.A. Ribeiro[1], I. Cardoso[1]
[1]Modulation in Neurodegenerative Disorders Group,
Instituto de Biologia Molecular e Celular (IBMC), Porto, Portugal

Objectives: Data from transgenic mice has shown Transthyretin (TTR) as a protective molecule in Alzheimer's disease (AD). The peripheral clearance of Amyloid-Beta (Abeta) is mediated mainly by the liver. In this study, we aimed at investigating the role of TTR in Abeta uptake by the liver.
Methods: We used SAhep cells, which does not express TTR, added fluorescent Abeta1-42 (FAM-Abeta1-42) in presence or absence of human recombinant TTR in the cell media, and measured FAM-Abeta1-42 internalization by Flow Cytometry. We also performed immunocytochemistry to observe the co-localization of TTR and FAM-Abeta1-42 in the cells using fluorescent microscopy. To confirm the results, we performed similar studies in primary hepatocytes derived from mice with different TTR genetic backgrounds (with 2 copies, 1 copy or without TTR gene).
Results: TTR promoted Abeta internalization in SAhep cells and the highest percentage of uptake was obtained in presence of 4-6 µg/ml of TTR. Fluorescent microscopy confirmed co-localization of Abeta and TTR in the cells. We were also able to optimize the isolation and establishment of primary cultures of hepatocytes derived from mice with different TTR genetic backgrounds. A preliminary experiment confirmed results obtained in the cell line. Further studies will be a key in confirming the importance of TTR in Abeta elimination by the liver.
Conclusions: TTR increases Abeta uptake by hepatocytes suggesting its participation in peripheral Abeta clearance at the liver. Given recent reports on decreased plasma TTR concentration in AD patients, restoring TTR levels might constitute a therapeutic approach for AD in future.

AUTOPHAGY ALTERATION UNDER ISCHEMIC CONDITION: A POSSIBLE LINK TO ALZHEIMER'S DISEASE

E. Lonati[1], G. Sala[2], V. Tresoldi[1], S. Coco[1], M. Masserini[1], P. Palestini[1], A. Bulbarelli[1]
[1]Department of Health Sciences, University of Milano Bicocca, Monza (MB), Italy
[2]Labortory of Neurobiology Department of Surgery and Translational Medicine Milan Center for Neuroscience, University of Milano Bicocca, Monza (MB), Italy

Objectives. To understand brain ischemia injury contribution to Alzheimer's disease (AD) onset, looking for post-translational modifications, turnover alterations and AD hallmarks secretion such as tau and amyloid precursor protein (APP), associated to autophagy activation.
Methods. Rat cultured hippocampal neurons are subjected to oxygen glucose deprivation (OGD) followed by normal culture condition restoration (R), mimicking an ischemia/reperfusion (I/R) event. Afterwards AD hallmarks and autophagy markers expression and secretion are analyzed in the cells lysate and in microvescicles (MVs) isolated from culture medium. Confocal microscopy is employed to evaluate the potential re- and co-localization of tau and autophagic markers after treatment.
Results. In our cellular model subjected to OGD/R, we observed tau and APP post-translational and protein level modifications in parallel to the autophagic markers (LC3II and beclin-1) expression alterations. Moreover, OGD/R treatment elicits a time-dependent increase in tau and APP C-terminal fragments (CTF) secretion by means of a heterogeneous MV population, including a group of LC3II positive vescicles. Preliminary data obtained by confocal microscopy suggest that LC3 might undergo re-localization after OGD/R treatment.
Conclusions. The obtained results suggest that OGD treatment leads to multiple unconventional secretion mechanisms for tau and APP CTFs, in which autophagy activation seems to partially outcome in the exophagy secretory pathway. Although exophagy might be a defensive mechanism to prevent intracellular accumulation of misfolded proteins under conventional autophagy alteration, the secretion of misprocessed proteins has been recently associated to dendritic degeneration and neuronal death becoming a possible link to Alzheimer's disease.

ALLN INDUCES ACCUMULATION OF NOVEL AMYLOID PRECURSOR PROTEIN (APP) FRAGMENTS

H. Wang[1], N. Sang[1], C. Zhang[2], R. Raghupathi[3], R. Tanzi[2], A. Saunders[1]
[1]Biology, Drexel University, Philadelphia, USA
[2]Neurology, Harvard Medical School / Massachusetts General Hospital, Charlestown, USA
[3]Neurobiology, Drexel University, Philadelphia, USA

Objectives:
Alzheimer's disease (AD) is a progressive neurodegenerative disease, characterized by the deposition of amyloid β (Aβ) plaques. Aβ is a proteolytic product of its precursor, amyloid precursor protein (APP). Considerable evidence suggested a pivotal role for Aβ in AD pathogenesis, and APP proteolysis is therefore of extensive interest. Canonical APP proteolysis occurs via α-/ β- and γ-secretases. Here, we investigated the role of protein degradation system in APP proteolysis.
Methods:
HEK293 cells and other cell types underwent pharmacological treatments as indicated before collection and Western blot analysis. In vitro proteasome activity assay was performed using proteasome substrate Suc-LLVY-AMC. Transient transfection was performed using Turbofect transfection reagents.
Results:
By pharmacologically inhibiting protein degradation systems with ALLN, we observed an accumulation of heretofore undocumented APP fragments (CTFs). These changes are not due to cytotoxicity or novel transcription/ splicing events. Here, we name the novel CTF of 25 kD as η-CTF. Further examination reveals that η-CTF accumulation is mediated via cathepsin inhibition, and not proteasome or calpain inhibition.
Conclusion:
Collectively, our results suggest that a subpopulation of APP undergoes alternative processing by undetermined mechanism, and the resulting η-CTF is rapidly processed/ cleared by cathepsin. Given that impairment in protein degradation is a common feature in aging and neurodegeneration, we reason that failure of clearance of these η-CTFs could potentially be involved in the disease/ aging process.

AMYLOID PRECURSOR PROTEIN REGULATION OF GDNF EXPRESSION CONTROLS NEUROMUSCULAR JUNCTIONS FORMATION

S. Stanga[1], N. Zanou[1], E. Audouard[1], B. Tasiaux[1], S. Contino[1], F. Clotman[1], F. Gailly[1], I. Dewachter[1], J.N. Octave[1], P. Kienlen-Campard[1]
[1]Cellular and molecular (CEMO), Institute of Neuroscience-Université catholique de Louvain, Brussels, Belgium

Objectives: Beside its crucial role in Alzheimer's disease (AD) pathogenesis, different functions have been attributed to the amyloid precursor protein (APP) but its pivotal role is difficult to depict. We found that APP regulates GDNF (Glial cell-line Derived Neutrophic Factor) expression. Our work aims at investigating the role of APP-dependent GDNF expression in neuromuscular junctions.
Methods: Following transcriptome analysis, qRT-PCR, ELISA and reporter gene assays were performed on APPKO mouse embryonic fibroblasts (APP -/- MEFs) stably re-expressing APP695 and APP751. APP and GDNF expression have been monitored throughout skeletal muscle differentiation (C2C12 cells) upon APP silencing (small interfering RNA) and/or GDNF plasmid expression. We performed grip strength tests, mechanic measurements on isolated muscles and immunohistochemistry (IHC) of neuromuscular junctions (NMJs) on APP -/- mice. A co-culture model of C2C12 and cholinergic neurons (NG108-15) was set up to analyze the effects of APP silencing or GDNF expression on NMJs formation and neuronal maturation by immunocytochemistry (ICC).
Results: GDNF mRNA and protein levels together with GDNF transcriptional activity are down-regulated in APP -/- MEFs and restored specifically by APP751 isoform. GDNF and APP levels increase during muscular differentiation. Their overexpression or silencing favors or affects the process, respectively. APP-dependent GDNF expression controls the muscular phenotype and defective NMJs in APP -/- mice. In the co-culture model, GDNF restores the number of NMJs and neuronal maturation impaired by APP silencing.
Conclusions: APP controls GDNF expression with a critical involvement in neuronal and muscular differentiation underlying NMJs formation.

PRONGF/P75NTR SIGNALLING IN HIPPOCAMPAL ADULT NEUROGENESIS: POTENTIAL TARGET FOR GENERATING NEW NEURONS IN ALZEIMER'S DISEASE

C. Espinet[1], C. Rampon[1], J. Egea[1], G. Pinyol[1], A. Arias[1], M. Peris[1], C. Fleitas[1]
[1]Ciencies Mediques Basiques, Institute for Biomedical Research (IRB LLEIDA), Lleida, Spain

Introduction

It has been established that a 10% of neurons generated in adult human brain, are able to establish synaptic connections that can be stabilized and incorporated into the neural network. In animal models of Alzheimer's disease, the induction of neurogenesis can reverse cognitive deficits of the disease. Previous studies demonstrate i) a significant increase stage - dependent of pro -NGF in human hippocampus and enthorinal cortex affected by AD ii) that a proNGF receptor, p75NTR is expressed not only in mature neurons but also in mitotic cells from mouse hippocampus, and that the injection of pro-NGF in adult mouse brain decreases hippocampal neurogenesis.

Methods

Immunoflurescence to detect proNGF, p75NTR, sortilin and markers of the different steps of maturation of new neurons in hippocampal preparations from C and AD affected human brains and in animal models.

Results

Adult new born cells in human Dentate Gyrus express p75NTR and are diminished in AD. Increased pro-NGF in adult hippocampal brain , may be responsible for the decrease of neurogenesis and the defective differentiation and synapse formation of new neurons blocking the effect of regeneration -inducing factors.

Conclusions

Disruption of proNGF/p75/sortilin signaling would be a relevant target in regenerative therapies for AD.

GPR3-DEFICIENT MICE DISPLAY AN IMPAIRMENT IN COGNITIVE FUNCTION

Y. Huang[1], L. Wolfs[1], E. Vandewyer[1], B. De Strooper[1], A. Thathiah[1]
[1]Center for Human Genetics and Leuven Institute for Neuroscience and Disease (LIND), KU Leuven, Leuven, Belgium

Objectives

G protein-coupled receptor 3 (GPR3) plays an important role in regulation of Aβ generation. In this study, we aim to determine the physiological function of GPR3 and understand the mechanism(s) regulating GPR3 function.

Methods

To establish the physiological function of GPR3, we determined the effect of the absence of GPR3 on cognitive and synaptic function, utilizing the Morris Water Maze (MWM) behavioral paradigm, immunohistochemical, and electrophysiological studies. In addition, we performed co-immunoprecipitation studies to identify a new binding partner for GPR3.

Results

The MWM paradigm showed that *Gpr3*$^{-/-}$ mice display reference memory and cognitive flexibility deficits. Furthermore, we observed a reduction in dendritic spine density in the hippocampi of *Gpr3*$^{-/-}$ mice and determined that GPR3 is localized to dendritic spines of hippocampal neurons, suggesting that GPR3 is involved in the regulation of synaptic function. We also identified a PDZ binding domain in the C-terminus of GPR3. Mutation of a serine residue in this domain significantly reduced β-arrestin recruitment to GPR3 and Aβ generation. Co-immunoprecipitation studies indicate that GPR3 interacts with PSD95 through the PDZ binding domain, suggesting that PSD-95 modulates the GPR3/β-arrestin-mediated Aβ generation through this PDZ binding domain.

Conclusions

These studies suggest that GPR3 is involved in the regulation of dendritic spine morphology and cognitive function. Furthermore, identification of a new binding partner for GPR3, the scaffolding protein PSD95, suggests that PSD95 may play a pivotal role in controlling the function of GPR3 at synapse.

THE MEN1/MENIN TUMOR SUPPRESSOR COORDINATES CHOLINERGIC GENE TRANSCRIPTION, SYNAPSE FORMATION AND POSTSYNAPTIC CONSOLIDATION: A NOVEL PERSPECTIVE ON ALZHEIMER'S DISEASE

A. Getz[1], F. Visser[1], F. Xu[2], E. Bell[3], P. Christensen[1], N.I. Syed[3]
[1]Neuroscience, University of Calgary, Calgary, Canada
[2]Physiology and Pharmacology, University of Calgary, Calgary, Canada
[3]Cell Biology and Anatomy, University of Calgary, Calgary, Canada

Objectives: Loss of cholinergic synaptic connections and transmission in the hippocampus is a neuropathological hallmark of early Alzheimer's disease (AD), however, our current understanding of cholinergic synaptogenesis, maturation, plasticity, and overall function in the CNS is extremely limited. We have recently demonstrated that the MEN1 tumor suppressor gene, under the control of neurotrophic factor (NTF) signaling, regulates cholinergic synaptogenesis in the CNS. The objective of the present study was to define the underlying synaptogenic mechanisms, and whether MEN1 expression and function is also disrupted in AD.
Methods: Primary neuron culture with cholinergic invertebrate and murine hippocampal neurons was used in conjunction with electrophysiological and molecular analysis to determine the influence of MEN1/menin on nAChR expression and cholinergic synaptogenesis. Molecular analysis was performed using hippocampi from the 5xFAD mouse model of AD.
Results: Regulatory proteolysis produces menin fragments that perform unique albeit coordinated tasks during cholinergic synapse formation. The N-terminal fragment is targeted to the nucleus and upregulates expression of nAChR subunits. The C-terminal fragment is targeted to postsynaptic sites where it regulates postsynaptic consolidation. In mutant 5xFAD hippocampi the expression of NTF, MEN1 and nAChR subunits are down-regulated, and proteolytic cleavage of menin is reduced.
Conclusions: This study identifies menin as both a transcriptional regulator of nAChR in the CNS, and a candidate molecule for the postsynaptic clustering of nAChR at central cholinergic synapses. This NTF-MEN1-nAChR axis was found to be disrupted in a mouse model of AD, and suggests that this pathway is a putative target for therapeutic intervention.

IP3R3-TOM70: A SCAFFOLD AT ER-MITOCHONDRIA CONTACT SITES WITH POTENTIAL IMPACT IN ALZHEIMER'S DISEASE PATHOGENESIS

B. Schreiner[1], B. Wiehager[1], N. Leal[1], C. Moreira Pinho[1], M. Ankarcrona[1]
[1]Neurobiology Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden

Objectives

Current Alzheimer's disease (AD) treatment is largely symptomatic. Hence, it is crucial to investigate pathomechanisms underlying progressive neurodegeneration in order to identify new targets for causal intervention strategies.

Recently, several lines of evidence point towards a role of ER-mitochondria contact sites between outer mitochondrial membrane (OMM) and ER membrane. A number of crucial metabolic processes that are significantly altered in AD are governed at this site.

New OMM and ER proteins composing the contact sites are constantly identified. Nevertheless, it's still unclear if such proteins are transiently or stably present at the contact sites and how their expression and/or distribution are/is regulated.

Methods

We performed subcellular fractionation of mouse brain and analysed the constituents of the fraction containing ER-mitochondria contacts by immunostaining. Newly identified components were verified by by immunocytochemistry, proximity ligation assay and co-immunoprecipitation.

Results

We have identified a so far unknown scaffold between ER and mitochondria by showing the interaction between IP3R3, on the ER-side and TOM70, a receptor component of the translocase of the OMM.

Conclusions

Here, we confirm for the first time the presence of a novel scaffold between ER and mitochondria in mouse brain tissue and primary hippocampal neurons. Considering that a considerable amount of the potentially neurotoxic amyloid beta peptide is produced at ER-mitochondria contact sites, we propose a scenario where changes in the contact sites cause an elevated production and mitochondrial import of amyloid beta peptide via the newly identified scaffold eventually leading to mitochondrial dysfunction-induced neurodegeneration.

P75 MEDIATES THE CONVERGENCE OF AMYLOID PRECURSOR PROTEIN AND BETA SECRETASE 1

X.F. Zhou[1], K. Saadipour[1], Y.J. Wang[2]
[1]School of Pharmacy and Medical Sciences, University of South Australia, Adelaide, Australia
[2]Department of Neurology, Daping Hospital, Chongqing, China

Alzheimer's disease (AD) is the most common form of dementia. Amyloid beta (Abeta) accumulation in the brain is the hallmark of AD. Abeta is one of the cleavage products of amyloid precursor protein (APP) via sequential enzymatic processing of beta secretase 1 (BACE1) and gamma secretase. Thus Abeta production requires the interactions between APP and BACE1. After synthesis, APP and BACE1 are segregated and transported to different compartments. How APP converges with BACE1 is not known. We propose that neurons sense the neurodegenerative signals from environment which promote over production of Abeta and the p75 neurotrophin receptor (p75) on cell surface regulates the convergence of APP and BACE1. We tested the idea in neuronal cell lines and primary neurons of wild type and p75 knockout mice. We found that p75 interacts with both APP and BACE1 as determined by co-immunoprecipitation. p75 ligands Abeta and proNGF increase their interactions. This result is confirmed by FRET assays which display strong signals between FRET pairs of p75-CFP/APP-YFP and p75-CFP/BACE1-YFP. These FRET signals are significantly enhanced when cells are incubated with Abeta or proNGF. Abeta and proNGF also increase the FRET signals between BACE1-CFP and APP-YFP. Abeta also increases the colocalization of APP and BACE1 in primary neurons of wt mice but not in p75 knockout mice. Our data suggest that p75 is a key receptor that senses neurodegenerative signals which promote the convergence between APP and BACE1 and is a therapeutic target for drug development for AD.

APPLICATION OF A GLOBAL (PHOSPHO)PROTEOMIC WORKFLOW TO ANALYSE FRESH/FROZEN BRAIN TISSUE IN TRANSGENIC MODELS OF NEURODEGENERATION

C. Russell[1], V. Mitra[1], M. Ward[1], I. Pike[1]
[1]Institute of Psychiatry, Proteome Sciences, London, United Kingdom

Many neurodegenerative diseases are characterised by abnormal post-translational modification (PTM) of proteins leading to their aggregation and ultimately to neuronal cell death. One of the most common forms of pathological PTM is phosphorylation, with phosphorylated forms of tau, TDP-43 and alpha-synuclein all associated with disease. Additionally, the important role of cell signalling pathways in modulating key aspects of neurodegeneration such as re-activation of cell cycle in neurons and activation of immune cells, is increasingly recognised. Accordingly, there is a strong rationale to develop and apply global phosphorylation profiling to neuronal cell cultures and brain tissue in neurodegenerative disease research.

We have recently reported SysQuant®, a global phosphoproteomic workflow employing isobaric Tandem Mass Tags (TMT) and differential chromatography to measure fractions of enriched phosphopeptides and non-phosphorylated peptides derived from tryptic digestion of tumour cell lysates of up to 10 samples in a single run. SysQuant® can quantitate over 23,000 unique phosphorylation sites and more than 7,000 individual proteins.

When we applied SysQuant® to frozen brain tissue from a mouse model of human tauopathy (TMHT Mouse, QPS Austria) treated with vehicle or vehicle + kinase inhibitors, we were able to demonstrate significant, potentially protective effects on the phosphorylation of aggregating proteins and regulation of key pathways such as glycolysis/gluconeogenesis, calcium signalling, and oxidative phosphorylation along with all major neurodegenerative KEGG pathways.

Using SysQuant® we have generated a detailed, quantitative phosphoproteomic map for 3x3x3 animals treated with vehicle or one of two kinase inhibitors from different brain regions in approximately 8 weeks.

ALZHEIMER'S DISEASE AND TYPE 2 DIABTES: NETWORK ANALYSIS ACROSS CLINICAL BOUNDARIES

L. Caberlotto[1], M. Lauria[1], T.P. Nguyen[1]
[1]The Microsoft Research -
University of Trento Centre for Computational Systems Biology, COSBI, Rovereto, Italy

Objectives: The concept that AD is fundamentally a metabolic disease that results in progressive impairment in the brain's capacity to utilize glucose and respond to insulin stimulation has recently gained increasing support. Based on this evidence and on the fact that Type 2 Diabetes Mellitus (T2DM) is a major risk factor for AD, we performed a cross-disease analysis to confirm the mechanistic links between these two multifactorial and chronic diseases of aging. Systems medicine approaches using network-based techniques in a context of protein-protein interactions were applied aiming at the thorough understanding of the mechanisms underlying these diseases and the potential comorbidities associated.
Methods: Disease signatures of AD and T2DM were obtained from transcriptomic data of post-mortem human brain and used in conjunction with a PPI network to construct two disease-specific networks. The overlapping AD/T2DM networks' proteins were then used to extract the most representative Gene Ontology biological process terms.
Results: This analysis revealed a major role of the autophagy process, a self-degradative process that is important for balancing sources of energy in response to nutrient stress, as the molecular basis of both diseases. In addition, AMP-activated kinase, a core signaling pathway in cellular homeostasis and crucial regulator of energy metabolism, was confirmed as a central dis-regulated process in AD and T2DM, in line with previous studies.
Conclusion: The present systems biology investigation identifies the autophagy pathway as a central dis-regulated process in neurodegenerative dementia and indicates the disease-specific molecules in the pathway that could be considered for therapeutic intervention.

METABOLIC PERTURBATIONS IN THE BRAINS OF PATIENTS WITH ALZHEIMER'S DISEASE DETERMINED BY GAS-CHROMATOGRAPHY MASS-SPECTROMETRY

J. Xu[1], P. Begley[2], S. Church[2], S. Patassini[3], H. Waldvogel[3], W. Lin[2], R.L.M. Faull[3], A. Dowsey[2], G.J.S. Cooper[2]

[1]School of Biological Sciences and Maurice Wilkins Centre for Molecular Biodiscovery, University of Auckland, Auckland, New Zealand

[2]Faculty of Medical and Human Sciences and Centre for Advanced Discovery and Exper imental Therapeutics (CADET), The University of Manchester, Manchester, United Kingdom

[3]Faculty of Medical and Health Sciences and Centre for Brain Research, University of Auckland, Auckland, New Zealand

Objectives:

Defective energy metabolism is a fundamental component of Alzheimer's disease (AD). This study aimed to elucidate the molecular basis of the metabolic defects in different brain regions from AD patients compared with matched controls.

Methods:

Brain tissue was obtained from nine cases of confirmed clinical/neuropathological diagnosis of AD and eight controls, matched for age, sex and *post-mortem* delay. Metabolite levels were measured in *post-mortem* brain tissues from seven regions (hippocampus, entorhinal cortex, middle-temporal gyrus, sensory cortex, motor cortex, cingulate gyrus, and cerebellum) by gas-chromatography/time-of-flight mass-spectrometry.

Results:

Of 69 metabolites identified, 48 were significantly altered in AD in at least one brain region. The levels of free glucose, sorbitol, and fructose were dramatically elevated in all seven regions, as were glucose-6-phosphate, glycerol-2-phosphate, glycerol-3-phosphate, 1,2-butanediol, beta-hydroxybutyric acid, threitol, uric acid, margaric acid, and N-acetylglucosamine. Decreased levels of glycerol, methyl phosphoric acid, urea, and uracil were also a consistent feature across all brain regions. The amino acids leucine, aspartic acid, glycine, serine, and proline were decreased in the AD brain whereas phenylalanine, tryptophan, and tyrosine were elevated. Other metabolites, including those of Kreb's cycle, showed variable changes that were more brain region-specific.

Conclusion:

Multiple novel findings were uncovered by this study, including: 1) impaired carbohydrate metabolism via the main physiological pathways (glycolysis and glycogenesis), 2) shifts in the use of alternative, non-carbohydrate, fuel sources, and 3) dysregulation of amino acids critical for neurotransmitter homeostasis.

METABOLIC PROFILING OF CEREBROSPINAL FLUID IN DEMENTING DISORDERS

O. Jääskeläinen[1], S.K. Herukka[1], M. Ala-Korpela[2], P. Soininen[3], H. Soininen[1]
[1]Institute of Clinical Medicine - Neurology, University of Eastern Finland, Kuopio, Finland
[2]Institute of Health Sciences - Computational Medicine, University of Oulu, Oulu, Finland
[3]School of Pharmacy, University of Eastern Finland, Kuopio, Finland

Objectives
Our goal is to profile metabolic aspects of dementing disorders by quantifying metabolic changes in cerebrospinal fluid (CSF). We wi**ll als**o explore relations between multivariate metabolic profiles and data from clinical diagnostics. We believe that this large scale metabolomics study is likely to give insight regarding the metabolic attributes of dementing disorders and their molecular interrelationships.
Methods
Our sample set consists of over 750 CSF samples extracted from patients with a diagnosed dementing disorder. The sample cases in this study are thus divided into the following categories: Alzheimer's disease, Parkinson's disease, frontotemporal dementia, mild cognitive impairment, vascular dementia, amyotrophic lateral sclerosis, Lewy-body dementia and a cognitively normal control group. Conventional proton nuclear magnetic resonance (NMR) spectroscopy was utilized to measure all CSF samples.
Results
NMR-based metabolic profiling of the CSF samples yielded quantitative data on 30 molecular constituents, which belong in low-molecular-weight biomolecule groups such as amino acids, short chain fatty acids and energy metabolites.
Conclusions
We present a platform for metabolic profiling of CSF. The acquired metabolic profiles could set the foundation for understanding the metabolic features and pathophysiology of dementing disorders. Research into correlations of metabolic profiles with other biomarkers may open new views to understanding of pathomechanisms of neurodegenerative diseases.

PLATELET-DERIVED EXTRACELLULAR VESICLES - A TRIGGER FOR ALZHEIMER'S DISEASE?

F. El Magraoui[1], A. Pienimaeki Roemer[2], K. Kuhlmann[3], G. Schmitz[2], H.E. Meyer[1]
[1]Biomedical Research, Leibniz-Institut für Analytische Wissenschaften -ISAS- e.V., Dortmund, Germany
[2]University Clinic of Regensburg,
Institute for Clinical Chemistry and Laboratory Medicine, Regensburg, Germany
[3]Ruhr University Bochum Germany, Medical Proteome Center, Bochum, Germany

Platelets are the smallest of the three major types of blood cells. They are produced from very large bone marrow cells called megakaryocytes and contribute to hemostasis. During their lifetime they release small vesicular particles, so called extracellular vesicles (EV) which make up till 90 percent of the circulating EVs in the bloodstream. These platelets derived extracellular vesicles (PL-EVs) are involved in various cellular processes like autoimmunity, chronic inflammation and neurodegeneration. In this study we purified fractions from PL-EVs concentrates and analyzed there composition. By using LC-MS/MS and label-free quantification we have been able to detect the amyloid precursor APP, the hallmark protein of Alzheimer’s disease, enriched in distinct platelet fractions. This result indicates the importance of platelet function and regulation in Alzheimer's disease.

[5]Department of Pathology, Kuopio University Hospital, Kuopio, Finland
[6]Department of Immunology Genetics and Pathology, Uppsala University, Uppsala, Sweden
[7]Neurosurgery of NeuroCenter, Kuopio University Hospital, Kuopio, Finland

Objectives

Several risk genes for Alzheimer's disease (AD) have been identified, but their effects on disease pathogenesis remain elusive. Assessing the expression and splicing in the affected brain areas may help to identify possible functions of these genes. Protein-fragment complementation assay (PCA) can reveal their effects on disease-associated pathways.

Methods

The expression and splicing of genes involved in the pathogenesis or affecting the risk of AD was assessed in the post-mortem inferior temporal cortex samples from 60 subjects with varying degree of AD-related neurofibrillary pathology. PCA was performed in HEK293T cells.

Results

More advanced AD-related neurofibrillary pathology was associated with decreased expression of *FRMD4A* and increased expression of *MS4A6A*. Increased expression of two exons in *CLU* and *TREM2* was observed, with similar but non-significant trend in other exons, suggesting a global change in the expression rather than altered splicing. In expression quantitative trait loci analysis we did not detect significant effects of the risk alleles on gene expression or splicing. Using PCA, we found that down-regulation of *FRMD4A* associated with increased APP-beta-secretase interaction, increased amyloid-beta40 secretion and altered phosphorylation of tau.

Conclusions

Taken together, we show that the expression of *FRMD4A, MS4A6A, CLU,* and *TREM2* is altered in relation to increasing AD-related neurofibrillary pathology, and that *FRMD4A* may be associated with amyloidogenic and tau-related pathways in AD. We conclude that studying the gene expression in the brain and the effects of these genes on disease-associated pathways *in vitro* may provide mechanistic insights on how these genes contribute to AD pathogenesis.

CURCUMIN ANALOGS IN ALZHEIMER'S DISEASE: BISDESMETHOXYCURCUMIN AS TRANSCRIPTOMIC REGULATOR

S. Gagliardi[1], D. Ryan[2], E. Sinforiani[3], P. Bini[4], J. Cashman[2], C. Cereda[1]
[1]Lab. Experimental Neurobiology, C. Mondino National Neurological Institute, Pavia, Italy
[2]Laboratory of Chemistry, Human BioMolecular Research Institute, San Diego, USA
[3]Laboratory of Neuropsychology/UVA, C. Mondino National Neurological Institute, Pavia, Italy
[4]Division of General Neurology, C. Mondino National Neurological Institute, Pavia, Italy

Objectives: Several strategies have been studied in recent years to improve the activities related to the immune system in AD. The natural product mixture of curcuminoids, that improve certain defects in innate immune cells of AD patients, is of particular interest, as they may selectively enhance Abeta phagocytosis, attenuate APP maturation and alter gene transcription (Fiala et al.,2007; Gagliardi et al., 2012). Different compound have been tested and one of the most potent was bisdesmethoxycurcumin (BDC).
Methods: We analyzed 10 AD patients and 10 controls for phagocytic functions such as beta1,4-mannosyl-glycoprotein 4-beta-N-acetylglucosaminyltransferase (MGAT3) and vitamin D receptor (VDR) gene by Real Time PCR. PBMC from AD patients and controls have been treated with Abeta (5 ug/mL) + BDC (1nM). We also performed immunofluorescence experiments to morphologically evaluate the sub-cellular distribution and appearance of Abeta, in AD patients and controls untreated and treated with with Abeta and BDC.
Results: Our data showed that compared to controls, MGAT3 and VDR mRNA levels were up-regulated in lymphoblasts from AD patients treated with AB and BDC. Immunofluorescence of lymphoblasts showed the reduction of Abeta aggregates in AD patients treated with BDC compared to the samples not treated.
Conclusions: We demonstrated that BDC treatment may impact both gene expression and Abeta phagocytosis. MGAT3 is a gene essential for phagocytic functions and the overexpression of VDR suppressed amyloid precursor protein (APP) transcription in neuroblastoma cells (Wang et al., 2012). This preliminary data suggest a proof of concept for a future pharmacological intervention using curcumins.

[4]Biomedicine Group, Neuro-DVI, London, United Kingdom

[5]Institute of Ecology and Biodiversity Faculty of Sciences, University of Chile, Santiago, Chile

Octodon degus, a small rodent endemic to Chile, has been found to naturally develop histopathological signs of Alzheimer's Disease: accumulation of beta-amyloid aggregates and hyper-phosphorylated tau protein, as well as cognitive decline in spatial memory and object recognition memory. The natural onset and development of neurodegeneration, without the need of genetic manipulation, validate O. degus as a suitable animal model for studying AD. The present work investigates the global gene expression profile of O. degus at the onset of the AD-like neuropathology. We developed a whole transcriptome analysis using RNA-sequencing on wild-type aged Octodon degus. To assess the quantity of soluble Aβ oligomers (Aβ42) we used MALDI-tof MS. For RNA-seq analysis, we used whole brain samples from both groups, according to their brain Aβ1-42 quantification. RNA-sequencing of paired-end libraries was done using ABI SOLID 5500xl system. We obtained an average throughput of 150 million reads per sample with 150X estimated depth coverage. Multi dimensional scaling plot were used to assess the biological coefficient of variation in the samples. Differential expressed genes according these criteria were analyzed using hierarchical clustering and Gene-Ontology (GO) enrichment analysis. Biological processes such us development and immune system response were enriched in GO-terms analysis. This work is the first genome-wide analysis in Octodon degus. We built a reference transcriptome for genetic O. degus research. The gene expression analysis reveals novel tentative biomarkers that could be useful for drug discovery in the fight to treat AD.

ADPD5-1728

GENETIC VARIANTS ASSOCIATED WITH ALZHEIMER'S DISEASE IN OCTODON DEGUS

L. Farias[1], F.J. Altimiras[1], P. Cogram[1]
[1]Biomedicine Group Center for Systems Biotechnology, Fraunhofer Chile Research Foundation, Santiago, Chile

Octodon degus, a small south-american rodent endemic to Chile develops naturally aggregation of amyloid-β-peptides plaques and neuro fibrillary tangles containing hyperphosphorylated tau protein. These two AD features were also linked in O. degus with synaptic dysfunctions, spatial and object recognition memory loss and problems in activities of daily living. This natural AD animal model could represent one of the most promising tools for the study of AD at a pre-clinical level. While investigation with O. degus in the field of cognitive sciences is still in its early stages, we believe that O. degus provides an excellent opportunity for exploring biomarkers characterized in human patients. With this aim, we develop a whole-transcriptome analysis using RNA-sequencing in wild-type aged O. degus. Animals were analyzed at 3-years old by behavioural testing and for the presence of amyloid-β-peptides by MALDI-tof MS. RNA-seq data from AB SOLID 5500xl platform was processed for SNP discovery. For calling variants were used SAMtools and VCFtools. The criterion used was quality>30 (Phred scale) and read-coverage>10. We found 320109 SNPs that are only present in the aged O. degus AD onset. Focus in APP, PSEN1, PSEN2 and APOE genes, different SNPs in these genomic regions were identified only in the AD onset. This work provides a novel systematic characterization in Octodon degus of different SNP variants as a power tool for Alzheimer's research.

DEREGULATION OF PURINE METABOLISM IN ALZHEIMER'S DISEASE

B. Ansoleaga[1], M. Jové[2], A. Schlüter[3], P. Garcia-Esparcia[1], A. Pujol[3], R. Pamplona[2], M. Portero-Otín[2], I. Ferrer[1]

[1]Institute of Neuropathology, Bellvitge University Hospital-Bellvitge Biomedical Research Institute, L'Hospitalet de Llobregat, Spain

[2]Metabolic Physiopathology, Biomedical Research Institute, Lleida, Spain

[3]Neurometabolic Diseases, Bellvitge Biomedical Research Institute, L'Hospitalet de Llobregat, Spain

Objectives

The neuroprotective role of adenosine and the deregulation of adenosine receptors in Alzheimer's disease (AD) have been extensively studied in recent years. However, little is known about the involvement of the purine metabolism in AD. The aim of our study is to identify possible alterations of the purine metabolism pathway in AD in human brain and to evaluate their functional effects by distinct "-omic" approaches.

Methods

First, gene expression was analysed in the entorhinal cortex of human controls and AD cases by whole-transcript expression arrays. Second, mRNA expression levels of twenty three purine metabolism genes was assessed by RT-qPCR in the entorhinal cortex, frontal cortex area 8 and precuneus of control samples and AD stages III-IV and V-VI of Braak and Braak, and controls. Finally, liquid-chromatography mass-spectrometry based metabolomics was performed in the entorhinal cortex.

Results

By whole-transcript expression arrays we identified differential levels of expression of a cluster of genes encoding enzymes involved in the purine metabolism pathway. RT-qPCR studies showed deregulation of *APRT, DGUOK, POLR3B, ENTPD3, AK5, NME1, NME3, NME5, NME7* and *ENTPD2* mRNAs, with regional and stage-dependent variations, in AD cases when compared to controls. Liquid-chromatography mass-spectrometry based metabolomics identified altered levels of dGMP, glycine, xanthosine, inosine diphosphate, guanine and deoxgyguanosine, all derived from this pathway.

Conclusions

Our results indicate stage- and region-dependent deregulation of purine metabolism in AD.

[5]Reta Lila Research Laboratories and Dept Molecular Neuroscience, University College London, London, United Kingdom

Objectives

By the time cognitive deficits are first detected in patients with Alzheimer's disease (AD) around 20% of the hippocampus has already been lost. Attempting to treat the disease at this late stage may be why clinical trials have not been successful. The objective of this study is to identify the earliest molecular changes that take place in mouse models of elevated Abeta, prior to deposition of plaques or neurodegeneration.

Methods

We use the Mouseac database (www.mouseac.org) that compares gene expression changes and histology, in the hippocampus, cortex and cerebellum at four ages, in four Amyloid mouse models, transgenic for familial mutations of *APP* and/or *PSEN1*. We use bioinformatics to identify the earliest genes/pathways altered during disease progression. In parallel, to detect the levels and species of soluble amyloid beta we use mass spectrometry, and to evaluate functional changes we use electrophysiology.

Results

Even before plaques develop in *APP/PSEN1* transgenic mice we detect differences in synaptic transmission in the hippocampus as early as 2 months of age compared to wild-type mice, concomitant with the rise of Abeta-42 levels. Our genome wide expression data and co-expression network analysis of the most varying genes reveals synaptic transmission also as the most significant gene module, and highlights several genes of interest that may provide novel targets, such as *Rims3* and *Atf5*.

Conclusions

Identifying the earliest changes that occur during the progression of Alzheimer's is essential for developing early interventions before neurodegeneration becomes irreversible.

EFFECTS OF SAPP-ALPHA AND SAPP-BETA ON SYNAPTIC PLASTICITY IN PRIMARY HIPPOCAMPAL NEURONS AND HIPPOCAMPAL BRAIN SLICES

R. Hesse[1], D. Fernández-Fernández[2], K.S. Kroker[2], H. Rosenbrock[2], C.A.F. von Arnim[1]
[1]Neurology, Ulm University, Ulm, Germany
[2]Div. Research Germany, Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, Germany

Objectives:
In patients with Alzheimer's disease cerebral metabolism of amyloid precursor protein (APP) is altered affecting A-beta and potentially sAPP-alpha and/or sAPP-beta levels. So far studies have focused on A-beta or sAPP-alpha showing impairment or enhancement of synaptic plasticity, respectively. However, little is known about the function of sAPP-beta on synaptic plasticity. Here, we show a comparative study of sAPP-alpha and sAPP-beta regarding synaptic plasticity in hippocampal slices and primary hippocampal neurons on structural and physiological levels.
Methods:
In primary hippocampal neurons, LTP was induced chemically by repeated KCl treatment, intracellular Ca^{2+} levels were recorded simultaneously using a FLIPR system and the phosphorylation status of LTP dependent kinases was evaluated. Alterations of neuronal morphology after treatment with sAPP peptides were determined by Immunocytochemistry and fluorescence microscopy.
In parallel we evaluated the effects of the sAPP peptides on short-term and long-term plasticity in mouse hippocampal slices by paired-pulse facilitation and LTP.
Results:
Treatment of primary neurons with both sAPP peptides led to a significant increase in free intracellular Ca^{2+} concentrations after chemical LTP induction by repeated KCl treatment, indicating increased glutamate sensitivity. The morphometric analysis showed neurotrophic-like effects of sAPP-alpha and sAPP-beta treatment revealing a significant increase of dendrite numbers and branches of neurons.
Conclusion:
Results of these experiments reveal neurotrophic-like properties of both sAPP metabolites. This corroborates previous reports on sAPP-alpha. However, it also indicates a similar role of sAPP-beta on synaptic plasticity. Furthermore, results of sAPP peptides regarding functional plasticity by using hippocampal PPF and LTP will be discussed.

CHOLINERGIC REGULATION OF HIPPOCAMPAL-DEPENDENT INFORMATION PROCESSING: IMPLICATIONS FOR ALZHEIMER'S DISEASE

M. Al-Onaizi[1], G. Parfitt[2], B. Kolisnyk[3], M. Prado[4], V. Prado[4]
[1]Anatomy and Cell Biology, Robarts Research Institute, London, Canada
[2]Graduate Program in Physiological Sciences, Universidade Federal do Rio Grande, Rio Grande, Brazil

[4]Anatomy and Cell Biology Graduate Program in Neuroscience Department of Physiolog y and Pharmacology, Robarts Research Institute, London, Canada

Pronounced degeneration in forebrain cholinergic neurons, which provide the major input to the cortex and hippocampus, is thought to underlie some of the cognitive and behavioural symptoms observed in Alzheimer's disease. Distinct hippocampal-dependent tasks recruit specific hippocampal circuitries, but whether cholinergic tone is involved in all modes of hippocampal information processing is unknown. Here we used mice with genetic and viral deletion of the vesicular acetylcholine transporter (VAChT), a critical protein required for acetylcholine (ACh) storage and release, to investigate the role of ACh in hippocampal-dependent information processing. Deletion of VAChT in forebrain neurons, or only on neurons projecting to the hippocampus, affected the performance of mice in several hippocampal-dependent tasks, including the spatial version of the Morris Water maze, tests of working memory and a touchscreen paired-associates learning task (currently utilized to identify individuals at high risk for developing AD). Mice with genetic elimination of VAChT were not able to learn the paired-associates task and the performance of mice with viral deletion of VAChT was correlated to hippocampal VAChT protein levels. These results suggest that cholinergic integrity is vital for acquisition in paired-associates learning. Spatial memory in the Morris water maze was only mildly affected in mice with reduced hippocampal levels of VAChT; in contrast, reversal learning was severely disturbed. Additionally, working memory was also compromised in mice with reduced levels of VAChT. These results provide a refined roadmap of how cholinergic signaling controls encoding and recall of information in tasks that recruit distinct hippocampal–dependent processes.

ALZHEIMER'S DISEASE PROGRESSION PREDICTION ANALYSIS PLATFORM WITH EEG SIGNALS FROM NORMAL TO ALZHEIMER'S DISEASE PATIENTS

M.S. Ryoo[1], J.C. Kim[2], Y. Shin[2], H. Lee[2], S. Kim[2], Y.S. Cho[2], K. Yun[2]
[1]Jet Propulsion Laboratory, California Institute of Technology, Pasadena CA, USA
[2]Neuroscience, Ybrain Research Institute, Seoul, Korea

Introduction

To investigate the possibility of progression from Mild cognitive impairment (MCI) to Alzheimer's disease (AD), we analyzed Electroencephalography (EEG) signal of patients diagnosed with AD and normal people. Previous studies have shown that multiple EEG biomarkers can predict conversion rate from MCI to AD with relatively low sensitivity (88%) and specificity (82%) (Poil, De Haan et al. 2013; Claudio, Francesco et al. 2014). By using real-time processing and multi-channel (32ch) EEG data, the progression rate from MCI to AD was predicted.

Methods

We developed time series-based machine learning algorithms to classify normal participants and AD. We applied support vector machine classifier with a non-linear chi-square kernel to make the final recognition. For evaluation, half/half random split validation setting was applied. Our dataset consists of brain EEG data of 140 subjects (AD and normal control). At each round, we randomly selected 70 samples (per class) as training data and 70 for testing. This random training/testing selection was repeated 100 times and their mean classification accuracy was computed.

Results

Our experiment confirmed that we are able to obtain reliable recognition performance: our approach showed 96.09% classification accuracy using 32-EEG-sensors attached subject's head. The performance was still reasonable (81.4586%) even with only 6 EEG sensors.

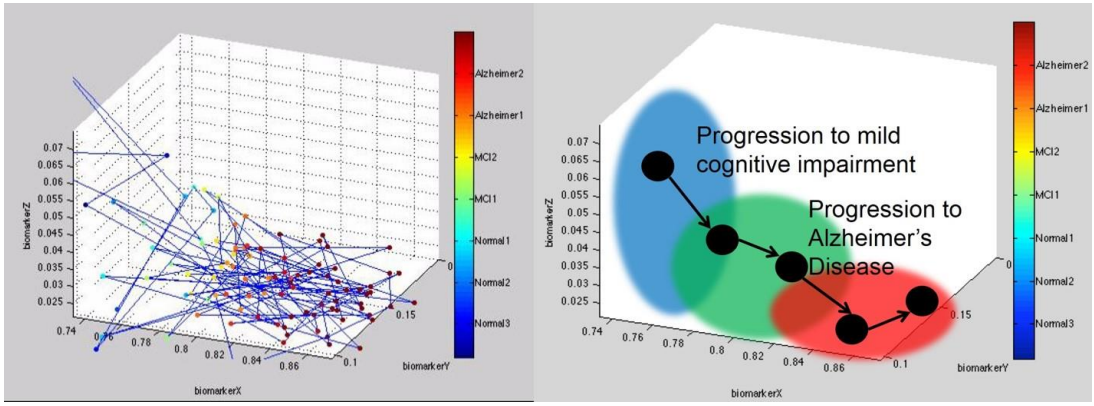

Figure 1. Predict progression result for normal, MCI and AD by EEG data

Conclusion

We performed the classification for diagnostics and prediction of AD progression with EEG data. These results imply that the prediction algorithm is sufficient for constructing big data platform to predict Alzheimer's disease progression.

PROGRESSION OF ALZHEIMER'S DISEASE IN THE HUMAN HIPPOCAMPUS - NEW INSIGHTS AND PROSPECTS

A. Schroetter[1], H. Heinsen[2], L.T. Grinberg[3], H.E. Meyer[1]
[1]Biomedical Research, Leibniz-Institut für Analytische Wissenschaften -ISAS- e.V., Dortmund, Germany
[2]Department of Psychiatry,
Laboratory of Morphological Brain Research University of Würzburg, Würzburg, Germany
[3]Department of Neurology, UCSF School of Medicin, San Francisco, USA

Alzheimer's Disease (AD) might be more complex than known so far. Regarding the last years of scientific research we conclude that the progression of AD in the human hippocampus is one of the key hallmarks of this neurodegenerative disease. Braak et al. (2000) observed that neuronal damage of the different regions of the human hippocampus (CA1, CA2, CA3, fascia dentata) occurs in a time dependent matter. Therefore we decided to analyse the content of the human hippocampal regions of interest by performing a differential proteomic study (label free LC-MS/MS approach) combined with a couple of functional analyses. Here we used the Laser-microdissection technique to separate the human hippocampal regions of interest by using 6 biological post mortem replicates. Afterwards we quantified the hippocampal proteoms and confirmed our findings with immunohistochemistry. Here we show new insights and prospects for the progression of AD in the human hippocampus by presenting novel candidate proteins.

EFFECT OF BETA AMYLOID PEPTIDE ON CA1 PYRAMIDAL NEURON: IONIC CONDUCTANCE BASED MATHEMATICAL MODEL STUDY FOR POSSIBLE TREATMENT

C. Mahapatra[1], *R. Manchanda*[1]
[1]*Bio Science & Bio Engineering, Indian Institute of Technology Bombay, Mumbai, India*

Evidence from a number of independent studies has demonstrated that generation of pathogenic β- amyloid (Aβ) peptides, one of the characteristic hallmarks of Alzheimer's disease (AD), can affect normal neuronal activity in various ways. In present scenario, the impact of Aβ amyloid peptide is not clearly understood. From ion channel hypothesis, we can assume that Aβ can affect the normal activity of a neuron; for example, making a neuron more excitable (by reducing the *A*-or *DR*- type K^+ currents) or less excitable (by reducing synaptic transmission and Na^+current). The aim is to establish a computational model with sufficient biophysical detail to quantitatively simulate CA1 cell electrical activities related to Aβ peptide and thereby inform future empirical investigations of physiological and pathophysiological mechanisms governing AD. In line with recent experimental evidence, we construct mathematical models for Na^+ current, voltage gated *DR*- type K^+ currents and synaptic current. The magnitudes and kinetics of each ionic current system in a borrowed CA1 cell with a specified surface area are described by differential equations, in terms of maximal conductances, electro chemical gradients and voltage-dependent activation/inactivation gating variables.

We have first modeled the different stages of AD by progressively modifying different active channels and synaptic properties of a realistic model neuron, where all parameters are adapted from experimental findings. We then tested sodium and potassium channel manipulations that could compensate for the effects of Aβ. The model points to possible pharmacological interventions of sodium and potassium ion channels in term of kinetic and activation properties.

IMPAIRED REELIN/APOER2 SIGNALING PATHWAY IN ALZHEIMER'S DISEASE

J. Saez-Valero[1], V. Balmaceda[1], T. Mata-Balaguer[1], I. Cuchillo-Ibañez[1]
[1]Universidad Miguel Hernández, Instituto de Neurociencias, Sant Joan d'Alacant, Spain

Background: Reelin is a signaling protein that has a crucial role in synaptic function and plasticity, and also controls tau phosphorylation. Binding of homodimers of Reelin, the active form, to its receptor, ApoER2, relays the signal into the cell. We have previously demonstrated that β-amyloid peptide (Aβ) alters Reelin expression and its glycosylation pattern. An altered Reelin signaling might affect progression of Alzheimer's disease (AD) pathology. However, there is no consensus on whether Reelin levels are increased or decreased in brain regions affected by AD.
Methods: Reelin and Aβ interaction was assessed by co-immunoprecipitation. Reelin levels in AD and non-disease brain extracts were analyzed by western blotting and qRT-PCR. Presence of Reelin was also analyzed in pellets from cortex solubilized with guanidine. Reelin heteromers were characterized by sucrose density gradient. ApoER2 interaction with Reelin was measured by immunoprecipitation, and the presence of a soluble ApoER2 fragment in cerebrospinal fluid (CSF) by immunoblotting.
Results: We show that Reelin interacts with β-amyloid in brain extracts. Reelin increases at transcriptional level in AD brain extracts, together with accumulation of the Reelin protein associated to insoluble (guanidine-extractable) β-amyloid deposits. Reelin from AD cortex forms large complexes instead of homodimers and displays reduced affinity for ApoER2. Finally, the soluble ApoER2 fragment generated after Reelin binding, is found at lower levels in AD CSF respect to non-dementia samples.
Conclusions: Reelin levels trend to increase in brain from AD subjects, but Aβ compromises its binding to the receptor and its biological function resulting in impaired Reelin signaling.

DOWN SYNDROME BRAINS REVEAL CRITICAL CHANGES IN THE TEMPORAL AND SPATIAL EXPRESSION OF SINGLE GABAA RECEPTOR SUBUNITS DURING DEVELOPMENT

I. Milenkovic[1], T. Stojanovic[1], W. Sieghart[2], G.G. Kovacs[1]
[1]*Institute of Neurology, Medical University of Vienna, Vienna, Austria*
[2]*Center for Brain Research, Medical University of Vienna, Vienna, Austria*

Objectives: The Down syndrome (DS), the most common congenital cause of mental retardation, is characterized by a disturbed proliferation and migration of neurons and glia cells. Previous studies in animal models suggested that some $GABA_A$ receptor ($GABA_A$-R) subunits might play a pivotal role in the pathogenesis of DS. Thus, our aim was to investigate the most abundant $GABA_A$-R subunits (alpha1-3 and gamma2) in developing human DS brains, as they influence cell proliferation, migration, differentiation, and cell death during development.
Methods: The amount of immunoreactivity was quantified on digitalized coronal brain sections for each of four $GABA_A$-R subunits (alpha1-3 and gamma2) in the hippocampus (CA1 and subiculum) and in cortical structures (marginal zone and intermediate zone) of 30 foetal human DS cases and was compared to age-matched control brains (from 14 GW until 3 months of the early postnatal period).
Results: Here we provide the first detailed immunohistochemical investigation of $GABA_A$-R subunits in human DS brain tissue. Our data reveal spatial and temporal differences in the expression patterns of single subunits in DS cases: 1) alpha1, alpha2, alpha3 and gamma2 subunits showed selective depletion in hippocampal regions; 2) the pattern of changes of the alpha2 subunit in the hippocampus resembled strongly those of the gamma2 subunit; 3) in the DS cortex the change in temporal expression and/or amount was layer-specific.
Conclusions: Our data strongly imply complex involvement of the GABAergic system in the pathogenesis of DS in humans, extending the assumption from animal models and opening new conceptual possibilities.

[4]Department of Neuropathology, Heinrich Heine University Medical School, Düsseldorf, Germany

[5]Pathology, VU medical center, Amsterdam, Netherlands

[6]Clinical Chemistry, VU medical center, Amsterdam, Netherlands

Introduction

Alzheimer's disease (AD) is characterized by protein aggregates such as amyloid beta (Aβ) in plaques and hyperphosphorilated tau (p-tau) in neurofibrillary tangles (NFT). BRI2 regulates critical proteins involved in initial steps of the amyloid cascade hypothesis. We found aggregated BRI2 ectodomain associated with Aβ plaques in early stages of AD. Here we investigated the effects of aggregated recombinant BRI2 ectodomain ($rBRI2_{76-266}$) on important molecular pathways involved in early stages of AD, including apoptosis, the unfolded protein response (UPR), and the phosphorylation of glycogen synthase kinase 3 β (GSK3β) and tau.

Methods

Non-differentiated SH-SY5Y cells were exposed to $rBRI2_{76-266}$. Cell viability was assed by MTT assay. Apoptosis was examined by analysis of caspases 3 and 9 activities. Pro- and anti-apoptotic proteins Bcl-2 and Bax, truncated tau and the phosphorylation of GSK3β (P-GSK3β) were analysed by western blot. The mRNA of UPR related proteins (BiP, CHOP and Xbp-1) was analysed by qPCR and the levels of p-tau were determined using ELISA.

Results

$BRI2_{76-266}$ led to a 10% cell death, increased Bax/Bcl-2 ratio and increased activity of caspases 3 and 9, indicating an activation of the apoptosis pathway. UPR mRNA markers were not modified after incubation with $BRI2_{76-266}$. Incubation with BRI2 increased the levels of p-GSK3β and truncated tau.

Conclusions

Our results indicate that $rBRI2_{76-266,}$ which is prone to aggregate, can induce apoptosis and tau truncation. Since BRI2 is able to regulate APP processing and Aβ load, we propose that aggregated BRI2 ectodomain is a potential nexus between Aβ, tau pathology and neurodegeneration.

ADPD5-1469

ALTERED GENE TRANSCRIPTION IN ALZHEIMER'S DISEASE TRHOUGH NFAT ACTIVATION

R. Requião[1], S. Ferreira[1], B.K. Robbs[2], D. Foguel[1]
[1]Institute of Medical Biochemistry, Federal University of Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil
[2]Department of Basic Sciences, Federal Fluminense University (UFF), Nova Friburgo, Brazil

Alzheimer's disease (AD) is a neurodegenerative disease characterized by a progressive loss of synapses and neurons, especially in the hippocampus region. An important feature of AD is the presence of amyloid plaques, found in the extracellular region of patients' brains, composed mostly of the peptide beta-amyloid (Aβ). Exposed neurons to Aβ display higher levels of intracellular calcium, which could lead to the activation calcineurin A, a phosphatase that is able to regulate the transcription factor NFAT. Inhibition of NFAT leads to a prevention of both spine loss and dendritic simplification, even though it is not known which genes could have been regulated. The primary objective of the project is to define the molecular mechanisms of gene control by the transcription factor NFAT that may be involved in the AD. We already demonstrated that mice primary neuron culture treated with Aβ oligomers display NFAT translocation to the nucleus that can be completely reversed by ciclosporin A (CsA), an inhibitory drug of the NFAT activation pathway. We also have evidence that these primary cultures treated with Aβ peptides have a smaller amount of dendritic spines and pre-synaptic terminals (in relation to the post-synaptic terminals), suggesting a decrease of synapses, which is also reversed by CsA. Based on these results, we can assume that Aβ peptides are promoting a decrease of spines and synapses through activation of the calcineurin/NFAT pathway. We now seek to investigated genes that may be regulated by NFAT and are involved in the process of neurodegeneration in AD.

ADPD5-1775

INHIBITION OF GSK3BETA ACTIVATION AND ABETA SECRETION BY PHARMACOLOGICAL MODULATION OF SPHINGOLIPID METABOLISM OCCUR INDEPENDENTLY OF GANGLIOSIDES DISTURBANCE IN A CELLULAR MODEL OF AD.

A. Noel[1], E. Planel[1], S. Ingrand[2], L. Barrier[2]
[1]neurosciences, CHU de Québec - Pavillon CHUL, Quebec City, Canada
[2]Médecine&Pharmacie, Université de Poitiers, Poitiers, France

Accumulating evidence implicate gangliosides and/or related-sphingolipids in the pathogenesis of Alzheimer's disease (AD). While gangliosides are thought to interfere with the proteolytic processing of the amyloid precursor protein (APP), it is not known whether a connection between these lipids and other important AD features such as deregulated insulin/Akt/GSK3 signaling occurs. Here, we analyzed the impact of aberrant gangliosides composition on GSK3 activation state and amyloid β peptide (Aβ) production in neuroglioma cells expressing the double Swedish mutation of human APP (H4APPsw) treated with several glycosphingolipid (GSL)-modulating agents. We found that both ceramide analogs D- and L-PDMP (1-phenyl 2-decanoylamino-3-morpholino-1-propanol), which have opposite effects on ganglioside synthesis, inhibited selectively GSK3β *via* Ser9 phosphorylation and reduced Aβ secretion, independently of the upstream insulin/Akt pathway. Concurrently, these two compounds strongly reduced the levels of long-chain ceramides. Moreover, the iminosugar N-butyldeoxynojirimycin (NB-DNJ) which also reduced cellular gangliosides levels but not that of ceramides, did not affect the phosphorylation state of GSK3β, but was able to reduce Aβ production in a different way from that of PDMP agents.
In sum, our data suggest that the regulation of both GSK3β activation state and APP processing might be independent of the altered cellular gangliosides composition, but rather implicated changes in ceramide levels. Nevertheless, this study provides novel information regarding the possibilities to target GSK3β and amyloidogenic processing of APP through modulation of sphingolipid metabolism. Furthermore, the anti-amyloidogenic effects of NB-DNJ reported here for the first time emphasizes a new potential therapeutic approach for AD.

ADPD5-2299

PRIORITISING A SYSTEMS BIOLOGY APPROACH TO ALZHEIMER'S DISEASE

J.L. Rollo[1], J.W. Crawford[2], J. Hardy[1]
[1]Department of Molecular Neuroscience, Institute of Neurology, London, United Kingdom
[2]Computational and Systems Biology, Rothamsted Research, Harpenden, United Kingdom

To better understand the mechanisms of Alzheimer's disease (AD) conventional experimental methodologies have commonly targeted individual, or small sets of genes/proteins. However, the strong message from computational systems biology (CSB) approaches in other applications, such as cancer, indicate control is distributed across the cell network and rarely restricted to a single point. Successful drug interventions are therefore likely to be multi-targeted, meaning an unguided search for new treatments faces an almost infinite combination of possibilities. It is timely to consider exploiting CSB to decipher the true disease complexity.

Despite the earliest successes of CSB being in neuroscience, the AD field now lags significantly behind other disciplines, maybe partly due to the overwhelming challenge - clearly AD must be confronted from the outset as a multi-cellular system, which significantly adds to the complexity of analysis.

Identifying priority targets from an overwhelming choice is daunting, however computational approaches enhance intuition and empirical measurement, and can assist identification. We believe researchers are ready to embrace the opportunities of CSB with the abundance of data and a converging consensus of the role of amyloid-beta in the development of AD.

To create a roadmap for AD, we present key studies demonstrating the value of CSB. We establish a path to begin moving from overwhelming complexity to an iterative scheme of hypothesis generation, prediction and validation to identify the key elements of the interaction network implicated in AD. We finish by outlining how this knowledge could be used to help identify combination therapies to enable personalised treatment.

RESVERATROL PROTECT RAT BRAIN FROM AGE-ASSOCIATED SEQUENTIAL PATHOLOGICAL CHANGES IN SPECIFIC HIPPOCAMPAL NEURONAL CIRCUITS.

M. Ponnusamy[1], P. Rajangam[1], A. Muthuswamy[1]
[1]Department of Biochemistry, Bharathidasan University, Tiruchirappalli, India

Background/Objective: Present study aims at investigating, age-specific degeneration of neuronal-circuits in hippocampal formation *(neural-layout of Subiculum-hippocampus proper-DG-EC)* and resultant cognitive impairment during aging that forms major risk factor for SAD like pathology. Further, neuroprotective effect of resveratrol on age-specific pathological changes in the hippocampal neuronal-circuits were evaluated. **Methods:**Radial-Arm-Maze (RAM) was performed to evaluate hippocampal-dependent spatial and learning memory. Nissl Staining of FC, subiculum, Hippocampal-proper (CA1→CA2→CA3→CA4), DG, amygdala, cerebellum, thalamus, hypothalamus, layers of temporal and parietal lobe of the Neocortex were examined for pathological changes in young and aged wistar rats, with and without resveratrol.**Results and Conclusion:** Extensive loss of glutamatergic and inhibitory GABAergic neurons were observed during aging. Moreover, Trisynaptic (EC layerII→DG→CA3→CA1) circuit forming new memory and monosynaptic circuit (EC→CA1) that strengthens old memories was disturbed. Loss of Granular neuron in DG and polymorphic cells of CA4 lead to decreased mossy fibers disturbing neural-transmission (CA4→CA3) in perforant pathway. Further, intensity of Nissl granules (SLM-SR-SO) of CA3 pyramidal neurons was decreased, disturbing the communication in Schaffer collaterals (CA3-CA1) during aging. We also noticed disarranged neuronal cell layer in Subiculum (PrS-PaS), interfering output from hippocampus to PFC, EC, Hypothalamus, and amygdala that interrupt thinking process. We conclude from our observations that neuronal-circuits of hippocampus (DG-CA4-CA1-Sub) were damaged leading to memory impairment that was supported by RAM analysis. Interestingly, resveratrol induced neurogenesis in DG and culminated the pathological events proving as good as therapeutic drugs against age associated neurodegeneration and memory loss.

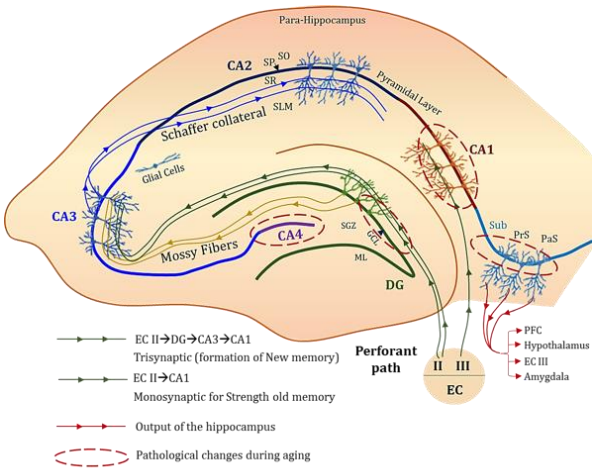

Figure:- A schematic representation of Age-associated sequential pathological changes in Hippocampal Circuits: CA, Cornu ammonis; DG, Dentate gyrus; SUB, subiculum; PrS, Presubiculum; PaS, Parasubiculum; GCL, granule cell layer; ML, molecular layer; SO, stratum oriens; SR, stratum radiatum, SP, Stratum pyramidal; SLM, Stratum lacunosum moleculare; EC, Entorhinal cortex; SGZ, Subgranular Zone

MODELING PRION-LIKE PROPAGATION OF NEURODEGENERATIVE DISEASE RELATED PROTEINS IN A IPSC DERIVED NEUROEPITHELIAL STEM CELL 3D CO-CULTURE SYSTEM

C. Sackmann[1], E.H. Juarez[1], E. Severinsson[1], M. Hallbeck[1]
[1]Clinical and experimental medicine, Linköping University, Linköping, Sweden

Objectives: Establishment of a novel iPSC-based model for the investigation of neuron-to-neuron transmission of neurodegenerative disease related proteins.
Methods: Using a well characterized iPSC derived neuroepithelial stem cell (NES) line, neuronally differentiated cells were co-cultured in a 3D extracellular matrix (ECM) gel. Alexa-Fluor 700 conjugated amyloid-beta oligomers (oAb) was fed to neurons and subsequently taken up by these cells. Amyloid-beta loaded cells were then seeded onto a mixture of ECM gel with embedded GFP-labeled differentiated neuronal cells in standard lab plastics, or in microfluidically isolated (Xona Microfluidics) chamber slides.
Results: We have demonstrated the ability to track the spread of labeled oAb between mature iPSC derived neurons in vitro. This interneuronal transfer can be visualized with confocal microscopy in real time, as well as separated by FACS for downstream biochemical analysis. Additionally, the cells can be investigated with electrophysiological techniques. In this way, we have developed a powerful tool which can be used to investigate the immediate and long term effects of transfer of oAb from loaded neurons to healthy acceptor cells. This approach has also been applied to microfluidically isolated slides, allowing for the visualization of protein transfer between two distinctly isolated populations. Fluidic isolation allowed for investigation of different endocytic inhibitors (Latrunculin B, Dynasore) in their ability to diminish neuron-to-neuron propagation.
Conclusions: We have developed two new approaches to 3D co-culture modeling applicable to the investigation of neuron-to-neuron propagation of neurodegenerative related proteins using iPSCs. These models could be used to further understand potential mechanisms of protein transfer.

AN INDUCED PLURIPOTENT STEM CELL MODEL FOR PHENOTYPIC SCREENING FOR INHIBITORS OF PRION-LIKE PROPAGATION OF BETA AMYLOID OLIGOMERS

J. Domert[1], E. Severinsson[1], M. Otrocka[2], C. Sackmann[1], M. Hallbeck[1]
[1]Department of Clinical and Experimental Medicine, Linköping University, LINKÖPING, Sweden
[2]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden

Objectives: The pathogenic progression of Alzheimer's disease spreads through interconnected brain areas causing neurodegeneration. Misfolded beta amyloid (Abeta) oligomer aggregates have been shown to propagate between neurons and act as seeds, recruiting new Abeta into the neurotoxic misfolded pool. One therapeutic strategy could be to decrease or stop this transfer of Abeta oligomers. We have previously shown that differentiated neuronal cells cultured in vitro are able to transfer Abeta between them. The aim of this study was to optimize a co-culture system with human induced pluripotent stem cells (iPSC) for high throughput screening of chemical libraries. This could potentially find compounds with an inhibitory effect on neuron-to-neuron Abeta transfer and the progression of Alzheimer's disease.
Methods: The acceptor subpopulation of neuronally differentiated iPS cells labeled with GFP is cultured on a layer of ECM gel in microtiter plates. Through endocytosis the donor subpopulation is loaded with Alexa-700-labelled Abeta oligomers, and subsequently seeded on top of the acceptor cells. The cells are co-cultured, and co-localization of GFP signal (acceptor cells) and Alexa700 (Abeta) is assessed. The possibility of automation of the different cell-culture steps was evaluated, as well as automated image acquisition and quantification.
Results: Neuron-to-neuron transfer of oligomeric Abeta was shown in the iPSC co-culture system. The co-culture system could be optimized for semi-automated handling. This system could thus be suitable for high throughput analysis.
Conclusions: We have developed a human iPSC based model of neuron-to-neuron Abeta oligomer transfer that can be used for phenotypic high throughput screening.

AMYLOID-BETA ASSOCIATED BRAIN-DERIVED EXOSOMES PROMOTE AMYLOID SEEDING IN A MOUSE MODEL OF AMYLOIDOSIS

R. Perez-Gonzalez[1], *E. Levy*[1]
[1]*Center for Dementia Research, Nathan S. Kline Institute, Orangeburg, USA*

Objective: Exosomes, bioactive secreted vesicles of endocytic origin, transport APP and APP metabolites into the extracellular space. The content of exosomes is protected from degradation due to the high stability of exosomal vesicles. We have previously shown that exosomes isolated from APP overexpressing Tg2576 mouse brains are enriched with the neurotoxic APP-C-terminal fragments (APP-CTFs), cleavage of which can result in the production of amyloid-beta (Abeta). Thus, exosomes are potentially capable of generating Abeta at sites distant from the cell that secreted the exosomes. Additionally, Abeta binds to the surface of the lipid-rich exosomal membrane, potentially forming a seeding site for amyloid. We investigated the ability of exosomes isolated from the brain of amyloid-depositing mice to induce Abeta accumulation in the brain of pre-depositing APP-overexpressing Tg2576 mice.
Methods: Brain exosomes from aged Tg2576 mice were isolated by a novel method developed in our laboratory, and injected into the hippocampus of pre-depositing Tg2576 mice. Injection of wild-type brain exosomes was used as control. Brains were analyzed three months post-administration for amyloid burden by thioflavin S staining and immunostaining with an anti-Abeta antibody.
Results: Greater amyloid pathology was observed in the hippocampus and adjacent cortex of Tg2576 mice administered with exogenous transgenic exosomes as compared to mice treated with wild-type exosomes.
Conclusions: This *in vivo* study demonstrates that brain-derived exosomes enriched with APP-CTFs and containing exosomal-surface Abeta can contribute to amyloid seeding in the brain.

EXOSOSMES CAN TRANSFER OLIGOMERIC AMYLOID BETA FROM NEURON TO NEURON, CONTRIBUTING TO THE PROGRESS OF ALZHEIMER'S DISEASE

M. Sardar Sinha[1], A. Ansell[1], M. Larsson[1], M. Hallbeck[1]
[1]Dept. of Clinical and Experimental Medicine, Linköping University, LINKÖPING, Sweden

Objectives:
Progressive accumulation of specific protein aggregates, is a defining feature of many major neurodegenerative diseases, including Alzheimer's disease (AD). Recent studies have suggested prion-like propagation of neurodegenerative proteins such as amyloid beta (Abeta) oligomers through the brain, thereby contributing to the development of the illness. The cellular mechanisms behind this transfer are not known. Recent reports suggest that secretory small vesicles called exosomes can contain normal Abeta. The objective is to investigate the involvement of exosomes, in the neuron-to-neuron transfer of the neurotoxic Abeta oligomers using a 3D co-culture system with neuronally differentiated human SH-SY5Y cells and induced pluripotent stem cells (iPSC).
Methods and Results:
Confocal microscopy of cells with fluorescent labeled oligomeric amyloid beta (oAbeta) and co-labeled with exosomal proteins (e.g. Flotillin-1, Alix) showed that Abeta aggregates were present in intracellular exosomes. Characterization and presence of Abeta in secretary exosomes isolated from conditioned media was confirmed by immunoblotting, EM, NTA and spectrofluorometer. In addition, these exosomes could later be fed to new cells, which internalized the oAbeta, showing that oAbeta can be transmitted from neuron-to-neuron via exosomes. Interestingly, the cellular uptake of oAbeta containing exosomes could be inhibited using dynasore, an inhibitor of dynamin dependent endocytosis.
Conclusion:
In conclusion, this study indicates that oAbeta transfers from neuron-to-neuron via exosomes and that the uptake is dynamin dependent. The results have important implications in understanding the disease propagation in AD pathogenesis.

IMPACT OF EXCITATION ON NEURON-TO-NEURON TRANSFER OF BETA AMYLOID OLIGOMERS IN HUMAN NEURONAL PROGENITOR CELLS

E.H. Juarez[1], A. Kale[1], B. Granseth[1], P. Olivius[1], M. Hallbeck[1]
[1]Clinical and Experimental Medicine, Linköping University, LINKÖPING, Sweden

OBJECTIVE: The pathogenic progression of Alzheimer's disease spreads through interconnected brain areas causing neurodegeneration. Misfolded beta amyloid oligomer aggregates have been shown to propagate between neurons and act as seeds, recruiting new beta amyloid into the neurotoxic misfolded pool. The objective of this study is to investigate the effect of electrophysiologically and pharmacologically excitation on the neuron-to-neuron transfer of beta amyloid oligomer in differentiated human neuronal progenitor cells (HNPCs).
METHODS: HNPCs were differentiated with bFGF, EGF, LIF, and supplemented with N2. Differentiated cells and neuronal networks were characterized for neuronal markers (beta-III tubulin, Sv2) and assessed by two independent techniques, calcium imaging and basic electrophysiology tools such as voltage and current clamp in whole cell configuration.
RESULTS: Differentiated HNPCs express the neuronal marker beta-III tubulin and can trigger calcium responses spontaneously as well as in presence of acetylcholine. Spontaneous extracellular postsynaptic currents at -70 mV were detected in HNPC-derived neurons. The effect of electrophysiologically and pharmacologically excitation on the neuron-to-neuron transmission fluorophore labeled beta amyloid oligomers are currently investigated.
CONCLUSIONS: HNPCs can be differentiated into neurons that create neuronal network with intrinsic electrical activity. This activity could be mediated by acetylcholine and glutamate acting on nACh receptors and AMPA receptors, respectively. We propose that HNPC-derived neurons could help to understand the underlying mechanism of amyloid beta transference and the synaptic process that affects its propagation.

CHOLINERGIC DYSFUNCTION OF BASAL FOREBRAIN AND MESOPONTINE TEGMENTUM IN ALZHEIMER'S DISEASE

L. Qian[1], N. Marks[1], A. Sharma[1], M.C. Bellingham[2], E.J. Coulson[1]
[1]Queensland Brain Institute, The University of Queensland, Brisbane, Australia
[2]School of Biomedical Sciences, The University of Queensland, Brisbane, Australia

Cholinergic neurons of the basal forebrain are particularly vulnerable in Alzheimer's disease, and the consequent cholinergic neurotransmitter decline affects other neurotransmitter systems. Epidemiological studies have shown that sleep apnoea - stopping breathing during sleep is a risk factor for Alzheimer's disease. The neurons of another major cholinergic nucleus in the brain, the mesopontine tegmentum (MPT), project to upper motor neurons to control upper airway muscle tone during sleep, and are also implicated in initiating and maintaining rapid eye movement (REM) sleep, which is considered fundamental for learning consolidation and retention of memory. MPT neurons also project to the basal forebrain and produce nerve growth factor (NGF) and thus may support basal forebrain neuronal survival and function throughout life. We found that lesions of MPT cholinergic neurons by stereotaxic injection of saporin toxin conjugated to the specific urotensin II receptor peptide ligand produce a subsequent and selective degeneration of basal forebrain cholinergic neurons and a resultant decline in spatial memory. Our results indicate that loss of MPT-derived NGF due to MPT neuronal dysfunction may in turn cause dysfunction of basal forebrain neurons with negative flow-on effects on cognitive function and the development of Alzheimer's disease.

A MALFUNCTIONING Aß CLEARANCE SYSTEM AS A MAJOR FACTOR ASSOCIATED WITH ALZHEIMER'S DISEASE

Y. Iturria Medina[1], R.C. Sotero[2], P.J. Toussaint[1], A.C. Evans[1]
[1]Neurology and Neurosurgery, Montreal Neurological Institute, Montreal, Canada
[2]Department of Radiology and Hotchkiss Brain Institute, University of Calgary, Calgary, Canada

Objectives
Mechanisms underlying intra-brain misfolded proteins (MP) propagation/deposition remain essentially uncharacterized. Here, we aimed to a) create a biophysical model capable of describe and reproduce intra-brain spatiotemporal patterns of MP propagation/deposition, and b) clarify the effects of MP production, clearance and onset age on disease progression.
Methods
We proposed a stochastic epidemic spreading model (ESM) for spatiotemporal MP dynamics that considers propagation-like interactions between MP agents and the brain's clearance response, across the structural connectome. The validity/applicability of the proposed model was explored using 733 individual PET amyloid-ß (Aß) datasets from the Alzheimer´s Disease Neuroimaging Initiative (ADNI).
Results
The results suggest that it is not an increased Aß production but mainly a deficit in Aß clearance processes and an early Aß onset age that result in the formation of an excessive Aß deposition pattern. The malfunctioning Aß clearance system was also found significantly more related to the AD progression than Aß production. Additionally, our results highlight the strategic role of the MP outbreak regions and their anatomical connectional architecture on the disease's temporal progression, as well as the impact of individual genetic and demographic properties on intra-brain Aß propagation and deposition.
Conclusions
The proposed ESM allows for reconstructing individual lifetime histories of intra-brain MP propagation/deposition, and the analysis of factors that promote such propagation/deposition (e.g., MP production and clearance). The growing body of evidence supporting a reduced Aβ clearance in AD development, in line with our results, could imply a turning point for associated therapeutic mitigation strategies.

[2]Department of Psychiatry and Psychotherapy, Universitätsklinikum Erlangen, Erlangen, Germany

Objective: Neurogranin (Ng) is a 78aa 7618 Da soluble post-synaptic protein with high expression in particular brain regions, including cortex and hippocampus. We have previously shown that elevated cerebrospinal fluid levels of Ng clearly separates both Alzheimer's disease (AD) patients ($p<0.001$) and individuals that progress from mild cognitive impairment to AD ($p<0.001$) from controls. The specific peptide Ng48-76 was also found to be significantly increased in AD ($p=0.002$). In the present study, the objective was to characterize the Ng peptide profile in human plasma.

Methods: Plasma samples from healthy controls (n=37) and AD patients (n=38) were analysed by immunoprecipitation (IP) followed by MALDI-TOF/TOF mass spectrometry (MS). The IP was performed using in-house-generated monoclonal Ng antibodies targeting the C-terminal region of Ng. Endogenous plasma Ng levels were determined in parallel by MS by adding an isotopic labelled Ng peptide to the plasma prior any sample preparation and by an immunochemical method on Meso Scale Discovery platform.

Results: Mass spectrometric characterization of plasma Ng revealed that a variety of endogenous Ng peptides, such as Ng38-75 and Ng44-78, as well as full length protein are reproducibly detected in both controls and AD individuals. Plasma Ng concentrations were similar in AD patients and control individuals.

Conclusions: Plasma Ng is metabolized into several shorter endogenous peptides which can be repeatedly detected and quantified. Although total Ng concentration did not differ between AD patients and control individuals, some of the Ng fragments may have new biomarker potential, which will be examined in future studies on paired plasma and CSF samples.

ADPD5-0688

INVOLVEMENT OF NMDA RECEPTORS IN ABETA TOXICITY

M.K. Mueller[1], *J. von Engelhardt*[1]
[1]*A300 INF280, German Cancer Research Center (DKFZ), Heidelberg, Germany*

Objectives

Aβ oligomers correlate with the memory decline observed in Alzheimer's disease patients. N-methyl-D-aspartate receptors (NMDAR) are glutamatergic receptors that play an important role in learning and memory, but also in excitotoxic processes. Several studies have shown a link between NMDARs and Aβ toxicity. Most of these studies have been performed in neurons from young mice. However, NMDAR subunits show a change in their expression patterns during development. Hence, it is important to investigate the role of NMDAR in Aβ toxicity in adult mice.

Methods

To investigate the role of NMDARs in Aβ toxicity we overproduced Aβ by a virus-mediated approach in brains of mice with conditional knockout of NMDAR subunits. NMDARs were deleted by virus mediated Cre-recombinase expression in adult mice, in which NMDAR genes are flanked by *loxP*-sites (GluN1fl/fl and GluN2Bfl/fl). Aβ toxicity was assessed by electrophysiological and morphological analyses in virus infected dentate gyrus granule cells of adult mice.

Results

3 weeks after virus-mediated Aβ overproduction, we observed a reduction in miniature excitatory post-synaptic current (mEPSC) frequency without morphological abnormalities (e.g. no change in spine number). Deletion of GluN1 (i.e. absence of all NMDARs) or the GluN2B averted the Aβ-mediated decrease in mEPSCs.

Conclusions

Our work demonstrates the importance of NMDARs and more specifically of GluN2B-containing NMDARs in the context of Aβ toxicity in adult mice. The fact that Aβ overproduction reduces mEPSC frequency without affecting spine number indicates that an initial alteration in Aβ toxicity is a reduction in functional synapses.

CALCIUM-FLUX-INDEPENDENT NMDA RECEPTOR ACTIVITY IS REQUIRED FOR ABETA OLIGOMER-INDUCED SYNAPTIC LOSS

C. Tackenberg[1], J.H. Birnbaum[2], R.M. Nitsch[1]
[1]Division of Psychiatry Research, University of Zurich, Schlieren, Switzerland
[2]Division of Psychiatry Research and Graduate Program of the Zurich Neuroscience Cen ter, University of Zurich, Schlieren, Switzerland

Synaptic loss is one of the major features of Alzheimer's disease (AD) and correlates well with the degree of dementia. NMDA receptors (NMDARs) have been shown to mediate downstream effects of beta-amyloid (Aβ). NMDARs can trigger intracellular cascades via Ca^{2+} entry, however also Ca^{2+}-independent (metabotropic) functions of NMDARs have been described. Here we show that transgenically produced Aβ as well as exogenously added synthetic Aβ oligomers induce dendritic spine loss and reductions in pre- and postsynaptic protein levels in slice cultures. Synaptic alterations were mitigated by blocking glutamate-binding to NMDARs using NMDAR-antagonist APV, but not by preventing ion-flux with Ca^{2+}-chelator BAPTA or open channel blocker MK-801 or memantine. Spine loss was mediated by active p38 MAPK. Aβ-induced p38 activation was reduced by APV but not by BAPTA, MK-801 or memantine treatment highlighting the role of glutamate binding to NMDAR but not Ca^{2+}-flux for synaptic degeneration. Our data suggest that Aβ-induced synaptic loss is signaled through metabotropic-like activation of NMDARs. This Ca^{2+}-independent NMDAR signaling may represent a therapeutic target for drugs designed to reduce synaptic deficits in AD.

AFFINITY PROTEOMICS AS A TOOL TO CHARACTERIZE AND QUANTITATE SYNAPTIC PROTEINS IN BRAIN TISSUE AND CEREBROSPINAL FLUID

A. Brinkmalm[1], G. Brinkmalm[1], W.G. Honer[2], H. Zetterberg[1], K. Blennow[1], A. Öhrfelt[1]
[1]Institute of Neuroscience and Physiology, University of Gothenburg, Mölndal, Sweden
[2]Department of Psychiatry, University of British Columbia, Vancouver, Canada

Objectives
Our objective is to identify cerebrospinal fluid (CSF) biomarkers of synaptic damage in neurodegenerative diseases. Synaptic loss occurs early in e.g. Alzheimer's disease, and measurements of altered synaptic function could be important to monitor disease progression and drug effects. The SNARE complex regulates synaptic neurotransmitter release and changed expression of SNARE proteins (SNAP-25, syntaxin-1 and VAMP) has been found to alter synaptic function. In this study we developed an affinity proteomics approach to identify and characterize forms of SNAP-25 in post-mortem brain tissue and CSF.
Methods
SNAP-25 was immunopurified from homogenized and biochemically fractionated human brain tissue (15 AD and 15 controls) or CSF samples and trypsinized. Stable isotope labeled peptide standards were added and the mixtures were analyzed by liquid chromatography-mass spectrometry (LC-MS). A top-down MS approach was utilized to identify novel modified forms of soluble SNAP-25. Quantification was performed either by selected reaction monitoring (SRM) MS or by high resolution selected ion monitoring (HR-SIM) MS.
Results
We report a new strategy to study synaptic pathology by combining affinity purification and proteomics to characterize and quantitate SNAP-25 in brain tissue and CSF. Novel, soluble forms of SNAP-25 were identified in brain tissue and characterized by the same method. Soluble SNAP-25 were also detected and quantitated in CSF samples from individual patients.
Conclusions
The strategy we present make it possible to compare levels of SNAP-25 in individual patient CSF samples. This could be important for earlier diagnosis, assessment of disease progression, and to monitor drug effects in treatment trials.

ADPD5-0845

TARGETED APP EXPRESSION IN HIPPOCAMPUS DEMONSTRATES THAT SYNAPSES POSTSYNAPTIC TO NEURONS EXPRESSING APP ARE THE EARLIEST SITES OF INJURY

E. Vicario Orri[1], K. Chiang[1], S.H. Tyan[1], E.H. Koo[1]
[1]Neurosciences, University of California San Diego, La Jolla, USA

Objectives: The mechanisms by which Abeta causes synaptic dysfunction in Alzheimer's disease (AD) are not well understood. It is difficult to determine from existing rodent models whether Abeta-induced synaptic injury is initiated by the pre- or post-synaptic neuron and how injury is propagated.
Methods: Targeting of APP to CA1 or CA3 neurons was achieved by combining Cre/loxP and Tet-Off systems, thus providing both temporal and spatial control of APP expression. Synapse loss was quantified by immunostaining of synaptic markers in dendritic layers of CA1 and CA3 neurons.
Results: Earlier studies demonstrated that LTP was impaired only in synapses where APP was expressed in pre- but not postsynaptic neurons. In one-year-old CA3-3xTg mice, where APP was expressed selectively in CA3, there was a significant 9% decrease in synaptophysin puncta only in axonal terminal field in stratum radiatum of CA1 neurons. In 18-month-old animals, significant reductions in synaptophysin (9-14%) were observed in dendrite fields of both CA1 and CA3 neurons indicating, a spread of injury to synapses that were both pre- or postsynaptic to neurons expressing APP. Consistent with these observations, preliminary studies in 10-month-old CA1-3xTg mice did not demonstrate any synapse loss CA1 dendritic fields.
Conclusions: These results showed that synapses most vulnerable to Abeta-induced injury are located postsynaptic to where APP was expressed. However, in older mice, even synapses presynaptic to dendrites of neurons expressing APP were susceptible to injury. Current efforts will determine the reversibility of synaptic loss by turning off APP expression.

EXCITATORY SYNAPTIC FUNCTION IN MOUSE MODELS OF NEURODEGENERATIVE DISEASE AND IN ADULT HUMAN NEURONS

C.M. Pegasiou[1], V.H. Perry[1], D. Gomez-Nicola[1], D. Bulters[2], A.I. Amhed[2], A. Zolnourian[2], H. Wobst[3], F. Denk[3], R. Wade-Martins[3], M. Vargas-Caballero[1]

[1]Centre for Biological Sciences, University of Southampton, Southampton, United Kingdom

[2]Department of Neurosurgery, University Hospital Southampton NHS Foundation trust, Southampton, United Kingdom

[3]Department of Physiology Anatomy and Genetics, Univeristy of Oxford, Oxford, United Kingdom

Objectives: The aim of our research is to study how excitatory synapses are affected by amyloid beta (Aβ) and tau, how they affect NMDA receptors, and in particular the GluN2b subtype, which is implicated in synaptic plasticity.

Methods: Glutamate receptor composition at the synapse was determined using whole-cell voltage clamp and pharmacology (using the specific GluN2b blocker Ro-256981), in mice with a genetic deletion of murine tau ($Tau^{-/-}$) and transgenic expression of human tau protein in the $Tau^{-/-}$ background. GluN2b components were analyzed in $Tau^{-/-}$ mice, $Tau^{-/-}$ mice expressing wild type human tau ($Tau^{-/-+}$ H1 haplotype) or a disease-associated mutation ($Tau^{-/-+}$ N296H), prior to and following acute application of $A\beta_{1-42}$. Furthermore, to investigate the relevance of our findings to adult human neurons, glutamatergic synapse composition was studied using human cortical tissue resected during neurosurgery.

Results: A decrease in the NMDAR current was observed in $Tau^{-/-+}$ H1 mice under control conditions, which was not further reduced by Ro-256981. A GluN2b sensitive current was observed in $Tau^{-/-}$ and $Tau^{-/-+}$ N296H neurons, while $A\beta_{1-42}$ further reduced NMDAR current in $Tau^{-/-+}$ N296H neurons. Recordings from cortical layer II-III human neurons showed insensitivity to Ro-256981, suggesting an absence of GluN2b subtype at the human synapses analyzed.

Conclusions: Results suggest that $A\beta_{1-42}$ impairs NMDAR-GluN2b receptor function via a tau-dependent mechanism, and expression of human tau affects GluN2b expression at the synapse in transgenic mice. Further studies are required to understand the synaptic composition of cortical adult human neurons.

ASSESSMENT OF THE PRESYNAPTIC PROTEIN SNAP-25 AS A NOVEL CEREBROSPINAL FLUID MARKER FOR SYNAPTIC PATHOLOGY IN ALZHEIMER'S DISEASE

A. Öhrfelt[1], G. Brinkmalm[1], W.G. Honer[2], L. Frölich[3], L. Hausner[3], L. Minthon[4], O. Hansson[4], A. Wallin[1], H. Zetterberg[1], K. Blennow[1], A. Brinkmalm[1]
[1]Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, Mölndal, Sweden
[2]Department of Psychiatry, University of British Columbia, Vancouver, Canada
[3]Department of Geriatric Psychiatry, Central Institute for Mental Health Mannheim, Mannheim, Germany
[4]Department of Clinical Sciences, Clinical Memory Research Unit, Lund, Sweden

Objectives
Synaptic pathology seems to be occurring early in Alzheimer's disease (AD) development. The cerebrospinal fluid (CSF) biomarkers reflecting synaptic pathology might therefore be valuable for earlier diagnosis, assessment of progression of disease and evaluation of treatment. We have developed an affinity mass spectrometry approach allowing reproducibly measurements of the low abundant proteolytic fragments of synaptosomal-associated protein 25 (SNAP-25) in CSF samples from individual subjects. Evaluation of SNAP-25 as a novel CSF biomarker for AD was assessed in three separate cohorts.

Methods
The CSF SNAP-25 proteoforms were immunoprecipitated, digested with trypsin and stable isotope labeled peptides were added. Quantification of SNAP-25 was performed by high resolution selected ion monitoring (HR-SIM-MS) on a Quadrupole-Orbitrap Mass Spectrometer (Q Exactive). SNAP-25 were measured in CSF samples from patients with prodromal AD (N=7), AD (N=9) and controls (N=9) (cohort I); non-demented controls (N=6) and AD (N=10) (cohort II) and finally in healthy controls (N=16) and AD (N=17).

Results
Levels of CSF SNAP-25 were found to be increased in early as well as later stages of AD in three independent case-control cohorts. Almost all of the measured tryptic peptides of SNAP-25 could differentiate AD from controls with an area under the curve of 0.800 to 1.000 depending on cohorts studied.

Conclusions
We have developed a sensitive method to analyze SNAP-25 levels in individual CSF samples. Levels of CSF SNAP-25 were found to be increased in early as well as later stages of AD in three independent case-control cohorts suggesting SNAP-25 to be a valuable marker.

03c. Pathophysiology & Disease Mechanisms: synapse pathology

ADPD5-1108

EFFECT OF NEUROFILAMENT LIGHT GENE KNOCKOUT ON PATHOLOGICAL FEATURES IN THE APPSWE/PSEN1DE9 MOUSE MODEL OF ALZHEIMER'S DISEASE

J. Vickers[1], C. Fernandez-Martos[1], R. Atkinson[1], A. Woodhouse[1], A. King[1]
[1]Wicking Dementa Research and Education Centre, University of Tasmania, Hobart, Australia

Objectives. Cortical neurons selectively containing neurofilament (NF) triplet proteins are vulnerable to degeneration in Alzheimer's disease (AD) and NFs accumulating in dystrophic neurites are an early feature of this condition. We examined the role of NFs by crossing the APP_{swe}/$PSEN1_{dE9}$ (APP/PS1) transgenic model onto a NF light (NFL) gene knockout background. APP/PS1 mice demonstrate pathological features that are characteristic of preclinical stages of AD.
Methods. F2 generation of mice from the APP/PS1 x NFL-/- cross were used for this study. APP/PS1/NFL-/- mice were compared to APP/PS1/NFL+/+ littermates, and as well as C57/BL/6 wildtype mice (n=5 animals per group). At 10 months of age, animals were terminally anaesthetised with sodium pentobarbitone (140mg/kg), brains fixed with 4% paraformaldehyde and processed for thioflavine-S staining and immunohistochemistry for phosphorylated NFs, synaptophysin, microglia (Iba1) and astrocytes (GFAP).Results. 10 month old APP/PS1/NFL-/- mice demonstrated a statistically significant ($p<0.05$) increase in thioflavine-S positive amyloid load compared to the APP/PS1/NFL+/+ mice (0.811±0.081% and 0.5673±0.026% respectively). There was reduced phosphorylated NF-labelled dystrophic neurites in APP/PS1/NFL-/- animals compared to APP/PS1/NFL+/+ mice. However, there was a statistically significant ($p<0.05$) increase in size, but not density, of synaptophysin labelled dystrophic neurites in APP/PS1/NFL-/- mice relative to APP/PS1/NFL+/+ mice. Microglia, but not astrocytes, were also increased in the APP/PS1/NFL-/- mice relative to APP/PS1/NFL+/+ animals.
Conclusions. NFL gene deficiency increases amyloid deposition, the size of a subtype of dystrophic neurite, as well as microglia, in the APP/PS1 model. This suggests an important role of this element of the cytoskeleton in pathological processes underlying AD.

ADPD5-1210

SYNAPSE SPECIFIC LOSS OF ACTIVITY DEPENDENT TRANSLATION MEDIATED BY DECREASED AKT-MTOR SIGNALING PRECEDES ALZHEIMER'S DISEASE PATHOLOGY IN TRANSGENIC MOUSE MODEL

E. Shaw[1], F. Ahmad[1], K.V. Rupanagudi[1], A. Ramachandran[1], V. Ravindranath[1]
[1]Centre for Neuroscience, Indian Institute of Science, Bangalore, India

Objectives

Synaptic dysfunction, seen structurally and functionally as loss of spines and LTP respectively, contributes to pathogenesis and progression of Alzheimer's disease (AD). The mechanisms underlying these dysfunctions, however, remain unclear. Activity-dependent protein translation at the synapse is essential for regulating long-lasting changes underlying synaptic remodeling and plasticity, such as those seen in LTP. We therefore examined activity-dependent protein translation and the underlying mechanisms at the synapse using a transgenic AD mouse model.

Methods

Synaptosomes and synaptoneurosomes were prepared from cortex of 3 and 9 months old wildtype and APPswe/PS1deltaE9 mice using differential gradient centrifugation and sequential filtration method, respectively. Activity-dependent translation was assayed following KCl stimulation in presence of S^{35}-methionine. Immunoblotting and immunoprecipitation was performed using standard protocols.

Results

Activity-dependent translation is severely diminished in synaptosomes from APPswe/PS1deltaE9 mice at 3 months of age prior to onset of behavioral dysfunction and pathology observed at 8-9 months. This is associated with synapse-specific loss of Akt-mTOR signaling as measured by loss of pAkt, pmTOR and downstream targets pS6K/p4EBP1 at 3 months of age. Further, Akt inhibition in wildtype synaptosomes is sufficient to abolish synaptic activity-dependent translation.

Conclusions

Synapse-specific loss of Akt-mTOR signaling and consequent disruption of activity-dependent protein translation seen in young adult mice, long before onset of symptoms indicate that the synapse is potentially an early target in pathogenesis of AD. Further, these deficits in young AD mice indicate that disease pathogenesis begins long before overt appearance of pathological symptoms, challenging the notion of AD being a disease of old-age.

EMERGENCE OF SYNAPTIC AND COGNITIVE IMPAIRMENT IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

S. Sri[1], D. Gomez-Nicola[1], C. Cave[2], D. Bannerman[2], V.H. Perry[1], M. Vargas-Caballero[1]
[1]Centre for Biological Sciences, University of Southampton, Southampton, United Kingdom
[2]Department of Experimental Psychology, University of Oxford, Oxford, United Kingdom

Objectives

Alzheimer's disease (AD) is the world's leading cause of dementia and yet we are still unclear as to the mechanisms behind memory impairment early in the disease. This study aims to uncover the relationship between cognitive dysfunction and early synaptic impairment to identify potential drug targets for this early phase of the disease.

Methods

We used a tet-off inducible AD mouse model expressing $APP_{Swe,Ind}$. Field recordings were made to measure synaptic transmission between hippocampal CA3-CA1 synapses and the T-maze was used to measure short-term memory. We used immunohistochemistry (Ab6E10) and Congo Red staining to assess the level of Abeta plaque load within these mice.

Results

$APP_{Swe,Ind}$ overexpression from birth leads to a significant impairment of basal synaptic transmission by 2 months of age. Surprisingly, levels of long-term potentiation (LTP) are similar between control and mutant mice.

To analyse how these synaptic changes emerge, we used this mouse model to allow short-term $APP_{Swe,Ind}$ overexpression in adulthood (6 weeks of age). Electrophysiological data show that three weeks of APP overexpression results in impaired LTP without affecting basal synaptic transmission. These mice are impaired in their short-term memory and we are establishing a test of long-term memory using a water maze.

Conclusions

We show that short-term inducible APP overexpression is sufficient to impair synaptic and cognitive function and that developmental expression can generate compensation mechanisms that require further study. Understanding the differences between the acute consequences of APP expression and compensatory mechanisms will guide us in the search for effective AD drugs.

The accumulation of neurofibrillary tangles in Alzheimer's disease (AD) propagates with characteristic spatiotemporal patterns which follow brain network connections, implying trans-synaptic transmission of tauopathy. Since misfolded tau has been shown to transmit across synapses in AD animal models, we hypothesized that synapses in AD patients may contain misfolded tau. Generally, tau exists in axons; But tau also mislocalizes to dendrites in AD. We isolated synaptic terminals from the cortical tissue of AD subjects and immunostained for tau and synaptic markers, followed by examination with fluorescence microscopy and flow cytometry.

Immunofluorescence microscopy of bipartite synapses from AD subjects showed tau protein in 38.4% of presynaptic and 50.9% of postsynaptic terminals. The pre/post distribution for hyperphosphorylated tau was 26.9%/30.7%, and for misfolded tau 18.3%/19.3%. Within the temporal cortex, microscopic aggregates of tau, containing ultra-stable oligomers, were found to accumulate inside trillions of synapses, outnumbering macroscopic tau aggregates such as tangles by 10,000 fold. Non-demented elderly also showed considerable synaptic tau hyperphosphorylation and some misfolding, implicating the synapse as one of the first subcellular compartments affected by tauopathy. Misfolding of tau protein appeared to occur *in situ* inside synaptic terminals, without mislocalizing or mistrafficking. Misfolded tau at synapses may represent early signs of neuronal degeneration, mediators of synaptotoxicity, and anatomical substrates for transmitting tauopathy. We also developed four-channel flow cytometry to detect protein localization in isolated synaptosomes, which was applied to an amyloid mouse model of AD to examine the colocalization of Aβ and tau at synapses.

ABETA FACILITATED MGLU5R-LTD IN HIPPOCAMPUS IN VIVO IS PROTEIN SYNTHESIS INDEPENDENT, BUT DEPENDENT ON LVA CALCIUM CHANNELS

N.W. Hu[1], *M.J. Rowan*[1]
[1]*Pharmacology & Therapeutics and Institute of Neuroscience, Trinity College Dublin, Dublin, Ireland*

Acetylcholine muscarinic receptor-dependent long-term depression (LTD) can be induced by high intensity low frequency stimulation (LFS) in the hippocampus *in vivo*. In contrast, in the presence of amyloid ß –protein (Aß) a metabotropic glutamate-5 receptor–dependent LTD is facilitated, usurping the requirement for mAChRs. The mechanisms of these two forms of LTD remain to be elucidated.

Objectives:

Here we studied the roles of voltage-dependent calcium channels and protein synthesis in control, mAChR-LTD and Aß facilitated mGlu5R-LTD *in vivo*.

Methods:

EPSPs were recorded in the CA1 area of urethane-anaesthetized adult male Wistar rats. Control LTD was induced by 900 pulses at 1Hz (LFS-900) and Aß-facilitated LTD by 300 pulses (LFS-300). Agents were injected via a cannula implanted in the lateral ventricle.

Results:

We found that: (i) Injection of mibefradil (25 nmol), a blocker of low voltage activated calcium channels (LVA), prevented control LTD completely whereas i.c.v. injection of the L-type high voltage activated calcium channels blocker methoxyverapamil (100 nmol) had no effect. (ii) In animals co-injected with mibefradil and Aß, LFS-300 failed to induce LTD whereas LFS-300 induced robust LTD in animals co-injected with methoxyverapamil and Aß. (iii) The protein synthesis inhibitor emetine (434 nmol) blocked the late, but not the early, phase of control LTD. (iv) In contrast, LFS-300 induced robust and persistent LTD after co-injection of emetine and Aß.

Conclusions:

Our data indicate that LVA channels are required for the induction of both control, mAChR-LTD and Aß facilitated mGlu5R-LTD while protein synthesis is only required for mAChR-LTD.

AGE-RELATED PROTEOMIC ANALYSIS OF S-NITROSYLATION SITES OF POSTSYNAPTIC DENSITY PROTEINS IN MOUSE MODELS OF ALZHEIMER'S DISEASE.

K. Bucholc[1], A. Wyslouch-Cieszynska[1], M. Dadlez[1], M. Zareba-Koziol[1]
[1]Mass Spectrometry Laboratory Department of Biophysics,
Institute of Biochemistry and Biophysics Polish Academy of Sciences, Warsaw, Poland

Alzheimer's disease (AD) is the most frequent neurodegenerative disorder, characterized by progressive loss of synapses and neurons, leading to deterioration of cognitive functions, learning and memory. The pathogenesis of AD is linked to oxidative/nitrosative stress caused by overproduction of reactive oxygen species (ROS) and reactive nitrogen species (RNS) and an imbalance in the redox state of the cells. One of the consequences of the RNS interaction with proteins is their S-nitrosylation - a covalent incorporation of a nitric oxide moiety into cysteine thiol group. This modification is emerging as an important redox signaling mechanism which can regulate a broad range of physiological functions. Our research focused on systemic analysis of endogenous S-nitrosylation of proteins from postsynaptic densities (PSDs) - multiprotein structures responsible for the proper functioning of excitatory synapses. PSDs were isolated from brains of transgenic mice with neuronal expression of human mutant APP protein (which are an accepted model of Alzheimer's disease) and control FVB mice. To monitor the changes in protein S-nitrosylation during AD progression the study was carried out on 3-, 6- and 14-month-old mice. In the project we used methods enabling us to selectively enrich the PSD fraction in S-nitrosylated proteins and mass spectrometry analysis for their identification. As a result we obtained lists of peptides present in the samples and peptide sequences assigned to proteins that were S-nitrosylated in the brains of FVB control mice and APP transgenic mice modeling Alzheimer's disease of 3, 6 and 14 months of age.

ADPD5-1766

GLOBAL ANALYSIS OF SYNAPTIC PROTEINS' S-SULFENYLATION IN MOUSE MODELS OF ALZHEIMER'S DISEASE

M. Zareba-Koziol[1], *M. Dadlez*[1]
[1]*Biophysics Department,*
Institute of Biochemistry and Biophysics Polish Academy of Sciences, Warsaw, Poland

Alzheimer's disease (AD) is characterized by progressive loss of memory and deterioration of cognitive functions. Although the hallmark lesions of the disease, amyloid plaques and intracellular neurofibrillary tangles were described —the molecular mechanisms underlying the disease are still unknown. Recent studies showed, synaptic dysfunction and the loss of synapses are early pathological features of Alzheimer's disease. The pathogenesis of this disorder is linked to the imbalance in production of reactive oxygen (ROS). One of the consequences of interaction ROS with proteins is S-sulfenylation. Cysteine S-sulfenylation is a reversible oxidation reaction that converts the thiol group of protein cysteine residues to a sulfenic acid group. S-sulfenylation, has long been regarded as a harmful cysteine modification, but is nowadays known as a messenger in signaling pathways. This modifications provides redox regulation of protein functions, but the global cellular impact of this transient post-translational modification remains unexplored.

The aim of our project is detection of changes in protein S-sulfenylation during progression of AD. In this work, we used selective cysteine sulfenic acid labeling technique combined with Western blot analysis, nano-LC MS/MS and bioinformatic approaches to globally map endogenously S-sulfenylated cysteines of brain synaptosomal proteins from wild type and transgenic mice overexpressing mutated human Amyloid Precursor Protein (hAPP).

This type of analysis help to defining the quantitative in S-sulfenylation of proteins among different biological states. The progress in the understanding of the molecular alterations underlying Alzheimer’s disease will be useful in developing successful preventive and therapeutic strategies able to block the neurodegenerative process.

Alzheimer's Disease (AD) is characterized by progressive memory loss eventually resulting in dementia. Over the course of AD, insoluble amyloid plaques are formed but synapse loss is known be better correlated with the progression of the disease. The exact role of AB is not fully understood but recent evidence suggests that subtle alterations of synaptic transmission precede neuronal degeneration in the AD progression. Using APP/PS1 transgenic mice we evaluated synaptic function during the initial development of the disease. We characterized the structural and functional age-dependent deficits of glutamatergic synaptic transmission in hippocampal CA3 pyramidal area, a brain structure that plays a key role in memory formation, and that is poorly studied in AD mice models. At 6 months APP/PS1 animals display deficits in several hippocampal dependent behavioural tasks, but no histological features of AD. We looked for correlations of structural and functional impairments in this model of AD by combining patch-clamp electrophysiological recordings in acute hippocampal slices with STED microsccopy to study morphological changes. The originality of this approach lies in our ability to analyze in detail the deficits of individual types of synapses by examining parameters which have been little studied in adult/aged animals, such as synaptic imbalance in the expression of different glutamate receptors subunits and synaptic plasticity of NMDA responses. Our work provides insight and mechanistic understanding to the deregulation of synaptic function and alterations of dendritic spines of different types of synapses present in the same CA3 pyramidal cells and putative rescues strategies for rescue of synaptic dysfunction.

[2]Biochemistry and Molecular Biology,

Faculty of Pharmacy University of Seville/ CIBERNED/IBIS, Seville, Spain

OBJECTIVES: We aim to investigate the effects of Abeta from young PS1/APP mouse model of Alzheimer`s disease (AD) on the synaptic integrity by different means. We analyzed the direct synaptotoxic effect of plaques in the hippocampus of this model and the repercussion of the soluble (S1) fraction in neuronal cultures.

METHODS: Hippocampal synapses were investigated by optic and electron microscopy. Primary neuronal cultures were incubated for 48 hours with 6 month-old PS1/APP and wild-type S1 fractions. Levels of several synaptic proteins were measured by Western-blots (WB).

RESULTS: Synapse number and synaptic-vesicles density were found to be significantly decreased in young PS1/APP mice, close to the Abeta deposits, in several hippocampal layers. Importantly, there was a correlation between these deficiencies and the distance to the plaques, which displayed oligomeric forms in their periphery. Some of the presynaptic elements were abnormally swollen and contained autophagic vesicles. In addition, we found by WB a decrease in several hippocampal synaptic markers as early as 4 months of age in this model and in neuronal cultures incubated with S1 fractions. These results correlated with early hippocampus-associated cognitive deficits.

CONCLUSIONS: Plaque-associated oligomeric Abeta induced an early deleterious effect on synapses along with memory deficits in young PS1/APP mice. Moreover, soluble Abeta derived from these transgenic mice reduced synaptic protein content in vitro. Therefore, this model produced synaptotoxic Abeta and may represent a valuable tool to test novel treatments to protect synapses as an early therapeutic approach for AD.

ADPD5-0479

DISSECTING COMMON PATHO-MECHANISMS BEHIND AD AND PD BASED ON PATHWAYS USING COMPUTABLE MODELS

A. Tom Kodamullil[1], M. Guendel[1], A. Iyappan[1], M. Naz[1], M. Hofmann-Apitius[1]
[1]Bioinformatics, Fraunhofer Institute for Algorithms and Scientific Computing (SCAI), Sankt Augustin, Germany

Objective: One of the fundamental questions in NDD research is whether Alzheimer's disease (AD) and Parkinson's disease (PD) are different phenotypic variants of the same molecular aetiology or whether multiple aetiologies can converge into the same clinical phenotype. The concept of "shared pathways" between NDDs is attractive as it bears the hope that only a limited number of mechanisms could lead to major neurodegenerative diseases. Therefore identification of common patho-mechanistic pathways between AD and PD could raise the possibility of not only discovering common drug targets for therapeutics but also facilitates repurposing of existing drugs.
Methods: Preliminary cross-disease analysis of pathways was performed using the in-house pathway terminology system (PTS) in the SCAIView knowledge discovery search engine[1]. The top relevant pathways obtained from SCAIView were used to build cause-and-effect computable models for both diseases, based on published knowledge in literature applying BEL, the biological expression language.
Results: The autophagy pathway was found to be one of the shared pathways with maximum co-mentions in literature specific for Alzheimer's and Parkinson's diseases. We found Beclin 1 (BECN1) as one of the main co-players for assembling an interactome with stimulating and suppressive components, which regulates the initiation of the autophagosome formation in both diseases.
Conclusion: Cross-disease analysis using computable BEL models enables us to find novel drug targets based on shared pathways. We propose BECN1 as a novel therapeutic target common for both AD and PD by regulation of autophagy pathway.

ASM REGULATES THE AUTOPHAGIC PROCESS BY CONTROLLING LYSOSOMAL BIOGENESIS IN ALZHEIMER'S DISEASE

H. Jin[1], J. Bae[2]
[1]College of Veterinary Medicine, Kyungpook National University, Daegu, Korea
[2]School of Medicine, Kyungpook National University, Daegu, Korea

In Alzheimer's disease (AD) abnormal sphingolipid metabolism has been reported, although the pathogenic consequences of these changes have not been fully characterized. Here we show that acid sphingomyelinase (ASM) is increased in fibroblasts, brain and/or plasma from patients with AD and in AD mice, leading to defective autophagic degradation due to lysosomal depletion. Partial genetic inhibition of ASM (*ASM*$^{+/-}$) in a mouse model of familial AD (*APP/PS1*) ameliorated the autophagocytic defect by restoring lysosomal biogenesis, resulting in improved AD clinical and pathological findings, including reduction of amyloid-b deposition and improvement of memory impairment. Similar effects were noted after pharmacologic restoration of ASM to the normal range in APP/PS1 mice. Autophagic dysfunction in neurons derived from familial AD patient-induced pluripotent stem cells (iPSCs) was restored by partial ASM inhibition. Overall, these results reveal a novel mechanism of ASM pathogenesis in AD that leads to defective autophagy due to impaired lysosomal biogenesis, and suggests that partial ASM inhibition is a potential new therapeutic intervention for the disease. This work was supported by the Bio & Medical Technology Development Program (2012M3A9C6050107, 2012M3A9C6049913) of the National Research Foundation (NRF) of Korea funded by the Ministry of Science, ICT & Future Planning, Republic of Korea.

C99 ACCUMULATION, LYSOSOMAL DYSFUNCTION AND AUTOPHAGIC FAILURE IN ALZHEIMER DISEASE CELLULAR AND ANIMAL MODELS

I. Lauritzen[1], R. Pardossi-Piquard[1], S. Lacas-Gervais[2], F. Checler[1]
[1]team of Dr Checler, IPMC, Valbonne, France
[2]microscopy center, CCMA, Nice, France

1-Objectives: Recently, we have shown, using the 3xTgAD mouse model (APPswe, PS1M146V, TauP301L), an early, age-dependent and hippocampus specific accumulation of the beta-secretase cleavage fragment C99 in Cathepsin B positive structures resembling autolysosomes. In the present work, we therefore investigated the relationship between C99 accumulation and autophagic function.
2-Methods: We used an *in vitro* model (SH5Y-APPswe cells) and the 3xTgAD mouse. Cells were treated with pharmacological agents affecting autophagy or with gamma-secretase inhibitors. Autophagy was evaluated by western blot analysis, Cathepsin dosage, electron microscopy and immunofluorescence. Animals were treated chronically with a gamma-secretase inhibitor.
3-Results: We found that autophagy plays a key role in the elimination of C99 and other APP C-terminal fragments (APP-CTFs). The pharmacological activation of autophagy or the overexpression of Cathepsin B both decreased APP-CTFs levels. In contrary, the pharmacological blockade of autophagy or the inhibition of lysosomal hydrolases (by Cathepsin inhibitors or lysosomal alkalization) lead to a large increase in APP-CTFs levels. Interestingly, we also found that APP-CTFs can themselves affect autophagic function, because the inhibition of gamma-secretase lead to the accumulation of APP-CTFs with associated loss of cathepsin activity, increase in autophagic markers and build-up of abnormal undigested autophagic vacuoles. Moreover, the chronical treatment of 3xTgAD mice with a gamma-secretase inhibitor lead to a massive increase in APP-CTFs in Cathepsin B positive structures and autophagic dysfunction.
4-Conclusion: Our data highlight a major role of autophagy in C99 clearance and also show a direct correlation between APP-CTF accumulation and autophagic dysfunction.

ADPD5-1274

STUDYING THE BIOLOGY OF MISFOLDING PROTEINS IN CULTURE TO ELUCIDATE CSF BIOMARKER CHANGES IN ALZHEIMER'S DISEASE

T. Olsson[1], K. Willén[1], O. Klementieva[1], I. Martinsson[1], O. Hansson[2], G.K. Gouras[1]
[1]Experimental Dementia Research, Lund University, Lund, Sweden
[2]Clinical Memory Research Unit Department of Clinical Sciences Malmö, Lund University, Lund, Sweden

Objectives:
Alzheimer's disease is characterized by the abnormal aggregation of Beta-amyloid (Abeta) in plaques and tau in tangles. Plaques contain alpha-synuclein as their 2nd most abundant component. Our understanding of why these misfolding proteins show different changes in CSF in AD is incomplete. There is a complex dynamic equilibrium of extra- and intracellular pools of misfolding proteins involved in AD, which depends on production, secretion, uptake and degradation. Because the endosome-lysosome and autophagy systems regulate the biology of misfolding proteins linked with AD, these systems are modulated to elucidate biomarker changes in AD.
Methods: Endosomal, lysosomal and mTOR dependent autophagic pathways are modified in untransfected, human APP, Swedish mutant APP or alpha-synuclein transfected N2a neuroblastoma cells or primary neurons in culture and analyzed by Western blot and immunofluorescence microscopy.
Results: Reducing the extracellular levels of Abeta or alpha-synuclein decreases their respective intracellular levels supporting a dynamic equilibrium of extra- and intracellular levels of Abeta and alpha-synuclein. Modulating endosome-lysosome and autophagy pathways alters this equilibrium, although with these treatments Abeta and alpha-synuclein do not change in the same direction.
Conclusion: The extra- and intracellular pools of misfolding proteins affect each other in a manner consistent with a dynamic equilibrium between the respective pools. Modulation of endosome-lysosome and autophagy systems differentially changes the dynamics of extra- and intracellular pools of misfolding proteins/peptides. We hypothesize that these results in cell culture systems can provide insights into why Abeta is decreased while alpha-synuclein is increased in the CSF with AD.

ADPD5-1477

IMPORTANCE OF SPHINGOSINE-1-PHOSPHATE-LYASE IN LYSOSOMAL METABOLISM OF THE AMYLOID PRECURSOR PROTEIN.

I. Karaca[1], *J. Walter*[1]

[1]*Molecular Cell Biology, Neurology, Bonn, Germany*

Sphingolipids are components of cellular membranes and play important roles in cellular signaling. Lack of the sphingosine-1-phosphate (S1P) degrading enzyme S1P-lyase causes accumulation of S1P and its precursor sphingosine. We recently showed that S1P-lyase activity is involved in the lysosomal turnover of the amyloid precursor protein (APP) and its C-terminal fragments (APP-CTFs). Our data also indicated impaired lysosomal Ca^{2+} mobilization in S1P-lyase deficient cells. Interestingly, APP metabolism could be partially normalized by selective Ca^{2+} release (Karaca et al, 2014). We now analyzed a potential invovlement of PKC in APP processing when S1P-lyase was absent. Analysis of APP metabolism was carried out using biochemical and cell biological approaches in mouse embryonic fibroblasts from wild-type (WT) and S1P-lyase-knock-out (KO) mice. Lipid analysis was performed by mass spectrometry. The subcellular distribution of PKC and other proteins were analyzed by cell fractionation and fluorescence microscopy. S1P-lyase deficient cells show significant increase of intracellular S1P and sphingosine. Inhibition of sphingosine-kinases caused a selective increase in cytosolic levels of PKC. Furthermore, fluorescence microscopy revealed altered morphology of endo-lysosomal compartments in KO cells. Interestingly, this phenotype was partially mimicked by pharmacological inhibition of PKC. In particular, PKC inhibition causes a strong accumulation of APP-CTFs and altered maturation of the lysosomal protease cathepsin-D. These results point to an involvement of PKC in S1P or sphingosine mediated metabolism of APP. It will be interesting to further dissect the role of PKC in the regulation of APP metabolism by sphingolipids, and its functional role in the pathogenesis of Alzheimer's disease.

ADPD5-2223
IMPAIRMENT OF CHAPERONE MEDIATED AUTOPHAGY INDUCES DOPAMINERGIC NEUROGENERATION IN RATS

L. Stefanis[1], O. Brekk[1], A. Polissidis[1], M. Xilouri[1]
[1]Laboratory of Neurodegenerative Diseases, BRFAA, Athens 11527, Greece

Objective: To investigate the physiological role of Chaperone Mediated Autophagy (CMA) in the adult brain and to elucidate the consequences of CMA failure in the rat substantia nigra, the area mainly affected in Parkinson's disease.

Methods: We have generated adeno-associated viruses expressing shRNAs targeting Lamp2a, CMA's rate limiting step, as well as control scrambled shRNAs. These viruses were injected stereotaxically into the rat nigra and at 4 and 8 weeks post-injection we assessed the efficacy of Lamp2a down-regulation, endogenous alpha-synuclein levels, dopaminergic system integrity and relevant behavioural deficits.

Results: Using two different shRNAs against Lamp2a we detected a significant decrease in Lamp2a levels within the dopaminergic neurons, accompanied by intracellular alpha-synuclein-positive puncta, indicating that CMA, a major pathway for alpha-synuclein clearance, was compromised. These puncta were also positive for ubiquitin. Strikingly, down-regulation of Lamp2a led to a significant impairment of dopaminergic system integrity, characterized by a 60% loss of nigral dopaminergic neurons, and a similar reduction in striatal dopamine levels. Measurement of d-amphetamine-evoked rotations is currently underway.

Conclusions: Our study highlights for the first time an important physiological role of the CMA pathway in the brain. Furthermore, the model presented herein recapitulates main features of Parkinson's disease, including the severe loss of dopaminergic neurons and the accumulation of aggregated alpha-synuclein within surviving neurons. This fact, in conjunction with previous biochemical and neuropathological evidence linking impairment of the CMA pathway to the disease, suggests that this model may be useful in investigating relevant mechanisms and therapeutic interventions.

[2]Experimental Neurology, Deutsches Institut fur Demenz Praevention, Homburg, Germany

Objectives: Immunization trials in AD patients have not been effective for curing or ameliorating dementia. Experimentally (line #85; APP_{Swe}-PSEN1Δexon 9), there is limited clearance of amyloid plaques. Therefore, more knowledge about the mechanism of Aβ plaque formation is a priority. We showed that misframed ubiquitin (UBB^{+1}) inhibits the ubiquitin proteasome system (UPS) resulting in ERAD dysfunction, mitochondrial clogging and impaired contextual behaviour (Dennissen, Prog. Neurobiol., 2012). Recently, GWAS studies, pathway analysis and proteomics identified protein ubiquitination as one of the key modulators of AD (Manavalan, Exp. Mol. Med., 2013). Crosstalk between a dysfunctional UPS and Aβ plaque formation has been surmised but never proven.

Methods: This issue was studied by crossbreeding 2 transgenic lines (lines #3413 with UBB^{+1} overexpression, line #85 with Aβ plaque formation at 4 months of age) and their crossbreed (#3413 x #85).

Results: In line 85, γ-secretase activity was decreased significantly at 3, 6 and 9 months of age, whereas α and β- secretases were unaffected. However, in the crossbreed (with a dysfunctional UPS) γ-secretase activity was enhanced at the age of 6 months; a critical period where Aβ plaque generation is attenuated. In the crossbreed, nest building and contextual memory are impaired. Our new data implicate a strong interaction between a dysfunctional UPS and Aβ plaque formation being mediated specifically via γ-secretase.

Conclusion: A striking inverse correlation is shown between γ-secretase activities and Aβ plaque load and will contribute to a better understanding of strategies to ameliorate or cure AD, via γ- secretase modulation.

[5]Department of Cellular and Molecular Medicine,
Centro de Investigaciones Biológicas (CSIC), Madrid, Spain

Objectives: We previously reported that control of cell cycle distinguishes lymphoblasts from sporadic and familial Alzheimer's disease patients (SAD and FAD). We found significantly increased basal p21 levels in SAD cells compared with FAD lymphoblasts. Since it is known that p21, besides controlling cell cycle, can regulate apoptosis, we checked whether p21 levels play a role in the cellular response of FAD and SAD cells to oxidative stress evoked by 2d-ribose (2dRib).

Methods: Cell viability after 2dRib and pifitrin (PFT–a) treatment was measured using MTT assay, mRNA levels were evaluated using real-time PCR and protein levels by immunoblotting. p21 levels in nuclear and cytosolic fractions were visualized using confocal laser scanning microscopy.

Results: FAD lymphocytes were more resistant to 2dRib-induced cell death than control or SAD cells. In response to 2dRib FAD cells showed significantly increased p21 mRNA and protein levels and preferentially cytoplasmic location of p21 as compared to SAD cells. Transcriptional activation of p21 was shown to be dependent on p53, as it can be blocked by PFT-a.

Conclusions: The increase in p21 transcription in FAD lymphoblasts and its cytoplasmic localization confer these cells a survival advantage, since PFT-a sensitized FAD cells to 2dRib-induced apoptosis. Thus, as some cellular mechanisms seem to be different in FAD and SAD cells, our data suggest a possibility for differential diagnosis of FAD and SAD based on p21 and p53, and individualized therapeutic approach for SAD and FAD.

BACH1 OVEREXPRESSION IN DOWN SYNDROME CORRELATES WITH THE ALTERATION OF THE HO-1/BVR-A SYSTEM: INSIGHTS FOR TRANSITION TO ALZHEIMER DISEASE

M. Perluigi[1], E. Barone[1], E. Head[2], D.A. Butterfield[3], F. Di Domenico[1]
[1]Biochemical Sciences, Sapienza University of Rome, Rome, Italy
[2]Sanders Brown center of Aging, University of Kentucky, Lexington, USA
[3]Chemistry, University of Kentucky, Lexington, USA

Objectives. Among the genes encoded on chromosome 21, Bach1 is a transcription repressor, which binds to antioxidant response elements (AREs) of DNA thus inhibiting the transcription of specific genes involved in the cell stress response including heme oxygenase-1 (HO-1). HO-1 and its partner, biliverdin reductase-A (BVR-A), are up-regulated in response to oxidative stress (OS) in order to protect cells against further damage. Since OS is an early event in Down Syndrome (DS) and might contribute to the development of multiple deleterious DS phenotypes, including AD pathology, we investigated the status of the Bach1/HO-1/BVR-A axis in DS and its possible implications for AD development.
Methods. Post mortem brain (frontal cortex) from DS patients with (mean age 59 ys) and without (mean age 25 ys) dementia, and from Ts65Dn mice, a Tg mouse model of DS, were analyzed. Western blot, immunoprecipitation and RT-PCR assays were performed to investigate Bach1/HO-1/BVR-A axis in the above samples.
Results. Our data show that the development of AD in DS subjects is characterized by (i) increased Bach1 total and poly-ubiquitination; (ii) increased HO-1 protein levels; and (iii) increased nitration of BVR-A followed by reduced activity. To corroborate our findings we analyzed Bach1, HO-1 and BVR-A status in Ts65Dn mouse model at 3 (young) and 15 (old) months of age.
Conclusions. The above data support that the dysregulation of HO-1/BVR-A system contributes to the early increase of OS in DS and provide potential mechanistic paths involved in the neurodegenerative process and AD development.

03f. Pathophysiology & Disease Mechanisms: oxidative damage

NITRATED P53 AS AN EARLY BIOMARKER OF UNBALANCE REDOX STATUS IN ALZHEIMER'S DISEASE (AD)

C. Prandelli[1], A. Delbarba[1], M. Marziano[1], A. Abate[1], M. Barcikowska[2], M. Styczynska[2], A. Szybinska[3], M. Memo[1], D. Uberti[1]

[1]Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy

[2]Medical Research Centre, Polish Academy of Science, Warsaw, Poland

[3]Laboratory of Neurodegeneration, International Institute of Molecular and Cell Biology, Warsaw, Poland

Objectives: An early Alzheimer's diagnosis is still missing because of the difficulty to establish a standardized method in periphery. On this basis the measurement of oxidative stress and p53 levels was made in immortalized B-lymphocytes AD patients to define a specific marker with prognostic value.

Methods: The levels of oxidative markers were measured (4-HNE, 3-NT and protein carbonyl) through western blot. The antioxidant activities of superoxide dismutase (SOD), glutathione peroxidase (GPx) and glutathione reductase (GRD) were measured by enzymatic assays. To study p53 conformations, immunoprecipitation experiments with PAb1620 (for p53 wild-type) and PAb240 (for p53 unfolded) antibodies, were performed. The effect of peroxynitrite compound (SIN-1) on p53 conformation was evaluated with FACS analysis.

Results: We observed increased levels of HNE and 3-NT only in familiar AD, compared with controls. A reduced SOD and GRD activity was evident in familiar and sporadic AD. Furthermore a significant amount of p53 was found conformational altered in both pathological groups in comparison with controls, demonstrated by the high reactivity to PAb240 antibody. Immunoprecipitation experiments followed by the immunoblotting with anti 3-NT antibody, showed in both groups an increase of nitrated tyrosine residues in samples immunoprecipitated with PAb240. Interestingly, the nitration of tyrosine residues of p53 could be responsible of the p53 conformational change towards an unfolded phenotype, as demonstrated by the SIN-1 experiment. A correlation between unfolded p53 and SOD activity was also found.

Conclusions: The oxidative stress could alter p53 conformation. Nitrated-p53 might be considered as a potential early biomarker for Alzheimer's disease.

HESPERIDIN: A NOVEL BIOFLAVONOID IN ATTENUATING LIPOPOLYSACCHARIDE-INDUCED COGNITIVE DEFICITS IN MICE.
N. El Sayed[1], S. El Mogy[1]
[1]Pharmacology & Toxicology, German University in Cairo, Cairo, Egypt
Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by multiple cognitive deficits, behavioral abnormalities and mood changes. Neuroinflammation and oxidative stress have been established as fundamental components of AD pathogenesis. Microglia are activated in response to amyloid beta (Aβ) aggregates initiating a chronic inflammatory response in the brain. In addition, Aβ may result in mitochondrial dysfunction and augmented ROS levels. The present study was designed to evaluate the possible effect of different doses of the citrus flavonoid hesperidin (HDN) on male Swiss albino mice after receiving intraperitoneal (i.p) injections of lipopolysaccharide (LPS) at a dose of 0.8 mg/kg to induce AD. HDN was injected at three dose levels (2, 4, 8mg/kg, i.p.). Indomethacin (1 mg/kg, i.p., 5 days) as well as ascorbic acid (120 mg/kg, i.p., 7 days) were used as a positive control for their antinflammatory and antioxidant effects. Behavioral changes were evaluated using y-maze, 8-arm radial maze and novel object recognition tests, while molecular changes were assessed by measuring TNF-alpha (TNF-α), malondialdehyde (MDA), superoxide dismutase (SOD) and glutathione reductase (GSH) levels in the mouse brain. Moreover, immunohistochemistry was used to assess Aβ1-42 deposition in the mouse cortex and hippocampus. Results showed that HDN reversed LPS-induced cognitive impairment in mice and suppressed LPS-induced changes in molecular markers of inflammation and oxidative stress in a dose dependent manner. This was accompanied by a reduction in Aβ deposition in the brain. Thus, our study suggests that HDN is a promising memory enhancer with potential benefits in prevention of AD.

CONFORMATIONALLY ALTERED P53 AFFECTS NEURON BIOLOGICAL FUNCTIONALITY

G. Abate[1], C. Prandelli[1], A. Delbarba[2], M. Marziano[1], M. Memo[1], D. Uberti[1]
[1]Department of molecular and translational medicine, University of Brescia, brescia, Italy
[2]Diadem ltd, University of Brescia, brescia, Italy

Objective. In this study we investigated a possible contribution of p53 unfolded protein in neurodegeneration occurring in Alzheimer's Disease.
Methods. An in-vitro model of a stable transfected SH-SY5Y clone overexpressing APP751wt was used to study oxidative stress markers, such as HNE Michael-adducts and 3-Nitro-Tyrosine as well as unfolded p53. p53 conformation was evaluated using two specific monoclonal antibodies: PAb1620 (that recognizes p53wt) and PAb240 (direct towards unfolded p53). Furthermore, growth-associated protein 43 (GAP43) was examined at mRNA and protein levels.
Results. We found that SY5Y-APP clone expressed an increased amyloidogenic processing with enhanced expression of C-terminal fragments C99 and C83 and β-amyloid peptide. High oxidative markers and unfolded p53 conformation, due essentially to nitration of its tyrosine residues, were also observed in SY5Y-APP cells. In addition, this clone was less sensitive to acute oxidative insult because of p53 impairment. SY5Y-APP cells expressed reduced GAP-43 mRNA and protein levels in comparison with control, affecting cell differentation and morphology. Both H_2O_2-sensitivity and GAP-43 expression were restored by modulating p53 conformation towards a wild-type phenotype. In particular, Zinc-supplementation reverted p53 wild-type tertiary structure and increased cells sensitivity to acute cytotoxic injury and GAP-43 levels in SY5Y-APP clone.
Conclusion. We propose p53 oxidation/nitration as one of early molecular event in the estabilishment of neuronal dysfunction, leading to cognitive impairment and AD pathology. In particular, elevated oxidative environment may affect p53 conformation towards an unfolded structure. In this unfolded state, p53 is not able to exert its proapototic activity and physiological role in axonal outgrowth.

[5]Alvarez Buylla General Hospital, Alvarez Buylla General Hospital, Mieres, Spain
[6]Diadem ltd, University of Brescia, brescia, Italy

Objectives This study investigated the alterations of extracellular and intracellular redox potential in peripheral blood cell (PBMC) and plasma of Alzheimer's Disease (AD), Mild Cognitive Impairment (MCI) patients and cognitively healthy subjects (CHS).
Methods 120 individuals (42 AD, 36 MCI and 42 CHS) from Spain were enrolled. All subjects were examined by behavioural neurologists and classified according to recently reviewed criteria. Superoxide Dismutase (SOD), Catalases (CAT) and Glutathione Peroxidases (GPx), activities were measured by enzymatic assays. Unfolded p53 expression was analysed by ELISA using the specific antibody PAb240.
Results We found that among the three antioxidant enzymes, SOD activity was significant reduced both in plasma and PBMCs of MCI and AD patients compering them with CSH. On the other hand unexpected enhancement in GPx activity was observed especially in plasma of MCI group, suggesting a compensatory mechanisms in the tentative to take under control pro-oxidants. While an increased unfolded p53 was found in plasma in both AD and MCI, but only AD expressed high levels of it in intracellular compartment. Interestingly both PBMC-SOD activity and PBMC-unfolded p53 direct correlated with MMSE.
Conclusion. The concomitant measurement of extracellular and intracellular antioxidant enzymes activity pointed out the dynamical evolvement of unbalance redox potential in AD pathology. Based on our results, we suggest that the early diagnosis of AD may benefit from the combined determination of both the redox profile and unfolded p53 in both PBMC and the plasma.

CELL PROLIFERATION RATE AND OXIDATIVE STRESS INVOLVED IN THE INVERSE ASSOCIATION BETWEEN ALZHEIMER DISEASE AND CANCER

D.P. Ponce[1], F. Salech[2], C.D. SanMartin[2], M. Henriquez[2], R. Rodrigo[2], M.I. Behrens[3]
[1]Departamento de Neurologia y Neurocirugia Hospital Clínico, Universidad de Chile, Santiago, Chile

[3]Departamento de Neurología y Neurocirugía Hospital Clínico and Dept Farmacología IC BM Facultad de Medicina and Clínica Alemana de Santiago, Universidad de Chile, Santiago, Chile

Introduction: We have proposed that deregulation of biological mechanisms involved in cell death/proliferation might explain the inverse association observed in epidemiological studies between Alzheimer's disease (AD) and a history of cancer. We reported that lymphocytes from AD patients have an increased susceptibility and those with a history of skin cancer a reduced vulnerability to oxidative death by H_2O_2 exposure (Behrens *et al.,* 2012).
Objective: To measure the proliferation rate cell and oxidative stress present in lymphocytes and fibroblasts from patients with AD, skin cancer history (CA) and healthy controls (HC).
Methods: Proliferation rate of cultured fibroblasts from patients older than 60 years with AD; CA; and HC, was measured by cell count. Reduced (GSH)/oxidized (GSSG) glutathione levels (fluorimetry) and lipid peroxidation (TBARs assay kit) were determined in lymphocytes.
Results: Cultured fibroblasts from AD patients had reduced proliferation rate while cancer fibroblasts had increased proliferation rate. Interestingly, the proliferation rate of cultured AD fibroblasts was increased by the addition of conditioned medium from cancer fibroblasts, and *vice versa*. Lipid peroxidation was increased and GSH/GSSG ratios reduced in lymphocytes from AD patients compared with CA and HC.
Conclusions: These results suggest that cell proliferation rate might be differently regulated in cancer and AD patients, in addition to the susceptibility to cell death due to higher basal oxidative stress levels in AD cells. In all, our results suggest that systemic circulating factors might be involved in the mechanism explaining the inverse association between cancer and AD. Fondecyt 1110189 (MIB), 3140273 (CSM).

EFFECT OF EXERCISE ON REACTIVE OXYGEN SPECIES (ROS) PRODUCTION IN ALZHEIMER DISEASE BY ELECTRON PARAMAGNETIC RESONANCE (EPR)

S. Moretti[1], S. Mrakic-Sposta[1], M. Gussoni[2], M. Montorsi[1], A. Vezzoli[1]
[1]Institute of Bioimaging and Molecular Physiology, National Council of Research, Segrate (Mi), Italy
[2]Department of Pathophysiology and Transplantation-Physiology Section, University of Milan, Milano, Italy

Objective: Oxidative Stress (OS) plays an important role in neurodegenerative diseases. OS may be evaluated measuring the Reactive Oxygen Species (ROS) production by Electron Paramagnetic Resonance (EPR), and/or the damage to biomolecules markers. Mini-invasive method detecting ROS concentration by EPR is now demonstrated suitable to monitor physiological and pathological conditions[1,2].
Methods: X-Band-EPR (~9GHz) ROS levels determination and enzymatic assays (Protein Carbonyls (PC), ThioBarbituric Acid Reactive Substances (TBARS) and Antioxidant Capacity (TAC) were utilized to evaluate OS in patients affected by Mild Cognitive Impairment (MCI), Alzheimer Disease (AD) and in healthy subjects (CTR). Incremental Exercise (IT) until voluntary exhaustion on cycle ergometer was performed.
Results: At rest, significantly (*; P<0.05) higher levels of ROS, TBARS and PC and lower TAC levels were calculated in AD respect to CTR (Table). At the end of exercise, an increase of ROS production was observed both in AD (p<0.0001) and CTR (p<0.001).
Conclusions: Our results confirm that neurodegenerations are related to an overproduction of OS. Moreover, strenuous aerobic exercise significant increased ROS production both in AD and CTR, while in AD the increase resulted more pronounced probably due to a loss in mitochondrial respiratory chain efficiency and/or antioxidant capacity.

REGULATORY IMPACT OF LUTEOLINE ON MITOCHONDRIAL ENZYMATIC ELEMENTS AND POTASSIUM CHANNELS OF PC12 CELLS

H. Digaleh[1], F. Khodagholi[1], F. Shaerzadeh[1]
[1]NeuroBiology research center,
Neuroscience Research Center Shahid Beheshti University of Medical Sciences Te, Tehran, Iran

Objectives
Oxidative stress has been reported extensively in the involvement of mitochondrial impairment that contributes in pathological manifestations of Huntington and Alzheimer's diseases. Luteoline is a widely distributed flavonoid that encompasses the structures essential for flavonoid's antioxidant activity. In the present study we examined the dose-dependent protective effects of Luteoline against H_2O_2-induced inhibition of electron transport chain (ETC) complexes and tricarboxylic acid (TCA) cycle enzymes activities with the assessment of Ca2+-activated K+ (mitoBKca) channel protein level in rat pheochromocytoma (PC12) cells.

Methods
Undifferentiated PC12 cells were applied to undergo different treatments. Citrate synthase, aconitase, fumarase, malate dehydrogenase and alpha ketoglutarate dehydrogenase (alpha-KGDH) assays were performed to assess TCA enzymes activities. Measurement of ETC complexes activities were done by spectrophotometric evaluation. Western blotting were conducted to measure protein levels of different mitoBKca channels (alpha, beta-2 and beta-4).

Results
H_2O_2-exposed PC12 cells showed significant decrease in the activity of TCA and ETC enzymes. Pretreatment of PC12 cells with Luteoline (20 µM), followed by exposure to H_2O_2 (150 µM) caused about 53% increase in the mean activity of TCA and ETC enzymes, compared to H_2O_2-only treated cells. H_2O_2 pretreatment resulted in decrease of mitoBKca channels activity, however, Luteoline increased protein level of α, β2 and β4 subunits, compared to H_2O_2 group.

Conclusion
Overall, our data suggest that Luteoline can be a potential candidate in the treatment of oxidative stress-induced mitochondrial dysfunction, seemed to be due to restoration of TCA and ETC activity along with mitoBKca channels reactivation.

Alzheimer's disease (AD) transgenic mice model (APPswe/PSEN1), present a decreased capacity to form allopregnanolone (APα), a natural neurosteroid, in the hippocampus, associated with deficits in hippocampal performance [1]. The APP-transfected SH-SY5Y cell line represents a commonly used model to study cellular and molecular mechanisms involved in AD. The effects of APα on mitochondrial activity will be compared to those of four chemically modified APα compounds (ANS).
We investigated the efficiency of APα and four ANS in restoring / ameliorating cellular bioenergetics. For that purpose, we determined ATP level, metabolic activity, mitochondrial respiration under physiological condition and reactive oxygen species (ROS) level under stress condition after a 24h treatment with APα or ANS at 500 nM in control and APP-transfected SH-SY5Y.
APα significantly improved ATP production, the capacity of respiration and cell proliferation in control as well as APP-transfected SH-SY5Y cells when compared to the respective untreated cells. Of note, among the four tested ANS, one of them was capable to ameliorate all this parameters. In addition, under stress condition, APα and this selected compound were able to reduce ROS level in both cell lines.
The screening of APα and ANS led to the identification of one promising molecule exerting beneficial effects on bioenergetics and mitochondrial homeostasis. These compounds will now be subjected to further in vivo investigations.

[2]Neurology, Dongsan Medical Center Keimyung University, Daegu, Korea
[3]Neurology, Bobath Memorial Hospital, Seongnam, Korea
[4]Psychiatry, Asan Medical Center, Seoul, Korea

Objectives: To investigate whether the genetic variants in the mortalin gene (*HSPA9*), encoding a mitochondrial heat shock protein, are associated with the risk of AD and PD.
Methods: Direct sequencing using an automated DNA sequencer (ABI 3730, Applied Biosystems, CA, USA) for the entire coding region (17 exons) and exon-intron boundary of 50 bp was performed in 24 AD patients, 24 PD patients, and 24 controls. The genetic variants with minor allele frequency (MAF) > 1% from sequencing data were selected for the second-stage genotyping. Common genetic variants (MAF > 5%) were also selected using the HapMap and 1000 Genomes Project JPT and CHB samples. We genotyped eight *HSPA9* genetic variants in 400 AD cases and 500 controls, and 10 *HSPA9* genetic variants in 500 PD cases and 500 controls, using the Fluidigm high-throughput platform. Logistic regression analysis with additive coding schemes as a primary analysis was performed.
Results: The *HSPA9* genetic variant rs41295739 showed a significant association with AD (OR = 1.78, 95% CI = 1.18 – 2.68, p = 0.0062). This significant association was observed in additive, dominant, and allele genetic coding schemes. Other *HSPA9* genetic variants were not associated with AD. There was no significant association of each genetic variant in the *HSPA9* gene and PD.
Conclusions: Our results demonstrate that the *HSPA9* genetic variant rs41295739 is significantly associated with AD. However, other common and rare genetic variants in the *HSPA9* may not play a major role in the development of AD and PD.

MITOCHONDRIAL FISSION ARREST IN ALZHEIMER'S DISEASE
J. Salisbury[1], L. Zhang[2], S. Trushin[2], T. Christensen[1], E. Trushina[2]
[1]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, USA
[2]Department of Neurology, Mayo Clinic, Rochester, USA
Mitochondrial dysfunction and altered cellular energetics have been implicated in the etiology of Alzheimer's Disease (AD). However, a mechanism linking mitochondrial behavior to the development of AD remains to be elucidated. Using 3D reconstruction electron microscopy (3D EM) of brain tissue from AD patients and animal models of familial AD (FAD), we demonstrate that AD neuronal mitochondria display a highly exaggerated fission arrest phenotype that resembles 'beads-on-a-string" (BOAS). The BOAS phenotype was mimicked in cultured neurons treated with cyclopentenone prostaglandin 2 (PGJ2) and in young mice under hypoxic conditions. Analysis of EM images, fission protein Drp1 activation, and kinetic modeling suggest that fission arrest occurs near the final stages of the process. Since fission is thought to provide a mechanism for quality control through the disposal of damaged mitochondria, we suggest that mitochondrial fission arrest may contribute residual mitochondrial functions extending a protective energetic margin that plays a role in neuronal cell survival.

PERIPHERAL ALTERATIONS IN MITOCHONDRIAL BIOGENESIS: NEW POTENTIAL BIOMARKER FOR ALZHEIMER'S DISEASE

A. Delbarba[1], C. Prandelli[2], G. Abate[2], M. Marziano[2], D. Uberti[2], M. Memo[2]
[1]Diadem ltd, University of Brescia, brescia, Italy
[2]Department of molecular and translational medicine, University of Brescia, brescia, Italy

Objective
For almost twenty years the amyloid cascade hypothesis has dominated Alzheimer's disease (AD). In Alzheimer's disease, mitochondria failure has been suggested by numerous studies.
The aim of this study was to investigate the mitochondrial biogenesis in its complexity identifying which factors of mitochondrial biogenesis can be altered/compromised in blood cells of patients affected by AD and Mild Cognitive Impairment (MCI).
Method
Lymphocytes from cognitive healthy subjects, MCI and AD patients, were isolated by Ficoll gradient density method. The expression of some markers of mitochondrial biogenesis were evaluated with quantitative rtPCR and immunoblotting. Mitochondrial DNA copy number was measured by means of qPCR. Cytochrome C oxidase and citrate synthase activity was also measured.
Results
All key factors re**gulatin**g mitochondrial biogenesis was found compromised in AD subjects, while MCI patients showed only specific alterations in the mitochondrial cascade. Copies number of mtDNA was significantly reduced in both AD and MCI. Interestingly, there are some correlations between these new findings and other major benchmarks of the disease
Conclusion
We demonstrated a defective program generating new mitochondria in PBMCs of AD patients, that resulted in turn in the reduction of mitochondrial control quality/content. These new findings point an intriguing relevance of mitochondrial biogenesis as an early peripheral marker for the detection of AD and MCI. In this contest, the selective and peculiar alterations in mitochondria cascade as well as in mitochondrial quality control might stand for risk factors, easy observable in blood cells, involved in AD progression.

DISSECTING THE EFFECT OF NEUROSTEROIDS IN ALZHEIMER'S DISEASE: MODULATION OF A-BETA AND TAU-INDUCED MITOCHONDRIAL DYSFUNCTION

A. Grimm[1], E. Biliouris[1], A.G. Mensah-Nyagan[2], A. Eckert[1]
[1]Neurobiology Lab for Brain Aging and Mental Health Associated Research Group Dept. Biomedicine, Psychiatric University Clinics Basel, Basel, Switzerland
[2]Biopathologie de la Myéline Neuroprotection et Stratégies Thérapeutiques UMR_S INS ERM U1119, Université de Strasbourg, Strasbourg, France

We aimed to characterize the bioenergetic modulating profile of a panel of diverse neurosteroids of the sex hormone family (progesterone, estradiol, estrone, testosterone, 3α-androstanediol), under normal condition or under pathological Alzheimer's disease (AD) condition. More specifically, we assessed whether the selected neurosteroids could attenuate the toxic effects of amyloid-β (Aβ) and abnormal tau on mitochondrial function.
The effects of neurosteroids were investigated in native human neuroblastoma cells (SH-SY5Y cells) or in cells overexpressing either the human amyloid precursor protein (APP), wild-type tau protein (wtTau), or mutant tau (P301L). After 24 hrs of treatment, the effects of neurosteroids (concentration of 100 nM) were investigated on bioenergetic parameters, such as ATP production, mitochondrial membrane potential (MMP), mitochondrial respiration and glycolysis.
Under normal condition (in native SH-SY5Y), most of the steroids tested were able to improve bioenergetic activity by increasing ATP levels, MMP, glycolysis and basal mitochondrial respiration, at least in part through steroid nuclear receptor activation. Each neurosteroid appeared to have a specific bioenergetic profile. In addition, the majority of these steroids were effective in enhancing ATP levels, MMP and mitochondrial respiration in cells overexpressing APP and mutant tau, attenuating the mitochondrial dysfunction observed in these cell lines compared to the respective control cells.
Thus, our results provide new insights in re-defining the biological model of how neurosteroids control neuronal functions and lend further evidence to the neuroprotective effects of neurosteroids in AD pathology.

EARLY ABNORMALITIES IN N-ACETYLASPARTATE METABOLISM IN THE 5XFAD MOUSE MODEL OF ALZHEIMER'S DISEASE

J.S. Francis[1], S.W.J. McPhee[2], P. Leone[1]
[1]Cell Biology, RowanSOM, Stratford, USA
[2]Gene Therapy, Asklepios Biopharmaceutical, Chapel Hill, USA

N-acetylasparate (NAA) is a prominent amino acid derivative in the brain, linked to neuronal mitochondrial function and energetic integrity. NAA synthesis is energy intensive and requires TCA cycle-derived AcCoA and mitochondrial aspartate. Reductions in NAA constitute an index of neuronal metabolic integrity across the entire neurodegenerative spectrum, including AD.

Objectives: To analyze early reductions in NAA in the 5xFAD mouse model of AD from the perspective of transcriptional regulation of the gene encoding for the NAA synthetic enzyme Nat8L, with a view to defining pathological reductions in NAA as a coordinated neuronal response to energetic crisis.

Methods: High Performance Liquid Chromatography; Immunohistochemistry; *In-situ* hybrydization; RT-PCR.

Results: A significant reduction in neuronal *Nat8L* expression from 2-4 months of age in the 5xFAD brain is manifest in association with overall diminished energetic potential. Reduced neuronal *Nat8L* is most prominent in the hippocampus, and is preceded by an increase in the expression of the NAA-catabolizing enzyme aspartoacylase (ASPA) in oligodendrocytes. A parallel analysis of *Nat8L* during normal postnatal development identified a significant increase between 2 and 4 weeks of age, with the *aspa*-null *nur7* mouse presenting with the premature upregulation of *Nat8L* at 2 weeks of age.

Conclusions: This study suggests the active downregulation of *Nat8L* via the induction of oligodendrocytic *aspa* is a means by which energetic resources are conserved, and implicates the complete NAA metabolic cycle in the neuronal stress response.

[3]Department of Pathology, College of Sciences University of Texas at San Antonio, San Antonio - Texas, USA
[4]Laboratory of Physiology,
Faculty of Medicine and Center for Neuroscience and Cell Biology, Coimbra, Portugal

Objectives: To unveil the role of the hypoxia up-regulated mitochondrial movement regulator (HUMMR - a protein that favors the anterograde movement of mitochondria in a hypoxia-inducible factor 1 (HIF-1alpha)-dependent process) on defective mitochondrial trafficking in Alzheimer's disease (AD).
Methods: Using human post-mortem brain cortex and hippocampus from AD subjects and differentiated SH-SY5Y cells (resemble mature neurons) exposed to amyloid-beta 1-42 ($Abeta_{1-42}$), HIF-1α and HUMMR protein levels and mRNA were evaluated by Western blotting and RT-PCR, respectively, and mitochondrial function and dynamics by fluorimetry and confocal microscopy.
Results: A progressive reduction in HIF-1alpha and HUMMR protein levels and mRNA was observed with increasing AD Braak stage. Furthermore, mature neurons treated with high levels of the amyloidogenic peptide $Abeta_{1-42}$ (10 µM; 24 hours) exhibited a marked reduction in mitochondrial membrane potential, loss of HUMMR co-localization with the mitochondrial marker MTCO1, reduced number of mitochondria presented in the axons and neuritic retraction.
Conclusions: These results suggest that during the initial phases of AD pathology, HUMMR promotes the anterograde movement of mitochondria in order to cope with the energetic demands within the synapses, acting as a cell quality control mechanism; however, with the progression of the disease this mechanism fails contributing to an energetic crisis and, consequently to neuronal loss.
Sónia C. Correia has a post-doctoral fellowship from the Fundação para a Ciência e a Tecnologia (SFRH/BPD/84163/2012). This work is supported by Alzheimer's Association (NIRG-13-282387).

MITOCHONDRIA-ER MEMBRANES AND NEURODEGENERATION
E. Area-Gomez[1], M. Pera[1], D. Larrea[1], E. Schon[1], C. Guardia[2]
[1]Neurology, Columbia University Medical Center, New York City, USA
[2]Pathology, Columbia University Medical Center, New York City, USA
Besides plaques and tangles, which typically accumulate late in disease progression, Alzheimer disease (AD) patients often present with other features that occur earlier in the course of the disease. One such feature is mitochondrial dysfunction (e.g. changes in bioenergetics and in organellar dynamics [e.g. shape, fusion/fission, and position]), but the reason for this is unclear.
Mitochondria communicate directly with the endoplasmic reticulum (ER), and this communication facilitates interorganellar signalling and mitochondrial behavior. We recently showed that presenilins and g-secretase activity regulate ER-mitochondrial connectivity, and that this connectivity is increased significantly in presenilin-mutant cells and in cells from both familial and sporadic AD patients. Importantly, mutations in mitofusin-2 (MFN2), a protein associated both with mitochondrial fusion and with ER-mitochondrial communication, also affect connectivity, but in a direction opposite to that of the presenilins.
We have found that changes apposition of mitochondria to ER in PS and MFN2-mutant cells is highly correlated with mitochondrial bioenergetics. Together with our other preliminary data, these results imply that there is an important role of ER-mitochondrial communication in the regulation of oxidative energy metabolism. We believe that this insight has direct relevance not only to the normal regulation of energy metabolism, but also to Alzheimer disease and related dementias (and to neurodegeneration in general), where such metabolism is deranged.

[3]Gene Network Laboratory, National Institute of Genetics, Mishima, Japan

Alzheimer's disease (AD) is the most common form of senile dementia without effective therapy. Morphological alterations and functional declines in synaptic mitochondria are observed in the brains of AD patients. These changes are thought to cause synaptic failure and degeneration. Thus, protecting synaptic mitochondria may be a potential therapeutic strategy for AD. However, the mechanism that initiates a series of mitochondrial abnormalities in the synapses remains elusive.

Using a *Drosophila* model of Amyloid β42 (Aβ42) toxicity, we have previously reported that mitochondria-targeting GFP (mito-GFP) signals were reduced in the axons and dendrites of fly brain neurons before the onset of memory defects or neurodegeneration. In the present study, we investigated the mechanism underlying these mitochondrial changes. We found that the reductions in mito-GFP signals in the synapses were not due to either morphological alterations, damages or reductions in the number of mitochondria. Rather, our results suggest that reductions in the mito-GFP signals in the synapses are due to reductions in the stability of mitochondrial proteins and/or delivery of mitochondrial proteins to mitochondria in the cell body. Interestingly, we found that a specific, but not all, chaperone protein have negative impact on the stability of mitochondrial protein and causes age-dependent behavioral deficits.

This study shows a potential mechanism initiating mitochondrial abnormality in the synapses in the pathological environment with proteostasis imbalance such as AD. These results also suggest that a certain chaperon protein may be a potential therapeutic target to prevent mitochondrial dysfunctions.

AMYLOID-BETA-INDUCED IMBALANCE BETWEEN MITOCHONDRIAL NETWORK AND BIOENERGETICS.

K. Schmitt[1], S.A. Brown[2], A. Eckert[1]
[1]Neurobiology Labor, University of Basel Psychiatric University Clinics Basel, Basel, Switzerland
[2]Institute of Pharmacology and Toxicology, University of Zurich, Zurich, Switzerland

Objectives: Once perceived as solitary structures, mitochondria are now recognized as highly dynamic, interconnected organelles in order to maintain the bioenergetic homeostasis in response to metabolic, cellular and environmental changes. Both mitochondrial bioenergetics and dynamics are hallmarks of amyloid-beta (Aβ)-induced neuronal toxicity in Alzheimer's disease (AD). In our study, we addressed the questions of whether Aβ contributes to abnormal mitochondrial dynamics and how this impairment affects mitochondrial bioenergetic balance in AD.
Methods: For this purpose, we evaluated mitochondrial network morphology by confocal microscopy, expression of several genes involved in mitochondrial dynamics, as well as mitochondrial bioenergetic profile including ATP level and Oxygen Consumption Rate (OCR) by using a Seahorse Bioscience XF24 in cell cycle-controlled human primary skin fibroblasts under normal and Aβ conditions.
Results: We found that mitochondrial networks oscillated between 3 distinct states (fragmented, intermediate and tubular) under normal condition. Moreover, in between the switch of tubular to fragmented mitochondrial network, we observed a transient increase in ATP level which correlated with a higher OCR in the basal respiration as well as in ATP turnover and maximal respiration. In contrast, Aβ almost completely dampened the oscillations of mitochondrial dynamics which directly lead to a decline of mitochondrial metabolism including reduced ATP level and OCR.
Conclusion: We gained new insights into the deleterious cycle between abnormal mitochondrial dynamics which seems to contribute to the decay of mitochondrial energy metabolism in the pathogenesis of AD.

[3]Department of Biochemistry, Nencki Institute of Experimental Biology, Warsaw, Poland

[4]Université Paris V, INSERM U807, Paris, France

Objectives: Alteration of the physical association between the Endoplasmic Reticulum (ER) and the mitochondria, known as mitochondria-associated membranes (MAMs), has been proposed to contribute to Alzheimer disease (AD) pathogenesis. To further investigate this issue, we studied the subcellular distribution of amyloid precursor protein (APP) and its proteolytic products and secretases, and analyzed the protein "interactome" of the APP and its metabolites in the MAM.

Methods: Cellular distribution of APP and its catabolites were analyzed by subcellular fractionation. We studied APP catabolites and MAM co-localization by using live cell imaging and immunofluorescence. We tested enzymatic activities of beta- and gamma-secretases. Proteomic approaches and Nano-LC/MS/MS analysis were used to reveal the APP protein "interactome" in the MAM.

Results: We revealed that APP and its catabolites accumulate in the MAMs both in cellular models overexpressing mutated APP and in brains of AD transgenic mice. We evidenced also that while the gamma secretase complex is present and active in both the MAMs and the pure mitochondria, beta secretase enzyme is present and active only in the MAMs. We demonstrated an increased ER-mitochondria contact sites in neuroblastoma cells overexpressing mutated APP and revealed the APP protein "interactome" in the MAM.

Conclusions: We demonstrated that both APP and secretases are present in the MAM where APP catabolites are also detectable. Furthermore, we showed that APP interacts with key proteins of the MAM (i.e. enzymes of lipid metabolism). These data may highlight a hitherto unrecognized role of MAM dysregulation in the pathogenesis of AD.

EVALUATION OF SKELETAL MUSCLE OXIDATIVE METABOLISM IN ALZHEIMER'S DISEASE

L. Rasica[1], S. Porcelli[1], M. Ramaglia[1], G. Bellistri[1], E. Riboni[2], C. Dallatomasina[2], M. Falautano[2], G. Magnani[2], M. Marzorati[1]

[1]Institute of Bioimaging and Molecular Physiology, National Council of Research, Segrate (MI), Italy

[2]Department of Neurology, IRCCS San Raffaele Hospital, Milano, Italy

Objectives: The aim of this study was to evaluate whether in patients affected by Alzheimer's Disease (AD) βAP deposits in skeletal muscle impair oxidative metabolism.

Methods: Eighteen AD (73±4.5 years, mean±SD) and twenty-six healthy control subjects (CTRL) (71.5±5.2 years) were investigated. Two incremental exercises were performed, in order to evaluate skeletal muscle oxidative metabolism: a cycloergometer (CE) and a one-leg knee extension (KE) exercise (see Figure). The following variables were determined: breath-by-breath pulmonary O_2-uptake (VO_2); cardiac output (CO); vastus lateralis muscle fractional O_2-extraction by near-infrared spectroscopy (Δ[deoxy(Hb±Mb)]); maximal voluntary contraction (MVC); total daily energy expenditure (TEE).

Results: Mean(±SE) values of the investigated variables obtained during CE and KE incremental exercise in the two groups of subjects (see Table). TEE was similar in AD and CTRL (2534±243.6 vs 2250±119.3 $kcal*day^{-1}$). As for MVC, no significant difference was found between CTRL and AD (440.5±39.5N vs 438.3±86.7N, respectively).

	CE		KE	
	AD	CTRL	AD	CTRL
Peak work-rate (W)	94.1±7.1*	128.3±8.5	50±5*	67.9±4.5
VO_2 peak ($mL*kg^{-1}*min^{-1}$)	22.0±0.8 *	26.4±1.1	10.7±0.7*	13.5±0.6
CO ($L*min^{-1}$)	14.4±0.5	15.3±0.8	10.93±0.49	11.62±0.91
Δ[deoxy(Hb±Mb)] (%)	51.05±5.8*	71.4±2.9	40.02±5.8*	61.01±4.7

*p<0.05

Conclusions: AD patients have a reduced exercise capacity compared to healthy control subjects, probably due to a reduced muscle fractional O_2-extraction capacity. The impairment of muscle oxidative function was evident also during KE, when cardiovascular constraints to oxidative metabolism were reduced.

INHIBITION OF AKT PHOSPHORYLATION DIMINISHES TRICARBOXYLIC ACID CYCLE ACTIVITY AND SUBSEQUENTLY RECOGNITION MEMORY DEFICIT IN RAT MODEL OF ALZHEIMER'S DISEASE

F. Shaerzadeh[1], F. Khodagholi[1], F. Motamedi[1], H. Digaleh[1]
[1]Shahid Beheshti University of Medical Sciences, Neuroscience Research Center, Tehran, Iran

Objectives: 3-methyladenine (3-MA), as a PI3K inhibitor, is widely used for inhibition of autophagy. Inhibition of PI3K class I leads to inhibition of Akt phosphorylation, a central molecule involved in diverse arrays of intracellular cascades in nervous system. Accordingly, in the present study, we aimed to determine the alterations of activity of specific mitochondrial enzymes of tricarboxylic acid cycle (TCA) in 3-MA-injected rats following amyloid beta (Aβ).
Methods: Activities of five critical enzymes Aconitase, α-ketoglutarate dehydrogenase (α-KGDH), malate dehydrogenase (MDH), citrate synthase (CS) and fumarase were determined using biochemical assays. Non-spatial memory was determined using novel object recognition test.
Results: Our data revealed that activities of three enzymes Aconitase, α-KGDH, and MDH reduced in the presence of 3-MA with or without Aβ insult. Although, activity of CS in 3-MA-administred rats decreased, this reduction was not significant relative to the control or Ab-injected rats and activity of fumarase did not show any changes in 3-MA-receiving rats with or without Aβ compared to the control rats. Decrease in enzyme activity in the rats receiving 3-MA and Aβ were more compared to the rats that received either alone; indicating the additive destructive effects of these two agents. In agreement with our molecular results, data obtained from behavioral test indicated that inhibition of Akt phosphorylation with or without Aβ injection impaired novel recognition memory.
Conclusions: Our results suggest that 3-MA amplified deleterious effects of Aβ by targeting central molecule Akt.

ABETA ATTACKS MITOCHONDRIAL-PROCESSING PEPTIDASE BETA SUBUNIT

F. Huang[1], M. Han[2]
[1]Stem cell and NanoMedicine,
Shanghai Advanced Research Institute Chinese Academy of Sciences, Shanghai, China
[2]Neurology, The Sixth People's Hospital affiliated to Shanghai Jiaotong University, Shanghai, China

Reduction of glucose metabolism in certain regions of the brain is one of the earliest changes in Alzheimer's disease patients, which is partially attributed to the beta amyloid (Aβ)-induced dysfunction of mitochondria, the power house of the cell. How does Aβ affect the functions of mitochondria remains to be determined. Here, we present immunoprecipitation mass spectrum, co-immunoprecipitation and western blot results to show that Aβ attacks a mitochondrial enzyme, mitochondrial-processing peptidase beta subunit (PMPCP), which controls the entrance and maturation of majority of the mitochondrial proteins. Moreover, over expression of PMPCP unregulated intraneuronal Aβ accumulation, and enhanced the neural dysfunction in Aβ-expressing fruit flies. Currently, we are studying the effect of Aβ-PMPCP interaction on the processing of mitochondrial preproteins.

[3]Cellular mechanisms of memory pathology, Institute of Cell Biophysics Russian Academy of Sciences, Moscow region Pushchino, Russia

Objectives: Mitochondria play a fundamental role in Alzheimer's disease (AD) pathology. We have observed mitochondrial dysfunctions in AD brain neocortex, hippocampus, and have focused on characterization of mitochondrial electron transport chain complexes and oxidative stress.
Methods: Olfactory bulbectomy in mice was developed as an appropriate model of sporadic form of Alzheimer's disease. Mouse brain mitochondria were isolated from hippocampus and neocortex by differential centrifugation with Percoll gradient. Oxygen consumption was measured with the Clark-type electrode and activities of mitochondrial respiratory complexes by spectrophotometer. Lipid peroxidation level was estimated by the malondialdehyde-thiobarbituric acid, mitochondria-generated reactive oxygen species by Amplex Red. Level of soluble β-amyloid was detected by ELISA.
Results: Five weeks after bilateral olfactory bulbectomized mice displayed a significant deficiency in spatial memory, high level of soluble β-amyloid in extracts of neocortex and hippocampus as well as in mitochondria from those tissues. Impairments of the mitochondrial electron transport chain and energy metabolism has been found. We observed a significant decline in the respiratory rate, low value of respiration control ratio as well as reduced activities of cytochrome-*c*-oxidase (complex IV) and NADH:ubiquinone oxidoreductase (complex I). We have established the substantial lowering of CcOX complex content and increased ROS production. Complex I was a source of detrimental free radicals and a target for oxidative damage by them.
Conclusion: We have found mitochondrial impairments in sporadic type AD. There is link between inhibition of respiratory chain complexes, oxidative stress, and soluble β-amyloid accumulation in mitochondria.

Recent studies suggest that lithium protects neurons from death induced by a wide array of neurotoxic insults, stimulates neurogenesis and could be used to prevent age-related neurodegenerative diseases. In this study, SH-SY5Y human neuronal cells were cultured in the absence (C) or in presence (Li+) of a low lithium concentration (0.5 mM Li_2CO_3, i.e. 1mM lithium ion) for 25 to 50 weeks. In the course of treatment, growth rate of (C) and (Li+) cells was regularly analyzed using Alamar Blue dye. Resistance to oxidative stress was investigated by evaluating 1) the adverse effects of high concentrations of lithium (4-8 mM) or glutamate (20-90 mM) on cell growth rate, 2) the levels of lipid peroxidation (TBARS) and total glutathione, 3) the expression levels of the anti apoptotic Bcl-2 protein. In addition, glucose metabolism was investigated by analyzing selected metabolites in culture media and cell extracts by 1H NMR spectroscopy. As compared to (C), (Li+) cells multiplied faster and were more resistant to stress, as evidenced by lower dose-dependent decrease of Alamar Blue reduction and dose-dependent increase of TBARS levels induced by toxic doses of lithium and glutamate. Total glutathione content and Bcl-2 level were increased in (Li+) cells. Glucose consumption and glycolytic activity were enhanced in Li+ cells and an important release of pyruvate was observed. We conclude that chronic exposure to lithium induces adaptive changes in metabolism of SH-SY5Y cells involving a higher cell growth rate and a better resistance to oxidative stress.

[4]Department of Biochemical Sciences "A. Rossi-Fanelli", Sapienza University of Rome, Roma, Italy

Objectives: Insulin plays a key role in learning and memory. Given that, insulin resistance (i.r.) – defined as inadequate response to insulin by target cells due to a down-regulated expression of the insulin receptor (IR), and/or the insulin receptor substrate (IRS) proteins – has been proposed as pathogenic signaling pathway associated with Alzheimer disease (AD) onset/progression. As previously reported, increased oxidative/nitrosative stress levels (OS/NS) were associated with reduced insulin secretion and sensitivity, thus suggesting OS/NS may underlie i.r. in AD. Here, we aimed to understand the crosstalk between age- and AD-associated changes of (i) OS/NS and (ii) insulin signaling cascade.
Methods: We evaluated changes of (i) protein carbonyls, (ii) protein-bound 4-hydroxy-2-nonenal and (iii) 3-nitrotyrosine levels as well as (iv) IR and IRS1 protein levels and (v) IRS1 (Ser307) phosphorylation (pIRS1) in the hippocampus of 3-, 6-, 12- and 18-month old 3xTgAD mice and their WT littermate controls as effect of either age or AD pathology.
Results: An early elevation of OS/NS markers was found in 3xTgAD mice starting at 6 months of age, whereas WT mice showed increased OS/NS only at 18 months. Interestingly, age-associated changes of OS/NS parallel with the rise of pIRS1 both in 3xTgAD and WT mice. Further, a reduction of IR and IRS1 levels and increased pIRS1 with the progression of AD was observed.
Conclusions: Our findings suggest that the elevation of OS/NS and the impairment of insulin signaling cascade are early events in AD pathology and play a crucial role in disease progression.

ADPD5-0816
MARKERS OF INSULIN RESISTANCE IN RATS WITH MODEL OF ALZHEIMER'S DISEASE

I. Gorina[1], *Y. Komleva*[1]
[1]*Biochemistry, Krasnoyarsk State Medical University named after Professor V.F.Voyno-Yasenetsky, Krasnoyarsk, Russia*

Alzheimer's disease (AD) is an untreatable neurodegenerative disease that deteriorates memory. In recent years, attention of scientists is focused on two key pathogenetic factors of AD. There are neuroinflammation and insulin resistance. However, the cellular and molecular mechanisms that connect insulin resistance, neuroinflammation and Alzheimer's pathogenesis remain largely unexplained.
The objective is to study the potential targets for the correction of insulin resistance in the brain tissue: IRAP, IL-18, and NLRP3.
Wistar rats (male; 200-250 g) were deeply anesthetized with chloral hydrate (0,35 mg/kg) and then fixed in the stereotaxic frame. Rats were randomly divided into two groups. Experimental group (administration of beta-amyloid 1-42 (5 µl) in Cornu Ammonis (CA1) of hippocampus bilaterally. A control group of sham-operated animals were injected with phosphate-buffered saline.
To investigate the expression of IRAP, NLRP3 and IL-18 in the hippocampus and olfactory bulb we performed immunohistochemical analysis of the brain samples taken from rats with Alzheimer's disease and sham- operated animals. In addition to this, we have carried out behavioral tests (Morris water maze, plus elevated maze).
We have measured expression of IRAP, NLRP3 and IL-18 in the neurons and astrocytes. We have shown disturbance of expression these markers after modeling AD. Since neuroinflammation and insulin resistance play an important role in the development of synaptic dysfunction and neurodegeneration, they can be regarded as potential targets for therapeutic intervention to prevent disease progression.

HYPERGLYCEMIA MODULATES EXTRACELLULAR AMYLOID-BETA LEVELS AND NEURONAL ACTIVITY IN VIVO

S. Macauley-Rambach[1], M. Stanley[1], S. Yamada[1], E. Caesar[1], M. Raichle[2], R. Perez[1], T. Mahan[1], D. Holtzman[1]

[1]Neurology, Washington University, St. Louis, USA

[2]Radiology, Washington University, St. Louis, USA

Objectives: Epidemiological studies suggest that type-2-diabetics, or those with elevated blood glucose levels independent of diabetes, have an increased risk for developing Alzheimer's disease (AD) and dementia. These observations suggest that abnormal glucose metabolism likely plays a role in the development of some aspects of AD. Thus, we investigated the effects of alterations in peripheral glucose homeostasis on neuronal activity and amyloid-β metabolism.

Methods: We teamed glucose clamps, a way to manipulate blood glucose levels, with in vivo microdialysis, a method to sample metabolites from the brain's interstitial fluid (ISF). This combination allows us to provide an acute hyperglycemic challenge to awake, freely moving mice while assessing real-time changes in Aß, glucose, and lactate within the brain's ISF.

Results: Acute hyperglycemia increases hippocampal ISF Aβ levels in young APP/PS1 mice, prior to the plaque deposition. In aged APP/PS1 mice with significant plaque pathology, a similar hyperglycemic challenge results in a further increase in ISF Aβ concentrations, suggesting that age- and pathology-dependent changes affect the brain's response to a metabolic insult. We identified inward rectifying, ATP-sensitive potassium (K_{ATP}) channels as a mechanistic link between hyperglycemia, neuronal excitability and Aß metabolism. Pharmacological manipulation of K_{ATP} channels results in altered neuronal activity and ISF Aβ levels. Furthermore, we found that hyperglycemia-dependent increases in ISF Aβ were blocked by K_{ATP} channel manipulation.

Conclusions: Taken together, this suggests K_{ATP} channel activation mediates the response of hippocampal neurons to elevated blood glucose levels by coupling metabolism with neuronal activity and ISF Aβ levels. Funding: NS080320(SLMR), NS080675(DH, MER)

CHARACTERISING IMPAIRED INSULIN SIGNALLING IN HUMAN ASTROCYTES: A ROLE IN THE DEVELOPMENT OF ALZHEIMER'S DISEASE?

C.J. Garwood[1], J.E. Simpson[1], P.R. Heath[1], P.G. Ince[1], S.B. Wharton[1]
[1]Sheffield Institute for Translational Neuroscience, University of Sheffield, Sheffield, United Kingdom

Objectives: Our group has previously shown that astrocyte hyper-trophy and injury occur early in the progression of AD neuropathology and using microarray analysis, that the insulin/IGF-1 signalling pathway is downregulated as Alzheimer-type pathology develops. We have developed a model of impaired insulin signalling in human astrocytes to investigate how reduced signalling through this pathway affects astrocyte function and their ability to respond to stress.
Methods: Impaired signalling was induced in human primary astrocytes using a combined insulin+fructose treatment protocol and confirmed by immunoblotting for insulin receptor as well as the downstream targets Akt and ERK1/2. Cell growth/viability was determined using Cyquant and MTT assays. To assess the response of insulin-impaired astrocytes to cellular stress astrocytes were treated with sub-lethal concentrations of hydrogen peroxide.
Results: A combined insulin+fructose (4d) treatment protocol resulted in decreased expression of IR, but not IGF-1R, and decreased phosphorylation of the downstream target Akt but not ERK1/2. Decreased IR persisted after 7d but there is recovery in Akt activity suggesting other signalling pathways eventually compensate for the reduction in IR. Impaired insulin signalling had no effect on astrocyte growth/viability. The effect of oxidative stress on insulin impaired astrocytes is currently under investigation.
Conclusions: We have developed a model of impaired insulin signalling in human astrocytes using a combined insulin-fructose treatment protocol and are now investigating the impact of this on astrocyte function. This is important since astrocytes maintain brain homeostasis and deliver essential substances to neurons and impaired astrocyte function may play a role in AD progression.

ADPD5-0247

MINOCYCLINE MODULATION THE NEUROPROTECTIVE EFFECT OF COENZYME Q10 AGAINST AMYLOID BETA 1-42 INDUCED COGNITIVE DYSFUNCTION IN RATS: BEHAVIORAL AND BIOCHEMICAL EVIDENCE

A. Singh[1], *A. Kumar*[1]
[1]*UIPS, Panjab University, chandigarh, India*

Objective- The aim of the study was to investigate the neuroprotective effect of CoQ10 and its modulation through minocycline against Aβ(1-42) induced cognitive dysfunction and biochemical alterations in hippocampus and cerebral cortex of rats.

Materials and Methods

Male SD rat were received bilateral, intrahippocampus Aβ(1-42) [1µg/µl] injection. Galantamine (2 mg//kg), CoQ10 (20, 40 mg/kg), Minocycline (50 mg/kg), were administered for period of 21 days. Various behavioral parameters (body weight, locomotor activity, elevated plus maze and Morris water maze) followed by biochemical estimations (LPO, GSH, Catalase, nitrite, SOD, AChE) were assessed in discrete areas of hippocampus and cortex.

Results

Bilateral intrahippocampus Aβ(1-42) administration significantly reduced body weight, impaired cognitive performance and oxidative damage as compared to sham treatment. CoQ10 (20, 40 mg/kg) treatment significantly attenuated body weight and improved cognitive performance in both tests (i.e. shortened transfer latency in elevated plus maze test, Morris water maze task as well as time spent in target quadrant), attenuated AChE level and oxidative damage (reduced lipid peroxidation, nitrite level and restoration of reduced GSH and Catalase activity) in both hippocampus and cortex as compared to control. Further, combination of CoQ10 (20, 40 mg/kg) with minocycline (50 mg/kg) significantly potentiated their protective effect as compared to their effect per se.

Conclusion

The present study highlight the involvement of possible microglia modulatory mechanism of CoQ10 against Aβ(1-42) induced cognitive dysfunction and oxidative damage.

ADPD5-0354
THE ROLE OF ASTROCYTES IN AIZHEIMER'S DISEASE
A. Sharifi Razavi[1], M. Sadati Kiadehi[2]
[1]Neurology, Mazandaran University of Medical Sciense, sari, Iran
[2]Reaserch, ACECR, sari, Iran
Alzheimer's disease (AD) is a neurodegenerative disease characterized by the aggregation of amyloid β-peptide (Aβ) into β-sheet-rich fibrils. Although plaques containing Aβ fibrils have been viewed as the conventional hallmark of AD. The actual role of astrocytes in AD remains elusive, as they seem to adopt different functions dependent on disease progression and the extent of accompanying parenchymal inflammation. Increased production of amyloid β-peptide (Aβ) and altered processing of tau in Alzheimer's disease (AD) are associated with synaptic dysfunction, neuronal death and cognitive and behavioural deficits. Neuroinflammation is also a prominent feature of AD brain and considerable evidence indicates that inflammatory events play a significant role in modulating the progression of AD. The role of microglia in AD inflammation has long been acknowledged. Substantial evidence now demonstrates that astrocyte-mediated inflammatory responses also influence pathology development, synapse health and neurodegeneration in AD.Astrocytes may contribute to the clearance of amyloid β-peptide (Aβ) and restrict the spread of inflammation in the brain. Conversely, they may contribute to neurodegeneration in AD by releasing neurotoxins and neglecting crucial metabolic roles. Several anti-inflammatory therapies targeting astrocytes show significant benefit in models of disease, particularly with respect to tau-associated neurodegeneration. However, the effectiveness of these approaches is complex, since modulating inflammatory pathways often has opposing effects on the development of tau and amyloid pathology. An increased understanding of interactions between astrocytes and neurons under different conditions is required for the development of safe and effective astrocyte-based therapies for AD and related neurodegenerative diseases.

MICROGLIAL RESPONSES TO ENVIRONMENTAL ENRICHMENT IN ALZHEIMER'S DISEASE MODELS

H. Xu[1], E. Gelyana[1], D.J. Selkoe[1]
[1]Center for Neurologic Diseases,
Brigham and Women's Hospital and Harvard Medical School, Boston, USA

Objectives

Emerging evidence suggests the central involvement of malfunctioning microglia and dysregulated neuro-inflammation in the progression of Alzheimer's disease, The interaction between soluble amyloid-beta oligomers (oAbeta)—the major cytotoxic species – and microglia is being studied intensively. Environmental enrichment (EE) has been examined in various mouse models as potentially beneficial against features of AD, and a few recent studies suggest possible cross-talk between EE and microglial biology. Our goal is to address whether and how the EE paradigm alters microglia and/or brain-entering monocytes and enhances resistance against oAbeta cytotoxicity in adult wild-type mice.

Methods

We perform stereotactic surgery to accurately microdeliver oAbeta species to hippocampus or lateral ventricle of WT mice housed under different conditions. To evaluate microglia, we perform a) immunohistochemistry on brain tissue using microglial-specific or functionally related protein markers followed by confocal microscopy and image analysis; b) microglial mRNA profiling, and c) *in vivo* microdialysis with a 1000 kDa MW probe.

Results

We observed a consistent ~20% increase in microglial density and associated morphological changes in the dentate gyrus of wt mice after 4+ weeks of EE. We also found decreased microglial responses of EE vs. control mice to oAbeta, shown by expression levels of a set of inflammatory genes measured by qPCR and Nanostring.

Conclusions

Prolonged exposure to a novel, enriched environment has an immunomodulating effect on microglia *in vivo* at the cellular and molecular levels, including changes in microglial density, morphology, and mRNA response profile to oAbeta, which may counteract Amyloid-beta toxicity in the brain.

THE FUNCTIONAL ROLE OF FYNT TYROSINE KINASE IN REACTIVE ASTROCYTES: RELEVANCE TO ALZHEIMER'S DISEASE

M. Tan[1], C.L. Lee[2], X.W. Tan[3], C.Y.B. Low[1], M.K.P. Lai[2]
[1]Clinical Research, Singapore General Hospital, Singapore, Singapore
[2]Pharmacology, National University of Singapore Yong Loo Lin School of Medicine, Singapore, Singapore
[3]School of Biological Sciences, Nanyang Technological University, Singapore, Singapore

Introduction:
Fyn tyrosine kinase has been proposed to have a pathogenic role in Alzheimer's disease (AD). Fyn exists in two major alternative spliced isoform, FynB as the predominant isoform found in the brain while FynT in cells of hematopoietic origins. Our recent findings revealed that isoform FynT was selectively up-regulated in AD brain and associated with two neuropathological hallmarks: neurofibrillary tangles and reactive astrogliosis.

***Objective*:**
In this study, we would like to determine the functional role of FynT tyrosine kinase in reactive astrogliosis, particularly in modulating TNFα mediated NF-kB signaling pathway in association with neuroinflammation in AD.

Approaches:
(1) Primary rat astrocytes treated with β-amyloid were monitored for changes of FynT and FynB expression; (2) Immortalized normal human astrocytes (iNHA) stably expressing FynT constitutive kinase active (FynT-CA) or kinase dead (FynT-KD) were treated with or without TNFα and monitored up to 3 day for expression changes of astrocytic markers, proinflammatory cytokines and genes associated with NF-kB signaling pathway.

Results:
(1) β-amyloid induced selective up-regulation of FynT with no change of FynB expression in rat primary astrocytes; (2) The observation of TNFα-induced up-regulation of astrocytic marker and proinflammatory cytokines in FynT-CA clones was attenuated in FynT-KD clones; (3) FynT kinase activity modulate TNFα-induced biphasic expression of IL-1β and IL-6 at the late phase, which was likely associated with the auto-regulatory feedback loop of NF-kB signaling pathway.

Conclusion:
In summary, our findings suggested that FynT may be a potential neuroinflammatory mediator associated with astrocyte activation in the pathogenesis of AD.

Objectives. The clustering of GFAP immunopositive astrocytes around amyloid-beta plaques in Alzheimer's disease has led to the widespread assumption that plaques attract astrocytes. However, recent studies show that astrocytes stay put in injury. Here we re-examine whether astrocytes migrate to plaques by analyzing with mathematical functions and computer modeling the topology of astrocytes in 3D images obtained by 2-photon microscopy from living APP/PS1 mice and wild type littermates.
Methods. Astrocytes were identified with topically applied sulforhodamine 101, a fluorescent dye that, unlike GFAP, labels both reactive and non reactive astrocytes, whereas amyloid-beta plaques were labeled with methoxy-XO4. Changes in astrocyte position were examined by the *g(r)* function of astrocyte-to-astrocyte spacing, and by domain-size distributions modeled by Voronoi tessellation (L_c) in the astrocytes closest to the plaques.
Results. Cortical astrocyte topology fits a model akin to a liquid of hard spheres that exclude each other in a confined space. This supports the ordered spacing of astrocytes based upon domains. Plaques do not disturb this arrangement except at very large plaque loads but, locally, they cause a slight but statistically significant expansion of Voronoi domains up to three tiers of astrocytes around plaques. The expansions mean that plaques have pushed astrocytes away 1-4 microns according to simulations.
Conclusions. One, repulsive chemoactive agents may be essential to maintain astrocyte spacing. Two, astrocytes respond to plaque-induced neuropil injury by showing strained inter-astrocyte interactions and changing phenotype, including increased production of GFAP and development of a 'reactive' appearance, rather than proliferating or migrating towards plaques.

NEUTROPHILS INDUCE ALZHEIMER'S DISEASE-LIKE PATHOLOGY AND COGNITIVE DECLINE VIA A MECHANISM DEPENDENT ON LFA-1 INTEGRIN

G. Constantin[1], E. Zenaro[1], E. Pietronigro[1], V. Della Bianca[1], G. Piacentino[1], S. Budui[1], A. Montresor[1], E. Turano[2], B. Bonetti[2]

[2]Department of Neurological and Movement Sciences, University of Verona, Verona, Italy

Objectives: Inflammation is a pathological hallmark of Alzheimer's disease and understanding the underlying mechanisms may facilitate the development of new treatments. Our aim was to study the role of inflammation mechanisms in the pathogenesis of AD.

Methods: Confocal microscopy, intravital microscopy studies using two-photon microscopy (TPM), fear conditioning and Y maze tests were performed in animal models of AD. Adhesion assays were performed on integrin ligands and integrin affinity was measured using ImageStream technology. Neuropathological studies were performed on human samples and brains from AD mice.

Results: Using mice with five familial Alzheimer's disease (5xFAD) mutations presenting amyloid pathology, and 3xTg-AD mice with both amyloid and tau pathology, we found neutrophils extravasating in areas with amyloid beta (Abeta) deposits, releasing neutrophil extracellular traps (NETs) and producing IL-17. Abeta1-42 peptide triggered the LFA-1 integrin high-affinity state and rapid neutrophil adhesion. TPM experiments showed that LFA-1 integrin controls neutrophil extravasation and intraparenchymal motility. Neutrophil depletion or the inhibition of neutrophil trafficking using LFA-1 genetic ablation or an anti-LFA-1 antibody dramatically rescued memory loss in 5xFAD and 3xTg-AD mice. Interfering with neutrophil activity also reduced microglial density and activation, amyloid deposition, tau phosphorylation and restored synaptic protein loss. In Alzheimer's patients, neutrophils adhered and spread inside brain venules or migrated into the parenchyma and released NETs in larger numbers than in control subjects.

Conclusions: Our results demonstrate that neutrophils induce cognitive impairment and neuropathological changes suggesting that the inhibition of neutrophil trafficking may represent a new therapeutic strategy to address Alzheimer's disease.

INFLAMMASOME FORMATION IN THE RAT BRAIN WITH MODEL OF ALZHEIMER'S DISEASE

Y. Komleva[1], I. Gorina[1], O. Lopatina[1], A. Chernykh[1], A. Salmina[1]
[1]Biochemistry, Krasnoyarsk State Medical University named after Professor V.F. Voyno-Yasenets, Krasnoyarsk, Russia

Neuroinflammation has a significant influence on the structural and functional plasticity of the brain (Dupret D., 2008). Alteration of neurogenesis is one of the key mechanisms of brain damage in Alzheimer's disease (AD) (Chuang T.T., 2010).
The objective is to study the molecular mechanisms of inflammasome formation in the neurodegeneration.
We used Wistar male rats aged 9 months. The animal model of AD was induced by injections of beta-amyloid into CA1 area. (Li X. et al., 2011). We tested memory consolidation and social recognition memory (five-trial social test). At two week postinjection brains were removed. Immunohistochemistry staining was used to determine NLRP1, NLRP3 expression in the neuronal and glial cells. We have evaluated expression of NLRP1 and NLRP3 in the cells expressing CD133 (stem cells), PNCAM (neuronal progenitor), NeuN (mature neurons), GFAP and S100beta positive cells (glial cells).
The changes in the functional activity of astrocytes in the in chronic neurodegeneration were associated with the production of inflammasomes and production of proinflammatory cytokines. It determines the nature of the participation of astroglial cells in the process of neurogenesis. Also we have investigated proliferation, migration activity of neuronal precursors and the efficiency of the integration of post-mitotic neurons in the synaptic chains depending on the nature of the expression different types of inflammasomes in experimental Alzheimer's disease.
The study of the molecular mechanisms of the effect of astrocytes and humoral inflammation mediators on neurogenesis may allow the identification of new target molecules for pharmacological correction of chronic neurodegeneration.

MICROGLIA DO NOT MODULATE ABETA OR TAU PATHOLOGY IN THE ALZHEIMER DISEASE BRAIN, BUT CONTRIBUTE TO COGNITIVE IMPAIRMENTS

E. Spangenberg[1], N. Dagher[1], B.L. West[2], F.M. LaFerla[1], K.N. Green[1]
[1]Neurobiology and Behavior, University of California Irvine, Irvine, USA
[2]Discovery, Plexxikon Inc., Berkeley, USA

Objectives: Chronic neuroinflammation is a key feature of the Alzheimer's disease (AD) brain. Much of this neuroinflammation is mediated by microglia that surround dense core plaques and react to their presence, but it is unknown if this response is protective (by limiting plaque growth), or harmful (by contributing to cognitive decline and/or tau hyperphosphorylation). We set out to directly determine the roles that microglia play in the disease process.
Methods: We have shown that microglia in the adult mouse brain are dependent upon colony-stimulating factor 1 receptor (CSF1R) signaling and that inhibitors rapidly eliminate >95% of all microglia CNS wide. 23-month-old 3xTg-AD mice were treated with a selective CSF1R antagonist for 3 months resulting in sustained elimination of ~90% of microglia for that duration. We then used behavioural testing followed by pathological analyses using confocal microscopy, ELISA and western blotting to measure microglia densities, plaque number and size, and levels of hyperphosphorylated tau species.
Results: Despite having no microglia for 3 months, Abeta/plaque levels were not altered in any form. Tau levels or hyperphosphorylation state were likewise unaltered by the absence of microglia. Cognitive testing revealed improvements in learning with chronic microglial-elimination, while levels of Il-1beta and TNFalpha were markedly reduced.
Conclusions: Together these results directly demonstrate that microglia in the aged AD brain do not contribute to the pathogenesis of Abeta or tau pathology but do contribute to the cognitive decline.

ADPD5-0951

AMYLOID-INDUCED PRO-INFLAMMATORY MECHANISMS AND ROS GENERATION IN ASTROCYTIC/GLIAL CELLS: RELEVANCE FOR THE INTEGRITY OF THE NEUROVASCULAR UNIT

A. Rostagno[1], *S. Cocklin*[1], *J. Ghiso*[1]
[1]*Pathology, New York University School of Medicine, New York, USA*

Objective: Vascular deposition of amyloid, a universal feature in Alzheimer's disease (AD), severely compromises the integrity of the neurovascular unit, a dynamic entity encompassing functional interactions among cells of the microvasculature, neurons, and astrocytic/glial populations. The complexity of the cellular mechanisms elicited by amyloid in astrocytic/glial cells and their relationship to the induction of pro-inflammatory conditions capable of affecting microvessel function/permeability remain to be fully elucidated. In this work we aimed to provide insight into the molecular pathways affected and identify potential new targets for drug discovery.
Methods: Astrocytic/glioma cells were challenged with wild-type Abeta and the E22Q vasculotropic variant associated with cerebrovascular deposition and hemorrhagic clinical phenotypes. A combination of FACs-analyzed bead arrays, ELISA, zymography, and confocal studies were employed to evaluate production of pro-inflammatory cytokines, activation of MMPs, and ROS generation whereas the vitamin-E analog Trolox was tested for prevention/amelioration of these detrimental cellular pathways.
Results: Oligomeric-Abeta triggered elevated production of the pro-inflammatory mediators IL-6, IL-8, and IFN-γ, enhanced activation of MMP-2, exacerbated ROS production, and cell death. In all cases, challenge with E22Q translated into a more pronounced response, in agreement with the high oligomerization tendency of the variant and the aggressiveness and early onset of the clinical phenotype. Trolox not only inhibited ROS production and MMP-2 activation, but also preserved cellular integrity and viability, highlighting the primary role of ROS in the initiation of amyloid-induced cell death pathways.
Conclusions: Our data emphasizes the detrimental role of astrocyte/glia-initiated Abeta-mediated pro-inflammatory pathways for the integrity of the neurovascular unit

THE EFFECT OF UBIQUILIN-1 ON ALZHEIMER'S DISEASE MOLECULAR MECHANISMS DURING NEUROINFLAMMATION

M. Takalo[1], T. Natunen[1], K.M.A. Kurkinen[1], P. Mäkinen[1], H. Soininen[2], M. Hiltunen[1], A. Haapasalo[2]

[1]Institute of Biomedicine, University of Eastern Finland, Kuopio, Finland

[2]Institute of Clinical Medicine - Neurology, University of Eastern Finland, Kuopio, Finland

Objectives: Ubiquilin-1 is a protein, which is involved in the regulation of levels, subcellular localization, aggregation and degradation of several proteins associated with the pathogenesis of Alzheimer's (AD) and other neurodegenerative diseases. Ubiquilin-1 also plays a role in unfolded protein response, endoplasmic reticulum and oxidative stress, and autophagy, mechanisms that are centrally involved in neurodegeneration.

Methods: The role of ubiquilin-1 during neuroinflammation was investigated in the co-cultures of E18 mouse primary cortical neurons and BV2 microglial cells. Neuroinflammation was induced by treating ubiquilin-1 overexpressing and control cells with lipopolysaccharide (LPS, 200ng/ml) and interferon-gamma (IFN-gamma, 5ng/ml) for 48 hours. As an outcome, neuronal viability, secretion of inflammatory cytokines, and levels of several AD-related proteins were analyzed.

Results: LPS and IFN-gamma treatment significantly induced the secretion of tumor necrosis factor alpha (TNFalpha) in neuron- BV2 cell co-cultures, when compared to untreated controls. Ubiquilin-1 overexpression further increased TNFalpha secretion and concomitantly significantly decreased the neuronal viability under neuroinflammation. Furthermore, ubiquilin-1 overexpression increased the levels of 3R-tau and BACE1 under neuroinflammation. LPS and IFN-gamma treatment also slightly, but not significantly, increased BACE1 levels in control cells without ubiquilin-1 overexpression.

Conclusions: These data indicate that ubiquilin-1 overexpression may aggravate the inflammatory response and neuronal cell death during acute neuroinflammation in co-cultures of primary cortical neurons and BV2-microglial cells. Together with previous reports, these results suggest that ubiquilin-1 may have diverse effects during different cellular stress conditions associated with neurodegeneration.

TUMOR NECROSIS FACTOR-ALPHA AS A COMMON MEDIATOR IN ALZHEIMER'S DISEASE AND RHEUMATOID ARTHRITIS PATHOGENESIS IN TRANSGENIC MICE

E. Paouri[1], S. Georgopoulos[1]
[1]Cell biology, Biomedical Research Foundation of the Academy of Athens, ATHENS, Greece

1. Objectives

TNF-α is a pro-inflammatory cytokine, involved in many autoimmune and neurodegenerative diseases, including rheumatoid arthritis (RA) and Alzheimer's disease (AD). In the brain TNF-α is synthesized by microglia and astrocytes. TNF-α is upregulated in cerebrospinal fluid and serum of AD patients, and colocalizes with amyloid plaques. TNF-α mediates the induction and maintenance of chronic inflammation in rheumatoid arthritis, and it has been reported that RA patients are protected from AD. To examine the role of TNF-α in AD and elucidate the molecular and cellular mechanisms involved we have used an established AD transgenic mouse model (5xFAD).

2. Methods

To assess the therapeutical potential of TNF-α inhibition in AD we have treated 5xFAD mice before the formation of amyloid plaques with infliximab, a TNF-α neutralizing antibody currently used in the treatment of RA patients. We have also genetically depleted TNF-α by mating 5xFAD with TNF-α knock-out mice.

3. Results

Our analysis has shown that inhibition of TNF-α can confer a protective effect in amyloid deposition. To examine the potential effect of TNF-α overexpression in AD we have employed a transgenic mouse that highly expresses human TNF-α (Tg197) and develops rheumatoid arthritis as well as neuroinflammation. Double transgenic mice (5xFAD/Tg197) are currently analyzed for amyloid deposition and brain inflammatory response, and treated with infliximab, which restores the arthritic phenotype, to evaluate the effect of anti-TNFα treatment in the AD-like pathology.

4. Conclusions

Our data provide evidence that modulating TNF-α expression can be a potent therapeutical approach in Alzheimer's disease treatment.

LOSS OF REACTIVE ASTROCYTES IN APP23 MICE EXACERBATES DISEASE PROGRESSION AND ALTERS INFLAMMATORY PROFILE

A.M. Birch[1], L. Katsouri[1], C. Willberg[1], A.W.J. Renziehausen[1], M. Sastre[1]
[1]Medicine, Imperial College London, London, United Kingdom

Objectives: Astrocytes actively contribute to neuronal functioning under normal and pathological conditions. In Alzheimer's disease (AD), they become reactive: clearing amyloid-beta and restricting the spread of neuroinflammation. However, they may also contribute to neurodegeneration by releasing neurotoxins and neglecting their crucial metabolic roles. We sought to establish the role of reactive astrocytes in AD by assessing the neuropathological consequences of ablating astrocytic proliferation in the APP23 mouse model.

Methods: APP23 mice were bred with GFAP-TK mice (APP/GFAP-TK), in which herpes simplex virus thymidine kinase (HSV-TK) is targeted to astrocytes via the GFAP promoter. At 9 months old, mice were infused into the right lateral ventricle with the antiviral drug, ganciclovir (GCV; $11\mu g \cdot \mu l^{-1} \cdot hr^{-1}$), or saline to ablate proliferating astrocytes. APP23 mice were also infused with GCV to control for the effect of drug infusion alone. Following this, changes in AD-like pathology were assessed.

Results: Ki67 staining confirmed that APP/GFAP-TK mice treated with GCV had a significant reduction in proliferating astrocytes in the cortex and hippocampus. The loss of proliferating astrocytes resulted in significantly increased levels of amyloid-beta 42, as measured by ELISA, concomitant with reductions in amyloid-beta staining with the pan-amyloid-beta antibody 6C3 in the cortex and hippocampus. In addition, APP/GFAP-TK mice treated with GCV showed significantly increased expression of IL1-beta in the cortex, suggesting that ablation of proliferating astrocytes leads to an enhanced pro-inflammatory response.

Conclusions: These results suggest that a loss of proliferating, reactive astrocytes in AD exacerbates disease progression, possibly via disruption of amyloid clearance and enhanced neuroinflammation.

ADPD5-1196

EFFECT OF AD-RISK VARIANTS ON THE PROCESSING AND BINDING PROPERTIES OF TREM2.

D. Sevlever[1], W.C. Lee[1], N. Sakae[1], S. Younkin[1]
[1]Neuroscience, Mayo Clinic, Jacksonville, USA

Objective We recently showed that TREM2, a microglia receptor involved in the phagocytosis of apoptotic neurons, is implicated in LOAD. In our case control series, R47H TREM2 showed significant association with LOAD (OR: 4, $p = 6.6\times10^{-9}$). In the same series, we found that a second TREM2 missense variant, D87N, was also associated with LOAD (p=0.02). The goal of this study was to understand how the R47H and D87N variants affect the disease pathophysiology.
Methods BV2 and 293 cells expressing WT, R47 and D87N TREM2 were used to analyze TREM2 processing. This analysis included cell surface and total expression, shedding into the medium, and susceptibility to endoH and PNGaseF enzymes. For binding experiments 293 cells were transfected with constructs encoding WT, R47H, and D87N extracellular domains of TREM2. Medium supernatants from these transfectants were incubated with apoptotic N2a cells. Analysis of cells extracts and media was done by Western blot.
Results The Western blot profiles of the de- and fully glycosylated WT, R47H and D87N TREM2 were undistinguishably. Shedding of the TREM2 extracellular domain into the medium was reduced by the D87N but not the R47H mutation. On the other hand, when the binding of TREM2 extracellular domain to apoptotic neuronal cells was analyzed, it showed that only the R47H mutation significantly reduced the association of the TREM2 extracellular domain with apoptotic N2a cells as compared to WT.
Conclusion Our data suggest that AD-risk variants could affect TREM2 function either by impairing shedding or ligand binding in apoptotic neurons.

CONTRIBUTION OF ASTROCYTIC INFLAMMASOME ACTIVITY IN THE PATHOGENESIS OF ALZHEIMER'S DISEASE

J. Couturier[1], I.C. Stancu[1], O. Schakman[1], N. Pierrot[1], F. Huaux[2], P. Kienlen-Campard[1], I. Dewachter[1], J.N. Octave[1]

[1]Cellular and Molecular (CEMO), Institute of Neuroscience - Université catholique de Louvain, Brussels, Belgium

[2]Louvain Centre for Toxicology and Applied Pharmacology, Institute of Experimental and Clinical Research - Université catholique de Louvain, Brussels, Belgium

Objectives: The proinflammatory cytokine IL1β is overexpressed in Alzheimer disease (AD) as a key regulator of neuroinflammation. Aβ peptide triggers activation of inflammasomes (protein complex responsible for IL1β maturation) in microglia, but nothing is known about activation of inflammasomes in astrocytes. We studied Aβ-mediated activation of astrocytic inflammasomes and its relevance in an AD mouse model.

Methods: ASC (a key protein in inflammasome complex) knockout mice were crossed with 5xFAD mice and tested for spatial reference memory using the Morris water maze, and amyloid load was quantified using thioflavine S staining. Astrocytes from ASC mice were cultured to measure IL1β production (ECLIA), to evaluate phagocytosis of labelled microbeads and to quantify inflammatory cytokines expression (qPCR).

Results: Cultured astrocytes primed with LPS and treated with fibrillar Aβ produced IL1β resulting from inflammasome activation mediated by Aβ phagocytosis and cathepsin B enzymatic activity. IL1β production was significantly decreased in ASC +/- astrocytes, in which a compensatory expression of TNFα and IL6 was measured. Moreover, ASC+/- astrocytes displayed a higher phagocytic activity as compared to ASC+/+ and ASC -/- cells. A significant decrease in amyloid load was measured in brain of 5xFAD mice carrying the ASC +/- genotype, most likely resulting from increased phagocytosis measured in ASC +/- astrocytes. In addition, rescue of spatial reference memory was observed in these mice as compared to 5xFAD mice.

Conclusion: All together, our results demonstrate that Aβ-mediated activation of astrocytic inflammasomes is involved in Aβ clearance and IL1β production in a well-established mouse model of AD.

ADPD5-1307

THE ROLE OF M1 AND M2 PHENOTYES ON THE UPTAKE AND NEURON-TO-NEURON TRANSMISSION OF AMYLOID-BETA OLIGOMERS

V. Koziski[1], A. Ansell[1], H. Lund[2], R. Harris[2], M. Hallbeck[1], C. Nilsberth[3]
[1]Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden
[2]Department of Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden
[3]Department of Geriatric Medicine, Linköping University, Linköping, Sweden

Objectives: Neuroinflammation is characterized as playing an influential role in AD pathology; however the mechanisms surrounding this phenomenon remain poorly understood. Microglia are responsible for a majority of these effects, characterized by either pro- (M_1) or anti-inflammatory (M_2) phenotypes. In this study, we are investigating the effects of M_1 and M_2 conditioned macrophage media (as a peripheral analogue to microglia) on the uptake and transfer of oligomeric amyloid-beta (oAb).

Methods: Differentiated human SH-SY5Y cells were pre-treated with M_0, M_1, or M_2 conditioned media and the effect on oAb uptake into the cells was investigated. To study the effect on the neuron-to-neuron transfer of oAb we used a 3D gel co-culture system; acceptor cells were labeled with GFP, and donor cells were loaded with Alexa-700-labelled oAβ and seeded on top of the acceptor cells. oAb uptake and transfer was quantified by confocal microscopy and flow cytometry. The cytokine profile of the conditioned media will be analysed by MSD.

Results: Our preliminary data suggests that the uptake of oA-beta by neuron-like cells is inhibited by the pre-treatment of the M_2 medium. This system will be further employed to quantify neuron-to-neuron transfer of oA-beta.

Conclusions: Chronic activation of the M_1 phenotype is associated with neurotoxic activities and while M_2 plays a more protective role. Our results indicate that the M_2 phenotype could reduce the uptake of oAb in neuronally differentiated SH-SY5Y cells. Intervention in the microglial M_1/M_2 polarization pathway may be a suitable avenue for future treatments in AD.

THE INFLUENCE OF ALZHEIMER'S DISEASE-LIKE AMYLOID PATHOLOGY ON THE IMMUNE SURVEILLANCE IN THE BRAIN

C. Gericke[1], C. Späni[1], N. Schweizer[2], T. Suter[2], L. Kulic[1], M.T. Ferretti[1], R.M. Nitsch[1]
[1]Division of Psychiatry Research, University of Zurich, Schlieren, Switzerland
[2]Department of Neurology Section of Neuroimmunology and MS Research, University Hospital Zurich, Zurich, Switzerland

Objectives. Chronic brain inflammation is a hallmark of Alzheimer's disease (AD); however, no protective autoimmunity against amyloid beta peptide (Abeta) is observed so far. Here, we tested the hypothesis that Abeta alters brain immune surveillance.
Methods. Antigen presenting cell (APC) and T cell numbers and phenotype were studied using e*x vivo* analysis via flow cytometry and confocal microscopy. Results from aged transgenic mouse models over-expressing amyloid precursor protein were compared with non-transgenic, age-matched littermates.
Results. In SweArc-transgenic mice we have observed reduced major histocompatibility class II (MHC-II) surface expression on APCs. Further analyses has revealed that most MHC-II accumulated intracellularly, suggesting an immature APC phenotype. Furthermore, we found a significant increase in brain $CD8^+$ T cell numbers with low expression of IFNgamma in parallel. We could confirm the altered MHC-II expression in brain APCs from a second model, the APP-PS1deltaE9. T cells here displayed a reduction of both IFNgamma and TNFalpha expression. No differences were observed neither in APC from cerebellum nor splenic T cells in transgenic and control animals, indicating a cerebrum and amyloid-specific effect.
Conclusions. Our preliminary results suggest that amyloid accumulation in the brain is accompanied by significant alterations in both MHC-II expression and T cell cytokine production. Further studies using both basic *in vitro* and *in vivo* approaches are underway to further explore the possibility that antigen presentation and immune surveillance are defective in the context of AD-like amyloid pathology. The results of these studies will help elucidating the role of the immune system in AD.

Harvard Institutes of Medicine Brigham and Women's Hospital and Harvard Medical School, Boston, USA
[3]Department of Neurosciences and the Center on Aging,
Medical University of South Carolina, Charleston, USA

Objectives: Inflammation is a prominent feature in Alzheimer's disease (AD). Recent results suggest that chronic inflammation can be a consequence of a failure to resolve the inflammation. Resolution of inflammation is mediated by several families of lipid mediators, coined the specialized pro-resolving lipid mediators (SPMs) that include the resolvins, protectins, maresins and lipoxins. Reduced levels of SPMs have been shown in AD hippocampus, and this correlated with decreased cognitive state. The aim was to further characterize the resolution pathwayin AD, by analysing the entorhinal cortex (ENT), the area first affected in AD pathogenesis, and to investigate whether stimulating resolution of inflammation is beneficial in AD-related cellular models.
Methods: ENT tissue from postmortem AD brain was analyzed using liquid chromatography-tandem mass spectrometry (LC-MS-MS) approach. The effects of SPMs on neuronal cell death was analysed in a model of staurosporine (STS)-induced cell death in neuroblastoma SH-SY5Y cells. Effects of SPMs on microglial phenotype and phagocytosis of Ab were studied.
Results: The levels of docosahexaenoic acid (DHA) derived SPMs, including maresin 1 (MaR1), protectin D1 (PD1) and the D-series resolvins, were lower in ENT of AD-patients compared to age-matched controls. SPMs including lipoxin A_4 (LXA_4), MaR1, resolvin D1 (RvD1) and PD1 were found to be neuroprotective, while only MaR1 was effective in stimulating microglial phagocytosis of Ab_{42} and reducing inflammatory markers.
Conclusions: Our findings support a disturbance of the resolution pathways for local inflammation in the AD brain, and indicate that pro-resolving agents can be of potential therapeutic value for AD.

THE ROLE OF GLIA IN THE PATHOLOGY OF THE NOVEL APP/ABETA K16N MUTATION

S. Hossain[1], G. Almazan[1], G. Multhaup[1]
[1]Pharmacology and Therapeutics, McGill University, Montreal, Canada

We previously described a novel familial mutation affecting the alpha secretase cleavage site of APP (APP_{770} K687N/Abeta K16N) identified in a heterozygous early onset Alzheimer disease patient (Kaden et al, 2012). It has a unique phenotype, where the mutant Abeta42 K16N protein was toxic to neuroblastoma cells only in the presence of the Abeta42 wild-type peptide. It withstood neprilysin degradation, and protected Abeta42 wild-type protein from degradation. Collectively, we hypothesize that the Abeta K16N mutation likely increases the half-life of toxic Abeta species to perturb effective Abeta clearance, and to contribute to disease pathology. Microglia and astrocytes are the glial cells critical for both amyloid clearance in the CNS and neuroinflammation. Here, we studied the impact of the Abeta K16N mutation and its state of aggregation on glial cell function.

We assessed cell survival and glial activation in primary rat cultures by MTT reduction, immunocytochemical staining, flow cytometry, ELISA and Western blotting. Size exclusion chromatography and electron microscopy were used to examine the aggregation states of Abeta species.

Long-term treatment of primary glial cultures with Abeta42 K16N decreased viability only in the presence of the wild-type Abeta42. Also, glial cells were more activated by a mixture of wild-type and mutant Abeta, compared to treatment with Abeta42 K16N peptide alone. Interestingly, we found glia took up mutant Abeta42 peptide faster than wild-type Abeta42 alone or an equimolar-mixture of the two peptides. These results suggest this novel alpha-secretase mutation alters glial cell functions to potentially trigger a detrimental neuroinflammatory response.

INCREASES BLOOD-BRAIN BARRIER VULNERABILITY TO SYSTEMIC INFLAMMATION AND REDUCED EXPRESSION OF IRON HOMEOSTASIS PROTEINS IN ALZHEIMER DISEASE

R. Raha-Chowdhury[1], A. Raha[1], J. Zhao[1], S. Stott[1], A. Bomford[2]
[1]Department of Clinical Neuroscience, John Van Geest Centre for Brain Repair, Cambridge, United Kingdom
[2]King's College Hospital, Institute of Liver Studies, London, United Kingdom

There is an association between neurovascular dysfunction, inflammation and imbalance iron homeostasis in Alzheimer's disease (AD). It may occur as a consequence of a series of damage signals in the blood brain barrier (BBB), failure of immunomodulation, or be associated with excessive iron deposition in the brain.
Neuroimmunomodulation focuses on the link between neuronal damage and brain inflammatory process, mediated by failure of phagocytosis and the progressive activation of astrocytes and microglial cells. To investigate immunomodulatory processes in human AD brains, APP transgenic (APP-tg) mouse and controls brain samples were analysed by RT-PCR, Western blotting and immunohistochemistry (IHC). In APP-tg mice, Western blotting revealed an overproduction of proinflammatory cytokines (IL-6, IL-1b and TNF-a) and a reduction of both triggering receptor expressed on myeloid cells 2 (TREM2) and the iron exporter ferroportin. Both proteins were detected by IHC in microglia and macrophages in choroid plexus in normal brain but were reduced in AD model.
The iron regulatory protein hepcidin and its receptor ferroportin levels were decreased significantly in AD brains and in the later stages of the APP-tg mouse. In this model loss of pericytes and extensive endothelial disruption was seen confirming the presence of severe vascular pathology. Loss of vascular integrity is also associated with abnormal iron accumulation as ferritin, located in haempositive granules associated with blood vessels. The reduction in ferroportin and hepcidin in AD brain is likely to be associated with the pro-inflammatory state, which leads to impaired amyloid clearance process and enhanced senile plaque formation.

ACCELERATION OF AMYLOIDOSIS BY INFLAMMATION IN THE AMYLOID-BETA MARMOSET MONKEY MODEL OF ALZHEIMER'S DISEASE

I. Philippens[1], P. Ormel[1], G. Baarends[1], E. Remarque[2], M. Doverskog[3]
[1]Immunobiology, Biomedical Primate Research Centre (BPRC), Rijswijk, Netherlands
[2]Parasitology, Biomedical Primate Research Centre (BPRC), Rijswijk, Netherlands
[3]Karolinska Institutet Science Park, Umecrine Cognition AB, Solna, Sweden

Background: A pro-inflammatory state is associated and mentioned as potential target for treatment of amyloidopathy. The marmoset monkey has potential as an Alzheimer's disease (AD) model due to its natural amyloidosis. Moreover, the marmoset shows a human-like immune system and aging phenotype, which is partly due to exposure to environmental pathogens causing transient or chronic latent infections. Aim was to investigate the effect of inflammation on amyloidopathy in the marmoset AD model.
Methods: Four middle aged (5-8y) and two old (13-14y) common marmoset monkeys (*Callithrix jacchus*) of both sexes were intracranially injected with amyloid-beta (Ab) fibrils at three cortical locations in the right hemisphere (frontal, parietal, and sensorimotor cortices) and both hemispheres were injected with PBS (n=3) or LPS (n=3). The effect of inflammation on amyloidopathy was also investigated in an animal that died due to a systemic inflammatory condition, marmoset wasting syndrome (MWS), which is associated with chronic colitis. The pro-inflammatory effect of LPS and Ab was also tested in an *ex vitro* blood analysis (flow cytometry) for immune cell biomarkers (CD45RA and CD95). Campbell-Switzer silver staining and IHC analyses (Ab, Ab42, Ab43, Iba1, and GFAP antibodies) were used on mirror sections to assess amyloidopathy and immune reaction.
Results: The MWS and two LPS+Ab monkeys developed plaques and the LPS+Ab animals had an early-AD immune blood cell expression profile as seen in human AD patients.
Conclusion: A pro-inflammatory condition accelerates amyloidopathy in the marmoset, which indicates the possible importance of immune modulation to decrease the susceptibility for AD.

[2]Neurometabolic Diseases Laboratory, IDIBELL, L'Hospitalet de Llobregat, Spain
[3]Department of Experimental Medicine, Biomedical Research Institute of Lleida, Lleida, Spain

Objectives: Inflammation occurs with aging in several systems but practically nothing is known about inflammation in the aged brain. Although neuroinflammation is well known in advanced stages of sporadic Alzheimer disease (sAD) information about early stages and regional differences in sAD are lacking. AD-related transgenic mice models are used to test anti-inflammatory therapies, but there is no information regarding similarities and differences in neuroinflammation in mice and humans.

Methods: Functional genomics in the cerebral cortex of WT and APP/PS1 mice followed by validation analysis of mRNA expression by qRT-PCR analysis in mice and in entorhinal, orbitofrontal and frontal cortex in human control and sAD stages I-II/0(A), III-IV/A-B and V-VI/C. Studies of β-amyloid plaque burden, soluble Aβ40 and Aβ42, and membrane-associated β-amyloid by immunohistochemistry, ELISA and western blotting. Analyses of protein expression of specific cytokines were examined by western blot and immunohistochemistry.

Results: mRNA deregulation of several inflammatory mediators occurs in mice aged 12 to 20 months, and in humans between 50 and 65 years. Neuroinflammation extends to several cortical regions in sAD at stages I-II/0(A), III-IV/A-B, and V-VI/C. No relationship is found between regional neuroinflammation and plaque, soluble and membrane-associated β-amyloid in the frontal and entorhinal cortex at early stages of sAD.

Conclusions: Neuroimmunoaging is common in early old age in mice and humans. Neuroinflammation in AD and related models is not a mere acceleration of neuroimmunoaging. Characteristics of neuroinflammation differ in sAD and APP/PS1 thus alerting about possible different responses of anti-inflammatory therapies in APP/PS1 and humans with sAD.

MODULATION OF MICROGLIAL RESPONSES BY A PUTATIVE TREM2 LIGAND

A. Phillips[1], S. Lovestone[2], J. Hardy[3], J. Pocock[1]
[1]Department of Neuroinflammation, Institute of Neurology, London, United Kingdom
[2]Department of Psychiatry, University of Oxford, Oxford, United Kingdom
[3]Department of Molecular Neuroscience, Institute of Neurology, London, United Kingdom

Objectives

Microglial responses critically underpin pathological processes associated with progressive neurodegenerative diseases such as Alzheimer's disease and PD. Recent GWAS have identified mutations in the gene for triggering receptor expressed on myeloid cells (TREM2) as putative risk factors for late-onset AD (Guerreiro et al., 2013). TREM2 is a major microglia-specific gene, ranked #31 of the most highly expressed microglia receptors. TREM2 may act as a lock to repress microglial pro-inflammatory cytokine production, whilst promoting protective microglial responses such as chemotaxis and phagocytosis. However, a full appreciation of the function of TREM2 is needed to understand the role of TREM2 mutations implicated in neurodegenerative cascades. Because the endogenous ligand of this receptor is currently unknown, we took advantage of a putative TREM2 ligand to explore the signalling processes in microglia associated with this receptor (Daws et al., 2003).

Methods

All experiments were carried out in the BV2 microglial cell line or primary cultures of rat whole brain derived ex-vivo microglia. Either a TLR4 ligand, lipopolysaccharide, or a TLR2 ligand, lipoteichoic acid were used to activate microglia.

Results

The putative TREM2 ligand modulates iNOS and TNFα expression, phagocytosis and the profile of cytokine secretion. Intracellular superoxide generation was also regulated by the ligand.

Conclusions

Preliminary data suggest regulation of TREM2 in microglia can alter subsequent microglial signalling. Further experiments will explore the interplay of other receptors on TREM2 responses in microglia.

NEUROINFLAMMATION AND KININS: IN VITRO AND IN VIVO STUDIES

S. FleisherBerkovich[1], S. Ben-Shmuel[1], K. Asraf[1]

[1]Clinical Biochemistry and Pharmacology, Ben-Gurion University of the Negev, Beer-Sheva, Israel

Background: Neuroinflammation is expressed by activated microglial cells that release inflammatory markers, e.g. nitric oxide (NO) and tumor necrosis factor-alpha (TNF-alpha). Bradykinin (BK) and other kinins are known as potent peripheral mediators of inflammation and exert their effects via two kinin receptors: B_1 and B_2 receptors. In Alzheimer's disease (AD), where neurionflammation plays role, BK release in brain tissues is up regulated early during the course of the pathology. Hence, BK is believed to promote neuroinflammation. However, BK was recently also reported to exert anti-inflammatory roles.

Aims: The aims of this study were a. to examine the effect of BK on microglial production of NO and TNF-alpha under lipopolysaccharide-stimulated conditions. b. to check the involvement of BK in regulation of amyloid plaques burden and gliosis in AD transgenic model.

Methods: BV2 microglial cell lines were used. We also used 5 X familial AD (5XFAD) transgenic mice as an *in vivo* model.

Results: The results show that BK and selective BK agonists attenuated both microglial NO and TNF-alpha release that had been stimulated with LPS. R-715, a specific B_1R antagonist, but not HOE-140, a specific B_2R antagonist increased amyloid plaques levels in the cortex of 5XFAD mice. Moreover, B_1 receptor blockade resulted in increased gliosis in the cortex of these mice.

Conclusions: These results suggest that kinins protect the brain against neuroinflammatory processes such as the release of toxic factors from microglial cells. B_1 receptor is involved in the regulation of Aβ clearance and gliosis *in vivo*. (ISF grant No. 101/11-15).

GLOBAL GENETIC REDUCTION OF THE PROSTAGLANDIN E2 RECEPTOR EP2 DOES NOT PREVENT NEURAL DYSFUNCTION IN HUMAN APP TRANSGENIC MICE

P.E. Sanchez[1], D. Kim[1], E. Johnson[1], K. Ho[1], G.Q. Yu[1], L. Mucke[1]
[1]Department of Neurology, The J. David Gladstone Institutes/ UCSF, San Francisco, USA

Objectives: The prostaglandin E2 (PGE_2) receptor EP2 may be involved in Alzheimer's disease (AD). Conditional ablation of EP2 in microglia ameliorated memory deficits in hAPP/PS1 doubly transgenic mice (J. Clin. Invest. 125:350). To assess the therapeutic potential of global reduction in EP2 signaling, we crossed hAPP mice from line J20 onto a *Ptger2* (EP2)-deficient background and analyzed the six resulting genotypes: *Ptger2*$^{+/+}$, *Ptger2*$^{+/-}$, *Ptger2*$^{-/-}$, hAPP/*Ptger2*$^{+/+}$, hAPP/*Ptger2*$^{+/-}$ and hAPP/*Ptger2*$^{-/-}$.
Methods: Adult mice were tested in the elevated plus maze, Y-maze and Morris water maze. Aβ levels in brain tissues were determined by ELISA. Brain sections were stained with Thioflavin-S to detect amyloid plaques and with different antibodies to determine hippocampal levels of the neuronal activity-dependent proteins calbindin and cFos.
Results: Global reduction or ablation of EP2 did not ameliorate behavioral and cognitive abnormalities or neuronal reductions in calbindin and cFos in hAPP mice. It also did not alter Aβ levels in cortical/hippocampal homogenates, although ablation of EP2 reduced the burden of Thioflavin-S-positive amyloid plaques. In mice without hAPP, EP2 ablation caused deficits in the Y-maze, but not in the other behavioral tests.
Conclusions: We confirmed that EP2 deletion decreases plaque burden, indicating that PGE_2/EP2 signaling has a role in the deposition or removal of plaques. However, our findings suggest that EP2 receptors do not mediate hAPP/Aβ-dependent neuronal, behavioral and cognitive abnormalities in hAPPJ20 mice and, thus, provide no support for the hypothesis that global inhibition of PGE_2/EP2 signaling might be of benefit in the prevention or treatment of AD.

[4]Behavioral Neuroscience Laboratory, Neuroscience Research Australia, Sydney, Australia

Objectives: Apolipoprotein-D (apoD) levels are increased in affected brain regions in Alzheimer's disease (AD). ApoD has a lipid antioxidant function, however, the mechanisms involved and relationship to AD pathology are unclear. We addressed these questions using in vitro and in vivo approaches.

Methods: Recombinant apoD and Met to Ala mutants were assessed for antioxidant activity (conversion of radical-generating lipid hydroperoxides to inert lipid hydroxides) by HPLC. ApoD monomers and dimers were assessed by western blotting of postmortem control and AD hippocampus and cerebellum. Tissue lipid peroxidation markers (conjugated dienes and F2-isoprostanes) were assessed by HPLC and GC-MS methods. ApoD null mice and Thy-1 human apoD transgenic mice were crossed with APP/PS1 mice. Amyloid pathology was assessed at 11 months by immunostaining.

Results: We identified an antioxidant role for apoD Met-93 in the catalysis of lipid hydroperoxides to lipid hydroxides. The reaction generates Met sulfoxide that destabilizes apoD leading to dimer formation. In human AD hippocampus, apoD was increase by 32% ($p<0.01$) and apoD dimer was increased 2.1-fold ($p<0.01$) compared to controls. Similarly, a hippocampal-dependent increase in conjugated dienes and F2-isoprostanes was selectively detected in the AD hippocampus. In APP/PS1 mice, loss of apoD resulted in a 2.2-fold ($p<0.01$) increase in hippocampal plaque load. Conversely, transgenic expression of neuronal apoD reduced hippocampal plaque load by 33% ($p<0.01$).

Conclusions: ApoD lipid antioxidant activity involves Met-93. This antioxidant process may contribute to apoD dimer formation in the AD brain. Our studies also indicate apoD regulates amyloid pathology in a mouse model of AD.

INHIBITION OF GLUCOSYLCERAMIDE SYNTHASE (GCS) ENHANCES NEURONAL RESISTANCE TOWARDS AMYLOID-BETA-MEDIATED TOXICITY

S. Herzer[1], S. Meldner[1], H. Gröne[1], V. Nordström[1]
[1]Cellular and Molecular Pathology, German Cancer Research Center (DKFZ), Heidelberg, Germany

Objectives:
Gangliosides synthesized by GCS are essential components of cell membranes particularly enriched in neurons. During the recent years, they have emerged as molecules involved in the pathogenesis of Alzheimer´s disease (AD). In parallel decreased neuronal insulin receptor (IR) signaling was shown to be a hallmark of AD. We aim to study if altered IR signaling exerts neuroprotective effects on ganglioside-deficient neurons upon exposure to soluble amyloid-beta oligomers (ADDLs). Furthermore, we investigate if ADDL-binding to synaptic sites and subsequent cell viability depend on plasma membrane gangliosides.
Methods:
Neuronal hippocampal cells were treated with the ganglioside biosynthesis inhibitor Genz-123346, subsequent ganglioside depletion was determined by thin layer chromatography. The cells were incubated with ADDLs for 24h and cell viability was measured in an MTT assay. Intracellular IR signaling in the ADDL-treated ganglioside-depleted cells was analyzed by western blot. Co-localization and interaction of gangliosides with IR and ADDLs were investigated with immunofluorescence (IF) stainings and co-immunoprecipitation (co-IP).
Results:
We found that ganglioside-depleted neuronal cells displayed higher resistance towards ADDL stress. Furthermore, ADDL-exposure of control neurons lead to decreased IR levels and signaling, however, this effect was rescued on ADDL-treated ganglioside-depleted neurons. Ganglioside/ IR interactions could be confirmed by IF stainings and co-IPs. Moreover we showed that ganglioside/ IR interaction as well as ADDL binding localize to synaptic sites.
Conclusions:
IR levels and signaling can be modulated via ganglioside depletion resulting in less sensitivity to ADDL-induced neurotoxicity. These results open up the possibility of a potential novel therapeutic strategy for AD.

[3]Physiology, University of La Laguna, La Laguna, Spain

Lipid rafts are membrane microdomains that provide a highly saturated and viscous physicochemical microenvironment facilitating protein-lipid and protein-protein interactions involved in cellular signal transduction. The presence of raft lipid alterations in the frontal cortex in early and late stages of Alzheimer's disease (AD) has been recently demonstrated.

The aim of this work was to investigate whether raft lipid matrix impairment may affect microstructure homeostasis and, consequently, modify the behaviour and dynamics of raft integrated proteins relevant to AD pathogenesis.

Our results show that changes in the raft lipid matrix in frontal cortex lipid rafts at the earliest stages of AD (AD I/II) affect, both, lipid classes and fatty acids, and were also detected in the entorhinal cortex, but not in the cerebellum. Paralleling these changes, lipid rafts from these brain areas displayed higher anisotropy for environment-sensitive probes, indicating an increased in membrane order and viscosity in these domains. Pathophysiological alterations were strengthened by redistribution of proteins related to amyloidogenic processing.

Overall, our results provide a mechanistic connection in these microdomains between lipid alterations, amyloidogenic processing of amyloid precursor protein and microstructural impairment initiated even at early stages of AD.

Supported by SAF2010-22114-C02-01/02, Seventh Framework Programme of the European Commission, grant agreement 278486: DEVELAGE. NF was hired from SEGAI.

LIVE-CELL MONITORING OF PROTEIN INTERACTIONS, PROTEOLYTIC PROCESSING AND LIPID RAFT LOCALIZATION OF PROTEINS INVOLVED IN THE PATHOGENESIS OF ALZHEIMER'S DISEASE

M. Merezhko[1], E. Pakarinen[1], P. Muggalla[1], N.P. Nykänen[1], X. Yan[1], P. Sakha[1], H.J. Huttunen[1]

[1]Department of Biological and Environmental Sciences, University of Helsinki, Helsinki, Finland

Objectives: Amyloid-beta precursor protein (APP) and Tau play central roles in pathophysiology of Alzheimer's disease (AD). Coordinated regulation of proteolytic processing of APP and Tau phosphorylation/dephosphorylation is important for maintenance of neuronal health. Both processes are associated with lipid rafts (LR), nanoscale membrane microdomains. Our aim was to develop improved live-cell methods to provide new insights to these processes and to help in functional genomic and drug discovery efforts in AD.

Methods: *Gaussia princeps* luciferase-based protein-fragment complementation assay (PCA) was used for live-cell monitoring of protein-protein interactions. PCA-detection of APP-BACE1 interaction was combined with alkaline phosphatase-based detection of shed APP fragments from the media to form a multiple readout assay. For monitoring trafficking of proteins to LR, we developed a PCA reporter carrying one half of the luciferase protein fused to the LR localization signal from the Fyn kinase.

Results: The APP multiplex assay with four readouts is capable of delivering mechanistic details on trafficking and processing of APP in live cells. LR-localization assay showed dynamic localization of APP and Tau as well as several proteins regulating their function to lipid rafts. Changes in glucose and 1-carbon metabolism strongly influenced LR-localization of Tau. Of the tested late-onset AD risk genes, ABCA7 coexpression had the most pronounced effects on Tau localization to lipid rafts.

Conclusions: Monitoring protein-protein interactions and lipid raft localization of pathophysiologically central proteins with the new live-cell assay platform can provide new insights into disease mechanisms and functional genomics of AD.

[3]CEMO, Institute of Neuroscience-Université catholique de Louvain, Brussels, Belgium

[4]Louvain Drug Research Institute, Université catholique de Louvain, Brussels, Belgium

Objectives: Neuronal cholesterol homeostasis is essential for basic synaptic function, plasticity and behavior. The beneficial effects of Liver and Retinoic X Receptors agonists (LRAs) reported on synaptic and cognitive functions are based on their ability to increase cholesterol efflux. Here we report that neuronal activity and synaptic plasticity were improved by LRAs only when increased expression of cholesterol efflux regulatory protein ATP-binding cassette transporter ABCA1 was compensated by an increased expression of HMG-CoA reductase (HMGCR), the rate-limiting step enzyme of the cholesterol synthesis pathway.

Methods: Primary cultures of rat cortical neurons, mice deficient for *ApoE* (the main brain cholesterol transporter), and 5xFAD transgenic mice, a mouse model of Alzheimer disease with extensive memory impairments, were used to assess the importance of HMGCR expression in synaptic activity. Two LRAs, GW3965 and bexarotene, were utilized to induce cholesterol efflux and to promote compensatory HMGCR expression.

Results: In neuronal networks, induction of expression of ABCA1 by LRAs was concomitant with increased expression of HMGCR and the resulting neuronal activity improvement was not observed following HMGCR inhibition. We report that LRA-mediated cholesterol efflux did not increase HMGCR and synaptic plasticity in wild type mice and that impaired cholesterol supply in *ApoE* deficient mice was compensated by an increased HMGCR expression improving synaptic plasticity. Moreover, HMGCR needs to be enzymatically active since its inhibition inhibits bexarotene-mediated rescue of synaptic plasticity deficits in 5xFAD mice.

Conclusions: Our results suggest that expression of HMGCR induced by LRAs-mediated cholesterol efflux is needed to improve synaptic plasticity and cognition.

THE ROLE OF SCAVENGER RECEPTOR CLASS B TYPE I (SR-BI) IN THE PATHOGENESIS OF ALZHEIMER'S DISEASE

K. Sarantari[1], E. Paouri[1], S. Georgopoulos[1]
[1]Basic Research, Biomedical Research Foundation of the Academy of Athens, Athens, Greece

Objectives
SR-BI is an HDL receptor, identified on astrocytes and vascular smooth muscle cells in Alzheimer's disease (AD) brain. We have previously shown that SR-BI reduction enhances amyloid plaque formation and exacerbates memory deficits in an AD mouse model (J20), suggesting that up-regulation of SR-BI could have a protective effect. To further elucidate the pathogenetic mechanism that involves SR-BI we will examine whether brain or peripheral expression of SR-BI is critical in AD pathogenesis.
Methods
We have generated a brain-specific and liver-specific AD transgenic mouse model to evaluate the effect of SR-BI up-regulation in the AD phenotype.
Results
We have expressed SR-BI in the J20 brain, using an astrocyte-specific promoter (GFAP) and bred the J20/GFAP-SRBI transgenic mice on the SR-BI knockout background. We have also generated J20/liver-specific SR-BI transgenic/ SR-BI knockout mice. We are currently analysing the amyloid phenotype of these mice, to evaluate the effect of SR-BI expression.
Conclusions
Our hypothesis is that SR-BI can exert an effect on the AD pathology either by regulating amyloid deposition in the brain, or by regulating cholesterol homeostasis, as SR-BI is involved in reverse cholesterol transport. To establish the protective role of SR-BI in AD and the mechanism involved we have generated transgenic mice that overexpress SR-BI in the brain and in the liver. Analysing these mice will help us establish a potential therapeutic role of SR-BI in AD.

ARACHIDONIC ACID-SPECIFIC ACYL-COA SYNTHETASE 4 (ACSL4): A KEY ENZYME FOR NEURONAL DIFFERENTIATION AND DISTRIBUTION OF CRITICAL PHOSPHOLIPID SPECIES

M.H. Thomas[1], *C. Paris*[2], *F.T. Yen*[1], *J.L. Olivier*[1]
[1]*URAFPA-BFLA, ENSAIA, Vandoeuvre-les-Nancy, France*
[2]*Laboratoire d'Ingénierie des Biomolécules, ENSAIA, Vandoeuvre-les-Nancy, France*

Background & Objectives
Western diets are characterized by excessive amounts of ω-6 fatty acid precursors and arachidonic acid (ARA). Competition between ARA and docosahexaenoic acid (DHA) for the incorporation into membrane phospholipids could contribute to lower DHA levels which are observed in Alzheimer's disease (AD) patients and could therefore favor the loss of synaptic plasticity and the neurotoxic effects of Aβ oligomers. Our objective was to test this hypothesis by analyzing the influence of the arachidonyl-specific acyl-CoA synthetase 4 expression (ACSL4) on neurite growth and ARA and DHA distribution into phospholipid species.
Methods
The murine hippocampal cell line HT22 was differentiated by phorbol ester, dibutyryl cAMP and NGF. The differentiation levels were quantified by morphological criteria and measurement of neuronal markers. ACSL4 expression levels were quantified in Western blot and quantitative RT-PCR experiments. MTT activities were measured to determine cell sensitivity to Aβ oligomers. Phospholipids species were analyzed by electrospray ionization/mass spectrometry.
Results
ACSL4 expression levels increased 3-4 fold in HT22 cells during the differentiation process and was further increased by 25% in presence of ARA. siRNA-mediated inhibition of ACSL4 expression did not modify HT22 cell neurite growth nor their sensitivity to Aβ oligomers. However, ARA uptake in HT22 cells reduced specific DHA-containing plasmalogen species and these modifications were abolished by reduction of ACSL4 expression.
Conclusions
ACSL4 expression is associated with neuronal differentiation/neurite growth and reduces DHA distribution into critical phospholipid species reported to be affected in AD.

IMPACT OF HUMAN APP OVEREXPRESSION ON CEREBRAL CHOLESTEROL METABOLISM IN MICE

T. Loeffler[1], C. Schweinzer[1], E. Steyrer[2], B. Hutter-Paier[1], M. Windisch[3]
[1]Neuropharmacology, QPS Austria GmbH, Grambach, Austria
[2]Institute of Molecular Biology and Biochemistry, Medical University Graz, Graz, Austria
[3], NeuroScios GmbH, Graz, Austria

Processing of APP and Abeta has been in the center of Alzheimer's disease (AD) research for decades. Beside many other variables, lipids, especially cholesterol and its derivatives, are discussed to contribute to AD pathogenesis. Several studies showed that cholesterol impacts on APP metabolism. But interestingly also the converse mechanism, the direct influence of Abeta on cholesterol metabolism was discovered. The presented study investigates whether human APP overexpression and changes in Abeta generation influence cholesterol metabolism in APP_{SL} mice, a well-established model of brain amyloidosis and AD?
Changes in cholesterol content and mRNA levels of cholesterol metabolism-associated genes were measured in brain tissue of APP_{SL} mice and non-transgenic littermates. To additionally investigate the impact of dietary cholesterol on these parameters, brain tissue of APP_{SL} and wild type (WT) mice that received a high-fat/high-cholesterol diet (HFD) for three months was examined as well.
Levels of free cholesterol were significantly reduced in cortices of APP_{SL} mice compared to WT animals. Therefore cholesteryl esters showed a tendency to be increased in APP_{SL} mice. Cortical mRNA levels of LDL-receptor, HMGCoA-reductase, ACAT 1 and 2 as well as ApoE were significantly altered in APP_{SL} mice compared to WT littermates both maintained on regular chow. The changes were more pronounced in mice on HFD. Changes of cortical cholesterol levels and mRNA expression patterns under normal diet and HFD conditions argue for an important role of APP in cerebral lipid metabolism, pointing towards a possible connection between APP overexpression and the amount and distribution of cerebral cholesterol.

HIGH FAT DIET DECREASES PLASMA ABETA LEVELS IN MICE OVEREXPRESSING HUMAN APP

C. Schweinzer[1], T. Loeffler[1], R. Rabl[1], M. Santha[2], E. Steyrer[3], B. Hutter-Paier[1], M. Windisch[4]
[1]Neuropharmacology, QPS Austria GmbH, Grambach, Austria
[2]Institute of Biochemistry, Biological Research Center, Szeged, Hungary
[3]Institute of Molecular Biology and Biochemistry, Medical University Graz, Graz, Austria
[4], NeuroScios GmbH, Graz, Austria

Sporadic Alzheimer's disease (AD) is influenced by a set of non-genetic risk factors, whereas dyslipidemia seems to play a crucial role. Interestingly, it was shown in mice overexpressing human ApoB-100, that a shift in the plasma lipoprotein composition towards higher LDL-cholesterol levels, without dietary intervention, is able to induce cognitive decline. To see whether this phenotype could be more pronounced by additional cholesterol uptake, a high-fat feeding study was conducted with animals overexpressing human ApoB-100 and/or human APP_{SL}.

Animals of every genotype, ApoBxAPP, ApoB-100, APP_{SL} and wild type (WT), received either a standard chow or iso-caloric high-fat-diet (HFD) for 3 months. At an age of 6 months, all animals underwent several behavioral tests, including the Morris water maze (MWM) and contextual fear conditioning (CFC) task. Abeta levels were assessed in brain and plasma samples. Blood plasma was also analyzed for HDL-cholesterol, LDL-cholesterol and triglycerides.

HFD feeding leads to the expected changes of the plasma lipid profile resulting in more atherogenic conditions in all genotypes, with the strongest response in ApoB-100 mice. Behavioral data show, that HFD mainly affects emotional learning (CFC), but has no measureable impact on spatial learning (MWM). Interestingly, HFD leads to a significant decrease of Abeta1-40 levels in the plasma (48% in ApoBxAPP and APP_{SL} mice), while cerebral Abeta species increase in the brains of HFD-fed animals. Histological changes are subject of current investigations.

While HFD barely influenced behavioral aspects, it strongly affected cerebral Abeta clearance in both strains of human APP overexpressing mice, ApoBxAPP and APP_{SL}.

MOLECULAR MECHANISMS OF BACE1 RECYCLING

J. Brault[1], D. Ladarré[2], C. Delevoye[1], S. Bardin[1], V. Fraisier[1], Z. Lenkei[2], B. Goud[1], S. Miserey-Lenkei[1]

[1]UMR144, Institut Curie, PARIS, France

[2]Neurobiology laboratory, ESPCI, PARIS, France

It is now over two decades that the amyloid cascade hypothesis was formulated and despite intensive research the molecular mechanisms that regulate intracellular transport and sorting of the amyloid precursor protein (APP) and the beta-site APP cleaving enzyme 1 (BACE1) remain to be perfectly understood. A comprehensive view of these events is yet essential as: (1) proteolytic cleavage of APP by BACE1 is the rate-limiting step in the production of the toxic amyloid beta-peptide (Abeta) that accumulates in the brain of patients suffering from Alzheimer's disease (AD), (2) Abeta production depends on the co-residence of APP and BACE1 in the same intracellular compartment. It is now clear that the overall endosomal machinery participates in regulating transport of APP and BACE1 and endosomes have been proposed as the main site of amyloidogenesis. Recent studies pinpointed the role of recycling endosomes in both intracellular trafficking of BACE1 and regulation of Abeta production by allowing a transient separation between APP and BACE1. Our work focuses at deciphering the molecular mechanisms that underlie BACE1 recycling pathway. Molecular and cell biology techniques such as mass spectrometry analysis and live-cell imaging as well as the use of in vivo AD models allowed us to discover new cellular factors involved in this process and to better understand how this transport route is a key step in the regulation of amyloidogenesis.

DHA EFFECT ON NEURONAL SURVIVAL AND ZINC HOMEOSTASIS IN SY5Y AND NT2 CELLS.

V. De Mel[1], C. Suphioglu[1]
[1]School of Life and Environmental Science, Deakin University, Geelong, Australia

Docosahexaenoic acid deficiency (DHA) is reported to induce neuronal cell death in M17 cells through zinc-induced apoptosis. We hypothesize that the same phenomena is present in other cell types similar to M17. SY5Y and NT2 cells were used to test the hypothesis and following the exposure to DHA supplemented or deficient media, opposite effects were seen in those two cell lines. NT2 cells in response to DHA-deficient medium reacted similar to M17 cells, where the active caspase-3 levels were increased. DHA supplemented NT2 cells showed an increase in ZnT3 mRNA and protein levels similar to M17 cells. However, SY5Y cells did not show a consistency in both caspase-3 and ZnT3 mRNA level changes. Which was more consistent to human keratinocyte cell line HaCaT which was used as a control.

Objectives
Many studies emphasize the importance of cholesterol in the build up of amyloid beta, regulating its production, aggregation and clearance. Despite cerebral cholesterol seems to be decreased in Alzheimer's disease, the reason behind this finding remains elusive. Here, we aim to elucidate how APP processing affects cholesterol metabolism in the brain.
Methods
Quantifying intermediates of cholesterol using isotope-dilution mass spectrometry. Elucidating the expression of key enzymes within the cholesterol synthesis pathway using RT-PCR and immunoblotting techniques. Utilizing dermal fibroblasts from AD patients and cell lines expressing the APP Swedish KM670/671NL double mutation (APP_{Swe}) and Presenilin 1 (PS-1) mutations.
Results
Decreased levels of SREBP2 in APP_{Swe}, was seen when the cells were challenged with cholesterol starvation, this however, was reversed in PS-1 expressing cells. Furthermore, HMG-CoA synthase and reductase along with LDL-receptor were observed to be reduced in PS-1 cells while showing no change or an increase in APP_{Swe}. Lower levels of cellular cholesterol in both APP_{Swe} and PS-1 were determined under lipoprotein starving conditions.
Conclusions
Aβ overproducing cells have compromised synthesis of cholesterol, affecting the function of brain processes such as synaptogenesis and neuroplasticity. In cholesterol starving conditions, cells expressing familial AD mutations such as APP_{Swe} have higher or standard expression of genes regulating key steps in cholesterol synthesis, which is the contrary with PS-1 mutations. Suggesting that even though both mutations lead to a decrease in cholesterol synthesis they achieve that through different mechanisms.

[3]Louvain Drug Research Institute, Université Catholique de Louvain, Brussels, Belgium

Objectives: We have previously shown that there is a tight link between neuronal cholesterol homeostasis and neuronal activity. In primary cortical neurons expressing human APP (hAPP), cholesterol turnover was decreased and consequently neuronal activity was abolished. In this study, we have used Liver and Retinoic X Receptors agonists (LRAs) in order to restore cholesterol homeostasis and neuronal activity in primary cortical cultures of neurons expressing hAPP.

Methods: Primary cultures of rat cortical neurons with hAPP expression mediated by an adenoviral vector were used. Expression of genes and proteins involved in cholesterol homeostasis were assessed by quantitative RT-PCR and western blotting. Neuronal activity was analyzed by calcium imaging and patch clamp recording. Two LRAs, GW3965 (LXR agonist) and bexarotene (RXR agonist), were tested in their ability to improve neuronal cholesterol homeostasis.

Results: In primary cultures of neurons expressing or not hAPP, LRAs increase expression of ATP-binding cassette transporter *ABCA1,* HMG-CoA reductase (HMGCR), the rate-limiting step enzyme of the cholesterol synthesis pathway, and 24-cholesterol hydroxylase, involved in neuronal cholesterol hydroxylation. Consequently, neuronal activity was improved in control neuronal networks and restored in hAPP expressing networks. Furthermore, the LRA-dependent increase in neuronal activity was abolished by mevastatin, an HMGCR inhibitor, suggesting that HMGCR has to be enzymatically active to observe constitutive calcium oscillations.

Conclusions: Here, we show that LRAs-mediated increase in cholesterol turnover is able to rescue and improve neuronal activity in primary cortical cultures of neurons expressing of not hAPP only when HMGCR is enzymatically active.

Objective:

Cholesterol is linked to Alzheimer's disease (AD) pathology. We previously showed that cholesterol levels control the partition of APP and its secretases in lipid rafts, APP endocytosis and Aβ secretion. It still remained unclear whether sporadic AD could be initiated by a change in membrane cholesterol. To test this hypothesis, we triggered an acute increase of cholesterol at the membrane of cultured neurons and analysed cellular changes detected early in the development of the disease.

Methods:

Primary rat embryonic hippocampal and cortical neurons were treated with 1.4 mM MethybCycloDextrine (MbCD)-cholesterol for 30 min. Aβ38, Aβ40 and Aβ42 were measured using Meso Scale Discovery. Early endosomes were labelled using an anti-EEA1 antibody and observed by confocal and electron microscopies. APP vesicular transport was analysed followinf electroporation with APP_{751}mCherry plasmid. Gene expression was measured on total RNAs extracted from neurons.

Results:

By comparing the list of genes differentially expressed after cholesterol treatment with gene expression profiles of sporadic AD brain samples from different Braak stages we found that cholesterol induced changes that are reminiscent of early stages. After cholesterol treatment we found: i/ Enlarged and aggregated EEA1-positive early endosomes using confocal and electron microscopy; ii/ Reduced speed of vesicular anterograde transport of APP; iii/ Increased Aβ42 secretion.

Conclusions:

Increase of neuronal membrane cholesterol triggers APP processing, endosomal trafficking and axonal transport abnormalities. We propose that an increase in membrane cholesterol linked with age is one of the initial events that could trigger sporadic AD.

GENE EXPRESSION AND METHYLATION IN ALZHEIMER'S DISEASE

S. Ma[1]

[1]*Psychiatry, The Chinese University of Hong Kong, Hong Kong, Hong Kong China*

Objective

To examine the correlation of methylation of 7 differentially expressed in Alzheimer's disease (AD) and the levell of gene expression to the risk of AD

Methods

80 AD patients and 180 age-matched control subjects were recruited for the study. Blood samples were collected from the subjects with consent and study was approved by institute ethic committee. Gene expression of CTSB, CTSD, DDT, TSC1, NRD1, UQCRC1 and NDUFA6 were quantitated by real-time RT-PCR. Methylation level was compared by Melting Curve Analysis-Methylation assay (MCA-Meth). Non-parametric Spearman's correlation was used to study the association between the methylation status and gene expression in the sample set. Independent t-test was performed to examine the association of methylation status and gene expression level in the group of AD patients and normal controls respectively. A nominal p-value of < 0.05 will be regarded as significant association.

Results

All 7 genes under investigation in this study showed differential gene expression levels among AD and normal controls. The gene expression of these 7 genes was significantly increased in AD patients and the increase ranged from 2.7-fold to 8.6-fold. UQCRC1 was highly methylated in AD patients but no significant difference in methylation status of CTSB, CTSD, DDT, TSC1, NRD1 and NDUFA6 between AD patients and normal controls.

Conclusions

UQCRC1 was highly methylated and expressed in AD and there might be methylation of this gene might serve as a regulatory mechanism for the expression of this gene and implicated in the role in AD pathogenesis.

TRANSLATIONAL REGULATION OF ADAM10 AND BACE1
S. Lammich[1], S. Zilow[1], A.K. Ludwig[1], I. Forne[2], C. Haass[3]
[1]Lehrstuhl für Stoffwechselbiochemie, Ludwig Maximilians University Munich, Munich, Germany
[2]Zentrallabor für Proteinanalytik, Ludwig Maximilians University Munich, Munich, Germany
[3]Lehrstuhl für Stoffwechselbiochemie,
Ludwig Maximilians University Munich & DZNE Munich, Munich, Germany
Objective: Anti-amyloidogenic processing of the amyloid precursor protein APP by α-secretase prevents formation of the amyloid-β-peptide (Aβ) which accumulates in senile plaques of Alzheimer disease patients. In contrast, cleavage of APP by β- and γ-secretase results in increased Aβ production. We recently demonstrated that the translation of the α-secretase ADAM10 as well as BACE1 is repressed by their 5'UTRs. We identified a translational inhibitory RNA-G-quadruplex secondary structure within the ADAM10 5'UTR, which is involved in translational repression of ADAM10. Furthermore we identified the cytoplasmic mRNA binding protein Unr as an ADAM10 5'UTR interactor, which is involved in translational regulation of ADAM10. We now extended our analysis and searched for BACE1 5'UTR binding proteins.
Methods: To identify BACE1 5'UTR binding proteins, we performed an affinity purification using internally biotinylated BACE1 5'UTR incubated with HEK293 cytosolic cell or mouse cytosolic brain extracts. Captured proteins were identified by LC-MS/MS. We analyzed the effect of the identified binding candidates on APP processing, by siRNA mediated knockdown or overexpression experiments in HEK293 cells.
Results: We identified HnRNP K and HnRNP E as the main BACE1 5'UTR binding proteins. Importantly, Unr does not bind to the 5'UTR of BACE1, however we observed significantly increased APPsβ and Aβ levels upon Unr overexpression, whereas BACE1 protein and mRNA level were not significantly altered.
Conclusion: In this study we demonstrate that the cytoplasmic protein Unr is able to modulate the expression and activity of ADAM10 and BACE1.

[5]Brain Research Centre, University of British Columbia, Vacouver, Canada
[6]Molecular Oncology, BC Cancer Agency, Vacouver, Canada

Background: Burgeoning evidence implicates aberrant activity of AMP-responsive protein kinase (AMPK) and its downstream target the eukaryotic elongation factor-2 kinase (eEF2K) in Alzheimer's disease (AD) pathogenesis. Defects in neuronal energy metabolism and synaptic plasticity are thought to underlie cognitive dysfunction and neuronal loss in AD. AMPK is a metabolic sensor and is believed to couple neuronal energy metabolism to neural activity. Furthermore, eEF2K plays a pivotal role in the regulation of dendritic protein translation vital to synaptic strength and plasticity. Our previous data show that eEF2K confers resistance in tumor cells to nutrient deprivation and modulates apoptotic pathways (Leprivier, G. et al, Cell, 2013). These results point to eEF2K inhibition as a potential treatment strategy in cancers. Our current studies aim to investigate the role of AMPK-eEF2K axis in AD and establish its therapeutic relevance.
Objectives: To establish the relevance of eEF2K inhibition as a novel therapeutic strategy in AD.
Methods: APPPS1 mice, 3xTG-AD mice, AD patient brain samples, Primary neuronal cultures, Immunohistochemistry, Protein biochemistry, ELISA, Pharmacological agents, Gene silencing.
Results. eEF2K activity, measured by phospho-eEF2 (Thr56) immnuohistochemistry, is increased in AD patient brains compared with controls. Results from biochemical and immunohistochemical analysis in two AD transgenic mouse models (APPPS1 and 3x-Tg AD) will be presented. In addition, the effects of pharmacological agents and gene silencing approaches targeting AMPK-eEF2K axis on Aβ neurotoxicity in neuronal cultures will also be discussed.
Conclusions. Our data support that eEF2K inhibition represents a highly promising therapeutic target in AD.

MICRO-RNA-29A AS A CANDIDATE BIOMARKER FOR ALZHEIMER'S DISEASE IN CELL-FREE CEREBROSPINAL FLUID

M.M. Verbeek[1], M. Mueller[1], L. Jaekel[1], I.B. Bruinsma[1], J.A. Claassen[2], H.B. Kuiperij[1]
[1]Neurology, Radboud University Medical Centre, Nijmegen, Netherlands
[2]Geriatric Medicine, Radboud University Medical Centre, Nijmegen, Netherlands

Objective: The identification of reliable biomarkers for Alzheimer's disease (AD) remains a major challenge. In recent studies, microRNAs (miRNAs) miR-27a, miR-29a, miR-29b and miR-125b were described to be abnormally expressed in cerebrospinal fluid (CSF) of AD patients. We aimed to investigate if these miRNAs may indeed be confirmed as diagnostic markers. Additionally, we were interested in whether blood contamination, which can occur during lumbar puncture of CSF, affects the levels of these miRNAs in CSF, and if so, how fast this may occur.
Methods: We studied the expression levels of the four miRNAs by quantitative PCR in CSF samples of 18 AD patients, all characterized by NINCDS-ADRDA criteria, and 20 healthy controls. We further investigated the effect of blood contamination on miRNA levels in CSF.
Results: MiR-29a levels were increased in CSF of AD patients compared to controls (p=0.0001), and miR-125b levels were slightly increased in AD patients (p=0.025). Furthermore, miR-27a levels were similar in CSF of AD patients and controls, while miR-29b was not detectable in most samples. Analysis of CSF samples spiked with blood showed that miR-27a and miR-29a, but not miR-125b levels were strongly influenced by the number of blood cells in the sample. In addition, the presence of blood cells in CSF almost immediately affected CSF miRNA levels.
Conclusions: MiR-29a may be a candidate biomarker for AD, but only when used in cell-free CSF. Previous findings of altered CSF levels of miR-29b, miR-125b and miR-27a could not be confirmed.

03m. Pathophysiology & Disease Mechanisms: micro RNAs

ADPD5-1236
MICRORNA EXPRESSION IN ALZHEIMER'S DISEASE
L. Bekris[1], M. Shaw[1], Y. Shao[1], T.J. Montine[1], E.R. Peskind[1], J.B. Leverenz[1]
[1]Genomic Medicine, Cleveland Clinic Lerner Research Institute, Cleveland, USA
MicroRNA (miRNA) play an essential role in post-transcriptional gene regulation in the brain. Genetic variants located across the APOE locus are the strongest risk factors for late-onset AD described to date. A complex regulatory structure exists at the APOE locus that includes putative regulatory sites within the TOMM40 gene. Little is known about the influence of miRNA post-transcriptional regulation at this locus. The aim of this investigation is to demonstrate that miRNA that are predicted to target the APOE locus are expressed differently in brain of AD compared to controls and associated with APOE and TOMM40 brain expression. MiRNA array and miRNA qRT-PCR were used to measure miRNA expression in post-mortem brain from AD (n=21) or cognitively normal age-matched control (n=21) hippocampus (HP) and cerebellum (CB). Quantitative RT-PCR was used to measure APOE and TOMM40 mRNA. Western blots were used to measure brain APOE and TOMM40 protein. Linear regression was used to determine if APOE and TOMM40 mRNA expression correlate with protein or mRNA expression in AD (n=8) compared to cognitively normal age-matched controls (n=8) or in HP compared to CB. MiRNA were identified that were associated with AD or control brain APOE or TOMM40 expression levels. These results suggest that a complex regulatory structure at the APOE locus may be fine-tuned by miRNA post-transcriptional modulation according to brain region or disease status.

MIRNAS AS THERAPEUTIC AGENTS FOR ALZHEIMER'S DISEASE: A PILOT STUDY

S. Parsi[1], C. Goupil[1], P. Smith[1], S. Hébert[1]
[1]Axe Neurosciences, Centre de recherche du CHU de Québec (CHUL), Quebec, Canada

Objectives: miRNAs are small non-protein-coding RNAs involved in the post-transcriptional regulation of gene expression. It is now well established that miRNAs can regulate several genes simultaneously, thus controlling biological or pathological "pathways". In this study, we aimed at identifying one or several miRNAs that could regulate simultaneously Aβ and Tau metabolism, providing a "silver bullet" for AD therapeutics. **Methods:** We used several bioinformatics programs to identify miRNAs that could potentially regulate APP and BACE1 expression as well as Tau phosphorylation. Transfection and luciferase assays were performed in different cell lines to validate these predictions. Candidate miRNA injection in the mouse brain was performed to validate our observations in vivo. APP, Aβ, BACE1, and Tau was analyzed by western blot analysis. The level of introduced miRNA was determined using qRT-PCR. Different brain tissues were used for iTRAQ proteomics analysis. **Results:** We identified various miR-15/107 family members (e.g., miR-16, miR-15a, miR-195) that can directly regulate the expression of APP and BACE1. Over-expression studies in HEK cell expressing APP Swedish mutation led to a strong decrease in Aβ levels. The same experiment in N2A and HT22 lines confirmed the effect of this family specifically on APP and BACE1. In vivo miRNA delivery results was also identified more potential targets of this family in vivo. **Conclusion:** Our data indicate that selected miR-16 family members can potentially function as combined endogenous regulators of Aβ and Tau in the mammalian brain opening a new vista to therapeutic strategies against AD.

[3]Department of Gastroenterology,
School of Medicine Pontificia Universidad Catolica de Chile, Santiago, Chile

Objectives: HDAC2, is implicated in the epigenetic repression in Alzheimer's disease (AD), however the mechanisms involved in HDAC2 regulation are not fully elucidated. Here we demonstrated that c-Abl induces tyrosine phosphorylation of HDAC2 increasing its levels and inducing the repression of synaptic genes expression.
Methods: We used i) in vitro – neurons and HT22 cells exposed to AbetaO, and ii) in vivo- APPswe/PSEN1dE9 mice, AD models. We modulated c-Abl activity by using Imatinib, a c-Abl inhibitor, or by transfection with c-Abl plasmids. Then we measured the activity and protein levels of HDAC2, the recruitment of HDAC2 and the expression of target HDAC2 synaptic genes by ChIP and RT-PCR, respectively.
Results: Our data demonstrate that: i) in neurons, c-Abl inhibition with Imatinib prevents the AbetaO-induced increase in HDAC2 levels, ii) c-Abl knockdown decreases HDAC2 levels, while c-Abl overexpression increases it,, iii) c-Abl inhibition reduces HDAC2-dependent repression activity and HDAC2 recruitment to the promoter of several synaptic genes, increasing their expression, iv) c-Abl induces tyrosine phosphorylation of HDAC2, a novel previously unknown posttranslational modification, affecting both its stability and repression activity and v) treatment with Imatinib decreases HDAC2 levels in a transgenic mice model of AD.
Discussion: Our results support the participation of the c-Abl/HDAC2 signaling pathway in the epigenetic blockade of gene expression in AD pathology.
Support: Fondecyt 1120512, FONDEF D10I1077 and CARE-Chile-UC (PFB 12/2007). Gonzalez Z.M. acknowledges CONICYT

CDK5 INHIBITION AND ITS NOVEL FUNCTION IN NEURONAL DEVELOPMENT AND TREATMENT OF NEURODEGENERATION

N. Taub[1], D. Havas[1], B. Hutter-Paier[1], R. Wronski[1]
[1]Neuropharmacology, QPS Austria GmbH, Grambach, Austria

Objectives

Cyclin-dependent kinase 5 (Cdk5) is a multifaceted serine/threonine kinase protein playing an essential role in neuronal development. Cdk5 activity regulates such pivotal cellular processes as neuronal migration, neurogenesis, synaptic plasticity, behavior, cognition or dendritic outgrowth. The aberrant activation of Cdk5 results in hyperphosphorylation of its various substrates, like Amyloid Precursor Protein, Tau protein and neurofilaments and subsequently to neuronal death. Dysfunction of Cdk5 is associated with diverse neurological disorders including Alzheimer's disease or amyotrophic lateral sclerosis. Thus, we were interested if Dinaciclib, a novel Cdk5 inhibitor succesfully used as therapeutic agent in advanced malignancies, is able to promote neurite outgrowth and neurogenesis in primary rat hippocampal neurons.

Methods

For this purpose, primary embryonic rat hippocampal neurons were treated with Dinaciclib for 48 h on DIV1. Subsequently, number of neurites, total length of neurites and length of the longest neurite were determined. To address the effects of Dinaciclib on neurogenesis, we determined the percentage of BrdU-NeuN double-positive cells within the total number of primary rat hippocampal neurons. For these analyses, a software supported automatic quantification method was generated (Axio.Imager Z1 microscope, ImageProPlus).

Results

Dinaciclib did not affect neurogenesis. However, for the first time, beneficial effects of the novel Cdk5 inhibitor Dinaciclib on neurite outgrowth of primary rat hippocampal neurons were shown.

Conclusions

Our data indicate inhibition of Cdk5 activity to be a promising strategy to treat neurodegenerative diseases by promoting neurite outgrowth. Furthermore, these data identify Dinaciclib as a promising new drug candidate in neurodegenerative diseases.

ADPD5-1368

TRUNCATION AND ACTIVATION OF DYRK1A BY CALPAIN I: A MOLECULAR MECHANISM LINKED TO TAU PATHOLOGY IN ALZHEIMER'S DISEASE

F. Liu[1], N. Jin[1], K. Iqbal[2], C.X. Cong[2]
[1]Jiangsu Key Laboratory of Neuroregeneration, Nantong University, Nantong, China
[2]Department of Neurochemistry,
New York State Institute for Basic Research in Developmental Disabilities, Staten Island, USA

Objectives: Abnormal hyperphosphorylation of tau and imbalanced expression of 3R-tau and 4R-tau are pivotally involved in the pathogenesis of Alzheimer's disease (AD) and other tauopathies. Dual-specificity tyrosine-phosphorylation-regulated kinase 1A (Dyrk1A) regulates alternative splicing of exon 10 and phosphorylation of tau. Overexpression of Dyrk1A contributes to tau pathology *via* suppression of exon 10 inclusion and hyperphosphorylation of tau in Down syndrome. However, the role of Dyrk1A in tau pathology in AD is not understood.
Methods. We employed *in vitro* proteolysis, enzyme kinetic analysis, *in vitro* kinase activity assay, and *in vivo* excitotoxicity mouse model to study the role Dyrk1A in tau pathology in AD.
Results. We found that truncation of Dyrk1A was increased and correlated with over-activation of calpain I as well as with an increase in the ratio of 3R-tau/4R-tau and hyperphosphorylation of tau in AD brain. Calpain I truncated Dyrk1A at its C-terminal *in vitro* and enhanced its kinase activity towards tau as seen by an increase in *Vmax*, but not *Km.* C-terminally truncated Dyrk1A was stronger than the full-length protein in leading to promotion of exon 10 exclusion and hyperphosphorylation of tau. Excitotoxicity induced by kainic acid (KA) caused Dyrk1A truncation, which coincided with an increase in 3R-tau expression and Thr212 phosphorylation of tau in mouse brains. Inhibition of calpain prevented these KA-induced changes.
Conclusions. Truncation and activation of Dyrk1A by Ca^{2+}/calpain I could be responsible for the increase in the ratio of 3R-tau/4R-tau through dysregulation of exon 10 splicing and the hyperphosphorylation of tau in AD brains.

[1]Biochemistry, Federal University of Rio Grande do Sul, Porto Alegre, Brazil

[2]Pharmacy, Federal University of Rio Grande do Sul, Porto Alegre, Brazil

Increasing evidence demonstrates that β-amyloid (Aβ) is toxic to synapses, resulting in the progressive dismantling of neuronal circuits. Counteract the synaptotoxic effects of Aβ could be particularly relevant for providing effective treatments for Alzheimer's disease (AD). Several studies have been shown that curcumin is associated with anti-amyloidogenic properties. Here we developed curcumin-loaded lipid-core nanocapsules (Cur-LNC) in an attempt to improve the bioavailability and the neuroprotective effect of this polyphenol. Organotypic hippocampal slice cultures exposed to Aβ1-42 were used to study the neuroprotective effects of curcumin through a spectral analysis of multi-electrode array (MEA) recordings of spontaneous neuronal activity. Whereas, in the in vivo experiments the animals received a single intracerebroventricular injection of Aβ1-42 and they were administered either free curcumin or Cur-LNC intraperitoneally for 10 days. The analysis of MEA recordings of spontaneous neuronal activity *in vitro* showed an attenuation of signal propagation induced by Aβ before cell death and curcumin-induced alterations to local field potential (LFP) phase coherence. Curcumin-mediated attenuation of Aβ-induced synaptic dysfunction involved regulation of synaptic proteins, namely phospho-CaMKII. Our findings also demonstrated that administration of curcumin was effective in preventing behavioral impairments and Akt/GSK-3β signaling pathway disturbances triggered by Aβ *in vivo*, and Cur-LNC in a dose 20-fold lower presented similar neuroprotective results compared to the effective dose of free curcumin. Considered overall, our data suggest that curcumin is a potential therapeutic agent for neurocognition and its nanoencapsulation in LNC might constitute a promising therapeutic alternative in the treatment of neurodegenerative diseases such as AD.

The J. David Gladstone Institutes University of California San Francisco, San Francisco, USA
[2]Neurological Disease, The J. David Gladstone Institutes, San Francisco, USA
[3]Departments of Neurosciences and Pathology, University of California San Diego, San Diego, USA

Objectives. We aim to determine the mechanisms that cause excessive neuronal DNA double strand breaks (DSBs) in Alzheimer's disease (AD) and the potential impact of these DSBs on cognitive functions. Physiological increases in neuronal activity increase neuronal DSBs in multiple brain regions, but these DSBs are rapidly repaired in wildtype mice [Nat. Neurosci. 16: 616–621 (2013)]. Human amyloid precursor protein (hAPP) transgenic mice, which simulate key aspects of AD have increased neuronal DSBs at baseline and delayed DNA repair.
Methods. We used immunohistochemical staining of brain sections from humans and mice to detect DSBs, comet assay to quantitate DNA fragmentation, western blot analysis to quantitate DNA repair factors, and behavioral tests to assess learning and memory. We used stereotactic injections of lentiviral vectors encoding shRNA to reduce neuronal expression of DNA repair factors in mouse brains. Scrambled shRNA served as a negative control.
Results. Humans with AD had a greater number of neurons with DSBs than non-demented controls. We are now comparing levels of neuronal DSBs across brain regions, at different stages of AD, and in other dementias. Compared with controls, AD patients and hAPP-J20 mice also had decreased hippocampal levels of the DNA repair factor BRCA1, but not of several other repair factors. Knocking down BRCA1 caused accumulation of neuronal DSBs in the dentate gyrus and learning and memory deficits in wildtype mice without causing neuronal apoptosis.
Conclusions. Impairments in DNA repair and abnormal persistence of DSBs may contribute to cognitive impairments in AD and related conditions.

Objectives: Aging, type 2 diabetes (T2D) and female gender are known risk factors for Alzheimer's disease (AD), but the underlying molecular mechanisms remain unclear. We hypothesized that gender affects insulin/IGF-1/estrogen-mediated signaling in T2D brain. We evaluated how gender may influence insulin/IGF-1/estrogen-related signaling and AD-like hallmarks in T2D rat brains.
Methods: We used brain cortical homogenates from middle-aged (8-month-old) male and female Wistar and T2D Goto-Kakizaki (GK) rats to evaluate insulin, IGF-1, cholesterol, sexual steroid hormones and amyloid-beta levels by ELISA, and density of signaling molecules by immunoblotting.
Results: Although male and female GK rats had higher glycemia than gender-matched controls, no significant changes occurred between genders. Despite the increased plasma estradiol levels in Wistar females than in males, its levels were similar between T2D females and males. T2D females had impaired brain steroid hormones' metabolism, lower IGF-1 levels and IGF-1 receptor density, whilst their blood and brain insulin levels and insulin receptor densities were increased. Therefore, a compensatory mechanism to maintain insulin receptor function and subsequently stimulating Akt activity may occur in GK females, thereby inhibiting BACE activity, and ultimately blunting brain amyloid-beta$_{1-42}$ accumulation and lipid and DNA oxidation.
Conclusions: Although brain steroid hormone cascade might be impaired in middle-aged T2D females, these appeared to be less vulnerable to oxidative stress and AD-like neuropathological markers associated to chronic T2D.

ADPD5-1294
THE ROLE OF NMDA-DEPENDENT ERK SIGNALING IN AMYLOID-BETA REGULATION

J. Hettinger[1], *J. Cirrito*[1]
[1]*Neurology, Washington University, St. Louis, USA*

Objectives: The concentration-dependent accumulation of the peptide amyloid-beta (Abeta) as oligomers and plaques is thought to be a key event in Alzheimer's disease (AD) pathogenesis. Previously, our lab utilized *in vivo* microdialysis to find that high doses of *N*-methyl-D-aspartic acid (NMDA) result in reduced Abeta levels in the interstitial fluid (ISF) of wild-type mice and a mouse model of AD. We have shown that this NMDA-mediated decrease acts through the activation of extracellular-regulated kinase (ERK). Certain other receptors that activate ERK do not show this effect on Abeta, suggesting that NMDA-Rs act on ERK and Abeta through a selective pathway. The ERK subfamily includes two isoforms, ERK1 and ERK2, which are both ubiquitously expressed. Traditionally thought to have identical roles, recent findings have revealed distinct isoform functions. It is the objective of this study to determine if ERK isoforms have differential effects on Abeta production.
Methods: We will use shRNA against ERK1 and ERK2 packaged in AAV8 to knockdown expression in APP/PS1$^{+/-}$ mice. We will then use microdialysis to measure changes in ISF Abeta levels in the hippocampus in response to 40 microM NMDA treatment.
Results: We expect to find an ERK isoform-specific response to NMDA such that ERK1 but not ERK2 blocks the effect of NMDA treatment on Abeta production.
Conclusions: Given that ERK signaling is involved in widespread cellular processes, the ability to selectively target a single ERK isoform as a means to reduce Abeta generation could present a novel therapeutic option.

POSSIBLE ROLE OF STORE-OPERATED CALCIUM CHANNELS IN MEMORY LOSS CONNECTED WITH FAMILIAL ALZHEIMER'S DISEASE

M. Ryazantseva[1], A. Goncharova[2], K. Skobeleva[1], N. Kamyshev[2], E. Kaznacheyeva[1]
[1]Institute of Cytology RAS, Russian Academy of Science, St. Petersburg, Russia
[2]Pavlov Institute of Physiology RAS, Russian Academy of Science, St. Petersburg, Russia

Familial Alzheimer's disease (FAD) which leads to memory impairments is caused by mutations in presenilin-1 (PS1) gene in approximately 40% of cases. PS1 is well known as a component of the gamma-secretase enzyme which cleaves APP to A-beta. To become a catalytic part of enzyme PS1 undergoes an endoproteolysis. It was shown that mutations in PS1 gene disrupt the endoproteolysis increasing uncleaved protein level in brain tissue of FAD patients. In our study we found effects of FAD PS1 mutants (PS1DE9, PS1 D247A) on activity of store-operated calcium (SOC) channels in mice hippocampal neurons and Neuro2a cell line. Increased uncleaved PS1 levels led to SOC channels hyperactivity detected with direct single-cell electrophysiological measurements and calcium imaging experiments with fura2-AM. The effects were caused by an impaired signal transduction from endoplasmic reticulum to SOC channels in plasmatic membrane. The impaired intracellular signal transduction by STIM1 sensor was revealed in live confocal imaging experiments and proved with STIM1 knock-down. Moreover, Drosophila melanogaster transgenes expressing human mutated PS1 in cholinergic nervous system feeding with pharmacological inhibitor of STIM1 sensor signal transduction 2APB led to rescue of the memory loss detected by courtship based assay with aged animals. Therefore hyperactive STIM1 signal transduction leads to increased SOC channels activity which could be the reason for memory loss in FAD.

P53 IN NEURODEGENERATION: IMPACT OF BETA-AMYLOID/P53 INTERFERENCE ON ALZHEIMER PATHOGENESIS

M. Serafini[1], A. Pinto[1], M. Racchi[1], D. Necchi[1], C. Lanni[1]
[1]Dept of Drug Sciences, University of Pavia, Pavia, Italy

Objectives: Zyxin and HIPK2 are proteins contributing to the activation of p53-regulated pathways. Zyxin is essential to maintain HIPK2 protein expression through interference with Siah-1 function. We described a link between zyxin-HIPK2-p53 signalling pathway and Alzheimer's disease (AD), finding that soluble beta-amyloid (Aβ) peptides modulate zyxin protein levels, fundamental in maintaining HIPK2 stability and in turn p53 wild-type conformation. The consequence is the loss of p53 transcriptional activity and failure to activate the proper apoptotic program when cells are exposed to *noxae*. Our aim is to describe the mechanisms of zyxin and HIPK2 regulation in presence of Aβ and its relationship to the correct control of cellular damage.
Methods: We examined the molecular mechanisms underlying zyxin and HIPK2 regulation in SH-SY5Y neuroblastoma cells and their counterpart stably transfected with wild-type APP751.
Results: We demonstrated that Aβ negatively modulates zyxin expression in protecting HIPK2 from Siah-1-mediated degradation, thus influencing the responsiveness to DNA-damaging agents. We further studied the alteration of cell death pathways induced by conformationally altered p53, mainly focusing on the regulation of autophagy. We investigated whether the loss of wild-type p53 conformation induced by Aβ could "free" mTOR, thus inducing abnormalities, which could contribute to system dysfunction.
Conclusions: These results may help to understand the pathogenesis of AD, through the dissection of events related to Aβ activities, shedding light on early events of AD pathogenesis related to an increase in the normal levels of Aβ and consequences related to disruption of the control of cell death via p53-dependent pathways.

[6]Neurology, University of Minnesota, Minneapolis, USA

Objectives:

Although numerous neurodegenerative disorders including Alzheimer's disease (AD) and Parkinson's disease are characterized and neuropathologically defined by the presence of fibrillar protein aggregates, sustained evidence supports the concept that soluble, non-fibrillar forms of the amyloid proteins constituting these lesions might be the primary bioactive deleterious agents in these brain disorders. As such in AD, endogenous oligomeric forms of the amyloid-beta (oAβ) peptides appear to exist under various molecular arrangements, which include putative dimers, trimers and larger assemblies such as Aβ*56, and to differentially accumulate within the preclinical to clinical spectrum. Despite considerable efforts, little is known about the molecular signaling pathways induced by these soluble species thereby limiting our understanding of their role in the pathophysiology of AD.

Methods:

To address how Aβ*56 alters neuronal function, we combined biochemical, imaging and functional analyses of human tissue, transgenic mice modeling AD and mouse primary cultured neurons.

Results:

Coimmunoprecipitation approaches indicated that Aβ*56 forms a complex with NMDA receptors (NMDAR) in human and mouse tissue. Signaling pathway analyses revealed an aberrant activation of the Ca^{2+}-dependent calmodulin kinase CaMKIIα, triggered by a sublethal enhanced NMDAR-mediated Ca^{2+} influx. The observed CaMKIIα hyperactivity induced abnormal changes in tau *in vivo* and *in vitro*, consisting of selective hyperphosphorylation and missorting. Importantly, other forms of endogenous Aβ oligomers did not lead to similar changes.

Conclusions:

Our results demonstrate that distinct endogenous Aβ oligomers activate neuronal signaling pathways converging onto tau in a highly selective manner and support the notion of an abnormal excitatory neurotransmission observed in AD.

REGIONAL VARIATIONS IN THE EXPRESSION OF CAPILLARY LRP, RAGE AND P-GP IN NORMATIVE AND ALZHEIMER BRAINS.

B. Jeynes[1], *J. Provias*[2]
[1]*Health Sciences, Brock University, St. Catharines, Canada*
[2]*Pathology, McMaster University University, Hamilton, Canada*

Senile plaques (SPs) accumulate pathogenic levels beta-amyloid (A-beta) in Alzheimer (AD) brains. This accumulation is facilitated by diminished efflux of A-beta by LRP, and / or enhanced influx of A-beta by RAGE, and / or diminished efflux of A-beta by P-gp. **Objectives**. In this study we investigated the expression of capillary LRP, RAGE and P-gp in brain samples of Alzheimer [AD] and normative brains [NM]. **Methods.** Superior temporal [ST] cortex, hippocampal [HC] and brain stem [BS] samples from 15 Alzheimer and 15 normative brains were selected from comparable sites. LRP, RAGE and P-gp positive capillaries and $Abeta_{42}$ plaques [SP] were quantified and statistical analysis of the non-parametric data was performed using the Mann-Whitney and Kruskal-Wallis tests. **Results.** In the ST, capillary expression of RAGE was greater in the AD condition ($p < .01$). For P-gp capillary expression there were no significant differences between the NM and AD conditions for any paired comparable sites. In the AD superior temporal cortex there was a positive correlation between the capillary expression of both LRP and RAGE with the presence of A-beta $_{42}$ senile plaques; but a negative correlation between P-gp expression and the presence of A-beta $_{42}$ senile plaques. **Conclusions.** These results indicate that regional variations in capillary LRP, RAGE and P-gp expression likely account for site-specific variations in SP lesion pathogenesis.

INTER-SITE VARIATIONS IN THE EXPRESSION OF CAPILLARY ENOS IN ALZHEIMERS BRAINS

J. Provias[1], B. Jeynes[2]
[1]pathology, Neuropathology, Mcmaster University, hamilton, Canada
[2]applied health sciences, brock university, St catherines, Canada

Fifteen Alzheimer [AD] and fifteen normative [NM] age-matched autopsy brains were examined within superior temporal cortex [ST] and brainstem [BS] samples. Endothelial nitric oxide synthase [eNOS] positive capillaries and β-amyloid $_{42}$ senile plaques were quantified in each site and in both conditions. The data was statistically analyzed using Mann-Whitney, Kruskal–Wallis and non-parametric Spearman's test.There was no significant difference in the expression of capillary eNOS between the AD and NM conditions in comparable sites. However, there was a significant difference in eNOS expression between superior temporal cortex and brainstem sites in both conditions [NM-p<.004; AD-p<.001].In both conditions the superior temporal cortex values were greater than those in the brainstem. In the NM superior temporal condition there was a positive correlation between eNOS expression and β_{42} senile plaque burden [<0.05]. In the AD superior temporal condition there was a negative correlation between eNOS expression and β_{42} senile plaque burden [<0.01].There were no significant correlations in either of the other two sites in either condition. The correlative results support the view that diminished capillary eNOS expression contributes to superior temporal cortex senile plaque pathogenesis. The inter-site comparative results demonstrate that capillary eNOS expression varies between sites in the brain, but not necessarily between NM and AD conditions. This inter-site variation in eNOS expression requires further study.

Military personals are often exposed to heat stress (HS) during combat operations in Middle East together with sand particles. HS induces breakdown of the blood-brain barrier (BBB) that is further aggravated by by SiO2 nanoparticles (SiO2 NPs) indicating more vulnerability of soldiers to development of Alzheimer's Disease (AD). This hypothesis was examined in a rat model of ameloid-beta peptide infusion (AbP 1-40, 250 ng/10 µl, i.c.v. daily) for 4 weeks.

Rats exposed to 1 h HS at 34°C in a biological oxygen demand (BOD) incubator for 30 days and also administered SiO2 NPs (50 mg/kg, i.p.) simultaneously. Control rats were kept at room temperature. After 30 days, AbP deposits in the brain and neuronal, glial or myelin pathology was examined.

AbP deposits within the cortex and hippocampus was 3- to 4-fold high in HS rats that further aggravated by 4 to 8 fold by SiO2 NPs treatment. Breakdown of the BBB to albumin, activation of astrocytes, myelin damage and neuronal injuries were also increased by 4 to 6 fold in HS and 6 to 10 fold in SiO2 NPs treated rats after AbP infusion. Cerebrolsyin (5 ml/kg, i.v. /day) treatment attenuated AD pathology in heat stressed rats intoxicated with SiO2 NPs, whereas only 2.5 ml/kg Cerebrolsyin is effective in control AD rats. This indicates for the first time that AD pathology depends on environmental factors and cerebrolysin is very effective in reducing AD pathology complicated with HS and SiO2 NPs.

[5]Department of Neuropathology, Heinrich Heine University, Duesseldorf, Germany

The neurovascular hypothesis of Alzheimer's disease (AD) states that amyloid-beta accumulation is caused by impairment of low density lipoprotein receptor-related protein-1 (LRP1) at the blood-brain barrier (BBB). LRP1 is discussed to be the major brain-to-blood transporter of amyloid-beta. However, there are still controversies about the relevance of the BBB in AD pathology and LRP1's contribution in amyloid clearance due to embryonic lethality of global LRP1 knockout, and hence the lack of LRP1 knockout models.

Using a brain endothelial specific Cre-expressing mouse line, we generated a novel LRP1 knockout model to study LRP1-mediated amyloid-beta transport across the BBB. Here, we present a novel conditional brain endothelial-specific LRP1 knockout mouse to evaluate the neurovascular hypothesis. For the first time in an *in vivo* model, we can calculate the relevance of LRP1-mediated amyloid clearance across the BBB and distinguish from LRP1-mediated degradation within the brain. We show that deletion of LRP1 in murine brain capillaries strongly reduces amyloid-beta brain efflux. Furthermore, we demonstrate that major amounts of injected radiolabeled amyloid-beta are cleared via endothelial LRP1 across the BBB. In an AD mouse model, brain endothelial-specific knockout of LRP1 results in reduced plasma amyloid-beta, elevated brain amyloid-beta, vascular pathology, and memory deficits emphasizing the importance of systemic amyloid elimination via the BBB.

The collective data underline the important role of the BBB in AD pathology. The new knockout mouse provides a powerful instrument for investigating the functions of LRP1 at the BBB and will help to further clarify LRP1's relevance in health and disease

Objectives

Alzheimer's disease (AD) is the most common form of dementia, posing a serious public health problem in worldwide. A central and peripheral inflammatory process is characterized in AD and is the subject of a debate on its beneficial or deleterious effects. Many data revealed the microglial senescence and suggested that a central distress could be support by peripheral blood mononuclear cells (PBMCs) going through the blood-brain barrier (BBB). At the molecular level, everything remains to be discovered. The objective of this study was to investigate the expression of some chemokines already known for their roles in the pathophysiology of AD in an *in vitro* human BBB model.

Methods

Two human cell lines constitute our BBB model: a human neuroglioma cell line **H4** from ATCC® and a human endothelial cell line **hCMEC/D3** from MTA with Inserm (PO Couraud, Institut Cochin, France). The study covers a total of 16 AD patients (MMSE between 10 to 25) by adding their PBMCs on BBB model. Chemokine levels were performed by using X MAP® Luminex assay after or not induction of amyloid stress with $Abeta_{1-42}$.

Results

We demonstrated that, regardless of amyloid stress, some chemokine expressions increased, certain strongly in endothelial cells. In contrast, others decreased in PBMCs, emphasizing negative environmental regulation of the BBB on PBMCs.

Conclusion

With this integrated human BBB model, we demonstrated the role of PBMCs from AD patients on the chemotactic environment at the BBB. The central origin of AD could be reviewed.

[3]Biopathologie cellulaire et tissulaire des tumeurs, CHU, Montpellier, France

Clinical evidence suggests a role of cerebrovascular damage in the progression of Alzheimer's disease (AD). However, the causality between amyloid depositions and cerebrovascular dysfunction is uncertain. We have used a genetic mouse model of AD (5xFAD), previously demonstrated to reproduce hallmarks of the human pathology, to define: i) age-dependent cerebrovascular permeability and regional vessel distribution; ii) modification of blood-brain barrier cells, including pericytes; iii) topographical correlation between amyloid deposition and cerebrovascular dysfunction; iv) pro-inflammatory changes.

Fluorescent micro-angiography was performed on aging 5xFAD mice using FITC-Albumin. Confocal vessel reconstruction was performed with thioflavin-S or 6E10 staining to determine plaque-vessel topography. Pericytes were stained using PDGFRβ while GFAP and Iba-1 were used to assess inflammation. Distribution of vessel number, branching and length was performed using ImageJ. A parallel evaluation of human AD brains is being performed to validate clinical relevance of the experimental findings.

Blood-brain barrier dysfunction was observed in the hippocampus and cortices of 5xFAD mice. Changes included decreased microvessel number, shortening of vascular branches, irregular FITC-Albumin perfusion and albumin parenchymal leakages. PDGFRβ pericytes were redistributed towards the BBB interface, including a reactive increase of cell ramifications. Vascular and parenchymal amyloid depositions colocalized with BBB pathological changes and pericytes reactivity. Regional inflammatory GFAP/IBA1 activation was associated with vascular abnormalities.

Our results point to a multi-cellular contribution to AD. The pathological cerebrovascular changes observed reproduce clinical findings, supporting investigation at pre-AD stages. The latter is being performed to untangle the exact timing between cerebrovascular dysfunction and the progression of AD.

Objectives: Transthyretin (TTR) is the major A-beta (Ab) binding protein in the cerebrospinal fluid (CSF), rescuing the peptide, inhibiting its aggregation and toxicity. In vivo, TTR stabilization by iododiflunisal decreased brain Ab deposition and improved cognitive function. Ab levels were reduced in plasma and tending for reduction in the CSF, suggesting TTR promoted Ab clearance from the brain and periphery. This project aimed at investigating the influence of TTR in Ab transport across the blood- brain barrier (BBB), using a cellular model – human cerebral microvascular endothelial cells (hCMEC/D3).
Methods: We performed internalization and efflux assays of labelled (FAM-Ab-1-42) and non-labelled (Ab-1-42) Ab in the presence and absence of TTR. We also performed intracranial injections of FAM-Ab-1-42 in mice carrying one copy of TTR gene ($TTR^{+/-}$) and animals without TTR ($TTR^{-/-}$). Measurements of Ab concentrations were done by fluorometric analysis or by ELISA.
Results: Fluorometric measurements of FAM-Ab-1-42 in cell lysates indicated TTR increased FAM-Ab-1-42 internalization by hCMEC/D3 cells. In addition, permeability studies using hCMEC/D3 monolayers established in transwells filters, showed that only TTR added to the basolateral (brain) chamber was able to promote Ab efflux (added to the brain side), comparing to TTR added to the apical (blood) side. Our preliminary *in vivo* study demonstrated that, 30 minutes post injection, brains from $TTR^{+/-}$ mice retained less peptide than $TTR^{-/-}$ animals, indicating TTR favored Ab clearance from the brain.
Conclusions: TTR increases Ab internalization and transport across the BBB model, further supporting a role for TTR in Ab brain efflux.

ADPD5-0997

THE RELATIVE CONTRIBUTIONS OF DEGRADATION AND BRAIN-TO-BLOOD ELIMINATION TO CEREBRAL CLEARANCE OF HUMAN AMYLOID-BETA PEPTIDE(1-40) IN MOUSE BRAIN

S. Ito[1], S. Ohtsuki[1], K. Matsumiya[2], S. Murata[2], Y. Katsukura[2], J. Kamiie[3], T. Terasaki[2]
[1]Pharmaceutical Microbiology, Kumamoto University, Kumamoto, Japan
[2]Membrane Transport and Drug Targeting, Tohoku University, Sendai, Japan
[3]Veterinary Pathology, Azabu University, Sagamihara, Japan

Cerebral clearance of soluble amyloid-β peptide (Aβ) involves both degradation in the brain and elimination across the blood-brain barrier (BBB). The relative contributions of these processes are poorly understood. The purpose of the present study was to estimate the relative contributions of degradation and elimination processes to the clearance of microinjected human amyloid-b peptide (hAβ(1-40)) from mouse cerebral cortex using a newly developed UPLC/MS/MS quantitation method for intact hAβ(1-40) and a radiolabeled hAβ(1-40). The clearance rate constant of intact hAβ(1-40) in mouse cerebral cortex was determined to be 3.21×10^{-2} min^{-1} under conditions where saturable process in elimination across the BBB was expected to be saturated. Thus, this clearance rate constant should mainly reflect degradation. The [^{125}I]hAβ(1-40) elimination rate across the BBB under nonsaturating conditions was determined to be 1.48×10^{-2} min^{-1}. Inhibition studies suggested that processes sensitive to insulin and phosphoramidon, which inhibit known Aβ degrading enzymes such as neprilysin and insulin-degrading enzyme (IDE), are involved not only in degradation, but also in elimination of hAβ(1-40). Internalization of [^{125}I]hAβ(1-40) into cultured mouse brain capillary endothelial cells (TM-BBB4) was significantly inhibited by either insulin and IDE inhibitors, but was not inhibited by phosphoramidon. The internalization of [^{125}I]hAβ(1-40) by TM-BBB4 cells was reduced by IDE-targeted siRNAs. In conclusion, our results suggest dominant contribution of degradation to cerebral hAβ(1-40) clearance, and that elimination of hAβ(1-40) from mouse brain across the BBB involves an insulin-sensitive process, mediated by IDE expressed in brain capillary endothelial cells.

PLASMA LEVELS OF BETA-AMYLOID 1-42 ARE ASSOCIATED WITH EXTENT OF SLEEP FRAGMENTATION IN PSYCHIATRISTS ON-CALL

T. Grimmer[1], T. Laub[1], A. Hapfelmeier[2], T. Eisele[1], H. Förstl[1], P. Alexopoulos[1]
[1]Psychiatry and Psychotherapy,
Klinikum rechts der Isar der Technischen Universität München, Munich, Germany
[2]Medical Statistics and Epidemiology,
Klinikum rechts der Isar der Technischen Universität München, Munich, Germany

Objectives: From mice there is evidence that the might be an association between sleep deprivation and plasma amyloid levels. In healthy subjects sleep fragmentation and low sleep efficiency are associated with impaired cognitive function, and impaired sleep quality predicts cognitive decline. Doctors with on-call duty represent shift working with utmost socioeconomic importance.
Hence, we examined whether plasma amyloid levels are associated with sleep duration or sleep fragmentation in Psychiatrists on-call.
Methods: Psychiatrists of Klinikum rechts der Isar, Technische Universität München, Munich, Gemany, underwent a venous blood draw at up to 8 consecutively nights with on-call duty at the beginning and at the end of their shift, respectively. Plasma beta amyloid 1-42 (Aβ42) concentrations were measured in quadruplicate with a commercially available ELISA.
Results: The generalized linear model solely including relative reduction of Aβ42 revealed a statistically significant reduction of Aβ42 over night (estimate 0.107, $p < 0.001$). The model with the outcome variable relative reduction of Aβ42 revealed for the variable number of sleep interruptions < 15 minutes a significant estimate of -0.037 ($p=0.001$), all other variables (inter alia sleep duration and total time of demand) were non-significant. This means that there is a significant decrease of the relative reduction of Aβ42 of 3.7% for every sleep interruption < 15 minutes.
Conclusions: The fact that reduction of plasma Aβ42 levels during night is decreased by the extent of sleep fragmentation raises the question whether on-call duty might be associated with an altered risk of developing Alzheimer's disease.

[3]Nuclear Medicine, Mayo Clinic, Rochester, USA

[4]Health Informatics, Mayo Clinic, Rochester, USA

Impaired brain clearance of amyloid beta (Abeta) peptides and perturbed brain insulin levels are closely associated with Alzheimer's disease (AD). Endowed with sophisticated cellular trafficking machinery and large interaction surface between blood and brain compartments, the blood brain barrier (BBB) effectively clears Abeta from the brain and serves as a major conduit for insulin delivery to the brain. Studies conducted in BBB cell culture models in vitro have shown that normal insulin signaling is necessary for receptor mediated insulin transport at the BBB. We observed that the insulin permeability at the BBB was significantly lower in AD transgenic mice (APP,PS1) compared to the age-matched wild type (WT) mice. Moreover, Abeta40 or Abeta42 exposure inhibited the uptake and permeability of insulin at the BBB to the levels observed in APP,PS1 mice . On the other hand, insulin altered the plasma membrane distribution of putative amyloid receptors such as LRP1 and RAGE; regulated vesicular trafficking machinery within the endothelial cell; and impacted BBB trafficking of Abeta40 and Abeta42. Following intravenous (IV) administration, insulin triggered differential trafficking of Abeta peptides at the BBB; the blood-to-brain permeability of Abeta40 was increased, whereas the Abeta42 permeability was decreased. Alternatively, the brain-to-blood efflux of both Abeta40 or Abeta42 was increased upon IV insulin administration. Hence, impaired insulin signaling, as observed in AD, could alter Abeta40:42 ratios and increase brain Abeta burden. The augmented Abeta levels could adversely affect brain energy metabolism, synaptic plasticity, memory and cognition.

AIMS: The role of choroid plexus in Alzheimer´s disease (AD) is being increasingly recognized. Recent studies suggest that the choroid plexus has a more important role in physiological and pathological brain functions than previously appreciated.
METHODS: To obtain additional insight on choroid plexus function, we performed a proteomic analysis of choroid plexus samples from AD stages I-II (n = 16), III–IV (n = 16), and V–VI (n = 11), and 7 age-matched control subjects. We used differential 2D electrophoresis (2-D DIGE) coupled with mass spectrometry to generate a complete picture of changes in choroid plexus protein expression occurring in AD patients.
RESULTS: We identified 6 proteins which are significantly regulated in AD pathology, with central physiological functions including mitochondrial dysfunction and apoptosis regulation: 14-3-3 b/a, 14-3-3 e, moesin, proteasome activator complex subunit 1 (PSME1), annexin V, and aldehyde dehydrogenase (ALDH).
CONCLUSSION: The data presented here offer additional significance to the emerging importance of molecular and functional changes of choroid plexus function in the development of AD pathology.

HYPERTENSION INDUCED VASCULAR REMODELING AND INCREASED SUSCEPTIBILITY TO STROKE IN MOUSE MODEL OF CEREBRAL AMYLOIDOSIS

V. Vasilevko[1], G. Passos[1], K. Kilday[1], D. Gillen[1], D. Cribbs[1]
[1]Institute for Memory Impairments and Neurological Disorders, University of California Irvine, Irvine, USA

Objectives: There is an increasing recognition that dysfunction in the cerebral vasculature can play a significant role in dementia, including AD where approximately 80-95% of the cases have cerebral vascular pathology The deposition of amyloid-beta peptides in the cerebral vasculature, known as cerebral amyloid angiopathy (CAA), is an important risk factor of intacerebral hemorrhage (ICH), and blood pressure controlling may significantly reduced the risk of CAA-related ICH. This study was designed to determine the effect of experimental hypertension on cerebral and cerebrovascular pathology in mouse model of amyloidosis.

Methods: This study aims to determine the effect of hypertension on Alzheimer's related pathology using an APP/Tg mouse model. Tg2576 mice and non-transgenic (nonTg) littermates were treated with an angiontensin II (AngII) infusion with ALZET Osmotic pumps (1000 ng/kg/min) and L-NAME (100 mg/kg/day) in drinking water to produce chronic hypertension. One week later, transient acute hypertension was induced by AngII injections (0.5 mg/g, twice daily). After appearance of stroke symptoms mice were analyzed for the AD related cerebral and vascular pathology.

Results: A similar increase in systolic blood pressure was observed in both Tg2576 and nonTg mice, however, compared with nonTg mice, Tg2576 mice developed signs of ICH with a markedly shorter latency. In addition, there was as an increase in inflammatory markers, CAA, and vascular remodeling factors pro-MMP-9 and p-selectin, which may explain increase in number and size of spontaneous microhemorrhages in hypertensive Tg2576 mice.

Conclusions: Hypertension, while been pharmacologically manageable, exacerbates Alzheimer's related pathology and vascular remodeling, leading to ICH.

PROTECTIVE MECHANISMS OF P66SHC DELETION IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

R. Derungs[1], C. Späni[1], F. Wirth[1], T. Welt[1], C. Hock[1], G.G. Camici[2], A. Eckert[3], R.M. Nitsch[1], L. Kulic[1]
[1]Division of Psychiatry Research, University of Zurich, Schlieren, Switzerland
[2]Institute of Physiology, University of Zurich, Schlieren, Switzerland
[3]Neurobiology Laboratory For Brain Aging and Mental Health, Psychiatric University Clinics Basel, Basel, Switzerland

Objectives

According to the “vascular hypothesis”, age- and cerebrovascular-related risk factors play a critical role in AD pathogenesis, leading to early vascular dysregulation, which is considered to precede significant Abeta-plaque deposition, cognitive decline and onset of neurodegenerative changes. The mitochondrial adaptor protein $p66^{Shc}$ is involved in ageing/longevity and vascular disease. $p66^{Shc}$ knockout mice show a 30% prolonged life span and are protected against age-associated endothelial dysfunction. Moreover, $p66^{Shc}$ activation has been shown to be involved in Abeta-induced neurotoxicity *in vitro*.

Methods

To study the role of $p66^{Shc}$ deletion on AD-related pathology *in vivo*, we generated a novel APP transgenic mouse line lacking $p66^{Shc}$. The four genotypes (wildtype, PSAPP, p66 ko, p66 ko/PSAPP) of this novel p66 ko/PSAPP line were analyzed at three different ages.

Results

Behavioural testing revealed cognitive deficits in the PSAPP group at 15 months in the Y maze and Novel object recognition task (NORT) and already at 3 months in the Barnes maze. Strikingly, all observed impairments were rescued by $p66^{Shc}$ ablation. This rescue effect was independent of Abeta pathology since we observed only minor differences in Abeta-plaque burden. Interestingly, we found a “hypervascularity phenotype” in the PSAPP mice, which was reversed by $p66^{Shc}$ ablation. Furthermore, the PSAPP mice showed a trend towards increased blood brain barrier leakages.

Discussion

The results of this study suggest that protective effects of $p66^{Shc}$ ablation on Abeta-related cognitive dysfunction are most likely downstream of Abeta deposition and may be mediated by beneficial effects on vessel architecture and subsequent vascular dysfunction.

ADPD5-1296

THE EFFECT OF EXERCISE ON THE VASCULATURE OF THE SENSORIMOTOR CORTEX IN A MOUSE MODEL OF ALZHEIMER'S DISEASE.

L.A.M. Thomason[1], A. Dorr[1], E. Maliszewska-Cyna[2], J. Steinman[3], I. Aubert[2], J.G. Sled[3], B. Stefanovic[3]

[1]Medical Imaging, Sunnybrook Research Institute, Toronto, Canada
[2]Laboratory Medicine and Pathobiology, University of Toronto, Toronto, Canada
[3]Medical Biophysics, University of Toronto, Toronto, Canada

Objectives: There is growing interest in the role of brain vascular injury in the etiology and progression of AD. Further, exercise has been shown to elicit increased angiogenesis, reduction of amyloid-beta load and improved cognitive function in mouse models of AD. We thus set out to investigate the effect of exercise on the cortical microvessels in the TgCRND8 mouse model of AD.

Methods: Twenty nine 3-month old TgCRND8 and their non-transgenic littermates were given ad libitum access to a running wheel for 12 weeks until 6-months of age. They were then injected with Methoxy XO4 to label amyloid-beta and 24 **h**our**s thereafter** perfused with a mercox-BABB (Benzyl Alcohol-Benzyl Benzoate) solution containing Nile red. The brains were fixed in 4% PFA, progressively dehydrated, and cleared by BABB. Two photon fluorescence images were acquired over 4 partially overlapped regions in the motor and somatosensory cortex, at 0.5x0.5um in plane resolution. Following deconvolution and stitching of imaged volumes, the vasculature was tracked using a multi-scale automated segmentation algorithm.

Results: We evaluated vessel density, branch density, tortuosity and calculated a map of distances to nearest vessels for all of parenchyma in each animal. The preliminary data suggest that vessel density is decreased by ~20% in the motor cortex of the TgCRND8 mice compared to controls and that this effect is partially resolved with the 3-month exercise regimen.

Conclusions: This work provides further mechanistic insight into the effect of exercise on brain microvasculature and underscores the significance of vascular injury in AD progression.

PRENATAL HIGH FAT DIET ALTERS THE NEUROVASCULAR UNIT AND CLEARANCE OF BETA-AMYLOID IN ADULT OFFSPRING

C. Hawkes[1], S. Gentleman[2], J.A.R. Nicoll[3], R.O. Carare[3]
[1]Life Chemical and Health Sciences, Open University, Milton Keynes, United Kingdom
[2]Medicine, Imperial College London, London, United Kingdom
[3]Medicine, University of Southampton, Southampton, United Kingdom

Background: Cerebral amyloid angiopathy (CAA) is characterized by the accumulation of β-amyloid (Aβ) peptides in the walls of cerebral blood vessels. Failure of perivascular drainage of Aβ along cerebrovascular basement membranes contributes to the development of CAA. Mid-life hypercholesterolemia is a risk factor for the development of CAA. Maternal obesity is associated with the development of hypercholesterolemia in adulthood, suggesting that the risk for CAA may be influenced by early dietary environment. **Objectives**: We tested the hypothesis that early life exposure to a high fat diet results in changes to the cerebrovasculature and failure of Aβ clearance from the brain. **Results:** Using a mouse model of maternal obesity, we found that exposure to a high fat diet during gestation and lactation induced changes in multiple components of the neurovascular unit, including a downregulation in collagen IV, fibronectin and apolipoprotein E, an upregulation in markers of astrocytes and perivascular macrophages and altered blood vessel morphology in the brains of adult mice. Sustained high fat diet over the entire lifespan resulted in additional decreases in levels of pericytes and impaired perivascular clearance of Aβ from the brain. In humans, vascular Aβ load was significantly increased in the brains of aged individuals with a history of hypercholesterolemia. **Conclusions:** These results support a critical role for early dietary influence on the brain vasculature across the lifespan, with consequences for the development of age-related cerebrovascular and neurodegenerative diseases.

ADPD5-2293

OLIGOMERIC AMYLOID-BETA INDUCES CEREBROVASCULAR ABNORMALITIES IN THE APP E393Q TRANSGENIC MOUSE WITH ALZHEIMER'S DISEASE LIKE COGNITIVE DEFICITS

D. Dara Dickstein[1], T. Warda[1], M.E. Ehrlich[2], M. Varghese[1]
[1]Neuroscience, Icahn School of Medicine at Mount Sinai, New York, USA
[2]Neurology & Pediatrics, Icahn School of Medicine at Mount Sinai, New York, USA

Objectives: Cerebrovascular pathology is observed in patients with Alzheimer's disease (AD). However, it is unclear whether the soluble oligomeric or the fibrillar form of amyloid-beta, the AD neurotoxic peptide, is responsible for cerebrovascular pathology. Our study aims to provide evidence for the effect of soluble oligomeric amyloid-beta on cerebrovascular pathology, in the absence of amyloid plaques.
Methods: We used transgenic mice expressing the Dutch APP E693Q mutation (DU mice) that display oligomeric amyloid-beta but no amyloid plaques in the brain. We identified morphological changes in brain vasculature of DU mice as compared to wild-type (WT) controls, using collagen immunohistochemistry and quantitative stereology. We also examined the changes in expression of vascular endothelial cell tight junction proteins in DU mice, by Western blot.
Results: There was no change in the overall vascular length density between DU and WT mice. We found increased incidence of abnormal vessel morphology, such as twisted vessels and string vessels, in the hippocampal formation of the APP E693Q mice as compared to WT controls. The expression of the tight junction protein zona occludens-1 [MV1] was altered in the hippocampus, but not the cortex, of DU mice as compared to WT. Future studies include characterization of other tight junction proteins, including claudin-5, occludin and VE-cadherin.
Conclusions: Our results indicate that the presence of soluble oligomeric amyloid-beta is sufficient to induce vascular abnormalities in the brain and may represent early changes occurring in AD prior to amyloid deposition.

[MV1]We only have n=2 for the Western data of ZO-1.

INITIATION OF ABETA DEPOSITION IMPAIRS ADULT HIPPOCAMPAL NEUROGENESIS

S. Waldkirch[1], D. Loreth[1], M. Prinz[2], M. Meyer-Luehmann[1]
[1]Neurology, University of Freiburg, Freiburg, Germany
[2]Neuropathology, University of Freiburg, Freiburg, Germany

Objectives
Alzheimer´s disease (AD) is characterized by the accumulation of Abeta which ultimately forms plaques. These Abeta deposits can be induced in young pre-depositing APP transgenic mice by intracerebral injection of Abeta-containing brain homogenate. Although previous studies reported a decline of neurogenic capacity in the brain of AD patients and AD mouse models it still remains unknown whether this impairment is specifically altered by Abeta plaques.
Methods
In order to determine the impact of amyloid-beta pathology on neural progenitor cells in the hippocampus we performed intracerebral injections of brain homogenate from aged transgenic mice into young pre-depositing APP transgenic mice. By using immunohistochemical stainings and western blot analysis we quantified Ki67 positive cells as a marker for proliferation, counted the number of doublecortin positive cells as a marker for neurogenesis and measured the Abeta content with an antibody against Abeta.
Results
We observed a dramatic decrease in proliferation and neurogenesis in mice that had been injected with Abeta-containing brain homogenate when compared to controls. Furthermore, the number of granular cells was significantly decreased, and signs of neuronal cell death occurred primarily in the vicinity of induced Abeta deposits. Additionally doublecortin positive cells differed in their morphology displaying less elaborated dendrites and developing shorter dendrite length indicating that the generation and maturation of newborn neurons is affected.
Conclusions
In summary our data suggest that induced Abeta deposition can lead to impaired adult hippocampal neurogenesis and contributes to neuronal vulnerability. We hypothesize that this might result in learning and memory deficits.

THE UCI ADRC IPS CELL CORE: A NOVEL RESOURCE TO EXAMINE RELATIONSHIPS BETWEEN GENOTYPE AND PHENOTYPE IN LATE-ONSET ALZHEIMER'S DISEASE

J. Davis[1], T. En Lim[1], C. Tu[1], A.J. Park[1], E.M. Abud[2], W.W. Poon[1], A. Pierce[3], M. Blurton-Jones[2]

[1]UCI Mind, University of California Irvine, Irvine, USA

[2]Department of Neurobiology & Behavior, University of California Irvine, Irvine, USA

[3]Department of Neurology, University of California Irvine, Irvine, USA

Objectives:

Twin studies have shown that late-onset Alzheimer's disease (AD) is highly heritable and GWAS studies have begun to uncover both common and uncommon genetic variants that influence disease risk. However, the precise relationship between these genetic markers and disease-associated phenotypes will likely be challenging to unravel. Recent advances in cellular reprogramming provide an innovative new way to examine these relationships by studying patient-derived induced pluripotent stem (iPS) cells. Yet given the variable penetrance and effect size of many of these genetic variants, it will be important to examine multiple well-characterized iPS cell lines.

Methods:

Here, we describe the creation of a federally-funded iPS Cell Core tasked with generating and distributing iPS cells from a well-characterized cohort of AD, MCI, and control patients. Skin biopsies are routinely collected from the UCI Alzheimer Disease Research Center patient cohort and iPS cells are generated via non-integrating Sendai viral reprogramming.

Results:

Stably reprogrammed iPS cells are expanded, tested for pluripotency and sterility, and karyotyped before banking. For each line, corresponding de-identified clinical and biomarker datasets and SNP analysis of 31 GWAS-associated genes are also available. For several of these lines neural stem cells have also been generated and banked. Using these iPSC-derived cells the iPS cell core has also now established protocols to generate neurons, astrocytes, endothelial cells, and microglia.

Conclusion:

The UCI ADRC iPS cell bank aims to provide an invaluable new resource to help researchers around the world to study the relationships between AD-associated genetic polymorphisms and disease-associated phenotypes.

THE AMYLOID PRECURSOR PROTEIN EXPRESSED IN THE CHOROID PLEXUS IS A KEY REGULATOR OF ADULT NEUROGENESIS

K. Arnaud[1], J.P. Röderer[2], K. Moya[1], A. di Nardo[1], U.C. Müller[2], A. Prochiantz[1]
[1]Centre Interdisciplinaire de Recherche en Biologie, Collège de France, Paris, France
[2]Department of Bioinformatics and Functional Genomics,
Institute for Pharmacy and Molecular Biotechnology, Heidelberg, Germany

Physiologically, the Amyloid Precursor Protein (APP) is cleaved by an alpha-secretase, releasing soluble APP (sAPP) an important regulator of adult neurogenesis. This cleavage prevents two others in positions beta and gamma that generate the ßA4 toxic peptide, a hallmark of Alzheimer Disease.

Next generation RNA-sequencing has revealed that *APP* is the 16th most expressed genes in the choroid plexus, more than in the hippocampus and cortex, suggesting that it may be a major source of sAPP and ßA4 in the cerebrospinal fluid (CSF). If so, adult neurogenesis in the SVZ and hippocampus may be regulated by the choroid plexus and impeded in mutations favoring ßA4 production.

The choroid plexus is easily accessible and can be target by viral vectors. This property was exploited to develop APP loss and gain of functions specifically in this structure and in the CSF. This has allowed us to confirm that modifying *APP* expression specifically in the choroid plexus is sufficient to modify adult neurogenesis.

In the course of this presentation we shall describe the adult neurogenesis model summarized above and discuss the preliminary experiments aimed at down-regulating mutated *APP* in the choroid plexus to replace it by the wild type gene.

ADPD5-0279
IRON INDUCED CHANGES IN MICROGLIA INCREASE APP PROCESSING IN CO-CULTURE.

D. Angelova[1], *D. Brown*[1]
[1]*Department of Biology and Biochemistry, University of Bath, Bath, United Kingdom*

As the brain ages, both glia and neurons undergo changes in numerous processes especially those associated with maintaining the redox balance. Microglia have also been shown to increase storage of iron. Microglia with high iron content are often dystrophic and such microglia may play a significant role in enhancing or exacerbating pathological conditions in the brain. We created a model of iron induced dystrophic microglia by growing microglial cell lines in high iron concentrations. Iron –fed microglia showed increased iron content and ferritin levels. Co-culture with such microglia induced neuronal loss in both primary neuronal cells and cell lines in culture. We used an assay for beta-amyloid formation that demonstrated that co-culture with microglia in general decreased APP processing, but if the microglia were activated with LPS or grown previously with high iron, there was a significant increase in APP processing. Increased exposure of cells to iron-fed microglia resulted in loss of cells. The cells killed by the microglia were predominantly those cells that showed higher APP processing. We are currently in the process of identifying the cytokines generated by the microglia that mediate these changes.

ASTROCYTIC ADENOSINE RECEPTOR A2A REGULATES MEMORY

A.G. Orr[1], E.C. Hsiao[2], M.M. Wang[1], K. Ho[1], D.H. Kim[1], X. Wang[1], W. Guo[1], J. Kang[1], G.Q. Yu[1], A. Adame[3], N. Devidze[1], D.B. Dubal[4], E. Masliah[3], B.R. Conklin[1], L. Mucke[1]
[1]Gladstone Institute of Neurological Disease, The J. David Gladstone Institutes, San Francisco, USA
[2]Division of Endocrinology and Metabolism, University of California San Francisco, San Francisco, USA
[3]Departments of Neuroscience and Pathology, University of California San Diego, San Diego, USA
[4]Department of Neurology, University of California San Francisco, San Francisco, USA

Objectives: To test the hypothesis that the G_s-coupled adenosine receptor A2A expressed by glial cells contributes to Alzheimer's disease (AD) pathogenesis. In particular, we determined if 1) A2A receptors are expressed by glial cells in humans with AD and in mouse models relevant to this condition, and 2) glial A2A receptors and G_s-coupled signaling affect learning and memory, and contribute to AD-related cognitive deficits.
Methods: To examine glial A2A receptor expression, we performed immunolabeling, western blotting, and qPCR in postmortem brain tissue from human cases with AD and transgenic mouse models of AD. To examine the roles of glial A2A receptors and G_s-coupled signaling in cognitive function, we conducted behavioral testing in transgenic mice with conditional genetic ablation of A2A receptors or inducible expression of a modified G_s-coupled receptor amenable to chemogenetic manipulation.
Results: A2A receptor levels were increased in hippocampal astrocytes of humans with sporadic AD and these increases correlated with disease progression. Astrocytic A2A receptor levels were also increased in the hippocampus of aging transgenic mice expressing human amyloid precursor protein (hAPP). Conditional genetic ablation of astrocytic A2A receptors enhanced long-term memory, but not learning, in young and aging mice without hAPP expression. Ablation of astrocytic A2A receptors enhanced memory also in aging hAPP mice without affecting their learning deficits. Chemogenetic stimulation of astrocytic G_s-coupled receptor signaling reduced long-term memory without affecting learning or short-term memory.
Conclusions: Astrocytic G_s-coupled A2A receptors negatively regulate memory and AD-linked increases in astrocytic A2A receptor levels may contribute to memory loss.

THE RESPONSE OF OLIGODENDOCYTES AND THEIR PROGENITORS TO THE ALTERED CHEMISTRY OF THE ALZHEIMER'S DISEASE BRAIN

K. Tse[1], J. Chan[1], A. Cheng[1], K.H.M. Chow[1], K. Herrup[1]
[1]Division of Life Sciences, Hong Kong University of Science and Technology, Kowlooon, Hong Kong China

Objectives
White matter pathology occurs in Alzheimer's disease (AD), but its cellular basis remains unknown. We report the use of immunocytochemical methods to test the hypothesis that oligodendrocyte progenitor cells (OPC) and their descendents are directly suceptible to Aβ toxicity and inflammation in AD.
Methods
R1.40 transgenic mice carrying the human APP gene with the Swedish mutation were used as an AD model. The number of OPC (NG2-positive) and mature oligodendrocytes (myelin basic protein [MBP]-positive) cells were quanitified in 18-20 month old R1.40 mice and their C57BL/6-wildtype littermates. The effects of fibrillar Aβ peptide and lipopolysaccharide (LPS)-induced inflammation on the numbers and morphology of OPC and mature oligodendrocytes (mOL) were quantified in mixed cultures of embyronic neocortical neurons (wildtype-DIV14).
Results
In immunostained sections of R1.40 hippocampus, the densities of OPC and mOL were 35% and 19% lower respesctively than in wildtype ($p < 0.05$). *In vitro*, both Aβ peptide and LPS reduced the number of OPC and mOL in a concentration-dependent fashion. At 10 μM, Aβ reduced OPC and mOL by 82.2% and 60.3% respectively after 24 h of treatment ($p < 0.001$). Both treatments also induced a substantial change in the normal morphology of cultured OPC and mOL.
Conclusions
OPC and mOL are both vulnerable to Aβ-toxicity *in vivo* and *in vitro*. The effects are especially dramatic *in vitro* and warrant further investigation into the contribution of amyloid and inflammation to the observed early white matter pathology in AD.

ACCUMULATION OF AMYLOID-BETA RESULTS IN GIANT ASTROCYTIC VACUOLES AND SECONDARY NEURONAL CELL DEATH

S. Söllvander[1], E. Nikitidou[1], D. Sehlin[1], L. Lannfelt[1], A. Erlandsson[1]
[1]Molecular Geriatrics, Public Health and Caring Sciences Uppsala University, Uppsala, Sweden

Objectives
A growing body of research suggests that astrocytes play an important role in the pathophysiology of Alzheimer's disease (AD). Reactive astrocytes, surrounding amyloid plaques have been demonstrated to engulf amyloid-beta (Aβ), but their effectiveness in Aβ degradation remains elusive. The aim with this study was to clarify the role of astrocytes in Aβ clearance by studying Aβ uptake, degradation and toxicity in a co-culture system of neurons, astrocytes and oligodendrocytes.

Methods
Neural stem cells from embryonic mouse cortex were differentiated to neurons, astrocytes and oligodendrocytes and exposed to Cy3-labeled Aβ1-40 monomers or Aβ1-42 protofibrils for 24h. The cultures were then thoroughly washed and followed for a period of 12 days. Uptake, degradation and toxic effects of Aβ were studied by time-lapse microscopy, immunocytochemistry and ELISA.

Results
Our data show that monomeric Aβ1-40 is effectively degraded by the cells, but Aβ1-42 protofibrils are accumulated for long times. Immunostainings with specific cell markers, demonstrated that astrocytes and oligodendrocytes engulf large amounts of Aβ, while neurons ingest very little. Interestingly, Aβ1-42 protofibril exposure results in extremely large astrocytic vacuoles. These vacuoles never appear in control cultures, indicating that they may be a way for the astrocytes to cope with the high Aβ load. Aβ has no direct toxic effect on neurons and glia, but causes secondary neuronal cell death several days after the Aβ removal.

Conclusions
The engulfment of Aβ1-42 protofibrils by glial cells results in Aβ accumulation, formation of pathological vacuoles in the astrocytes and secondary neuronal cell death.

MILD TRAUMATIC BRAIN INJURY IN APP/PS1 KNOCK-IN MICE INDUCES ALTERED GLIAL RESPONSES AND ACCELERATED COGNITIVE DEFICITS

A. Bachstetter[1], *S. Webster*[1], *L. Van Eldik*[1]
[1]*Sanders-Brown Center on Aging, University of Kentucky, Lexington, USA*

Objectives: Epidemiological studies show a history of head injury is associated with earlier onset, and increased Alzheimer's disease (AD) pathological and cognitive changes. Currently, little is known about how a single head injury accelerates onset of AD; yet, clinically, neuroinflammation has been found to be chronically elevated after a single head injury. As neuroinflammation can affect AD neuropathology and cognitive impairment, we tested whether an altered inflammatory response following a traumatic brain injury might be a contributing factor.
Methods: APP/PS1 knock-in (KI) mice and wild-type (WT) controls received a closed head injury (CHI) at 8 months of age, prior to cognitive deficits in the KI mice, and then various endpoints were measured at 9h, 1d, 7d, 1m, and 2m post-injury.
Results: At 1m post-injury, injured KI mice exhibited a significant impairment in radial arm water maze compared to sham KI mice or injured WT mice. Unexpectedly, we found that the temporal astrocyte and cytokine response in the injured KI mice was delayed compared to the injured WT mice. However, once activated, the glial injury response in the KI mice failed to resolve compared to the injured WT mice, resulting in chronic glial activation.
Conclusions: In agreement with clinical findings, our experimental model suggests that a single head injury can accelerate cognitive impairment, and that the mechanism may involve a dysregulated neuroinflammatory response.

HIPPOCAMPAL INCREASE IN TNF-ALPHA CORRELATES WITH TRANSLOCATOR PROTEIN AND MICROGLIA MARKER IBA1 UP-REGULATION DURING THE ASYMPTOMATIC STAGE OF ALZHEIMER'S DISEASE

S. Krantic[1], A. Doméné[2], G. Page[3], S. Bodard[2], C. Klein[4], S. Chalon[2]
[1]équipe 17, Cordeliers Research Center UMRS872, Paris, France
[2]UMR INSERM 930, Université de Tours, Tours, France
[3]EA 3808, Université de Poitiers, Poitiers, France
[4]CICC, Cordeliers Research Center UMRS872, Paris, France

OBJECTIVES: Our main goal was to assess glia activation during the asymptomatic stage of Alzheimer's disease. The hippocampal expression of TNFalpha and mitochondrial translocator (TSPO) protein were used as out-read of glia activation. To determine whether both microglia and astrocytes contribute to putative glia activation, the expression of their respective (Iba1 and GFAP) phenotypic markers was correlated with the level of TSPO and TNFalpha.
METHODS: Transgenic APPswePS1dE9 and the littermate non-transgenic female mice aged 3 months (n=6-11 per genotype) were used. Amyloid precursor protein (APP), TNFalpha, TSPO, GFAP and Iba1 expressions were quantified in the hippocampus by western blot. TNFalpha and TSPO were additionally assessed by ELISA and [3H]-PK11195 autoradiography, respectively.
RESULTS: Considered globally, the inter-individual variability was important independently of the genotype and no statistically significant difference was found between mean values for any of the studied parameters. However, linear regression analysis indicated that the increase in APP correlates positively with both TNFalpha ($r=0.878$, $p=0.0002$) and GFAP ($r=0.913$, $p=0.0001$) which are also mutually correlated ($r=0.907$, $p=0.0001$ for GFAP *versus* TNFalpha). By contrast, APP is not correlated with Iba1 ($r=0.372$, $p=0.2338$). Moreover, TSPO induction is not correlated with APP ($r=0.362$, $p=0.2469$), but is correlated positively with Iba1 ($r=0.768$, $p=0.0035$) which is in turn correlated with TNFalpha ($r=0.586$, $p=0.0452$).
CONCLUSIONS: Both astrocytes and microglia contribute to the increase in TNFalpha during the early stages of Alzheimer's-like pathogenesis though TSPO appears selectively up-regulated only in microglia.

[2]Hertie-Institute for Clinical Brain Research, Department of Cellular Neurology, Tübingen, Germany

Alzheimer's disease (AD) is a primary neurodegenerative disorder characterized by neuronal loss, neurofibrillary tangles and accumulation of β-amyloid (Aβ) plaques. While central nervous system (CNS) resident microglia are believed to be ineffective at phagocytosing and clearing Aβ, evidence from transgenic AD mouse models suggests that peripheral myeloid cells constitute a heterogenous cell population with greater Aβ clearing capabilities. To assess the ability of peripherally-derived macrophages to reduce Aβ plaque pathology, we exchanged the pool of resident microglia with peripherally-derived myeloid cells using APPPS1 mice crossed to CD11b-HSVTK mice (APPPS1-TK), which allow for selective ablation of CD11b+ cells. We found that under certain experimental conditions, depletion of microglia is invariably followed by rapid and large-scale infiltration of peripheral macrophages. Using this approach to exchange the CNS myeloid cell pool, we evaluated the effects of microglial depletion and repopulation by peripherally-derived myeloid cells on Aβ plaque load in 150 day-old APPPS1-$TK^{+/-}$ mice. While there was no change in plaque burden *per se* in these animals compared to APPPS1-$TK^{-/-}$ animals that were not depleted of resident microglia and had little or no invasion by peripheral myeloid cells, additional manipulation such as non-specific or Aβ-targeted stimulation revealed that peripherally recruited myeloid cells have greater amyloid clearing capacity than resident microglia in response to activating signals, highlighting the therapeutic potential of cell-based therapy for Alzheimer's disease.

[2]Pathology, University of California San Diego, San Diego, USA

Objectives: Amyloid-β (Aβ) engages toll-like receptors (TLRs) to stimulate 'host defense' mechanisms, resulting in pro-inflammatory activation of microglia, the brain's innate immune cells. TLRs transduce their signals through MyD88 and the serine/threonine IL-1 receptor-associated kinase (IRAK). The IRAK family of kinases generally upregulate TLR signaling, with the notable exception of the inhibitory kinase IRAK-M. IRAK-M expression is specific to cells of monocytic lineage, including microglia, and plays a critical role in the maintenance of innate immune homeostasis by dampening inflammation.
Methods: We crossed mice deficient in IRAK-M (IRAK-M$^{-/-}$) with mice over expressing mutant human amyloid precursor protein, the PSAPP mouse model of cerebral amyloidosis. We then assayed behavioral impairment and evaluated the state of immune cell activation and cerebral Aβ burden and in age and sex-matched littermates from PSAPP-IRAK-M^{+} and PSAPP-IRAK-M$^{-/-}$ mice at 15 months of age.
Results: Transgene-associated behavioral deficits were reversed in PSAPP-IRAK-M$^{-/-}$ mice including hyperactivity and spatial working and reference memory. Immunohistochemistry for the macrophage/microglia-specific protein Iba1 disclosed statistically significant increased expression in PSAPP-IRAK-M$^{-/-}$ *vs.* PSAPP-IRAK-M^{+} mice in the hippocampus, cingulate cortex and entorhinal cortex (up 38-42%), brain regions associated with AD-type pathology in humans. Additionally, *in vivo* quantification of Aβ encapsulation within Lamp1^{+} lysosomes revealed a phagocytic mechanism of IRAK-M$^{-/-}$ microglia-mediated Aβ clearance.
Conclusions: Collectively, these data suggest that IRAK-M negatively regulates brain innate immunity in a mouse model of cerebral amyloidosis. Disinhibition of IRAK-M may represent a means to target microglial remodeling of amyloid pathology.

SILENCING OF UPREGULATED KV3.4 POTASSIUM CHANNEL SUBUNIT REDUCES BETA-AMYLOID LEVELS IN TG2576 AD MICE

R. Ciccone[1], A. Casamassa[1], C. Franco[1], F. Boscia[1], A. Pannaccione[1], A. Vinciguerra[1], G. Di Renzo[1], L. Annunziato[1]

[1]Dept. Neuroscience, Università "Federico II", Naples, Italy

Astrocyte dysfunction emerges early in Alzheimer's disease (AD) and may contribute to its pathology and progression. In the present study we investigated the expression and functional activity of the voltage-gated potassium channel subunit $K_V3.4$, that has been recognized to be relevant for AD pathogenesis, in astrocytes.

To this aim we evaluated: 1) the $K_V3.4$ expression by means immunofluorescence and western blot analysis and 2) the functional activity of the $K_V3.4$ by means patch-clamp. The protein expression and the activity of $K_V3.4$ were significantly upregulated in rat primary astrocytes exposed to β-amyloid peptide 1-42 (Ab_{1-42}). Furthermore, $K_V3.4$ expression was intensely upregulated in the astrocytes of the hippocampus, corpus callosum, and cerebellum of six-month-old Tg2576 AD mice at the early stages of AD. Coexpression and co-immunoprecipitation studies revealed a large overlap of $K_V3.4$ with, and direct binding to, the astrocyte-specific intermediate filament GFAP. Conversely, the selective knockdown of $K_V3.4$ expression significantly downregulated both GFAP and Ab protein levels in the brain of Tg2576 AD mice.

In conclusion, our results demonstrate that $K_V3.4$ have a critical role in astrocyte activation during the early stages of Tg2576 AD mice. Therefore, modulating astrocyte activity through a regulation of $K_V3.4$ channel functioning might open new avenues for developing innovative therapies capable of actually slowing down the progression of AD at its earliest stages.

TMT CALIBRATOR PLUS REVEALS MARKERS OF MICROGLIA ACTIVATION IN AD CSF

C. Russell[1], A. Heslegrave[2], V. Mitra[1], J. Pocock[2], I. Pike[1], H. Zetterberg[3]
[1]Institute of Psychiatry, Proteome Sciences, London, United Kingdom
[2]Institute of Neurology, UCL, London, United Kingdom
[3]The Sahlgrenska Academy at the University of Gothenburg, Institute of Neuroscience and Physiology, MoIndal, Sweden

An early event in neurodegenerative pathology involves activation of microglial cells that will secrete distinct proteins into the brain and possibly then into CSF. The challenge is how to find these molecules. Traditional unbiased proteomic approaches have struggled to detect low abundance markers due to the high dynamic range of CSF proteins. To improve biomarker discovery in peripheral fluids, we developed TMTcalibrator+; a novel MS workflow.

Using isobaric Tandem Mass Tags (TMT) allows tissue/cell lysate samples to be labelled and mixed into labelled samples of peripheral biofluids at a concentration sufficient to ensure the majority of MS/MS acquisitions are made on tissue/cell-derived peptides. We used a cultured microglial cell-line to represent activated microglia in Alzheimer's disease (AD) brain. Peptide preparations from microglial cells were TMT labelled to form a reference peptide mix. CSF samples from three patients with AD, and three non-AD controls were digested and labelled with the remaining TMT tags. All labelled digests were pooled together to form the TMTcalibrator+ analytical sample for analysis by LC-MS/MS.

By comparing the levels of each TMT reporter ion generated upon fragmentation, we can determine which microglial proteins are found in CSF and which are differentially expressed in AD. We have identified multiple up-regulated peptides in the CSF of AD patients belonging to proteins originating from microglia.

Application of our pioneering TMTcalibrator+ MS approach has allowed the identification of low abundant proteins in the CSF of AD patients which warrant further investigation as they may represent early events in the disease process.

IMMUNOHISTOCHEMICAL ANALYSIS OF WATER CHANNEL PROTEIN AQUAPORIN AND GLUTAMATE TRANSPORTER GLT-1 EXPRESSION IN ALZHEIMER'S DISEASE

A. Hoshi[1], A. Tsunoda[1], M. Tada[2], Y. Ugawa[1], M. Nishizawa[3], A. Kakita[3]
[1]Neurology, Fukushima Medical University, Fukushima, Japan
[2]Pathology, Brain Research Institute University of Niigata, Niigata, Japan
[3]Neurology, Brain Research Institute University of Niigata, Niigata, Japan

Objectives: We have previously reported marked changes in the expression of astrocytic aquaporin 4 (AQP4) and AQP1 in relationship to amyloid β peptide (Aβ) deposition in human Alzheimer's disease (AD) brains (Hoshi A et al, JNEN, 2012). GLT-1, the dominant astrocytic glutamate transporter in the cerebral cortex seems to be significantly reduced in AD. No studies have demonstrated any correlation between the expression of AQP and that of GLT-1 in AD. We, therefore, investigated the expression of AQP in association with GLT-1 in autopsied brains affected by AD.
Methods: Expression of AQP4, AQP1, and GLT-1 in the temporal lobes of 8 patients with AD and 5 age-matched controls were examined immunohistochemically.
Results: In the AD group, AQP4 immunoreactivity appeared more intense and number of AQP1-positive astrocytes was larger with decreased GLT-1 expression than those observed in the control group. Intriguingly, double immunofluorescence of AQP4 and GLT-1 showed numerous Aβ plaque-like AQP4/GLT-1 expressions. On the other hand, AQP1/GLT-1 double positive structures were rarely observed in the AD group.
Conclusions: There are no reports regarding to Aβ plaque-like AQP4/GLT-1 expressions in AD. These findings suggest a pathomechanism of senile plaque formation in association with reactive astrocytes expressing AQP4/GLT-1. Additionally, in AD brains, AQP1 positive astrocytes seem to appear in some population of astrocytes with reduced GLT-1 expression. In conclusion, AD neurodegenerative processes may progress mediated with disruption of water and glutamate homeostasis.

P2Y12 MEDIATES AMYLOID-BETA CLEARANCE BY MICROGLIA
C.H. Andersson[1], S. Strand[1], P. Kettunen[1]
[1]Neuroscience and Physiology, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden
Alzheimer's disease (AD) is a degenerative brain disorder affecting around 10% of people older than 65 years. It is generally thought to be caused by the extracellular accumulation of amyloid-beta, Aβ, in the brain, causing neurodegeneration and memory loss at its later stages. It has previously been shown that microglial cells are involved in the pathogenesis of AD and that microglia are part of clearing and degrading Aβ from the brain. However, competing theories claim that microglia might actually contribute to the neurodegeneration in AD. In this study, we investigate how injected Aβ is cleared from the brain by microglia in zebrafish larvae using *in vivo* imaging. Our experiments demonstrate that microglia has neuroprotective features against Aβ toxicity. Our results also show that the p2y12 receptor plays an important role in the clearance of Aβ. In conclusion, our study indicates that microglia could serve as a drug target for future AD treatments.

NLRP3 INFLAMMASOME IS EXPRESSED AND FUNCTIONAL IN BRAIN MICROGLIA BUT NOT IN ASTROCYTES

M. KIRCHMEYER[1], A. Gustin[1], E. Koncina[1], P. Felten[1], S. Losciuto[1], T. Heurtaux[1], A. Tardivel[2], P. Heuschling[1], C. Dostert[1]

[1]Neuroinflammation, University of Luxembourg, Luxembourg, Luxembourg

[2]Biochimie, Biochemistry Institute, Lausanne, Switzerland

Neuroinflammation is the local reaction of the brain to infection, trauma, toxic molecules or protein aggregates. The brain resident macrophages, microglia, are able to trigger an appropriate response involving secretion of cytokines and chemokines, resulting in the activation of astrocytes and recruitment of peripheral immune cells. IL-1 beta plays an important role in this response; yet its production and mode of action in the brain are not fully understood and its precise implication in neurodegenerative diseases needs further characterization. Our results indicate that the capacity to form a functional NLRP3 inflammasome and secretion of IL-1 beta is limited to the microglial compartment in the brain. We were not able to observe IL-1 beta secretion from astrocytes, nor do they express all NLRP3 inflammasome components. Microglia are able to produce IL-1 beta in response to different classical inflammasome activators, such as ATP, Nigericin or Alum. Similarly, microglia are able to secrete IL-18, IL-1 alpha and HMGB1, three other inflammasome-linked pro-inflammatory factors. Cell stimulation with neurodegenerative disease-related peptides, such as alpha-synuclein, did not result in the release of active IL-1 beta by microglia despite their pro-inflammatory effect. Amyloid-beta peptides are able to activate the NLRP3 inflammasome and IL-1 beta secretion occurs in a P2X7 receptor-independent manner. Thus microglia-dependent inflammasome activation can play an important role in the brain and especially in neuroinflammatory conditions.

STUDY ON NEUROPROTECTIVE POTENTIAL OF MALAYSIAN TUALANG HONEY IN ALZHEIMER'S MODEL OF RATS.

A. Saxena[1], H. Phyu[2], N. Talib[1]
[1]Basic Medical Sciences, International Islamic University Malaysia, Kuantan, Malaysia
[2]Pharmacology, International Medical School Management and Science University, Kuala Lumpur, Malaysia

Objectives: One of the mechanisms which is thought to play a significant role in neurodegenerative disorders including Alzheimer's disease (AD) and dementia is oxidative stress and neuroinflammation leading to neuronal cell death. Since, honey has an antioxidant and anti-inflammatory activity, the present study was planned to study the neuroprotective capacity of Tualang honey in Alzheimer's model of rats.
Methods: Reduction in cerebral blood flow (CBF) due to aging has been linked to AD. Experimentally, chronic cerebral hypoperfusion due to reduced CBF can be created by permanent bilateral occlusion of common carotid arteries (2VO) in rats. Thirty Sprague Dawley rats weighing 200-250 g were divided into three groups (n=10). Group A – Sham control; Group B – 2VO; and Group C – 2VO+H (treated daily with honey, 1.2 g/kg freshly diluted with distilled water, orally by gastric gavage every morning following 2VO). On 10^{th} week, all the rats were euthanized and hippocampi were dissected out. Viable neuronal cells were counted in the hippocampal CA-1 region.
Results: In Group – B (2VO), damaged, distorted, irregular cells with shrunken cytoplasm and dark pyknotic nuclei were seen as compared to Sham control Group – A ($p<0.001$). Treatment of rats with honey restored the hippocampal CA-1 cells to their normal structure and revealed the reduced loss of neuronal cells in 2VO+H rats as compared to untreated 2VO rats ($p<0.001$).
Conclusions: This study shows that Malysian Tualang honey might have a therapeutic benefit in the management of chronic cerebral hypoperfusion induced neurodegenerative disorders like Alzheimer's disease.

ADPD5-0294

AN IN VITRO MODEL OF ALZHEIMER'S DISEASE: AN ATTEMPT TO EXPEDITE THE SEARCH FOR NEW DRUG ENTITIES.

J. Biswas[1], P. Goswami[1], S. Gupta[1], D. Verma[1], M. Singh[1], C. Nath[1], N. Joshi[2], S. Singh[1]
[1]Division of Toxicology, Central Drug Research Institute, lucknow, India
[2]Center for Gene Regulation in Health and Disease Department of Biological Sciences, Cleveland State University, Cleveland, USA

Objective: The available medications for Alzheimer's disease (AD) are not able to prevent the disease progression. Therefore, a rapid screening test model is required to mitigate the cost and time required for screening new drugs. Streptozotocin (STZ, intracerebroventricularly) induces AD like pathology in rodent brain. The present study was performed to assess the potential of STZ treated neuronal cell line N2A as the experimental test model for the screening of drugs for AD.
Methods: AD related pathological markers like tau phosphorylation, amyloid aggregation, choline levels were estimated in STZ (10, 50, 100 and 1000 microM) treated N2A cells. Also, cell viability, cytotoxicity, glucose uptake, mitochondrial membrane potential, caspase-3 expression and DNA fragmentation were assessed in STZ treated N2A cells. STZ treated cells were also co-treated with clinically used anti AD drug donepezil (1microM) to validate the test model.
Results: The STZ treated neuronal cells exhibited the increased phosphorylation of tau protein, amyloid aggregation and decreased choline level which are the widely accepted pathological markers of AD. The STZ treatment also caused significant decrease in cell viability, inhibited glucose uptake, elevated mitochondrial stress and increased expression of caspase -3 and DNA damage. STZ induced AD related pathological markers were inhibited with donepezil treatment, but did not attenuate the STZ induced apoptosis.
Conclusion: Finding suggests that STZ treated N2A cells express the pathological markers hence could be used as *in vitro* rapid screening test model to screen new anti-AD drug entities.

A DEFENSIVE WARBUR-LIKE EFFECT PROTECTS NEURONS IN THE EARLY PHASE OF APOPTOSIS

A. Bobba[1], G. Amadoro[2], G. La Piana[3], P. Calissano[4], A. Atlante[1]
[1]CNR, Istituto di Biomembrane e Bioenergetica, Bari, Italy
[2]CNR, Istituto di Farmacologia Traslazionale, Rome, Italy
[3]Università di Bari, Dipartimento di Bioscienze Biotecnologia e Biofarmaceutica, Bari, Italy
[4]EBRI, European Brain Research Institute, Rome, Italy

OBJECTIVES: Cerebellar granule neurons, undergoing low potassium induced apoptosis, were used as a cell model system for Alzheimer Disease (AD) to investigate the metabolic changes that occur during the entire time frame of cell death.
METHODS: Enzymatic assays were performed in the presence or absence of specific inhibitors of glucose metabolism. The expression levels of some glycolytic enzymes were detected by immunoblotting.
RESULTS: Cerebellar granule cells apoptosis can be divided into an early (reversible) and a late (irreversible) phase. In the early phase, several events, such as antioxidant system upregulation, proteasome activation and cytochrome *c* release, occur in an attempt to counter the death program. At this stage, aerobic glucose metabolism is enhanced with upregulation of the key proteins internalizing and metabolizing glucose, *i.e.* glucose transporter, hexokinase and phosphofructokinase. Concomitantly, mitochondria activity partially decreases with reduction in oxygen consumption and L-lactate accumulation. In the late phase, caspases become active, mitochondrial impairment goes further with alteration of the adenine nucleotide translocator and aerobic glycolysis is forced through the anaerobic pathway.
CONCLUSIONS: Results so far obtained point to a scenario in which a Warburg-like effect, with enhanced glycolysis and low-active mitochondria, takes place in the early phase when cells actively counter the death process in a manner resembling the apoptotic resistance mechanism of surviving neurons in the AD brain. However, in the late phase, a metabolic shift towards anaerobic glycolysis, mainly due to mitochondrial impairment, occurs and can exacerbate the pathophysiological processes associated with AD thus leading inevitably neurons to death.

CYTOSOLIC RELEASE OF LYSOSOMAL ENZYMES TRIGGERS NEURONAL DEATH IN ALZHEIMER'S DISEASE PATHOLOGY

Y. Wang[1], D. Westaway[2], S. Kar[3]
[1]Psychiatry, University of Alberta, Edmonton, Canada
[2]Medicine, University of Alberta, Edmonton, Canada
[3]Medicine & Psychiatry, University of Alberta, Edmonton, Canada

Objectives
Up-regulation of certain lysosomal enzymes within lysosomes can prevent sub-lethal damage, whereas sustained release of the enzymes into cytosol can induce cell death via cytochrome c release from mitochondria. However, very little is known about the subcellular distribution of lysosomal enzymes and their significance in Alzheimer's disease (AD). Since endosomal-lysosomal system is critical in the generation of β-amyloid (Aβ) peptides, which play important roles in the degeneration of neurons and development of AD pathology, we hypothesize that release/activation of lysosomal enzymes may participate in Aβ-mediated toxicity and development of AD pathology.
Methods
We used oligomeric human $A\beta_{1-42}$-induced primary mouse cortical neuronal death model to evaluate the levels/activities and subcellular distributions of lysosomal enzymes i.e. cathepsins B and D and related neuronal death mechanisms during neurodegeneration. Experiments are also being carried out in the cortex of TgCRND8 mouse model of AD.
Results
We found levels of cathepsins B and D were increased with time during the oligomeric $A\beta_{1-42}$-induced neuronal death. The increased cytosolic release of cathepsins B and D was associated with increased expression of pro-apoptotic molecular markers. In parallel, levels of cathepsins B/D and their cytosolic release were found increased in the cortex of TgCRND8 mice compared to age-matched control mice, and these changes were associated with increased neuronal loss.
Conclusions
Cathepsins B/D were increased in $A\beta_{1-42}$-mediated neuronal death and the cortex of mice exhibiting AD-related pathology. Increased cytosolic release of cathepsin B/D may be associated with $A\beta_{1-42}$-mediated neuronal death.

LIPOPROTEIN RECEPTORS IN REGULATION OF NEURONAL CELL DEATH

K. Kysenius[1], C.A. Brunello[1], P. Muggalla[1], K. Mätlik[2], U. Arumäe[2], H.J. Huttunen[1]
[1]Neuroscience Center, University of Helsinki, Helsinki, Finland
[2]Institute of Biotechnology, University of Helsinki, Helsinki, Finland

Objectives: Lipoprotein receptors are multifunctional receptors that hold key functions in brain development, plasticity, cholesterol homeostasis and neuronal viability. Early Alzheimer's disease pathology is characterized by Reelin depletion, altered brain lipoprotein receptor expression and neuronal hypometabolism. Apolipoprotein receptor 2 (ApoER2) and very-low density lipoprotein receptor (VLDLR) are the primary Reelin and ApoE receptors in the brain, but they also interact with clusterin/ApoJ, APP and Tau. However, the role of ApoER2 and VLDLR in AD development and neurodegeneration remain poorly characterized. The objective of this study was to elucidate the role of lipoprotein receptors in the regulation of neuronal survival.
Methods: Primary neuron cultures were used in combination with lentiviral RNAi and various inducers of cell death to study the role of lipoprotein receptors in neuronal degeneration. Cell viability was assessed by immunofluorescence, Western blotting, and cell toxicity and mitochondrial assays.
Results: (1) Induction of the endogenous lipoprotein receptor inhibitor PCSK9 and concomitant downregulation of ApoER2 is used as a developmental switch to trigger neuronal apoptosis in cerebellar granule neurons. (2) A potential PCSK9 inhibitor and a widely used nutraceutical berberine caused robust mitochondria- and NMDA receptor-dependent neuron death. (3) At subtoxic nanomolar concentrations, berberine sensitized neurons to rotenone and glutamate toxicity. (4) VLDLR expression was specifically increased in hypoxic conditions through HIF-1alpha and Nrf2-pathways. Although berberine neurotoxicity does not directly involve lipoprotein receptors, mitochondrial hypofunction is linked to transcriptional regulation of VLDLR.
Conclusions: ApoER2, VLDLR and their inhibitor PCSK9 contribute to the regulation of neuronal cell death via multiple mechanisms.

ROLE OF NMDA RECEPTOR SUBUNITS IN NEURONAL TOXICITY OF AMYLOID BETA OLIGOMERIC FRACTIONS

N. Callizot[1], M. Combes[1], P. Poindron[1]
[1]Neuropharmacology, Neuro-Sys, Gardanne, France

Number of studies have clearly indicated that amyloid β oligomers (Aβo) toxicity is mediated, at least in part, by glutamate-mediated excitotoxicity, which could involve activation of the NMDA receptors (NMDAR), leading to elevated intracellular Ca^{2+} and consequent stimulation of a cascade of enzymes resulting in cell death. This is supported by recent data showing that inactivation of the NMDA receptor by antagonists, could protect neurons from amyloid toxicity. Taken together, these studies suggest that glutamate receptor activation may be involved in part for amyloid β–induced cell death. In this study, we investigate the sequence of acute toxicity linked to Aβo (1-42) in primary cortical neurons. In presence of NMDAR antagonists (memantine, ifenprodil, MK801), Ca^{2+} influx was recorded immediately after Aβo administration and hyper-phosphorylation of Tau protein was assessed by western blot. The role of 2A/2B subunits was deeply investigated. For this purpose we used siRNA of NMDAR2A and 2B. We showed that MK801 and the specific inhibitor of NMDAR2B (ifenprodil) could fully protect neurons from Aβo injuries. Memantine (NMDAR2A) showed moderate inhibition proving that the 2A subunit was partially involved in the neurotoxic process. Moreover, a clear Ca^{2+} influx was observed in the few minutes after Aβo application, interestingly in Ca^{2+} free medium, no toxic damage was observed proving indirectly the role of the Ca^{2+} influx in the Aβo toxicity. In conclusion, we showed that the Aβo acute toxicity mainly involved the NMDAR2B activation inducing a massive entry of Ca^{2+} driving the apoptotic pathway and tau hyperphosphorilation.

DETAILED QUANTITATIVE STUDIES OF CU(II) BINDING TO ABETA1-16: BEYOND THE COMPONENTS MODEL.

W. Bal[1], M. Mital[1], E. Kurowska[1], W. Goch[1], M. Rozga[1], I. Zawisza[1], A. Bonna[1], K.J. Barnham[2], S.C. Drew[2]

[1]Biophysics, Institute of Biochemistry and Biophysics Polish Academy of Sciences, Warsaw, Poland

[2]Mental Health Research Institute, The University of Melbourne, Melbourne, Australia

Objectives

Complexation of Cu(II) by Abeta(1-40/42) peptides accelerates their aggregation and is considered to contribute significantly to neuronal damage in AD brains. Detailed knowledge of Cu(II)/Abeta interactions is important for designing AD therapeutic strategies. Abeta(1-40/42) bind one Cu(II) ion specifically, in a pH-dependent fashion. Previous spectroscopic studies on the Abeta(1-16) model peptide led to a proposal of four Cu(II) binding modes (so-called Components I-IV) in the pH range 6-11. A rigorous study performed at pH 7.4 (containing Components I and II) yielded conditional log K values of 10.4 for Abeta(1-40) and 10.1 for Abeta(1-16). Such data were not available for other pH values, because previous attempts to determine them did not agree well with spectroscopic results. We aimed to obtain a consistent binding model, ready for predictions of Abeta peptide interactions with Cu(II) ions at various pH that can be encountered in the brain.

Methods

The model Abeta(1-16) was synthesized using standard Fmoc methodology. Its protonation and Cu(II) affinity constants were determined by potentiometry in a broad pH range and verified quantitatively by electronic absorption spectroscopy and EPR.

Results

The combination of potentiometry and spectroscopic methods revealed the presence of eleven peptide and complex species over the studied pH range (3-11). Absolute protonation and affinity constants were obtained for each of them. The value at pH 7.4 was consistent with previous spectroscopic studies.

Conclusions

We obtained a correct set of data, which expands the understanding of Abeta/Cu(II) interactions beyond a four component model and a single affinity constant.

EXTREMELY HIGH CU(II) AFFINITY AND REDOX PROPERTIES MAKE ABETA 4-X KEY FACTORS IN COPPER-RELATED NEUROTOXICITY IN AD

N. Wezynfeld[1], M. Mital[1], T. Frączyk[1], A. Bonna[1], M. Wiloch[2], U. Wawrzyniak[2], C. Tumpach[3], K. Barnham[3], S. Drew[3], W. Bal[1]
[1]Department of Biophysics,
Institute of Biochemistry and Biophysics Polish Academy of Sciences, Warsaw, Poland
[2]Faculty of Chemistry, Warsaw University of Technology, Warsaw, Poland
[3]Florey Department of Neuroscience and Mental Health, The University of Melbourne, Melbourne, Australia

Objectives
The N-terminally truncated Abeta(4-40/42) peptides are abundant in healthy and AD brains. The Abeta(4-42) peptide predominates in plaques present in human AD brains, but not in most transgenic mouse models, which until very recently have expressed only human Abeta(1-40/42). The deletion of the DAE tripeptide creates a novel N-terminal FRH sequence in Abeta(4-40/42) peptides. Peptides containing such sequences are known to bind a Cu(II) ion avidly, with conditional log K values at pH 7.4 in the range of 12.0-14.6, much higher than that determined for the Abeta(1-40) peptide (log K = 10.4 at pH 7.4). Our aim was to verify this concept experimentally.
Methods
The model Abeta(4-16) was synthesized using standard Fmoc methodology. Its protonation and Cu(II) affinity constants were determined by potentiometry in a broad pH range and verified by spectroscopic techniques: electronic absorption, CD and fluorescence.
Results
The combination of potentiometry and spectroscopic methods revealed the presence of several complex species over the studied pH range (3-11). For the 1:1 Cu(II):peptide stoichiometry the sole binding site is provided by the FRH sequence. The conditional log K value at pH 7.4 under these conditions was 14.9. At a 2:1 Cu(II) excess over the peptide, another Cu(II) complex could be detected with a conditional log K value at pH 7.4 of ca. 8.0.
Conclusions
Extrapolating from the model peptide, our results indicate that Abeta(4-40/42) peptides can bind one Cu(II) ion with an extreme, femtomolar affinity. Such complexes will resist all chelating drugs currently considered for therapeutic intervention in AD.

STIM2 PROTEIN IS DOWNREGULATED IN CONDITIONS OF AMYLOID SYNAPTOTOXICITY

E. Pchitckaia[1], E. Popugaeva[1], O. Vlasova[1], I. Bezprozvanny[1]
[1]Laboratory of Molecular Neurodegeneration,
St. Petersburg State Polytechnical University, St. Petersburg, Russia

In our recent breakthrough study we observed that reduced postsynaptic neuronal store-operated calcium entry (nSOC) is responsible for mushroom spine loss in knock-in mice expressing mutant human presenilin 1 (PS1-M146V-KI)- mouse model of Alzheimer's disease (AD). We have shown that key player of SOC STIM2 but not STIM1 is downregulated in the hippocampus of PS1-KI mice and that hyperexpression of STIM2 protein rescues synaptic nSOC and mushroom spine loss in PS1-KI hippocampal neurons (Sun at al (2014) **Neuron**. 82:79-93). However, PS1-M146V-KI mice do not express human amyloid precursor protein and do not form Ab40 and Ab42. Since amyloid hypothesis is still considered to be dominant the next question arises: does similar pathological STIM2-nSOC process take place in conditions of amyloid toxicity? At the current study we have developed in vitro and in vivo models of low amyloid synaptotoxicity. In our studies we observed decrease in STIM2 protein levels in vitro and in vivo models of amyloid synaptotoxicity. Moreover, in in vitro and in vivo conditions we detected reduction of mushroom spines fraction. We observed that overexpression of mSTIM2 significantly increase percentage of mushroom spines in neurons treated with Ab42 in in vivo conditions. This indicates that STIM2 overexpression is able to protect mushroom spines from amyloid toxicity.

Our results suggest that downregulation of STIM2-nSOC pathway may play a general role in AD-related synaptic pathology and that modulators/activators of nSOC may be considered as potential therapeutic agents for treatment of AD patients.

INTRACELLULAR CA2+ STORES CONTRIBUTE TO IN VIVO NEURAL NETWORK DYSFUNCTION IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

B. Brawek[1], C. Lerdkrai[1], O. Garaschuk[1]
[1]Insitute of Physiology 2, Eberhard Karls Universität Tübingen, Tübingen, Germany

Objectives

In vitro studies suggest that Alzheimer's disease-related mutations in presenilin genes cause a dysfunction of intracellular Ca^{2+} stores in neurons. However, little is known about the role of intracellular Ca^{2+} stores *in vivo* as well as their dysfunction in the amyloid-depositing brain. Here we analyzed the *in vivo* properties of intracellular Ca^{2+} stores in amyloid-depositing mice and their contribution to network-driven neuronal activity.

Methods

Functional properties of intracellular Ca^{2+} stores were analyzed in cortical neurons of 10-14 months old $APP_{Swe}PS_{G384A}$ mice and age-matched wild type (WT) littermates using *in vivo* two-photon Ca^{2+} imaging. Ryanodine receptor (RyR)-mediated Ca^{2+} release from stores was evoked by brief pressure application of RyR agonist caffeine. Network-driven spontaneous Ca^{2+} transients were measured under control conditions and in the presence of Cyclopiazonic acid (CPA), which reversibly empties intracellular Ca^{2+} stores.

Results

Amplitudes of caffeine-induced Ca^{2+} transients were similar in both mouse strains but the duration of the transients at a half amplitude (T/2), decay time constant tau, and normalized area under the transient were significantly higher in amyloid-depositing mice compared to WT littermates ($p<0.05$; Mann-Whitney test). CPA significantly reduced the frequency of spontaneous Ca^{2+} transients in mutant mice ($p<0.01$). In addition, hyperactivity of neurons in the vicinity of amyloid plaques (see Busche et al., 2008) decreased dramatically upon store depletion.

Conclusions

Our *in vivo* data reveal a dysfunction of intracellular Ca^{2+} stores in amyloid-depositing mice and show that they are critically involved in controlling the network-driven neuronal activity.

CHANGES IN CALCIUM-ASSOCIATED PROTEINS DURING THE PROGRESSION OF ALZHEIMER'S DISEASE

K. Kurbatskaya[1], G. Dentoni[1], J. Atherton[1], D.P. Hanger[1], W. Noble[1]
[1]Basic and Clinical Neurosience, Institute of Psychiatry Psychology and Neuroscience, London, United Kingdom

Objectives: Disrupted neuronal calcium homeostasis is implicated in the development of Alzheimer's disease (AD). In late-stage AD brain, we have previously shown that elevated beta-amyloid burden was associated with increased calpain-1 activation and calpain-mediated cleavage and inactivation of the sodium calcium exchanger (NCX)3. The purpose of the present study was to investigate temporal changes in markers of calcium dysregulation during the progression of AD.
Methods: Frozen post mortem human temporal cortex from control and Braak Stage II-VI AD brain was obtained from the MRC London Brain Bank for Neurodegenerative diseases. Hallmark AD pathologies and calcium-associated protein amounts in each tissue were determined by western blotting and ELISA. Correlative relationships between specific protein changes were determined following regression analysis.
Results: Increased amounts of active calpain-1 were detected in early stage AD (Braak II) brain, and this change was sustained throughout disease progression. The increase in calpain activity was associated with elevated cleavage of its substrates, including NCX3. Moreover, calpain-1 activity correlated with total tau amounts and also with activity of the key tau kinase, glycogen synthase kinase (GSK) 3, which can be activated upon N-terminal calpain cleavage. Calpain-1 alterations were also associated with changes in the amounts of pre- and post-synaptic proteins, suggesting a relationship with synapse health in AD.
Conclusions: This study identified a close association between calpain, tau kinases activities and tau amounts, and supports the hypothesis that calcium dyshomeostasis occurs in early, pre-symptomatic stages of AD and is sustained throughout disease progression.

[5]Neuronal Networks & NRW Research group 'Dendritic integration in the CNS' Departme nt of Epileptology,
Deutsches Zentrum fur Neurodegenerative Erkrankungen & University of Bonn Medical Center, Bonn, Germany

Dendritic architecture and neuronal electrical properties are inseparably linked, defining the dendritic integration of synaptic signals, their propagation and their capability to evoke action potential output. The diversity of dendritic architectures enables neurons to fulfill their specialized circuit functions during cognitive processes. It is well known that dendritic integrity is impaired in patients with Alzheimer's disease and in animal models. It is unknown, however, whether such structural degeneration translates into neuronal dysfunction. We used *in vivo* whole-cell patch-clamp recordings, high-resolution STED imaging and computational modeling of CA1 pyramidal neurons in a mouse model of Alzheimer's disease to reveal that dendritic structural degeneration and neuronal hyperexcitability are critically linked. We demonstrate that a structure-determined amplification of synaptic input to action potential output conversion may constitute a novel mechanism underlying network dysfunction with a potential relevance for other neurodegenerative diseases with dendritic pathology.

ADPD5-0634

SIMPLE REACTION TIME IS MODIFIED IN ALZHEIMER'S DISEASE: AN INDIRECT MEASURE OF THE CHOLINERGIC LOSS?

C. Balla[1], J.L. Pepin[1]
[1]Department of Neurology, CHR Citadelle, Liege, Belgium

Objectives: We studied simple reaction time (sRT) in Alzheimer's (AD) patients before and after 2 months of treatment with 10 mg of donepezil in order to assess the alertness of their motor system.
Methods: 8 patients in early AD (70 +/- 6,3 years old) were compared to 15 normal subjects (71,1 +/- 4,2 years old)
Patients and normal subjects pushed their index on a button as quickly as possible after a randomly computer-generated visual red flash, determining the sRT. A surface electrode placed on the extensor indicis proprius recorded the EMG activity determining the onset of muscular movement time (sMT). The latency of sRT and of sMT were recorded by a CED1401 system.
Results:
Mean sRT was 207,3 +/- 25,5 ms in normals and 253,0 +/- 32,5 ms in AD patients before donepezil ($p < 0,001$)
Mean sRT was 229,9 +/- 30,6 ms in AD after donepezil ($p < 0,01$ compared to normals ; $p < 0,02$ compared to AD before donepezil)
Mean sMT was 159,3 +/- 29,3 ms in normals and 203,8 +/- 29,0 ms in AD patients before donepezil ($p < 0,001$)
Mean sMT was 180,8 +/- 32,2 ms in AD patients after donepezil ($p< 0,01$ compared to normals ; $p < 0,01$ compared to AD before donepezil)
Conclusions: sRT and sMT are significantly increased in AD patients compared to normal subjects of the same age. Donepezil improves the simple reaction time and the simple movement time in Alzheimer's disease patients supporting a cholinergic modulation of motor alertness.

BRIVARACETAM, BUT NOT ETHOSUXIMIDE, REVERSES MEMORY IMPAIRMENTS IN ALZHEIMER MOUSE MODEL

H. Nygaard[1], A. Kaufman[1], T. Sekine-Konno[1], L. Huh[1], H. Going[1], S. Feldman[1], M. Kostylev[1], S. Strittmatter[1]

[1]Neurology, Yale University School of Medicine, New Haven, USA

Introduction:

Recent studies have shown that several strains of transgenic Alzheimer's disease (AD) mice overexpressing the amyloid precursor protein (APP) have cortical hyperexcitabilty, and suggested that this aberrant network activity may be a mechanism by which amyloid-b causes more widespread neuronal dysfunction. Specific anticonvulsant therapy reverses memory impairments in various transgenic mouse strains, but it is not known whether reduction of epileptiform activity might serve as a surrogate marker of drug efficacy in an AD mouse model.

Methods:

Transgenic AD mice (APP/PS1 and 3XTg-AD) were chronically implanted with dural EEG electrodes, and epileptiform activity was correlated with spatial memory function and transgene-specific pathology. The anticonvulsant drugs (AEDs) ethosuximide and brivaracetam were tested for their ability to suppress epileptiform activity, and to reverse memory impairments and synapse loss in AD mice.

Results:

We report that in two transgenic mouse models of AD (APP/PS1 and 3xTg-AD), the presence and severity of spike-wave discharges (SWDs) correlate with impairments in spatial memory. While both AEDs reduce mouse SWDs, only brivaracetam reverses memory impairments in APP/PS1 mice, without altering Ab metabolism or synaptic density.

Conclusions:

Our data confirm an intriguing role of anticonvulsant drugs targeting Synaptic Vesicle Protein 2A (SV2A) across AD mouse models. Chronic ethosuximide dosing did not reverse spatial memory impairments in APP/PS1 mice, despite reduction of SWD. Our data also indicate that SWDs are not a reliable surrogate marker of target appropriate target engagement in APP/PS1 mice.

BRAIN STRUCTURAL, FUNCTIONAL, AND COGNITIVE CORRELATES OF RECENT VERSUS REMOTE AUTOBIOGRAPHICAL MEMORIES IN MILD COGNITIVE IMPAIRMENT

C. Tomadesso[1], A. Perrotin[1], J. Mutlu[1], F. Mezenge[1], B. Landeau[1], S. Egret[1], V. de La Sayette[2], F. Eustache[1], B. Desgranges[1], G. Chételat[1]
[1]Inserm-EPHE-UCBN U1077, GIP Cyceron, Caen, France
[2]Inserm-EPHE-UCBN U1077-CHU de Caen Service de Neurologie, CHU de Caen, Caen, France

Deficits in autobiographical memory appear earlier for recent than for remote life periods over the course of Alzheimer's disease (AD). The present study aims at further our understanding of this graded effect by investigating the cognitive and neural substrates of recent versus remote autobiographical memories in patients with amnestic Mild Cognitive Impairment (aMCI).

20 aMCI patients and 25 Healthy controls (HC) underwent neuropsychological tests assessing remote (20-to-30 years old) and recent (the ten last years) autobiographical memory as well as episodic and semantic memory, executive function and global cognition. All patients also had a structural MRI and an FDG-PET scan.

Correlations were assessed between each autobiographical memory score and the other tests as well as grey matter volume and metabolism. Within the aMCI, the remote period correlated with semantic autobiographical memory, episodic memory retrieval whereas the recent period only correlated with episodic memory retrieval. Neuroimaging analyses revealed significant correlations between the remote period and temporal pole and temporo-parietal cortex volumes and anterior cingulate gyrus metabolism, while the recent period correlated with hippocampus volume and posterior cingulate, medial prefrontal and hippocampus metabolism. The brain regions related with the recent period showed greater atrophy/hypometabolism in MCI patients compared to HC than those involved in remote memories.

Recall of recent memories essentially rely on episodic memory processes and brain network while remote memories also involve other processes such as semantic memory. This is consistent with the semantization of memories with time and may explain the better resistance of remote memory in early AD.

[4]Molecular and Cellular cognition,
German Center for Neurodegenerative Diseaes (DZNE), Bonn, Germany

Hippocampus dependent learning and memory requires coordinated firing of neurons that form a memory trace during encoding. The reactivation of neurons belonging to a memory trace is thought to take place during memory retrieval. Moreover, changes on the synaptic level maybe required to strengthen or weaken connections between neurons that form a memory trace. We wanted to find out if memory traces do exist in the hippocampus of living mice and how they are represented on the synaptic level. Therefore, we combined a hippocampus dependent learning and memory test with longitudinal two-photon in vivo imaging of CA1 neurons in the hippocampus. To monitor neuronal activity we used the immediate early gene c-fos in a mouse model that expresses GFP under the c-fos promotor. Fear conditioning induced structural changes on the synaptic level were analyzed in excitatory and inhibitory neurons. To identify mechanisms of learning and memory impairment, we analyzed a mouse model of amyloidosis. By monitoring neuronal activity of CA1 neurons in fosGFP mice throughout fear conditioning, we found a large fraction of neurons that are constantly active plus a smaller fraction that is specifically reactivated and stabilized. In APPPS1 transgenic mice already the memory formation was found to be impaired. On the synaptic level, we found an increased density of lost spines on excitatory radial oblique dendrites that may reflect altered network connectivity due to learning and memory. Summarizing, we identify cellular and synaptic correlates of learning and memory that are impaired in mouse model of Alzheimer's disease.

Università di Modena e Reggio Emilia, Rome, Italy
[3]Institute of Cell Biology and Neurobiology, CNR, Rome, Italy

A complication of Alzheimer's disease (AD) is the occurrence of epileptic seizures, but whether this hyper-activity contributes to cognitive impairment in AD has not yet been clarified. To answer this question, we performed experiments on the Tg2576 mouse model, bearing the human APP Swedish mutation, at both a pre-symptomatic and a symptomatic age. We characterized, by *in vitro* slice electrophysiology, the excitability properties of CA1 pyramidal cells to pinpoint neuronal signaling alterations underlying both epileptiform activity and hippocampal dependent memory deficits at their onset. We found significant differences in excitability properties of cells from Tg2576 vs wild-type mice at both stages, and indications that some of the electrophysiological alterations at the *onset* of cognitive deficits could actually be homeostatic responses to previous changes. Furthermore, experiments using anti-epileptic drugs in slice suggest that these could actually exacerbate some of these homeostatic responses.
In a different set of experiments, we induced seizures *in vivo* at the pre-symptomatic stage to investigate whether these play a role in inducing cognitive impairment specifically in the AD phenotype. Our data suggest that this is indeed the case.
Overall our *in vitro* and *in vivo* data provide a framework to elucidate the contribution of seizures in determining cognitive deficits in AD and for a use of anti-epileptic drugs based on the knowledge of the underlying neuronal signaling alterations at the different stages of the disease.

ADPD5-0288

THE ROLE OF AGEING IN NEURONAL VULNERABILITY IN DROSOPHILA.

F. Kerr[1], O. Adesakin-Sofola[1], D. Ivanov[2], C. Slack[1], P. Martinez[1], J. Adcott[1], R. Callard[1], M. Khericha[1], J. Thornton[2], S. Lovestone[3], L. Partridge[1]
[1]Institute of Healthy Ageing and GEE, University College London, London, United Kingdom
[2]Wellcome Trust Genome Campus Hinxton, EMBL-European Bioinformatics Institute, Cambridge, United Kingdom
[3]Department of Psychiatry Warneford Hospital, University of Oxford, Oxford, United Kingdom

Objectives: The incidence of neurodegenerative diseases, including Alzheimer's disease (AD) and Parkinson's disease (PD) increases markedly with advancing age. Recent research using model organisms, such as worms, flies and mice, has revealed that the aging process itself can be ameliorated by the manipulation of single genes. This provides an exciting new avenue for discovering much-needed treatments that can prevent or delay the progression of several age-related neurodegenerative diseases simultaneously, because aging is the major risk factor for all of them.
Methods: Models of neurodegenerative diseases in the fruit fly *Drosophila* are well established. Flies, due to their short lifespan and ease of genetic manipulation, provide a useful tool for studying the interaction between aging and disease. Our previous work has shown experimentally that older flies are intrinsically more susceptible to Aβ42 toxicity in neurons, suggesting that the aging process itself does indeed increase vulnerability to neurodegeneration. We have now examined the role of several candidate longevity-assurance processes, including cellular detoxification, defence against oxidative stress and proteasomal degradation, on Aβ42 toxicity in our fly model.
Results: We found that Aβ42 expression reduced activity of cncC, a *Drosophila* homologue of Nrf-2, which activates transcription of several antioxidant and cellular detoxification genes. Moreover, genetic enhancement of cncC protects against toxicity in Aβ42-expressing flies.
Conclusions: Our future studies will examine the mechanisms by which these pathways mediate both their lifespan-extending effects and protection against amyloid toxicity, with the aim of discovering new targets for disease-modifying therapies for neurodegenerative conditions.

RESVERATROL PROTECTS THE BRAIN FROM SPORADIC ALZHEIMER'S DISEASE (SAD) LIKE PATHOLOGY BY REDUCING EXTRACELLULAR ACCUMULATTION OF AMYLOID-BETA VIA ALPHA-SECRETASE ACTIVATION

A. Muthuswamy[1], *M. Ponnusamy*[1]
[1]*Department of Biochemistry, Bharathidasan University, Tiruchirappalli, India*

Background: Cerebral deposition of amyloid-β (Aβ) is the beginning of amyloid cascade leading to Alzheimer's disease (AD). Approximately 95% of AD accounts from SAD during aging. $A\beta_{42}$-peptides and plaques, generate from APP through sequential actions of β- and γ-secretases, whereas cleavage by α-and γ- secretases prevent toxic Aβ formation.
Objectives: Although localization of APP and secretases (ADAM10, BACE1 and PS1) are key proteins for regulating amyloidogenic pathway, it is unclear, whether aging promotes altered levels of expression and its subcellular distribution. Present study thus aimed to elucidate the cellular effect of resveratrol, on localization of AD related proteins during aging.
Methods: Using double immunofluorescence technique, the expression and subcellular localization (ER, Golgi and Mitochondria) of ADAM10, BACE1, PS1, APP and Aβ were examined in young and aged wistar rat brain regions with and without resveratrol.
Results: Absolute weight of the aged brain was increased (~26.5%), whereas the relative weight was decreased (~52%). We further identified decreased levels of ADAM10 (~50%) and elevated levels of BACE1 in aged rats. Although cell surface PS1 level was reduced, total expression remains unchanged, providing clue for enhanced Amyloidogenic pathway facilitating extracellular Aβ accumulation during aging. Resveratrol treatment significantly reduced BACE1 elevation and increased the expression of ADAM10 levels, further normalized cell surface PS1 expression.
Conclusion: From our results we conclude that aging promotes altered expression and subcellular distribution of secretases that may favor SAD, while resveratrol treatment exhibited positive influence on non-amyloidogenic pathway.

ADPD5-0870

PROTECTIVE ROLE OF RESVERATROL ON SMS1 ALTERATION LINKED MITOCHONDRIAL PRESENILIN-1 EXPRESSION IN RAT BRAIN REGIONS DURING AGING

P. Palanisamy[1], A. Muthusamy[1]
[1]Department of Biochemistry, Bharathidasan University, tiruchirappalli, India

***Background*:** APP processing by γ-secretase strongly depends on cellular membranes, which are highly sensitive to even slight alterations in membrane environment. Sphingomyelin synthase (SMS1) is one such determinant of mitochondrial membrane composition. Mitochondrial dysfunction has long been associated to SAD, while the mechanism remains unclear. Decreased SMS1 expression has also been reported during aging facilitating ceramide mediated mitochondrial apoptosis.
Objective: SMS1 mediated alteration in sphingomyelin levels may influence altered function of membrane bound enzymes in particular PS1 in case of SAD, promoting Aβ formation during aging. Thus we intend to study the influence of SMS1 over mitochondrial PS1 activity during aging and to exhibit the role of sirtuin in regulating these altered metabolic events.
***Methodology*:** 20 mg/kg body weight of resveratrol as sirtuin enhancer was treated for young and aged male wistar rats for 15 days. Rat brain regions were assessed for mitochondrial abnormalities. SMS1, SMS2 levels were analyzed to determine sphingolipid alterations. Mitochondrial (APP, PS1, CTFs) and SIRT1 levels were analyzed using western blotting.
***Results*:** SMS2 expression was increased and in contrast SMS1 and SIRT1 levels were decreased significantly in aged rats. Mitochondrial APP was found to decrease with a significant increase in CTFs. Surprisingly, there wasn't any significant increase in Aβ formation. Mito-PS1 activity displayed a significant increase of $p<0.001$ compared to young rat brain regions.
***Conclusion*:** The current study thus provided a rationale relationship between SMS1 and altered mitochondrial PS1 activity during aging. Resveratrol found to exhibit a homeostatic effect in regulating age associated key metabolic events.

[7]Nutrition, University of Montreal, Montreal, Canada
[8]Neurobiology, Yale University, New Haven, USA

1. Objectives

There is no effective treatment to prevent memory decline in the elderly or patients diagnosed with mild cognitive impairment (MCI). The striatal-enriched protein tyrosine phosphatase (STEP) occupies a key position in the cascade of events involved in memory by controlling the activity of proteins implicated in memory, such as ERK and the GluN2B subunit of the NMDAR. The objective of this study is to uncover the role of STEP in age-related memory deficits across different species.

2. Methods

Memory performances of aged rats and mice (STEP KO, Het, and WT) were tested in the Morris water maze and Y maze tasks. Cognitive deficits of rhesus monkeys were evaluated in the paired associate learning test and delayed matching to sample task. Protein Levels of STEP and its substrates were quantified by western blots, and STEP activity was analyzed by immunoassay.

3. Results

We found an elevation in the levels and activity of STEP in aged memory-impaired mice and rats. We also observed increased STEP expression in aged rhesus monkeys and humans with MCI. These increases are linked to enhanced dephosphorylation of the STEP substrates GluN2B and ERK. STEP accumulation with aging appears to involve dysfunction of the ubiquitin-proteasome system. Genetic reduction of STEP levels alleviates age-related memory decline.

4. Conclusions

Elevated STEP levels that occur with advancing age constitute a molecular mechanism common to several species that contributes to age-related cognitive deficits, and may represent a target for pharmacological therapy to enhance cognition in the elderly and MCI patients.

REVERSE SIZE EFFECTS IN A PATIENT WITH POSTERIOR CORTICAL ATROPHY; A CASE REPORT

M. Yamada[1], H. Satoh[2], A. Satoh[2], M. Tsujihata[2]
[1]Rehabilitation, Nagasaki Kita Hospital, Nagasaki, Japan
[2]Neurology, Nagasaki Kita Hospital, Nagasaki, Japan

Background: We herein report the case of a PCA patient who showed a greater difficulty perceiving the large letters than the small letters.
Case report: A 53-year-old, right-handed female housewife was admitted to the hospital because of four-years visual symptoms, including difficulties in reading a text and writing letters, problems with driving or parking a car, color recognition impairment and difficulties performing dual tasks at the same time. The findings of neuropsychological examinations, such as the MMSE24/30, Digit Span(forwards)9, (backforwards)4, Tapping Span (forwards)1, (backforwards)0, WAIS-III, VIQ91, PIQ47, FIQ66, VC95, PO50, WM76, PS50, showed the greater visual problems than the verbal problems. When she was asked to read a Japanese Kanji, she could read it if it was shown in a small size, but, she could read only part of the Kanji shown in a large size. She read large “H” as “I”, but could read “H” shown in a small size. Occipitoparietal atrophy, particularly in the right side, was observed by MRI, and marked hypoperfusion was noted in the same regions by SPECT.
Discussion and Conclusions: The reverse size effect (the ability to better read small than large prints) is a rare phenomenon in PCA(Crutch et al. 2011). The difficulty in reading large written Kanji observed in this patient is consistent with the reverse size effect described by Crutch et al. The responsible region is suspected to have been in the right occipitoparietal region.

SEVERE DEPRESSION EFFECTS ON CLINICAL DEMENTIA STAGING

S.Y. Park[1], M.J. Wang[1], Y.H. Park[1], M.J. Baek[1], S.Y. Kim[1]
[1]Clinical Neuroscience Center, Seoul National University Bundang Hospital, Gyeonggi-do, Korea

Objectives
Neuropsychological test has a distinct role in the detection and monitoring of cognitive and functional changes, so it provide unique value as biomarkers of dementia. Clinical dementia rating (CDR) is another tool to evaluate the severity of symptoms of cognitive decline. And the two scale is known to have relevance each other. We aimed to assess the dissociation between neuropsychological test and CDR-SOB according to severe depression in MCI to early stage of dementia.
Methods
From 3873 patients who were assessed at the Seoul National University Bundang hospital, 364 patients with clinically questionable impairment (CDR-SOB 0.5-2.0) and 54 patients with very mild dementia (CDR-SOB 2.5-4.0) were identified as severe depressed status. Detailed neuropsychological test scores were compared with those of patients whose geriatric depression score were normal range.
Results
In clinically questionable impairment group, severe depressed patients showed significantly lower scores in immediate recall, word fluency and stroop test ($p<0.01$). On the other hands, in clinically very mild dementia group, severe depressed patients showed significantly higher scores in memory discrimination test($p=0.027$) and had tendency to higher level in delayed recall test ($p=0.07$).
Conclusion
Whether severe depression is present or not may affect the clinical assessment of cognitive function showing a gap between neuropsychological value and clinical dementia scale.

People who have Down syndrome, which is caused by trisomy of chromosome 21, are at significantly increased risk of developing Alzheimer's disease (AD). An additional copy of the chromosome 21 encoded gene, APP, is known to promote the development of AD. However, the effect of trisomy of the other ~300 chromosome 21 genes on disease is unclear. Here we show, using mouse models, that trisomy of chromosome 21 (in the absence of APP duplication) makes a significant contribution to the development of AD. Trisomy of chromosome 21 significantly enhances ABeta deposition and associated synaptic transmission and cognitive deficits, and reduces survival. We show that trisomy of chromosome 21 alters the development of ABeta pathology by a novel mechanism that modulates the production and resultant aggregation of ABeta. These data suggest that people who have Down syndrome have an increased risk of developing Alzheimer's disease not only because they have an additional copy of APP but because trisomy of a further chromosome 21 encoded gene, or genes, modulates disease. We now aim to identify this gene or genes, to provide further novel mechanistic insight into the development of Alzheimer's disease.

HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) AXIS DYSREGULATION IN ALZHEIMER'S DISEASE USING IN-VIVO AND IN-VITRO MODELS.

S. Kootar[1], M.L. Frandemiche[1], P. Rodrigues[1], A.R. Salgueiro Pereira[1], X. Mouska[1], J. Barik[1], H. Marie[1]

[1]laboratory of Molecular mechanisms of neuronal plasticity in health and disease, IPMC, Valbonne, France

The function of the hippocampus, a key structure responsible for memory encoding, is affected early in Alzheimer's disease (AD) leading to progressive and irreversible memory loss. The molecular mechanisms underpinning this memory loss remain elusive but are crucial to identify for the development of effective therapies. There is strong evidence that both amyloid-beta (Ab) and the main stress hormone, cortisol (corticosterone (CORT) in mice), are abnormally elevated during the early phase of AD. CORT signaling is regulated by the Hypothalamic–pituitary–adrenal (HPA) axis. Using a hAPPswee-overexpression mouse model of AD, which accumulates Ab in the hippocampus, we characterized the onset and extent of HPA dysfunction during the early phase of hippocampus-dependent memory impairments. We show that the first alterations are represented by CORT increase in the plasma and loss of the feedback mechanism induced by dexamethasone treatment, while ACTH levels and the weight of HPA-axis related organs remain normal. We are also investigating the relationship between Ab, glucocorticoid receptors (GRs) and synaptic function in cultured hippocampal neurons. Our data suggest a complex relationship between synaptic GRs, synaptic AMPA receptors and presence of Ab. Together, these data should help clarify the mechanistic relationship between APP misprocessing and HPA axis dysfunction in AD.

CEREBROSPINAL FLUID THYROID HORMONES IN AD PATIENTS: A MASS-SPECTROMETRY STUDY.

A. Vergallo[1], F.S. Giorgi[1], R. Donzelli[2], A. Saba[2], F. Baldacci[1], L. Kiferle[1], L. Petrozzi[1], G. Tognoni[1], R. Zucchi[2], U. Bonuccelli[1], A. Accorroni[2:3]

[1]Clinical and Experimental Medicine, university of pisa, Pisa, Italy

[2]Department of Pathology, university of pisa, Pisa, Italy

[3]Scuola Superiore di Studi Universitari e di Perfezionamento Sant'Anna, Pisa, Italy

Background: Thyroid hormones might play a role in AD pathogenesis. In the last decades several studies have assessed thyroid hormone (TH) levels in serum and CSF in AD patients, with conflicting results. Mass spectrometry allows quantifying precisely their levels, and better discriminating triiodothyronine (T3) from reverse T3 (rT3) [originating from the conversion of thyroxin (T4) by Type II and Type III deiodinase, respectively], differently from the immunoenzymatic methods used so far.

Methods: We assessed nine consecutive patients with a diagnosis of probable AD (according to NINCDS-ADRDA revised criteria) submitted to cerebrospinal fluid (CSF) analysis (for Ab1-42, tau and phospho-tau analysis), full neuropsychometric evaluation, neuroimaging investigations with fluoro-deoxy-glucose positron emission tomography and brain magnetic resonance imaging. T3, rT3, T4 levels were assessed by mass spectrometry in CSF and serum (in this case, discriminating between protein-bound and unbound forms, differently from other techniques). The same hormones were assayed in CSF of non-demented patients.

Results: Serum and CSF levels of free and total TH were similar in AD patients and controls. CSF rT3/T3 ratio was lower in AD than in controls. We also performed a correlation analysis between CSF TH levels, CSF biomarkers and neuropsychometric/ neuroimaging data.

Conclusion: Our data show a reduced ratio between rT3/T3 in AD CSF, with mass spectrometry, a technique giving reliable values as compared with current routine lab techniques. Speculative hypothesis on their role, based on correlative data are provided.

Objectives

Synapse loss and synaptic dysfunction in Alzheimer's disease (AD) are linked to membrane loss and altered membrane composition. Neurons require specific nutrients for the formation and maintenance of synaptic membranes. These nutrients fuel the metabolic pathways that synthesize new phospholipids, the main constituents of membranes. While AD patients may benefit from higher availability of the phospholipid-synthesizing nutrients that can support synapse formation and function, many patients have lower plasma levels of these nutrients. Such compromised nutritional status may progress during the course of the disease and may already be evident in earlier stages of AD. We aimed to investigate the role of these potential biomarkers in the pre-dementia stages of AD as well as in AD.

Methods

We currently investigate whether blood and cerebrospinal fluid (CSF) levels of phospholipid-synthesizing nutrients differentiate between subjects with subjective memory complaints (n=150), mild cognitive impairment (n=150), or AD (n=150) in a retrospective cohort study. Subjects were selected from the memory clinic based Amsterdam Dementia Cohort of the VUmc Alzheimer Center.

Results

Analyses of paired CSF, serum, and plasma samples of the Amsterdam Dementia Cohort are ongoing. Among others, levels of the following nutrients are being measured: plasma and CSF choline, folic acid, uridine, and homocysteine and plasma polar lipid profile.

Conclusions

The current study may further elucidate the role of these nutrients in AD pathology by identifying their levels in plasma and CSF at different stages of the disease. In addition, these nutrients may have potential to serve as (modifiable) biomarkers for AD.

DETECTION OF ANTI ABETA40-ANTIBODIES IN THE BRAIN OF TWO TRANSGENIC MICE MODELS OF AD AFTER ACTIVE IMMUNOTHERAPY

P. Pesini[1], M. Izco[1], V. Perez-Grijalba[1], A.M. Lacosta[1], M. Sarasa[1]
[1]R&D laboratory, Araclon Biotech Ltd, Zaragoza, Spain

Active immunization against Aβ40 of two transgenic mice models of AD (tg2576 and APPswe/PS1dE9) produces a marked Aβ40 level increase and anti-Aβ40 antibody titers in plasma.

We explored here this increase in Aβ40 levels and ascertain whether self-generated anti-Aβ40-antibodies reach brain tissue.

ABtest40 cannot detect Aβ40 bound to self-antibodies generated by immunization; unless they are displaced by competing xeno-antibodies. To determine whether plasma Aβ40 levels increase was caused by free Aβ40 or peptide bound to self-anti-Aβ40-antibodies we devise an ELISA for the detection of Aβ40-antibody complex. This ELISA was run either with or without the addition of label-free competing anti-Aβ40-xeno-antibodies. Lack of signal differences between the two runs of each sample would denote lack of displacement meaning that the signal obtained in ABtest was due to free Aβ40.

Antibody titers in plasma and the concentration of anti-Aβ40 IgG in brain extract from twelve vaccinated mice were assessed by ELISA in plates coated with Aβ40.

On average, the plasmatic signal for Aβ40-antibody complex dropped just 11 % when the samples were run in the Aβ40-antibody complex assay with competing antibodies. This drop did not reach statistical significance ($p = 0.120$).

Relevant concentrations of anti-Aβ40-antibodies were found in brain extracts correlating with plasma antibody titers (tg2576 $R^2 = 0.654$, $p < 0.001$; APP/PS1 $R^2 = 0.723$, $p < 0.001$)

The increment in plasma Aβ40 concentration after vaccination is mainly due to accrued free peptide. These results indirectly favor the sink hypothesis together with a central action of specific antibodies in the brain.

A NOVEL ANTIBODY EFFICIENTLY NEUTRALIZES ALZHEIMER'S DISEASE-RELATED IMPAIRMENTS IN SPATIAL MEMORY AND SYNAPTIC PLASTICITY IN RATS

J. Qi[1], L. Cheng[1], J. Zhang[1], X. Li[1], Y. Pan[1], X. Chen[1], J. Qiao[1]
[1]Physiology, Basic medicine, Taiyuan, China

Objectives: Although the immunotherapy for Alzheimer's disease (AD) showed exciting results, both active and passive immunization against amyloid β protein (Aβ) in human AD have been suspended because of serious side effects which partly arise from the damage of physiological amyloid precursor protein (APP). Our previous studies indicated that the sequence 31-35 in Aβ is a shorter active center responsible for the Aβ neurotoxicity. In the present study, we prepared a novel antibody specifically targeting the sequence 31-35 of Aβ, observed the effects of the antibody on $Aβ_{1-42}$-induced impairments in spatial cognitive behavior of rats, and investigated its possible electrophysiological and cellular mechanisms. **Methods:** Morris water maze, neuronal culture and *in vivo* hippocampal field potential recording techniques were used in the study. Anti-Aβ31-35 antibody and Aβ1-42 were injected into the lateral ventricle of SD rats two weeks before performing spatial cognitive test. Anti-Aβ31-35 antibody in co-application group was delivered 15 min before Aβ1-42 injection. **Results:** Anti-Aβ31-35 antibody efficiently protected against the Aβ1-42-induced impairments in spatial memory and hippocampal long term potentiation (LTP) of rats. The cytotoxicity induced by Aβ1-42 in cultured cortical neurons was also potently inhibited by the anti-Aβ31-35 antibody in a dose-dependent manner. **Conclusions:** These results suggest that the anti-Aβ31-35 antibody is probably an effective immunotherapy approach for AD, and the sequence 31-35 of Aβ may be a new therapeutic target.

Keywords: Anti-Aβ31-35 antibody; Amyloid-β protein; Spatial learning and memory; Long-term potentiation; Neuronal cytotoxicity

ADPD5-0564

NT4X-167; NOVEL N-TERMINAL ABETA SPECIFIC ANTIBODY, PREVENTS IN VITRO AND IN VIVO TOXICITY OF HIGHLY TOXIC ABETA4-42 SPECIES

G. Antonios[1], T. Pilot[2], V. Pena[3], T.A. Bayer[1]
[1]Department of Psychiatry and Psychotherapy Division of Molecular Psychiatry, University Medicine Göttingen, Göttingen, Germany
[2]-, SynAging, Nancy, France
[3]Department of Cellular Biochemistry, Max-Planck Institute of Biophysical Chemistry, Göttingen, Germany

Objectives: The novel monoclonal antibody (NT4X-167) specifically reacts with N-truncated ABeta at position 4 of ABeta. It binds N-truncated ABeta under native and denaturing conditions but only rescues *in vitro* toxicity of $ABeta_{4-42}$ and not that of pyroglutamate ABetapE3-42. One objective was to determine whether the NT4X-167 antibody and its respective Fab fragment could prevent working memory deficits caused by $ABeta_{4-42}$ injection in wildtype mice.
Methods: Cell toxicity assay, *in vivo* toxicity, Y-Maze, mAB antibody production, immunostaining
Results: The novel $ABeta_{4-x}$ immunoreactive antibody NT4X-167 detected high molecular weight aggregates derived from N-truncated ABeta species. Phenylalanine at position four of ABeta was imperative for antibody binding. Both full-length and the Fab fragment of the antibody were able to prevent the *in vitro* toxicity caused by ABeta4-42 in rat primary cortical neuron cultures. Intracerebroventricular ABeta4-42 injection into wildtype mice induced a behavioral deficit, shown as a reduction in alteration rate in a Y-Maze, which was prevented using the NT4X-167. The Fab fragment of the antibody, at a higher dosage, was also able to prevent the behavioral deficit in a replicate experiment.
Conclusions: NT4X-167 and Fab demonstrate binding and prevention of ABeta4-42 toxicity *in vitro*. NT4X full length antibody and Fab prevent $ABeta_{4-42}$ induced behavioral deficits in wildtype mice. Functionally, the full length antibody and its respective Fab fragment exhibit the same profile. It would thus be of great interest to study the structural binding characteristics of the NT4X-167, represented by its Fab fragment, to the highly toxic N-truncated ABeta4-x species.

ANTIBODIES DRAMATICALLY INCREASE THE NEUROTOXICITY OF AMYLOID BETA OLIGOMERS IN PRIMARY NEURONAL-GLIAL CULTURES BY ACTIVATING MICROGLIA

R. Morkuniene[1], S. Jankeviciute[1], P. Cizas[1], I. Dalgediene[2], A. Zvirbliene[2], V. Borutaite[3]
[1]Institute of Neurosciences, Lithuanian University of Health Sciences, Kaunas, Lithuania
[2]Institute of Biotechnology, Vilnius University, Vilnius, Lithuania
[3]Institute of Neurosciences, Lithuanian University Of Health Sciences, Kaunas, Lithuania

Objectives. Beta amyloid (Aβ) oligomers are thought to contribute to the pathogenesis of Alzheimer's disease (AD). The success of anti-Aβ immunotherapies in preclinical studies led to the initiation of anti-Aβ in clinical trials, but halted due to brain inflammation, the mechanisms of which are poorly understood. In the present study we aimed to investigate the effects of antigen-antibody complexes formed by oligomeric Aβ and specific monoclonal antibodies in primary neuronal-glial cultures. Methods. Monoclonal antibodies generated against synthetic Aβ1-42 were preincubated with Aβ1-42 then added to cultures. The viability of neurons was examined by fluorescence microscopy. Results. We found that antibodies dramatically increased the neurotoxicity of Aβ oligomers. Complexes of antibodies plus monomeric Aβ had no effect on neuronal viability. The neurotoxicity of antibody-oligomeric antigen complexes was abolished by removal of the Fc region from the antibodies or by removal of microglia from cultures, and was accompanied by inflammatory activation and proliferation of microglia. However, the preincubation of cultures with inhibitors of NADPH oxidase and NO synthase did not prevent neuronal death caused by antibody-oligomeric Aβ. Conclusions. Antibody-antigen complexes formed by Aβ oligomers or other oligomeric antigens and their specific antibodies exert strong toxic effects on neuronal cells via Fc-dependent microglial activation. Our study provides new insight into the mechanism of possible Aβ neurotoxicity in the presence of Aβ-specific antibodies in AD brain and also may be important clinically in the development of safer vaccines for AD treatment.

ADPD5-0674
CONFORMATIONAL SPECIFICITY AND DIVERSITY OF THE IMMUNE RESPONSE TO ABETA42 AMYLOID FIBRILS

C. Glabe[1], *A. Hatami*[1]
[1]*Molecular Biology and Biochemistry, University of California Irvine, Irvine, USA*

Objectives: Abeta forms multiple conformationally distinct types of aggregates, so the objective was to isolate as many different monoclonal antibodies against distinct Abeta epitopes as possible.
Methods: Monoclonal antibodies were isolated from rabbits vaccinated with Abeta42 fibrils and 23 unique antibodies were isolated.
Results: These antibodies define 18 distinct immunological profiles of Abeta and. display a strong preference for aggregates over monomer, indicating that they recognize conformational epitopes. Most antibodies recognize N-terminal linear segments of Abeta, although many recognize a discontinuous epitopes. Many antibodies that recognize linear Abeta segments also recognize generic fibril epitopes contained in fibrils from unrelated amyloid sequences, indicating that linear epitope mapping is not a reliable indicator of sequence specificity. The antibodies display strikingly different patterns of immunoreactivity in Alzheimer disease and transgenic mouse brain. One antibody stains unique nuclear deposits in early AD and another is specific for a subset of vascular amyloid, indicating that the conformational differences are observed in human and Tg mouse brains.
Conclusions: The humoral immune response to Abeta42 fibrils is diverse and reflects the structural polymorphisms in fibrillar amyloid structures. No single antibody recognizes all of the different aggregation states under all conditions. Reliance on only a few monoclonal antibodies may restrict scientists to the observation of only a subset of the amyloid involved in pathology and also may not target all of the pathological aggregates necessary to be therapeutically effective.

[3]/, Janssen Alzheimer Immunotherapy Research & Development, South San Fransisco CA, USA

Amyloid-related imaging abnormalities (ARIA) have been reported in Alzheimer disease (AD) patients. Moreover, an increased risk of ARIA upon β-amyloid (Aβ) immunotherapy has been reported. It has been proposed that reduced vascular integrity caused by aggressive lowering of central and vascular Aβ might be involved. In the current study we applied T_1 mapping MRI, in combination with Gadolinium (Gd, Dotarem®) injection, to probe for blood-brain-barrier (BBB) integrity applying 3D6 (the murine equivalent of bapineuzumab) immunotherapy in PDAPP mice.

PDAPP mice (12 months) were treated weekly with either 3D6 or saline. Wild type animals served as controls and were treated with saline for a period of 5 weeks. T_1 weighted images were acquired weekly on a 7T small animal MRI system, before (baseline) and after intravenous administration of Gd (0.2 mmol kg^{-1}). T_1 values were quantified.

No differences in cortical T_1 values were observed at baseline. Interestingly, five mice (out of 12) showed a considerable larger drop in T_1 values (~300ms) after 2-5 weeks of treatment with 3D6, which was not observed in the saline-treated PDAPP group. This suggests increased vascular permeability, probably induced by the clearance of vascular Aβ.

This study shows for the first time *in vivo* increased cerebral vascular permeability upon Aβ immunotherapy. The time course of these events was documented and the methodology may be useful to assess ARIA risk in the development of other Aβ lowering compounds. Hence, our findings are important to increase our understanding of ARIA observed in AD patients upon Aβ lowering therapies.

Oligomers of the amyloid-beta (Abeta) peptide play key roles in neurotoxicity and region-to-region spreading of Alzheimer's disease (AD) neuropathology. Here we describe a novel immunological epitope that is accessible to antibody binding only when Abeta is in an oligomeric form, termed cSNK.

Specificity of a monoclonal antibody raised against the cSNK epitope, 5E3, was evaluated by surface plasmon resonance, dot blotting/immunoblotting, immunohistochemistry, and atomic force microscopy. Therapeutic potential of the 5E3 antibody was assessed in *in vivo* assays of oligomer behavioral toxicity and acute treatment of aged AD mouse models. Immune responses elicited by cSNK vaccine formulations were evaluated in young mice.

The oligomer-specific epitope consists of a constrained turn at residues 26-28: cyclized serine-asparagine-lysine (cSNK). A monoclonal antibody raised against this novel epitope (5E3) binds to synthetic Abeta oligomers (ABO) with high affinity (K_D = 2.02 nM), but is unreactive to monomeric and fibrillar Abeta, as well as to amyloid plaques. 5E3 specifically recognizes soluble analyte in high-speed clarified saline brain extracts and cerebrospinal fluid from AD patients, while displaying negligible reactivity to healthy control samples. Pre-clinical evaluation indicated that the antibody is effective at blocking ABO toxicity and reducing ABO levels in CSF and brains of treated APP/PS1 and Tg2576 mice, with no apparent effect on pre-existing plaques. Moreover cSNK vaccinated mice produced an ABO specific immune response, without producing a response targeting Abeta monomers.

Together, the data demonstrates that cSNK is a unique ABO specific epitope with clear therapeutic and diagnostic potential.

[4]Laboratory of Immunology, INSERM U932 - Institut Curie, PARIS, France

OBJECTIVES

Besides innate immune responses mediated by microglia and monocyte-derived macrophages, recent reports suggest that adaptive immunity, and particularly T cell responses, may be implicated in the pathophysiology of Alzheimer's disease (AD). However, the role of different T cell populations in disease progression remains poorly defined. We previously showed that regulatory T cells (Tregs) critically control the magnitude of Abeta-specific CD4+ T cell responses in both physiological and pathological settings. Here we analyzed the impact of Tregs on disease progression in a murine model of AD.

METHODS

Preclinical studies were carried in the APPPS1 mouse model. Treg cells were either depleted using anti-CD25 antibodies, or selectively amplified through low-dose IL-2 treatment. Impact of Treg modulation on neuropathology, disease-related gene expression, and cognitive functions was assessed.

RESULTS

Depletion of Tregs accelerated the onset of cognitive deficits in APPPS1 mice, without altering Abeta deposition. Early cognitive impairment was correlated with reduced recruitment of microglia towards amyloid plaques, and altered disease-related gene expression profile in the brain. Conversely, targeted amplification of Tregs enhances microgliosis and the recruitment of microglia around amyloid deposits, and delays the onset of cognitive deficits in APPPS1 mice.

CONCLUSION

Treg cells play a beneficial role in the pathophysiology of AD, and new immunotherapy strategy targeting Tregs proves efficient at delaying disease progression in preclinical studies. Altogether, these data suggest the therapeutic potential of such Treg-based innovative immunotherapy approaches for the treatment of AD.

[3]Department of Chemical and Biological Engineering Physical Chemistry,
Chalmers University of Technology, Gothenburg, Sweden

Over the last few decades, attempts were made in order to prevent the beta amyloid peptide (Aβ) aggregation. One approach achieved was the development of a peptide $iAβ_5$ capable of inhibit these aggregation. Though, due to the blood brain barrier (BBB) this potential drug for the treatment of Alzheimer's disease (AD) can not reach the brain in sufficient concentrations.

To circumvent this problem a novel carrier-based brain drug delivery system made of PLGA polymer with surface functionalized with transferrin receptor monoclonal antibody (OX26) and anti-Aβ (DE2B4) was prepared to delivery encapsulated $iAβ_5$ to the brain. The immuno nanoparticles (NPs) were synthetized by the nanoprecipitation method, resulting in a particle size with around 160nm, making them a suitable vehicle for intravenous administration.

The porcine brain capillary endothelial cells were used as a model of the BBB. Uptake of immune NPs was substantially higher compared to the non functionalized nanoparticles. Furthermore, the peptide release behavior indicates a controlled delivery of the peptide at 37ºC.

In conclusion, these Trojan horses have a higher probability to cross BBB, bind to Aβ peptide and deliver the drug tested in the local of action. By this way, they represent a novel platform technology for treatment of central nervous system (CNS) disease.

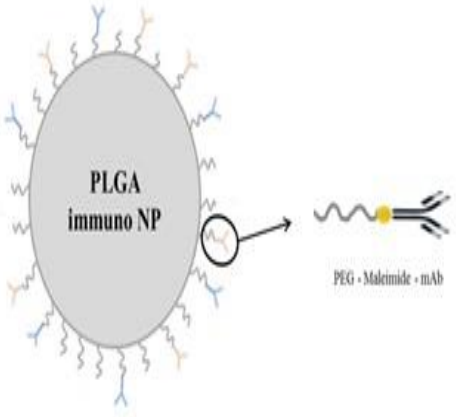

Figure 1. Schematic representation of developed PLGA NPs conjugated with two different types of antibodies.

ADPD5-2291

FUNCTIONAL EFFICACY OF PASSIVE IMMUNIZATION AT TREATMENT-SENSITIVE STAGES IS NOT INCREASED BY EARLIER START OF THE TREATMENT IN AD MODEL

A. Savonenko[1], D. Lee[1], J. Troncoso[1], A. Hiatt[2], T. Melnikova[1]
[1]Pathology, Johns Hopkins School of Medicine, Baltimore, USA
[2]Immunology, MAPP Biopharmaceutical Inc, San-Diego, USA

As a number of clinical trials with passive anti-Abeta immunization are under way, the critical mechanisms required for the efficacy of this approach are still poorly understood. In this study, we compared functional efficacy of three similar monoclonal anti-Abeta antibodies (AB) raised against an internal domain of Abeta (Abeta13-28). As detected by a surface plasmon resonance analysis the ABs had no significant differences in affinities to monomeric or oligomeric Abeta. Comparative efficacies of the ABs in amelioration of Abeta accumulation and cognitive deficits were tested after one month of i.p. treatments in 12-mo-old APPswe/PS1dE9 mice that had already developed plaques and cognitive deficits in episodic-like memory. All three ABs increased plasma Abeta concentrations, two ABs decreased levels of Abeta accumulated in brain, and only one of the latter ABs was also effective significantly ameliorating cognitive deficits. To test whether earlier start of the treatment increases efficacy in restoring cognition, 12-mo-old APPswe/PS1dE9 mice were tested after 6 month-long therapy with the cognitively-effective AB. This longer treatment initiated at the onset of plaque deposition showed efficacy equal to that after just one-month-long treatment. We proceeded to test whether longer duration of the treatment has any benefits in older, 18-mo-old, APPswe/PS1dE9 mice. In the older mice, despite of the presence of duration-dependent amelioration in Ab load, no cognitive benefits were detected after one- or six-month-long treatments. Taken together, these findings suggest that efficacy of passive immunization at treatment-sensitive stages might not be increased by earlier start / longer duration of the treatment.

[7]Dialysis Center, Kanayama Clinic, Nagoya, Japan

Objectives;
We have been developing Extra-corporeal Abeta Removal System (EARS) as a novel therapeutic method of Alzheimer's Disease. We followed hemodialysis patients prospectively to investigate whether the repeated removal of blood Abeta affect plasma Abeta concentrations, cognitive functions and Abeta burden in the brain.
Methods;
This study was approved by the institutional review boards of Fujita Health University and the hospitals involved. The plasma Abeta concentrations by ELISAs (WAKO) and the cognitive functions by MMSE were investigated in 30 patients on hemodailysis (age,71.8 ± 3.3 yo; duration of dialysis, 12.9 ± 8.8 years) at Baseline and 18 or 36 months later (2ndline). Postmortem brain cortices of 16 hemodailysis patients (75.8 ± 9.8 yo) and 16 non-hemodialysis controls (79.0 ± 12.5 yo) were retrospectively analyzed with anti Abeta antibodies.
Results;
Hemodialyzers removed blood Abeta effectively and triggered the influx of Abeta from outside of the blood. This Abeta-influx ceased in association with the end of hemodialysis. From Baseline to 2ndline, plasma $Abeta_{1-40}$ decreased (750.3pg/ml to 689.4 pg/ml, p=0.031), but plasma $Abeta_{1-42}$ increased (41.5 to 69.6pg/ml, p<0.001). Individual MMSE scores were slightly improved (p=0.057, Wilcoxon signed-rank-test). The brains of hemodialysis patients contained significantly fewer plaques than controls. Brain Abeta imaging of hemodialysis patients will also be discussed.
Conclusions;
Heamodialysis removed blood A-beta effectively and improved or maintained cognitive functions. It might trigger the Abeta-influx from the brain into the blood.

RETINOIC ACID SKEWS THE T HELPER CELL RESPONSE TOWARDS AN ANTI-INFLAMMATORY TH2 PHENOTYPE IN AMYLOID-BETA PEPTIDE IMMUNIZED MICE

G. Gevorkian[1], R. Perez-Garmendia[1], G. Acero[1]
[1]instituto de Investigaciones Biomedicas, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico

Objectives: The beneficial effects of Abeta immunotherapy may be counteracted by inflammatory responses. Taking into account a chronic inflammatory environment in the AD brain, therapeutic strategies that would not result in a worsening of this phenomenon should be designed, and the induction of the Th2 response by immunotherapy should be more beneficial and safer than a Th1 response. In this study we evaluated antibody production and T cell response in mice after immunization with Abeta in the presence of all-trans retinoic acid (ATRA) as an immunomodulator.
Methods: C57BL/6J wild type and 3XTg-AD mice were immunized with four major Abeta pathological species present in human AD brain (Abeta 1-42, AbetaN3(pE), Abeta 11-42 and AbetaN11(pE)) using saponin as an adjuvant and ATRA. ELISA and cell proliferation assay followed by flow cytometric analysis and supernatant cytokine measurement were performed using standard protocols.
Results: We have demonstrated that ATRA skews anti-Abeta antibody and cytokine production to the potentially safer anti-inflammatory Th2 phenotype in mice immunized with full length Abeta 1-42, but not with N-truncated/pyroglutamate modified peptides in the presence of saponin adjuvant. Interestingly, we didn´t observe proliferation of Abeta 11-42 or AbetaN11(pE) immunized mouse T cells in vitro in the presence of any Abeta peptide/epitope probably because of the loss of the known T cell epitope mapped to the central region of Abeta 1-42 in previous studies.
Conclusions: Our results may have implication in future design of new immunotherapeutic protocols for AD minimizing the risk of neuroinflammation-related toxicity.

[2]Russian Academy of Sciences, Institute of Cell Biophysics, Pushchino, Russia

It is known that oligomeric Abeta binds receptors on neuronal cell surface and this interaction can mediate cell death and amyloid plaque formation during AD. We proposed that short receptor fragments representing the potential binding sites of Abeta are able to bind Abeta and to prevent its interaction with the receptors.Thus administration of these receptor fragments will decrease brain level of Abeta and improve the memory state.

We have selected and synthesized the 14 peptide fragments from four potential receptors of Abeta:alpha-7 acetylcholine receptor, prion protein, p75 neurotrophin receptor and receptor for advanced glycation end products. Synthetic peptides were intranasally administrated into animals with experimentally induced form of AD - bulbectomized mice. Then memory of mice was examined in the water Morris test. We have found that administration of only one fragment of receptor for advanced glycation end products effectively prevented the murine memory from impairment and decreased Abeta level in the brain of experimental mice. The revealed synthetic fragment seams perspective for development of new medicine for AD therapy. Supported by RFBR Grants No. 13-04-40106-H, 13-04-00633,15-04-01360

ABETA-INDUCED ALTERATIONS IN SYNAPTIC EXPRESSION OF PHOSPHORYLATED NMDA RECEPTOR SUBUNITS IN RAT HIPPOCAMPUS

Y. Wu[1], L. Chang[1], Y. Song[1], A. Lv[1], Y. Li[1], Y. Fang[1], J. Liu[1]
[1]Anatomy, Capital Medical University, Beijing, China

Aβ synaptotoxicity is NMDA receptor-dependent, and post-translation phosphorylation of NMDA receptor is a reversible modification regulating protein activity, location, mobility and protein-protein interaction. Based on our previous results, we tried to further explore Aβ-induced alterations in synaptic expression of phosphorylated NMDA receptor subunits in rat hippocampus, and found that Aβ-induced decreases in protein levels of pTyr1472-NR2B and Fyn, but no changes in protein levels of pTyr1325-NR2A and Src during the early stage of Aβ treatment. The results suggest changes of pTyr1472-NR2B are more significant in Aβ synaptotoxicity. Furthermore, we surprisedly found Aβ induced decreases in puncta densities of synaptic pTyr1472-2B and extrasynaptic pTyr1325-NR2A, which imply complex alterations happened in synaptic and extrasynaptic locations during the early stage by Aβ treatment. This study is to investigate the cellular and molecular mechanisms of synaptic alterations during the development of Alzheimer's disease, and will contribute to prevention and early therapy of Alzheimer's disease.

[2]School of Medicine, Tsinghua University, Beijing, China

Soluble amyloid-β oligomers are thought to induce synaptic dysfunction during the early stage of Alzheimer's disease (AD). Different NMDA receptor (NMDAR) subunits have been linked with Aβ-induced synaptotoxicity. In this report, we revealed Aβ-induced selective reduction in protein levels of NR2B, but no changes in protein levels of NR1, NR2A and SAP102 during the early stage of Aβ treatment. The results suggest the change of NR2B is more striking in Aβ synaptotoxicity. Furthermore, we surprisedly found Aβ could induce significantly reduced puncta densities of synaptic NR2A and SAP102, which imply complex alterations happened in synaptic and extrasynaptic locations by 1h Aβ treatment. Our study indicates the complex effects of Aβ on different NMDAR subunits and synaptic associated proteins during the early stage of Alzheimer's disease. This may explain the difficulty and the great challenge to seek appropriate drug targets for preventing synaptic dysfunction and loss related to abnormal NMDARs in the early stage of AD.

COLIVELIN AMELIORATES AMYLOID BETA PEPTIDE-INDUCED IMPAIRMENTS IN SPATIAL MEMORY, SYNAPTIC PLASTICITY AND CALCIUM HOMEOSTASIS IN RATS

M. Wu[1], L. Zhou[1], Z. Wang[1], J. Zhang[1], J. Qi[1]
[1]Physiology, Basic medicine, Taiyuan, China

Objectives: Amyloid β peptide (Aβ) has been thought to be neurotoxic and responsible for the impairment of learning and memory in Alzheimer's disease (AD). It is reported that the Aβ induced cell death can be effectively prevented by Colivelin (CLN), a most potent Humanin derivative. In this study, we further investigated the neuroprotective effects of CLN against Aβ25-35-induced impairments in spatial learning and memory, synaptic plasticity, and intracellular calcium levels. **Methods:** SD rats pretreated with Aβ25-35 and CLN via intrahippocampal injection were first subjected to Morris water maze test to examine the spatial learning and memory. After behavioral testing, *in vivo* hippocampal field excitatory postsynaptic potential (fEPSP) was evoked to record the long term potentiation (LTP) induced by high frequency stimulation. At last, intracellular calcium level in primary cultured hippocampal neurons was examined by using confocal calcium imaging technique. **Results:** CLN alone, even at a high concentration, had no significant effect on the escape latency and the time in the targeted quadrant compared to vehicle-injected animals, but CLN (0.2 nmol) pretreatment effectively prevented Aβ25-35 (4nmol)-induced deficits in spatial learning and memory of rats. The suppression of *in vivo* hippocampal LTP by Aβ25-35 was nearly completely prevented by CLN, while paired-pulse facilitation (PPF) was not affected. In addition, CLN pretreatment also effectively inhibited Aβ25-35-induced calcium overload. **Conclusions:** CLN has significant *in vivo* neuroprotective properties against Aβ, and CLN might holds great promise for the treatment and prevention of AD.

RECEPTOR FOR ADVANCED GLYCATION ENDPRODUCTS AS A PROMISING TARGET FOR AMYLOID BETA PEPTIDE INDUCED BLOOD BRAIN BARRIER DYSFUNCTION

S. Askarova[1], A. Tsoy[1], T. Teng[2], J. Lee[2]
[1]Center for Life Scienses, Nazarbayev University, Astana, Kazakhstan
[2]Bioengineering, University of Missouri, Columbia MO, USA

Objectives

Recent studies have demonstrated that receptor for advanced glycation endproducts (RAGE) is promising therapeutic target in β-amyloid diseases. In this study, we examined the effects of antiRAGE primary antibody (Ab_{RAGE}) and azelnidipine (a dihydropyridine-based calcium channel blocker) on $A\beta_{42}$-induced reactive oxygen species (ROS) generation, activation of NADPH oxidase, phosphorylation of ERK1/2 and cPLA2α, and expression of P-selectin on the surface of the cerebral endothelial cells (CECs).

Methods

In this study, immortalized CECs (bEnd3) were applied. To confirm Aβ-RAGE and azelnidipine -RAGE binding, we examined the quantitative immunofluorescence microscopy (QIM) of cellular surface RAGE for bEnd3 cells pretreated with azelnidipine or $A\beta_{42}$and stained with Ab_{RAGE}. To quantify the ROS production and surface P-selectin expression, we applied fluorescence microscopy method. Confocal immunofluorescence microscopy of double immunofluorescent labeled gp91-phox and p47-phox subunits was performed to characterize NADPH oxidase complex assembly. Western blot analysis was applied to characterize phosphorylation of ERK1/2 and cPLA2α.

Results

We report that both $A\beta_{42}$and azelnidipine competed with Ab_{RAGE} to bind to RAGE on the surfaces of CECs. In addition, Ab_{RAGE} and azelnidipine abrogates $A\beta_{42}$-induced ROS production and co-localization between the cytosolic (p47-phox) and membrane (gp91-phox) subunits of NADPH oxidase. Moreover, Ab_{RAGE} and azelnidipine suppressed $A\beta_{42}$ induced phosphorylation of ERK1/2 and cPLA2α in CECs, and accumulation of P-selectin on the surface of the cells.

Conclusions

This study demonstrated that blocking of RAGE can, at least partially, neutralize toxic effect of Aβ on the CECs *in vitro*. Therefore, there is a need to investigate new promising Aβ/RAGE axis blockers.

[7]Clinical, Parexel, Glendale, USA

Objective: To evaluate the effects of AZD3293 (a novel BACE inhibitor) on plasma and CSF Aβ biomarkers in AD patients.

Methods: A Phase 1, randomized, double-blind, placebo-controlled, 2-part multiple ascending dose study (NCT01795339) was conducted in healthy young and elderly adults (Part 1) and AD patients (Part 2). Results of Part 1 were previously reported. In Part 2, mild to moderate AD patients received 15 mg, 50 mg, or 150 mg AZD3293 or placebo (total N=16) as a single dose on Day 1 followed by multiple daily doses on Days 3 through 14. Plasma was collected for pharmacokinetic and biomarker analysis. CSF was collected on Day -1 (baseline) and at Day 14 (steady state) for biomarker analysis.
Results: AZD3293 was safe and well-tolerated in this small cohort of AD patients. At steady-state, maximal plasma concentrations of AZD3293 were achieved at 1-3 h and mean effective half-life was 16-21 h. Significant plasma and CSF Aβ1-40 and Aβ1-42 reduction was seen at all doses tested compared to placebo. At Day 14, levels of plasma Aβ1-42 were reduced to the maximal extent measureable. Levels of CSF Aβ1-42 were reduced by 52%, 76%, and 90% for the 15 mg, 50 mg, and 150 mg AZD3293 dose groups, respectively. Results for Aβ1-40 levels were comparable to the Aβ1-42 results. PK and biomarker results in AD patients were comparable to those observed in Part 1.
Conclusions: AZD3293 is safe and well-tolerated, and potently inhibits Aβ in the periphery and CSF in AD patients.

[4]Center for Neurologic Diseases, Brigham and Women's Hospital, Boston, USA

[5]Biocenter, Probiodrug AG, Halle (Saale), Germany

Objectives:

Pyroglutamate-3 Aβ (pGlu-3 Aβ) is an N-terminally truncated and modified Aβ species found in Alzheimer's disease (AD) brain (Saido et al., 1995; Lemere et al., 1996). Following truncation of the first 2 Aβ residues, pGlu-3 Aβ is formed by the cyclization of glutamate at residue 3 by glutaminyl cyclase and is associated with increased aggregation and neurotoxicity (Russo et al., 2002; Schilling et al., 2006; Nussbaum et al., 2012). Antibody Ig isotype and specificity for deposited Aβ may influence plaque removal and initiate clearance through Fc receptor-mediated microglial phagocytosis (Bard et al., 2000; DeMattos et al., 2012). Here, we compared the effector functions of different Ig isotypes of the same anti-pGlu3 Ab mAb.

Methods:

An *ex vivo* phagocytosis assay was used to compare different Ig isotypes (IgG1, IgG2a, and IgG2a variant) of the same pGlu-3 Aβ mAb (07/1): frozen brain sections from plaque-rich aged APP/PS1ΔE9 mice were pre-incubated with an Aβ mAb for 1h and then covered with primary microglia or N9 cells for 24h. Plaque clearance was measured by immunofluorescent staining and Aβ ELISA.

Results:

In general, the 07/1 IgG2a anti-pGlu3 Aβ mAb provided the most Aβ clearance with the greatest effect on reducing Aβx-40 and pGlu-3 Aβ levels; intermediate plaque clearance was observed by the 07/1 IgG2a variant mAb. Further analyses will determine cytokine levels and inflammatory changes that may be associated with effector function.

Conclusion:

We conclude that pGlu-3 Aβ mAb Ig isotype strongly affects microglial-mediated clearance of Aβ.

SPINOGENIC AMYLOID-TARGETING BENZOTHIAZOLES (ATBAS) AS POTENTIAL THERAPEUTICS FOR AMYLOID-ASSOCIATED NEURODEGENERATIVE DISEASES

J.L. Cifelli[1], T. Chung[1], L. Dozier[2], H. Liu[3], M. Mayer[3], G.N. Patrick[2], J. Yang[1]
[1]Chemistry and Biochemistry, University of California San Diego, La Jolla, USA
[2]Biology, University of California San Diego, La Jolla, USA
[3]Biomedical Engineering and Chemical Engineering, University of Michigan, Ann Arbor, USA

Objectives: We present the rational design and evaluation of amyloid-binding benzothiazoles that exhibit advantageous properties for potential treatment of neurodegenerative diseases including Alzheimer's Disease (AD). In particular, the therapeutic potential of this class of compounds towards neuroprotection and improving cognitive function is discussed.
Methods: Design of novel ATBAs included consideration of a balance between hydrophobic/hydrophilic characteristics in order to improve the therapeutic window for this class of compounds. Compounds were evaluated for their potential to protect against amyloid-beta induced cellular toxicity as well as for their effect on dendritic morphology in primary neurons.
Results: All new ATBAs were found to be less toxic to SH-SY5Y neuroblastoma cells and had lower propensity to lyse membranes than their parent compound, thereby increasing biocompatibility. In addition, the compounds retained their amyloid-binding capability, were found to have cytoprotective properties, and increased dendritic spine density in primary hippocampal neurons.
Conclusions: This class of ATBAs has shown promise for their ability to be both neuroprotective and spinogenic, while also exhibiting low toxicity. These characteristics allow for ATBAs to potentially serve as therapeutics for not only amyloid-associated neurodegenerative disease like AD but for protection against general cognitive decline as well.

[2]Biochemistry and Molecular Biology, BioArctic Neuroscience, Stockholm, Sweden
[3]BioArctic Neuroscience, BioArctic Neuroscience, Stockholm, Sweden
[4]Department of Public Health /Geriatrics, Uppsala University, Uppsala, Sweden

Objectives

The objective of the present study was to investigate the efficacy of an Abeta protofibril selective murine monoclonal antibody, mAb158, on reducing soluble toxic species of Abeta in aged APPArcSwe transgenic mice using an acute dose setting.

Methods

A transgenic mouse model, APPArcSwe, that overexpresses human APP with the Swedish (K670N/M671L) and Arctic (E693G) mutations, was used to study acute efficacy with mAb158 on brain and CSF large oligomer/protofibril Abeta lowering. Fourteen to sixteen months old APPArcSwe transgenic mice received a single intraperitoneal injection of mAb158 at 50 mg/kg body weight, or sterile PBS as negative control. Animals were sacrificed two or three weeks after injection, and analyzed for brain and CSF exposure and Abeta protofibril levels.

Results

As expected, the exposure was lower in plasma, CSF and brain in the group that was sacrificed three weeks after injection compared to the group that was sacrificed two weeks after injection. The Abeta protofibril levels in brain were reduced by 38-51% in animals sacrificed after two weeks and by 27-50% in animals sacrificed after three weeks, depending on the extraction method and assay used.

Conclusions

In this study, brain Abeta protofibril lowering was confirmed already after a single dose of mAb158 in APPArcSwe transgenic mice. These results support Abeta protofibril immunotherapy as effective in reducing soluble toxic species of Abeta in brain and hence potentially as a useful therapeutic intervention in Alzheimer's disease.

STABLE AMYLOID OLIGOMERS AS TRACTABLE DRUG TARGETS AND VERSATILE RESEARCH TOOLS IN AD AND PD.

A.W.J.W. Tepper[1], E.C. de Boer[1], F. van Diggelen[1], E. Hoogveld[1], D.J. Vis[1], I.C. Schut[1], I.J. Vereyken[1], A.P.H. Scheefhals[1]

[1]R&D, Crossbeta BV, Utrecht, Netherlands

Accumulating evidence supports a major role for soluble oligomers as toxic entities in Alzheimer's, Parkinson's and other diseases. Unfortunately the instability and limited characterization of oligomer preparations have seriously impeded research and development in this field.

Here we showcase the utility of reproducibly generated stable oligomers of several peptides including amyloid beta (1-42 and pGlu3-42) and alpha-synuclein. Crossbeta stable oligomers are free from monomers and fibrils and demonstrate representative properties and functionality for the non-stable oligomeric analogues. For example, the stable oligomers induce depression of Long Term Potentiation (LTP) after administration *in vivo* in the rat brain. When stored frozen the oligomers have a shelf life of more than 6 months.

The availability of the stable oligomers opens up previously inaccessible avenues for R&D. For example, it enabled high throughput screening of drug-like compound libraries (100k+300k compounds). This resulted in the identification of multiple oligomer binding hits that inhibit oligomer binding to a receptor implicated in AD. We present *in vivo* proof of concept by showing that our front-runner compound when given systemically effectively protects against the oligomer induced depression of LTP in rat.

In another application we show that Crossbeta oligomers are excellent reference standards in biomarker assays. Several groups have demonstrated that Abeta oligomers can be detected in CSF of AD patients, thus potentially providing a much needed early AD biomarker for clinical studies and/or diagnosis. Yet, the variation and sensitivity of these assays has been notoriously difficult. Here we show that Crossbeta oligomers abrogate these problems.

[4]Department of Molecular Biochemistry and Pharmacology, IRCCS Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy
[5]MediCity/PET Preclinical Laboratory, University of Turku, Turku, Finland

Alzheimer's Disease (AD) is a neurodegenerative disorder characterized by deposition of the β-amyloid (Ab) peptide in the brain. Although many Ab-centric therapies have been attempted, they all failed and no efficacious therapy is available yet.
Objectives. Main objectives of this study were to investigate the efficacy of multi-functional liposomes (Lip), designed to target the brain, to 1. promote disaggregation of brain Ab assemblies in AD mouse brain, 2. reduce brain Ab burden and 3. restore mouse memory, at a post-symptomatic stage. 4. Arrest pathology progression at a pre-symptomatic stage.
***Methods*.** Functionalized Lip with a peptide derived from apolipoprotein-E receptor-binding domain (mApoE) for blood-brain barrier targeting, and with phosphatidic acid (PA) for Ab binding (mApoE-PA-Lip) were administered (I.P.) for 3 weeks in post- and 4 months in pre-symptomatic APP/PS1 mice subsequently tested in the novel object recognition memory test (NORT). At the end mouse brains were collected and analyzed through histology and biochemistry for Ab deposition.
Results. Administration of mApoE-PA-Lip decreased total insoluble brain Ab_{1-42}, total plaque area and Ab oligomers. Plaque reduction was confirmed by PET imaging with [^{11}C]-PIB. The reduction of brain Ab was associated with its increase in liver and spleen. Treatment also restored mouse impaired memory to normal at post-symptomatic ages and prevented its loss when administered at pre-symptomatic ages.
Conclusions. These data suggest that bi-functionalized Lip destabilize brain Ab aggregates and promote peptide removal from the brain and its peripheral clearance. This innovative therapeutic approach can be considered as a new candidate for AD treatment.

YOUTHFUL SYSTEMIC MILIEU AMELIORATES ALZHEIMER'S DISEASE PATHOLOGY

A. Urayama[1], V. Kharat[2], D. Morales-Scheihing[1], I. Moreno-Gonzalez[1], C. Soto[1]
[1]Neurology, University of Texas Medical School at Houston, Houston, USA
[2]School of Public Health, University of Texas Health Science Center, Houston, USA

Objectives: Alzheimer's disease (AD) is characterized by memory loss, neuronal death, synaptic alterations, brain inflammation and the presence of amyloid plaques. Compelling evidence suggest that young blood conveys potent factors capable to ameliorate aging-related cognitive decline. To study if young systemic milieu reverses AD pathology, we developed a technique of whole blood exchange (BE) which replaces >50% of the original blood volume by normal blood from mice having same genetic background.

Methods: TG2576 (TG) mice received BE from 3 to 17 months of age (Group I) to test its preventive effect, and from 13 to 17 months of age (Group II) to test the effect of BE on pre-existing brain plaques. Spatial memory was tested by Barnes maze at 13 or 17 months of age in groups I and II, respectively.

Results: Histological analysis found age-matched Sham TG in group I showed intense amyloid plaques predominantly in the cerebral cortex and hippocampus. In contrast, BE mice showed significant reductions in these regions. Group II confirmed that BE significantly reduced brain amyloid deposition, even when the treatment was initiated after the development of cerebral plaques. Such decreases in brain plaques reflected in improved performance in spatial memory test in both groups. Brain clearance of amyloid-beta across the blood-brain barrier (BBB) remained unchanged in BE mice compared to age-matched Sham mice.

Conclusions: Young blood clearly affects brain environment and ameliorates brain pathology in AD model mice. This study draws topical interests in seeking disease-modifying treatment for neurodegenerative diseases.

NEUROPROTECTIVE EFFECTS OF SCYLLO-INOSITOL TREATMENT ON DISEASE-BEARING MOUSE MODEL OF AD

M. Brown[1], L. Thomason[2], I. Aubert[1], K. Ma[1], J. McLaurin[1]
[1]Biological Sciences, Sunnybrook Research Institute, Toronto, Canada
[2]Physical Sciences, Sunnybrook Research Institute, Toronto, Canada

Objective: To determine the neuroprotective role of *scyllo*-inositol treatment in an Alzheimer's disease model after the onset of cognitive and pathological deficits.
Methods: We undertook a microarray study on the hippocampi of TgCRND8 mice treated with *scyllo*-inositol for 30 days after the onset of spatial cognitive dysfunction and significant amyloid load. These data identified two different neuronal pathways that contribute to neuronal function, neurogenesis and GABAergic neuronal signalling as well as upregulation of the hormone, Proopiomelanocortin (POMC) . We subsequently undertook pathological studies to characterize these two neuronal processes in the presence and absence of scyllo-inositol and a function of POMC expression.
Results: We found a profound deficit in neurogenesis and in GABAergic interneurons with increasing amyloid load. The deficits in neurogenesis early in pathology correlate directly with Amyloid-beta peptide load, whereas later in pathology are more directly related to the loss of neurotrophic support. We also report that GABAergic interneuron loss is of the somatostatin expressing cells and protection from loss is correlated with POMC expression. We did not find deficits in the cholinergic neuronal population at the ages that we examined.
Conclusions: *scyllo*-inositol treatment of disease-bearing mouse model of AD protects adult neurogenesis and GABAergic interneurons within the hippocampus

TRANSTHYRETIN-DERIVED PEPTIDES AS AMYLOID-BETA AGGREGATION INHIBITORS: POTENTIAL USE AS THERAPEUTICS FOR ALZHEIMER'S DISEASE

L. Saelices[1], Q. Cao[1], Y. Zhao[2], C. Liu[1], G. Cole[2], S. Frautschy[2], D.S. Eisenberg[1]
[1]Department of Biological Chemistry, University of California Los Angeles, Los Angeles, USA
[2]Department of Neurology,
David Geffen School of Medicine at the University of California Los Angeles the Geriatric Research and Clinical Center Greater Los Angeles Veterans Affairs Healthcare System, Los Angeles, USA

Objectives: The beneficial effect of the human tetrameric protein Transthyretin (TTR) over Amyloid-beta (Ab) totoxicity has been reported both *in vitro* and *in vivo.* However, the mechanism of protection remains unclear. We pursued to characterize such mechanism, and identify the minimum peptide sequence of TTR capable of preventing Ab from aggregation.
Methods: Mutational analysis of TTR was performed to elucidate the mechanism of protection. Based on the resulting model, peptide inhibitors were designed using TTR sequence as a reference. The toxicity of Ab was then measured to assess effectiveness of the peptide inhibitors.
Results: Mutational analysis of TTR revealed that although TTR fibrils are not capable of preventing Ab from being toxic, the ability to aggregate is required for TTR in order to be protective. An amyloidogenic 13-residue segment of TTR prevented Ab aggregation and toxicity only when was unable to self-associate by addition of a charged tag.
Conclusions: We propose a protection model where a small hydrophobic segment of TTR is exposed only when the tetramer dissociates into monomers, and binds to Ab preventing its aggregation. In order to use the segment as inhibitor, the addition of a charged tag was needed, to hinder self-association and allow Ab binding. Comprehensive analysis revealed that the peptide inhibitors were efficient at hindering Ab aggregation and toxicity. This work provides a novel methodology for Ab aggregation inhibition that is likely to initiate an innovative strategy for the development of a therapy for Alzheimer's Disease.

[3]Department of Drug Design and Target Validation, Fraunhofer Institute of Cell Therapy and Immunology IZI Leipzig, Leipzig, Germany

Objectives: Main hallmarks of brains of patients affected by Alzheimer's disease (AD) are pathogenic deposition of Abeta peptides and chronic inflammation. Both features may be fueled by the action of glutaminyl cyclases, QC and isoQC, catalyzing the conversion of N-terminal Gln/Glu-residues of Abeta peptides and chemokine (C-C motif) ligand 2 (CCL2) into pyroglutaminated (pE) forms. We here focused on the regional and cellular expression of isoQC and its substrate CCL2 in brain tissue of wild type mice and humans compared to inflammatory conditions seen in aged APP transgenic mouse brain and *post mortem* brain tissue from AD patients.
Methods: We used enzymatic activity assays and immunohistochemistry of mouse and human brain tissue followed by confocal laser scanning analyses to reveal brain region and cell type-specific expression of isoQC and its putative pro-inflammatory substrate CCL2.
Results: In mouse brain, isoQC was ubiquitously expressed in neurons of neocortical, hippocampal and subcortical structures, localized to the endoplasmic reticulum and Golgi apparatus and co-expressed with its substrate CCL2. In APP-transgenic Tg2676 mice and in AD, isoQC and CCL2 proteins were found to be co-induced in Abeta plaque-associated reactive astrocytes. In brains of AD patients, correlations of isoQC and CCL2 with pGlu-Abeta load and with the decline in mini mental state examination were established.
Conclusions:The wide-spread isoQC expression in brain suggests a number of yet unidentified physiological functions. Additionally, the neuronal co-expression with the pro-inflammatory chemokine CCL2 and the co-induction of both proteins in reactive astrocytes indicates an involvement in pathogenic conditions in AD.

PYROGLUTAMATE ABETA42 CORRELATES WITH INCREASED PIB BINDING IN POSTERIOR CINGULATE CORTEX AND PRECUNEUS OF SUBJECTS WITH MCI AND ALZHEIMER'S DISEASE

M. Ikonomovic[1], V. Pivtoraiko[1], E.E. Abrahamson[1], W.E. Klunk[2], E.J. Mufson[3]
[1]Neurology, University of Pittsburgh, Pittsburgh, USA
[2]Psychiatry, University of Pittsburgh, Pittsburgh, USA
[3]Neurobiology, Barrow Neurological Institute, Phoenix, USA

Objectives: Positron emission tomography imaging demonstrates increased retention of [C-11] Pittsburgh compound B (PiB) in the default mode network (DMN) in Alzheimer's disease (AD). This likely reflects accumulation of fibrillar amyloid-beta (Abeta). N-truncated and pyroglutamate-modified Abeta forms, e.g., Abeta(pE3-42), are particularly fibrillogenic. We hypothesized that Abeta(pE3-42) concentration corresponds to regional PiB retention in the DMN.
Methods: We quantified [H-3]PiB binding and formic acid-extracted Abeta(pE3-42) in the precuneus (PreC, BA7) and posterior cingulate cortex (PC, BA23), regions in the DMN, from cases with a premortem clinical diagnosis of no cognitive impairment (NCI, n=19), mild cognitive impairment (MCI, n=20), or AD (n=24).
Results: Compared to NCI and MCI, AD cases had higher Abeta(pE3-42) concentration (PC, p2= 0.0039; PreC, p2<0.0001) and higher [H-3]PiB binding (PC, p2=0.001; PreC, p2=0.0001). Overall, higher PreC and PC Abeta(pE3-42) levels correlated with greater [H-3]PiB binding (PC, R=0.7938, p2<0.0001; PreC, R=0.7455, p2<0.0001). When AD cases were divided into mild-moderate (N=18) and severe (N=6) AD, the two groups were comparable by Abeta(pE3-42) levels in both regions, while [H-3]PiB binding was higher in the PreC, but not the PC, of the severe AD compared to the mild-moderate AD group.
Conclusions: Although Abeta(pE3-42) and PiB binding correlated closely in PreC and PC, these data suggest regional differences in the progression of amyloid pathology in the DMN of AD dementia cases. Abeta(pE3-42) may be a particularly good substrate for PiB, and a clinically relevant biomarker.

The reduction of amyloid-beta peptides (Ab) is considered a primary therapeutic target to minimize the neurodegeneration in Alzheimer's disease (AD), a pathology characterized by accumulation of Ab in the brain. A possible strategy to reduce Ab levels is to exploit the peripheral-sink effect that is based on the removal of plasma Ab, drawing out soluble Ab from the brain. *Objectives.* The aim of the present study was to investigate the potential effect of multi-functional liposomes binding Ab on the peptide exchange across an *in vitro* model of the blood-brain barrier (BBB). *Methods.* Liposomes were prepared by extrusion procedure and bi-functionalized with phosphatidic acid and with a modified ApoE-derived peptide (mApoE-PA-LIP) for Ab binding. An *in vitro* BBB model made of human brain endothelial cells (hCMEC/D3) was set up on a transwell system and soluble small Ab42 assemblies were added to the basolateral compartment (brain side). The Ab translocation across the BBB was evaluated both alone or with mApoE-PA-LIP present in the apical compartment (blood side). Also the permeability of liposomes from basolateral-to-apical compartment in the presence of Ab was analyzed. *Results.* The presence of mApoE-PA-LIP strongly enhanced (5-fold) the basolateral-to-apical transcytosis of Ab across the BBB model, compared to the peptide alone, in a lipid dose-dependent manner. Moreover, the transcytosis of Ab was due to a peripheral-sink effect since mApoE-PA-LIP were not able to transport the peptide across the cellular monolayer. *Conclusions.* This study provide a rationale for the use of Ab-binding particles as a potential therapeutic strategy for AD.

A NOVEL ALZHEIMER'S DISEASE VACCINE CLEARS ABETA PLUGS, SUPPRESSES T CELL INFLAMMATIONS IN BRAINS AND IMPROVES COGNITIONS IN ANIMAL MODEL

B. Wang[1], S. Wang[1], Y. Yu[1], C. Kaether[2]

[2]Membrane traffic and Alzheimer's Disease, Leibniz Institute for Age Research, Jena, Germany

Background

Alzheimer's Disease (AD) is an age-dependent neurodegenerative disease that commonly results in brain degeneration associated with severe impairment of cognitive function. Amyloid β-peptide (Aβ), particular the Ab42, plays a key role in the pathology of Alzheimer's disease and becomes a potential target for vaccines. Aβ42 (AN-1792) vaccine phase II trials were halted when 18 of 298 patients immunized with AN-1792 presented with brain inflammations likely due to T cells-mediated infiltrations and inflammations in brains. We developed a co-immunization protocol to induce high levels of antibodies and iTreg cells previously. In this study, we aimed to demonstrate that a co-immunization protocol with Aβ42 protein and its DNA vaccine could clear the Ab42 plaques and prevent inflammations in brain in a murine AD model.

Methods

After we co-immunized the Abeta transgenic mice, behavior improvements, Aβ42 plaques clearances and T cell infiltrations and inflammations in brain were determined.

Results

The co-immunization could induce high levels of anti-Ab42 antibodies and iTreg cells, and reduce Aβ plaques and significantly ameliorate cognitive deficits. Importantly, induced iTreg suppresses T cell-mediated brain inflammations and infiltrations. This study demonstrates that the co-immunization protocol can improve animals' cognitions and behaviors. More importantly, such protocol could eliminate T cell infiltrations and inflammations in the brain of these tested animals.

Conclusions

The co-immunization protocol could clear Abeta plaques and suppress T cell inflammations in brains in animal model. Such protocol could leads to the development of a safer immunotherapeutic/preventive strategy against AD in humans.

[4]BioMEMS Resource Center, Massachusetts General Hospital Harvard Medical School, Boston, USA

Objectives:
Cromolyn Sodium is an FDA-approved drug used in the treatment of asthma. Because of its structural similarity with fisetin, which inhibits amyloid aggregation, we hypothesized that Cromolyn Sodium prevents Aβ fibrillization and Aβ metabolism. In this study, we evaluated the efficacy of Cromolyn Sodium on amyloid pathology in a mouse model of Alzheimer's disease.
Methods:
We first performed Aβ fibrillization and oligomerization assays *in vitro*, using Thioflavin T fluorescence and a split-luciferase complementation, respectively. We also intraperitoneally administered Cromolyn Sodium to APP/PS1 mice daily for one week, and then measured the levels of soluble and insoluble Aβ within the cerebral parenchyma and the interstitial fluid (ISF) using *in vivo* microdialysis technique. Finally, to elucidate the mechanisms, we examined the efficiency of Aβ uptake by microglial cells using double immunostaining between Iba1 and Aβ in brain and the *in vitro* microglial Aβ uptake assay.
Results:
In vitro, Cromolyn Sodium inhibits the aggregation of monomeric Aβ into oligomers and fibrils. *In vivo*, the drug rapidly decreases the amount of soluble monomeric Aβ in the brain by ~50% and within the ISF by ~30%. The half-life of ISF Aβ is significantly reduced in Cromolyn Sodium treated mice. Finally, we revealed that Cromolyn sodium increases the percentage of Iba1 immunoreactivity co-localizing with amyloid in mice and microglial Aβ uptake *in vitro*.
Conclusions:
Cromolyn Sodium prevents Aβ oligomerization. This effect favors Aβ clearance from CNS, which are in part attributed to an increased efficiency for uptake and degradation of Aβ by microglial cells.

ADPD5-1727

THE GLUTAMINYL CYCLASES QC AND ISOQC ARE DIFFERENTIALLY EXPRESSED IN BRAIN REGIONS AFFECTED IN ALZHEIMER'S DISEASE

C. Höfling[1], A. Waniek[1], M. Morawski[1], H. Cynis[2], S. Schilling[2], H.U. Demuth[2], S. Rossner[1], M. Hartlage-Rübsamen[1]
[1]Neurochemistry, Paul Flechsig Institute, Leipzig, Germany
[2]Drug Design and Target Validation,
Fraunhofer Institute for Cell Therapy and Immunology, Halle/Saale, Germany

Objectives: Glutaminyl cyclases (QCs) catalyze the physiological formation of pyroglutamate (pGlu) from glutamine precursors at the N-terminus of a number of peptide hormones, neuropeptides and chemokines. However, QCs are also implicated in the pGlu modification and stabilization of pathogenic Abeta variants and of pro-inflammatory CCL2. These pGlu-modified peptides are resistant to proteolytical degradation and accumulate in brains of Alzheimer's disease (AD) patients. For the generation of respective animal models and for pharmacological treatment studies the characterization of the mouse strain and brain region-specific expression of QC and isoQC is indispensible.
Methods: We used enzymatic activity assays and specific antibodies to detect both QC and isoQC variants by immunohistochemistry in nine different mouse strains.
Results: The highest enzymatic QC/isoQC activity was detected in ventral brain, followed by cortex and hippocampus. Immunohistochemical stainings revealed that QC/isoQC activity in cortex mostly arises from isoQC expression. For most brain regions, the highest QC/isoQC activity was detected in C3H and FVB mice, whereas low QC/isoQC activity was present in CD1, SJL and C57 mice. Quantification of QC- and isoQC-immunoreactive cells by unbiased stereology revealed a higher abundance of isoQC- than of QC-immunoreactive neurons in Edinger-Westphal nucleus and in substantia nigra. In the locus coeruleus, however, there were comparable densities of QC- and of isoQC-immunoreactive neurons.
Conclusions: These observations are of considerable importance with regard to the selection of appropriate mouse strains for the study of QC/isoQC relevance in mouse models of neurodegeneration and neuroinflammation and for the testing of therapeutical interventions in these models.

04b. Therapeutic Targets & Mechanisms for Treatment: Abeta, truncated & pGlu-Abeta

ADPD5-1774

HIGH-THROUGHTPUT PHENOTYPING AND PATHOLOGY OF THE APP/PS1 DOUBLE TRANSGENIC MODEL

D. Brunner[1], H. Hain[1], M. Mazzella[1], R. Avila[2], Z. Kurowska[2], J. Beltran[1], V. Alexandrov[1], E. Sabath[1], M. Windisch[1], A. Ghavami[1]
[1]PsychoGenics, New York, USA
[2], Renovo Neural Inc, Cleveland, USA

Objective: Double transgenic mice from the cross between Tg 2576 (mutant APP) and a mutant presenilin (PS1) line develop increased amyloid- beta 40 and 42 levels and early amyloid pathology in the cerebral cortex and in the hippocampus. The usefulness of new behavioral technologies for detection of early symptoms in relation to biochemical changes is presented and discussed.
Methods: PhenoCube® NeuroCube® and SmartCube® are high-throughput platforms that assess circadian, cognitive, motor behavior, anxiety, gait, and other domains using PGI's proprietary Computer Vision automated scoring system and machine learning algorithms to define phenotypic signatures. Other standard test follow published protocols. Immunohistochemistry with fluorescence or with DAB labeling was used to detect epitopes of interest in hippocampus and cortex. Levels of amyloid- beta 40 and 42 were measured by ELISA (EMD Millipore, Billerica, MA); data was normalized to the total protein content.
Results: Transgenic mice are hyperactive and show memory deficits as early as 12 weeks of age as assessed in our high-throughput phenotypic platforms and in standard tests assessing spontaneous alternation, fear conditioning and spatial learning. We also present an assessment of inflammatory markers (Iba1, FAP), and accumulation of phospho-tau, amyloid-beta oligomers and plaques in these transgenic mice.
Conclusion: The possibility to evaluate behavioral deficits with the novel high-throughput technology early in life forms a basis to test therapeutic interventions at early stages of developing brain pathology. This may allow collecting important data for human trials in prodromal AD.

ADPD5-1795

IDENTIFICATION OF THYROTROPIN-RELEASING HORMONE AS HIPPOCAMPAL GLUTAMINYL CYCLASE SUBSTRATE IN NEURONS AND REACTIVE ASTROCYTES

A. Waniek[1], M. Hartlage-Rübsamen[1], C. Höfling[1], A. Kehlen[2], S. Schilling[3], H.U. Demuth[3], S. Roßner[1]
[1]Neurochemistry, Paul Flechsig Institute, Leipzig, Germany
[2]Molecular Biology, Institute for Medical Microbiology, Halle, Germany
[3]Department of Drug Design and Target Validation MWT Halle, Fraunhofer Institute of Cell Therapy and Immunology IZI Leipzig, Halle, Germany

Objectives: Abeta peptide variants with an N-terminal truncation and pyroglutamate modification were shown to be highly neurotoxic and prone to aggregation. This modification of Abeta is catalyzed by glutaminyl cyclase (QC) which was initially described in hypothalamus, where thyrotropin-releasing hormone (TRH) is a physiological substrate. Recently, in the hippocampus a novel neuroprotective function of TRH has been reported following excitotoxicity and Abeta-mediated neurotoxicity. Functionally matching this finding, we recently demonstrated QC expression by interneurons of mouse hippocampus.
Methods: We used brain tissue of Tg2576 mice and primary astrocytes for analysis by qPCR and immunohistochemistry to reveal brain region and cell type-specific expression of QC and TRH.
Results: We detected neuronal co-expression of QC and TRH in the hippocampus of adult wild type mice. In neocortex of aged but not of young mice transgenic for amyloid precursor protein an increase of QC mRNA levels was found compared to wild type littermates. This was not observed in hippocampus, which is later affected by Abeta pathology. However, in hippocampus of transgenic mice a correlation between QC and TRH mRNA levels was revealed. Interestingly, the enzyme QC and its substrate TRH were detected in reactive astrocytes in proximity of Abeta deposits and co-regulated in primary astrocytes challenged by pro-inflammatory stimulation.
Conclusions: Functionally, the expression of QC in astrocytes could play a role in neuroprotection by activation and release of TRH due to diminished excitotoxicity and in neurodegeneration due to the formation of pGlu-Abeta.

[2]Dept. of Drug Design and Target Validation, Fraunhofer Institute for Cell Therapy and Immunology IZI Leipzig, Halle/S, Germany
[3]Institute of Neuroscience and Medicine - Medical Imaging Physics, Forschungszentrum Jülich GmbH, Juelich, Germany

1. Objectives

Until today, treatment of Alzheimer's disease (AD) can only be provided palliatively. Our group has developed the D-enantiomeric peptide D3, which has been shown to ameliorate cognition and to reduce beta-Amyloid (Abeta) plaque load in transgenic AD mouse models. Here we tested D3 and a very potent derivative in the mouse model TBA2.1 that produces N-terminally truncated and pyroglutamated Abeta (pGlu-Abeta). In contrast to other AD mouse models these mice suffer from severe neurodegeneration in the hippocampus and cerebellum. After initial characterization of the motor phenotype we treated the mice with D3 and the derivative to assay their therapeutic potentials in the TBA2.1 model.

2. Methods

TBA2.1 mice were characterized regarding motor balance, motor phenotype and Abeta deposits in the brain. For treatment studies we administered D3, its derivative or placebo intraperitoneally over 4 weeks. Motor balance, motor phenotype and Abeta deposition were analyzed before and after treatment.

3. Results

Cross-sectional characterization of homozygous TBA2.1 mice revealed a progressive phenotype and reduced motor balance compared to wildtype performance starting from 3 months of age. Treatment with both, D3 and its derivative, stabilized motor balance and the D3 derivative was also able to inhibit deterioration of the motor phenotype. Abeta deposition, however, seemed to be unchanged compared to placebo group.

4. Conclusions

Although Abeta deposition does not seem to correlate with the neurological and motor phenotype in TBA2.1 mice these treatment studies indicate that the D3 derivative is an even more effective agent than D3.

IDENTIFICATION OF A COMPOUND WHICH DISRUPTS BINDING OF AMYLOID-BETA TO THE PRION PROTEIN USING A NOVEL FLUORESCENCE-BASED ASSAY

W. TAYLOR[1], E. RISSE[1], A. NICOLL[1], M. BADONI[1], X. YANG[1], M. FARROW[1], J. COLLINGE[1]

[1]MRC Prion Unit, Institute of Neurology, London, United Kingdom

Objectives

The prion protein (PrP) has been implicated both in prion diseases such as Creutzfeldt-Jakob disease (CJD), where its monomeric cellular isoform (PrP^C) is recruited into pathogenic self-propagating polymers of misfolded protein, and in Alzheimer's disease (AD) where PrP^C may act as a receptor for synaptotoxic oligomeric forms of amyloid beta. There has been considerable interest in identification of compounds which bind to PrP^C, stabilising its native fold and thereby acting as a pharmacological chaperone to block prion propagation and pathogenesis. However, compounds binding PrP^C could also inhibit the binding of toxic amyloid beta species and may have a role in treating AD, a highly prevalent dementia for which there are currently no disease-modifying treatments. However, the absence of a unitary, readily measurable, physiological function of PrP makes screening for ligands challenging, and the highly heterogeneous nature of amyloid beta oligomer preparations makes conventional competition binding assays difficult to interpret.

Methods

We used site-specific fluorescent labelling recombinant prion protein (PrP) to identify compounds which bind to PrP and inhibit both amyloid beta binding and prion propagation.

Results

Here we present results from the development of a high throughput screen capable of identifying small molecule inhibitors of amyloid beta binding to the prion protein.

Conclusions

The fluorescence-based assay allows high throughput screening and identification of compounds capable of disrupting the binding of amyloid-beta to the prion protein.

NEUROCOGNITIVE PROTECTIVE EFFECT OF S-NITROSOGLUTATHIONE (GSNO) IN ALZHEIMER'S DISEASE

I. Singh[1], J.S. Won[2], B. Annamalai[2], S. Choi[1], A. Singh[2]
[1]Pediatrics, Medical University of South Carolina, Charleston, USA
[2]Pathology and Laboratory Medicine, Medical University of South Carolina, Charleston, USA

Objective: S-nitrosoglutathione (GSNO) is an endogenous nitric oxide carrier molecule involved in physiological regulation of vascular function. We have previously reported that treatment of rats subjected to permanent bilateral common carotid artery occlusion (pBCCAO) producing a state of chronic cerebral hypoperfusion (CCH) with GSNO improved spatial learning and memory functions and decreased amyloid-β (Aβ) accumulation and decreased induction of vascular inflammation in the brains. To further investigate the effect of GSNO on neuroprotection and underlying mechanisms under CCH and AD conditions, we designed the experiments as followings:
Methods: The effect of GSNO treatment on neuronal survival, tau-hyperphosphorylation, and activities of tau-kinase and its regulators were analyzed in *in vitro* (primary rat cortical neuron cultures), *ex vivo* (purified synaptosomes), and in vivo (rats subjected to pBCCAO and APPSw/PS1dE9 mice).
Results: GSNO administration significantly attenuated the impaired spatial learning process and neurodegeneration in rats with pBCCAO and APPSw/PS1dE9 mice. GSNO treatment decreased pathological tau hyperphosphorylation (Ser202/396/404 and Thr205) in the brains of tested animals, and primary cultured neurons and purified synaptosomes treated with Aβ peptide. In these experimental models, GSNO inhibited GSK-3β activities and Cdk5 activities which play critical role in tau hyperphosphorylation. Mechanistically, GSNO inhibited GSK-3β activity via inhibiting phosphorylation of GSK-3β (Tyr279) and Cdk5 activity via inhibiting calpain-mediated p35 proteolysis leading to generation of p25.
Conclusions: Taken together with our previous report, these data suggest the therapeutic potential of GSNO as neuro- and cognitive-protective agent for CCH/AD.

LEUCETTINES, A CLASS OF DYRKS/CLKS DUAL INHIBITORS: IMPLICATIONS FOR TREATMENT OF ALZHEIMER'S DISEASE AND DOWN SYNDROME

L. Meijer[1], T. Tahtouh[1], E. Durieu[1], B. Villiers[1], C. Bruyère[1], X. Fant[2], E. Limanton[3], J.P. Bazureau[3], F. Carreaux[3]
[1]Biology, ManRos Therapeutics, Roscoff, France
[2]Protein Phosphorylation & Human Disease, CNRS Station Biologique, Roscoff, France
[3]Laboratoire Sciences Chimiques, Université de Rennes 1, Rennes, France

Objective

The protein kinases DYRKs (dual specificity tyrosine-phosphorylation-regulated kinases) and CLKs (cdc2-like kinases) are involved in Alzheimer's disease (AD) and Down syndrome (DS). We wanted to investigate the structure-activity relationship (SAR) in Leucettines, a class of pharmacological inhibitors of DYRKs/CLKs, derived from the marine sponge natural product Leucettamine B (1, 2, 3).

Methods

78 Leucettines were synthesized and tested for their inhibitory action on 11 purified recombinant kinases (CLK 1-4, DYRK1A, 1B, 2, 3, GSK-3, CK2, Pim1). Leucettines were also tested in four cellular assays: (i) modulation of CLK1 pre-mRNA splicing, (ii) protection towards glutamate -induced cell death in HT22 hippocampal cells, (iii) induction of autophagy and (iv) phosphorylation of Tau on Thr212.

Results

The enzymatic SAR highlights an excellent fit with previously determined Leucettine/DYRK co-crystal structures and suggests directions for improvements in potency and selectivity.

The cellular SAR highlights correlations between inhibition of specific targets and some but not all cellular effects.

Conclusion

Leucettines warrant further development as potential therapeutics against neurodegenerative diseases on the basis of their multiple molecular targets and cellular effects.

[3]Cancer Sciences & Clinical and Experimental Medicine, University of Southampton, Southampton, United Kingdom
[4]Laboratoire Sciences Chimiques, Université de Rennes 1, Rennes, France
[5]Department of Pharmaceutical Sciences, University of Connecticut, Storrs, USA

Objective

Analyzing the potential of pharmacological inhibitors of DYRK1A (dual specificity tyrosine-phosphorylation-regulated kinase 1A) in Alzheimer's disease (AD) and Down syndrome (DS).

Methods

After the identification of the marine sponge Leucettamine B as a DYRKs inhibitor (1), a structure-activity relationship was established based on 500+ analogues (Leucettines), leading to an optimized product, Leucettine L41, which was tested in cellular and animal models.

Results

Leucettines were co-crystallized with DYRK1A, and 4 other kinases, and their selectivity was extensively studied (2). L41 displayed neuroprotective effects on glutamate-induced cell death in immortalized mouse hippocampal cells and enhanced autophagy without inducing cell death (3). L41 inhibited phosphorylation of Tau Thr212. L41 was tested in tgBACDyrk1a mice (a model expressing three DYRK1A gene copies) and in Ts65Dn mice (a partial trisomy model). Both models overexpressed DYRK1A (about 1.5-fold increase in mRNA and protein levels and in catalytic activity) and displayed cognitive impairment related to DS and AD. L41 treatment of mice led to normalization of the DYRK1A activity and fully corrected the novel object recognition deficit. No effect was observed with kinase-inactive, control Leucettines or on wild-type animals. Extensive proteomic and phosphoproteomic studies elucidate on the molecular actions of L41 in the brains of these mouse models.

Conclusion

The multi-target selectivity of Leucettines may account for their neuroprotective and positive behavioral effects. This family of kinase inhibitors warrants further optimization as potential therapeutics against AD and DS.

[2]Alzheimer's Disease Research Unit, Yale University School of Medicine, New Haven, USA
[3]Diagnostic Radiology, Yale University School of Medicine, New Haven, USA
[4]Alzheimer's Institute, Banner Health Research Institute, Sun City, USA

Objectives
Recent findings strongly implicate oligomeric Amyloid–beta in the pathogenesis of Alzheimer's disease. We recently described a putative signaling cascade whereby oligomeric Amyloid-beta binds to neuronal cellular prion protein (PrPC), activating the intracellular kinase Fyn leading to synaptotoxicity. Fyn has long been implicated in AD pathophysiology, but has not been previously tested as a therapeutic target in this disease. Herein, we present a Phase Ib trial of AZD0530, a Src family kinase inhibitor specific for Fyn and Src kinase, for the treatment of patients with mild-moderate AD.
Methods
The study was a single site, multiple ascending dose, randomized, placebo-controlled, double-blind Phase Ib trial of AZD0530 in patients with AD and MMSE ranging from 16-26. A total of 24 patients were enrolled in 3 sequential groups, and treated with AZD0530 or placebo for one month, at doses of 50, 100, or 125mg. Primary endpoints were safety, tolerability, and CSF penetration of AZD0530. Secondary endpoints included changes in neuropsychological performance (ADAS-Cog, MMSE, ADCS-ADL, NPI, and CDR-SOB), and changes in brain glucose metabolism measured by 18FDG-PET.
Results
AZD0530 was generally safe and well tolerated across doses. Plasma:CSF ratio of AZD0530 was 0.4. One-month treatment with AZD0530 did not affect cognitive or behavioral function, activities of daily living, or 18FDG-PET measures.
Conclusions
AZD0530 is safe and well tolerated in patients with mild-moderate AD, achieving good CNS penetration with oral dosing. Targeting Fyn kinase is a promising therapeutic approach in AD, and our current data support a larger Phase IIa clinical trial.

PROTECTIVE EFFECTS OF SALVIA ROSIFOLIA AND S. HUBERI ON BETA AMYLOID PEPTIDE INDUCED NEUROTOXICITY THROUGH GLYCOGEN SYNTHASE KINASE-3 BETA INHIBITION

A.H. Dokumacı[1], P. Gürbüz[2], B. Odabaşı Cumaoğlu[1], E. Köngül[2], D. Eroğlu[2], M.B. Yerer Aycan[1]
[1]Pharmacology, Erciyes University Faculty of Pharmacy, Kayseri, Turkey
[2]Pharmacognosy, Erciyes University Faculty of Pharmacy, Kayseri, Turkey

Objectives

S. officinalis and salvianolic acid has been shown to protect from neurotoxicity in several studies. The aim of this study is to investigate the protective effects of endemic *Salvia* species*; S. rosifolia* and *S. huberi* against amyloid beta (A*β*1-42) induced toxicity on SHSY5Y neuroblastoma cell lines and to clarify its protective effect is due to its GSK-3*β* inhibitory activity or not.

Methods

The methanol extracts of both plants were fractioned between water, petroleum ether, n-butanol. The sub-extracts were examined for *in vitro* GSK-3*β* inhibitory activity due to manufacturer's procedures. The n-butanol extracts' GSK-3*β* inhibitory activity were further high compared to other extracts so it was fractioned via Polyamide CC with various polarities of H_2O:MeOH. Five fractions were obtained (FR1-5).
SHSY5Y cells were incubated at 37 °C and %5 CO_2 and %88 humidity and real time cell profiles obtained by X-celligence system. Cell indexes have been recorded and the cell response profiles obtained every 15 minutes during 60 hours.

Results

Enzyme activity studies showed that both n-butanol extracts, FR5 for *S. rosifolia* and FR4 for *S. huberi* have higher inhibitory activity compared to others.
FR5 and FR4has protective effect on amyloid beta induced toxicity on SHSY5Y cells due to X-celligence profiles.

Conclusions

Fractions among the ones tested for both amyloid beta toxicity and GSK-3*β* inhibitory reflecting that the *S. rosifolia* and *S. huberi* might show its neuroprotective effect over their GSK-3*β* inhibitory activities. **Acknowledgement**
This study was supported by the scientific and technological research council of Turkey (TÜBİTAK 112S553).

ADPD5-0653

NEURONAL ILEI REDUCES AMYLOID-BETA PRODUCTION BY DESTABILIZING AMYLOID PRECURSOR PROTEIN

M. Nishimura[1], L. Liu[1], I. Tooyama[1]
[1]Molecular Neuroscience Research Center, Shiga University of medical science, Otsu, Japan

Objectives: Amyloid-beta (Abeta) peptide is produced through beta- and gamma-secretase-mediated sequential proteolysis of amyloid precursor protein (APP). Although gamma-secretase is a major target for therapeutic intervention for Alzheimer's disease (AD), non-selective inhibition of its activity caused serious adverse effects due to blockade of Notch signaling and accumulation of neurotoxic APP-C-terminal fragments (CTFs). We searched for additional proteins that affect Abeta production by interacting with the gamma-secretase complex, and identified a secretory protein named ILEI (also known as FAM3C). In this study, we examined the expression and function of ILEI.
Methods: We examined the effect of ILEI expression on Abeta production using cultured cells and transgenic mice. ILEI expression in the brain was studied with western blotting and immunohistochemistry.
Results: ILEI destabilizes APP-CTFs by binding to the gamma-secretase complex and interfering with its chaperone properties. Notch processing and gamma-secretase activity are not affected by ILEI. ILEI is predominantly expressed in neuronal cells, and transforming growth factor-beta induces ILEI in the brain. The level of secreted ILEI is declined with age in the monkey brain, and the protein and mRNA levels of ILEI are decreased in autopsy brains of AD patients. Transgenic overexpression of ILEI significantly reduces the brain Abeta burden and ameliorates the memory deficit in AD model mice.
Conclusions: ILEI destabilizes APP-CTFs and reduces Abeta production. Decrease in ILEI expression may be a risk factor for Abeta accumulation in the brain, and ILEI may be a plausible target for the development of disease-modifying therapies for AD.

ADPD5-0976

ACTIVATION OF ADAM10 AS A THERAPEUTIC STRATEGY FOR ALZHEIMER'S DISEASE: SHEDDING OF PRION PROTEIN REDUCES ABETA OLIGOMER BINDING AND TOXICITY

H.H. Griffiths[1], *N.M. Hooper*[1]
[1]*Faculty of Medical and Human Sciences, University of Manchester, Manchester, United Kingdom*

Objectives

The cellular prion protein (PrP^C) is a neuronal receptor for amyloid-beta (Abeta) oligomers, mediating neuronal impairment via the activation of Fyn kinase and phosphorylation of tau. The alpha-secretase, ADAM10 cleaves the amyloid precursor protein (APP), releasing sAPPalpha thereby precluding the formation of Abeta, also sheds PrP^C from the cell surface. We hypothesised that modulation of the shedding of PrP^C by ADAM10 would alter the binding and neurotoxicity of Abeta oligomers.

Methods

SH-SY5Y cells were treated with ADAM10 targeted siRNA, ADAM10 inhibitor or pharmacological agents (e.g. carbachol). ADAM10 activity was monitored by detection of sAPPalpha/ beta by immunoblotting or by using the MESO scale multiplex immunoassay. Immunofluorescence microscopy was used to monitor cell surface PrP^C and Abeta oligomer binding following treatments. Phosphorylation of Fyn kinase was monitored by immunoblotting,

Results

Inhibition of ADAM10 resulted in increased Abeta oligomer binding to cells as a direct result of increased cell surface PrP^C. Conversely, up-regulation of ADAM10 activity promoted shedding of PrP^C, and reduced binding of Abeta oligomers. The specificity of each activator for ADAM10 was tested by monitoring sAPPalpha production following inhibition of ADAM10. Carbachol and resveratrol differentially modulated ADAM10 activity, with resveratrol showing a greater specificity. Modulation of ADAM10 activity also altered the ability of the Abeta oligomers to activate Fyn kinase.

Conclusions

Developing specific agonists of ADAM10 will not only preclude Abeta formation and up-regulate neuroprotective sAPPalpha, it will also prevent the binding of Abeta oligomers to PrP^C and prevent the aberrant activation of signalling pathways which lead to neurotoxicity.

MTDL BASED DERIVED COMPOUNDS AS NOVEL THERAPEUTIC AGENT, EFFECTIVE AGAINST AD PROMOTING ENZYMES IN APP OVEREXPRESSING CHO CELL LINES

A. Muthusamy[1], *P. Palanisamy*[1]
[1]*Department of Biochemistry, Bharathidasan University, Tiruchirappalli, India*

Background: AD is the resultant of multifactorial process that makes single-target strategy difficult to shed desirable therapeutic effect. The current study utilized Multi-target-directed ligands (MTDL) to generate novel therapeutic compound that targets multiple proteins involved in AD.

Objective: Until now, there is no effective therapeutic compounds, that target multiple factors, viz., Apo-E4, ACAT, BACE-1 and Acetylcholinesterase, that are possible promoters of AD pathophysiology and memory loss. The present study thus aim at screening novel Multi-target-directed compounds from medicinal plants that thought to inhibit AD promoting enzymes.

***Methodology*:** We applied computer assisted methodology unifying molecular docking studies to identify potent inhibitors against AD promoting enzymes from medicinal plants clinically proved to have memory enhancing properties. 616 compounds were retrieved from TCM database and docked into active site of AD promoting enzymes using Glide. The bio-potentiality of these best hit compounds were assessed in CHO-APP cell lines.

Results: Two best hits were arrived from Insilco experiments that had a great glide score and binding energy with more number of hydrogen bonding with active site amino acids of AD promoting enzymes. Interestingly, these best hit compounds could decrease the pathological expression of extracellular Aβ peptide, inhibiting BACE1 and simultaneous repression of AChE activity.

***Conclusion*:** Our findings strongly suggest that these two hit compounds had best inhibiting activity against BACE1 and Aβ generation. Further studies with other enzymes might prove the efficacy of these hit compounds as novel multiple target compound.

SCREENING FOR COMPOUNDS THAT CAN DECREASE THE ACTIVITY OF BACE BY USING A NOVEL APP/BACE DROSOPHILA MODEL OF ALZHEIMER'S DISEASE

A. Brorsson[1], *L. Bergkvist*[1]
[1]*Department of Physics Chemistry and Biology (IFM), Linköping University, 581 83 Linköping, Sweden*

Objectives: Production of Amyloid-β (Aβ) peptides caused by the proteolytic cleavage of the transmembrane amyloid β precursor protein (AβPP) through proteolysis by the β-secretase activity of the β-site AβPP-cleaving enzyme (BACE) and by the intramembraneous enzyme γ-secretase is a key molecular event in the pathogenesis of Alzheimer's disease (AD). Therefore, screening for compounds that can reduce the activity of these enzymes is an important approach to find possible treatments for AD. We are aiming to find molecules that can decrease/inhibit BACE activity.
Methods: To achieve this, we use *Drosophila melanogaster* (fruit flies) co-expressing human AβPP (hAβPP) and human BACE (hBACE). *Drosophila* has endogenous orthologs of both hBACE and human γ-secretase but only the ortholog of γ-secreatse is able to process hAβPP normally. Therefore, hAβPP needs to be co-expressed with hBACE in the flies to achieve a complete cleavage of hAβPP to generate Aβ peptides. The processing of hAβPP in this fly model have been characterized using biochemical and histochemical assays and the pathological effects have been examined by analysing the disruption of eye morphology and the longevity and locomotor behavior of the flies.
Results: Early evaluation of our AD fly model shows a strong toxic effect when co-expressing hAβPP and hBACE in the fly that can be used as a phenotypic marker for BACE activity.
Conclusion: We have succeeded to establish a novel fly model of AD that can be used to screen for BACE inhibitors in a search for lead compounds for drug development.

LYSOSOMOTROPISM OF BASIC BACE1 INHIBITORS CONTRIBUTES TO INCREASED CELLULAR POTENCY AGAINST CATHEPSIN D AND OCULAR TOXICITY

D. Riddell[1], A. Zuhl[1], C. Nolan[1], A. Atchison[1], C. Ambroise[1], E.M. Beck[1], S. Niessen[1], X. Hou[1], C.W. am Ende[1], B. O'Neill[1], M.A. Brodney[1], D.S. Johnson[1]
[1]Neuroscience, Pfizer, Cambridge, USA

Objectives: The development of BACE1 inhibitors (BSIs) for the treatment of AD has been plagued by ocular toxicity in preclinical animal models. We hypothesized that ocular toxicity was caused by off-target inhibition of Cathepsin D (CatD), a closely related homolog of BACE1, and an enzyme highly enriched in lysosomes of the retinal pigment epithelium (RPE). However, many of our toxic compounds showed CatD selectivity in purified enzyme assays. Many drug candidates contain a basic functional group that results in lysosomotropism--the accumulation of drug in the acidic lysosomes. We thus hypothesized that our basic BSIs were lysosomotropic.
Methods: We generated a clickable photoprobe analog of a lead Pfizer BSI that exhibited ocular toxicity in rats and performed photoaffinity labeling studies in live cells.
Results: Firstly, radiolabeled BSIs were shown to accumulate in acidic compartments in RPE cells. Secondary, long-term administration of the basic BSIs potently increased cellular and tissue protein levels of CatD. This stabilization to proteolytic degradation has been shown for many Cathepsins following enzyme inhibition. Thirdly, our BACE1 photoprobe potently bound to CatD in RPE cells. Finally, we created the first cellular assay for CatD in live RPE cells using the photoprobe. Many BSIs showed >100-fold potency increases for CatD in live cells compared to purified enzyme – resulting in a significant lowering of the BACE1/CatD selectivity window.
Conclusions: Basic BSIs have reduced selectivity against cellular CatD compared to those predicted using purified enzyme assays and cellular CatD potency must be used to predict off target engagement *in vivo.*

CHRONIC ADMINISTRATION OF A GAMMA SECRETASE MODULATOR HALTS AMYLOID PLAQUE ACCUMULATION IN A TRANSGENIC MOUSE MODEL OF ALZHEIMER'S DISEASE

E. Hajos-Korcsok[1], F. Pan[1], C. Gonzales[1], K. Wood[1], C. Nolan[1], K. Atchison[1], D. Riddell[1]
[1]Neuroscience Research Unit, Pfizer Global Research and Development, Boston, USA

Objectives: Amyloid-β (Aβ) plaque deposition plays a central role in the pathogenesis of Alzheimer's disease (AD), therefore inhibiting the production of amyloidogenic Aβ peptides represents a potential therapeutic strategy. Unlike inhibitors, γ-secretase modulators (GSMs) shift the generation of longer, amyloidogenic Aβ42 and Aβ40 towards shorter, non-amyloidogenic forms. Present study evaluated plaque-lowering efficacy of a novel GSM compound in transgenic mice expressing human mutant amyloid precursor protein and presenilin-1.
Methods: In vivo 2-photon fluorescence microscopy was used to serially image amyloid plaques through a thinned-skull cranial window in the somatosensory cortex of PS1(G384A)/APP(K670N/M671L) transgenic mice during GSM compound (50 and 100 mg/kg) or vehicle treatment for 2 months starting at age 6-months. Individual plaque volume was quantified by a custom image analysis package. At the conclusion of the study, brain Aβ levels were determined by DELFIA.
Results: Parenchymal and vascular amyloid plaque load increased over 2 months in vehicle-treated PS1/APP mice by 1.8-fold and 3.4-fold, respectively, compared to baseline at age 6-months. Chronic treatment with the GSM compound resulted in near complete inhibition of both parenchymal and vascular plaque growths. Biochemical analysis of brain homogenates showed that GSM treatment resulted in significant reductions of SDS soluble Aβ42 and Aβ40 (58% and 47% of vehicle, respectively), and GuHCl solubilized Aβ42 and Aβ40 (71% and 58% of vehicle, respectively).
Conclusions: Present studies demonstrate that chronic administration of a GSM compound effectively halts parenchymal and vascular amyloid plaque accumulation. These results provide robust support for the utility of GSMs for disease-modifying treatment of AD.

OVEREXPRESSION OF TRPC6 IMPROVED LEARNING AND MEMORY IN AD MOUSE MODEL

Z. Qu[1], J. Wang[1], R. Lu[1], Y. Wang[1]
[1]Laboratory of Neural Signal Transduction Institute of Neuroscience, Institute of Biochemistry and Cell Biology, Shanghai, China

Alzheimer's disease is characterized with progressive synaptic dysfunction and memory impairment. How to prevent synapse loss and memory decline remains challenge for the disease. Transient receptor potential (Trp) channels are a large family of nonselective cation channels, which have been reported to mediate extracellular calcium influx to induce cellular responses in a number of biological processes. Previous work in our lab found that TRPC6 promoted dendritic spine formation and enhanced spatial learning and memory of mice. In this study, we explored the possible roles of TRPC6 in AD. We crossed TRPC6 transgenic mice with APP/PS1 mice and found that overexpression of TRPC6 in neurons reduced spine loss and alleviated impairment of spatial working memory in the AD mouse model. Additionally, we found that the amyloid plaque load in APP/PS1/TRPC6 mouse brain was greatly reduced. Thus, overexpression of TRPC6 in AD mouse model could diminish the pathological deterioration and prevent the memory decline.

KOREAN MEDICINAL PLANT EXTRACTS EXHIBIT POTENTIAL THERAPEUTIC VALUE AS ALPHA-SECRETASE ENHANCERS

F. Schuck[1], U. Schmitt[1], S. Reinhardt[1], C. Freese[2], I.S. Lee[3], E. Thines[4], T. Efferth[5], K. Endres[1]

[1]Department of Psychiatry and Psychotherapy, University Medical Center, Mainz, Germany

[2]REPAIR-lab Institute of Pathology, University Medical Center, Mainz, Germany

[3]College of Pharmacy, Chonnam National University, Gwangju, Korea

[4]Department of Biotechnology, Institute of Biology, Mainz, Germany

[5]Department of Pharmaceutical Biology, Institute of Pharmacy and Biochemistry, Mainz, Germany

One crucial element in the pathogenesis of Alzheimer's disease is the proteolytic cleavage of the amyloid precursor protein (APP). While cleavage by the beta-secretase BACE-1 leads to generation of neurotoxic Abeta peptides and finally to disease-characteristic plaque formation (amyloidogenic processing), cleavage by the alpha-secretase ADAM10 in turn leads to generation of neurotrophic and neuroprotective sAPPalpha fragments.

Since current treatment options are only of symptomatic nature, efforts in developing novel drugs targeting disease mechanisms are urgently needed. Instead of targeting the amyloidogenic pathway which remains fruitless until today in human application, an approach focusing on potential alpha-secretase enhancers has emerged during the last years. Also, medicinal plant extracts used by indigene people have come into focus of current drug research for their abundance of potential novel lead substances.

Here we employed a promoter-based screening approach using 313 Korean medicinal plant extracts that yielded four potential candidates selectively enhancing ADAM10 promoter activity in a neuroblastoma cell line without affecting APP. *In vivo* studies with wild type mice proved the extracts were harmless and one of the four candidates was able to induce ADAM10 gene expression in peripheral tissue but not in the brain. *In vitro* blood-brain-barrier (BBB) studies delineated a potential hindrance of transport into the brain explaining lack of effect in the respective tissue. We were able to fractionate the most promising candidate extract to further decipher potential active compounds responsible for ADAM10 enhancement, which can be a future basis for modulating them and achieving penetrance into the brain.

DESIGN, SYNTHESIS AND EVALUATION OF SOME NEW SEMICARBAZONES OF P-AMINOBENZOIC ACID AS AN ANTIAMNESIC AND COGNITION ENHANCING AGENTS

S. Shrivastava[1], *S. Sinha*[1]
[1]*Department of Pharmaceutics, Banaras Hindu University, Varanasi, India*
Pharmaceutical Chemistry Research Laboratory, Department of Pharmaceutics, Indian Institute of Technology, Banaras Hindu University, Varanasi, U.P., India-221005

Objective: Discovery of new drug to treat Alzheimer's disease is challenging as characterised by selective loss of cholinergic neurons and accumulation of β-amyloid protein in selective brain areas.
Methods: Some new semicarbazones of p-aminobenzoic acid was synthesiezed, characterised and evaluated for antiamnesic, cognition enhancing and anticholinesterase activity through their respective in-vitro, in-vivo and computational models.
Results: The IC_{50} value and selectivity of synthesized compounds showed a comparable activity of **19** (0.046±0.016 μM and 11.96±0.64), (260) with reference standard donepezil (0.04±0.012 μM and 15.24 ± 0.86 μM), (381) for AChE and BChE inhibition respectively, whereas its enzyme kinetic study revealed a non-competitive inhibition for both AChE and butyrylcholinesterase (BChE) enzymes (Ki = 0.041± 0.60 and 8.46± 0.66 μM). Significant inhibitions in AChE activity by all the synthesized compounds were found in specific brain regions i.e. prefrontal cortex, hippocampus and hypothalamus. Docking studies predicted the binding modes of these compounds in AChE and BChE active sites and showed an affinity with the key peripheral anionic site residues Trp-286, Tyr-124 and Tyr-341 of AChE and Leu-286 and Val-288 of BChE, which were further processed for molecular dynamics simulation for calculating binding free energies using Molecular Mechanics-Generalized Born Surface Area (MM/GBSA).
Conclusion: The newly synthesized derivatives have illustrated an enhanced cognition effect

NOVEL STRATEGY FOR SYMPTOMATIC AND DISEASE-MODIFIYING TREATMENT OF ALZHEIMER´S DISEASE

A. Garcia-Osta[1], C. Garcia-Barroso[1], J. Oyarzabal[2], M. Cuadrado-Tejedor[1]
[1]Neuroscience, FIMA, Pamplona, Spain
[2]Small Molecule Discovery Platform, FIMA, Pamplona, Spain

Objective: The goal of this study was the identificationof a novel mode of action to treat Alzheimer´s disease. We postulated that the simultaneous inhibition of specifc histone deacetylase (HDAC2 and/or HDAC6) and a non-epigenetic target, both involved in independent pathways related to AD pathology, could restore memory deficits in AD mouse models.
Methods: We use in vitro (neuronal cultures) and in vivo AD models (Tg2576 mice). The effects of treatments on AD-related cognitive decline are evaluated using the fear conditioning and Morris water maze tests. After behavioural testing, animal brains are used to analyze amyloid and tau pathology. Spine density in apical dendrites inpyramidal neurons is determined using Golgi-Cox method. Affymetrix microarrays technology is used to analyze gene expression analysis.
Results: We demonstrated that beneficial effects on reversing AD-phenotype, including memory deficits, synaptic loss and amyloid and tau pathology, are only achieved when both pathways are target simultaneously. A lead compound (CM-414) hitting both targets simultaneously was synthesized and tested in vivo, confirming the beneficial effects observedby using reference compounds. Microarray expression analysis identified differential genes involved in the beneficial effect observed in treated animals.
Conclusions: A novel dual approach, hitting two different pathways, involved in memory formation and other AD-related features, leads to a synergistic therapeutic effect in the Tg2576 mouse model.

National Institute of Pharmaceutical Education and Research (NIPER), HYDERABAD, India
[3]Pharmaceutical Analysis,
National Institute of Pharmaceutical Education and Research (NIPER), HYDERABAD, India

Objectives: Present study was conducted to explore the phytopharmaceuticals from *Desmodium gangeticum* as possible leads for Alzheimer's disease therapy.
Methods: Major phytoconstituents in *D.gangeticum* Petroleum ether extract (DG), Quercetin, Rutin, Gallicacid, Kaempferol and Stigmasterol were identified using LC-MS/MS. They were screened for *invitro* Acetylcholinesterase inhibition (AChEI) and Butyrylcholinesterase inhibition (BChEI) along with DG in male Sprague Dawley (SD) rat brain homogenate, IC_{50} values were calculated. Also *exvivo* enzyme inhibitory assays were performed in SD rats with 6 per group, received 10 mg/kg dose PO, after 1 h animals were sacrificed and brain homogenates were used for assays.
Results: Quercetin exhibited greater *invitro* AChEI and BChEI with IC_{50} 18.31±0.34 and 62.80±2.76 µM respectively. Rutin, Gallic acid, Kaempferol, Stigmasterol and DG showed AChEI and BChEI IC_{50} of 86.14±0.92 & 300.11±7.98 µM, 41.20±1.12 & 78.36±1.92 µM, 128.19±1.94 & 142.01±1.87 µM, 302.09±8.34 & 384.12±6.34 µM, 20.30±0.79 & 51.04±1.02 mg respectively. The percentage inhibition for above mentioned treatments in *exvivo* AChEI and BChEI was found to be respectively 28±0.34 & 11±0.12, 12±0.71 & 08±0.32, 06±0.57 & 01±0.39, 10±0.61 & 02±0.98, 18±0.76 & 16±0.98, 06±0.94 & 02±0.56. Quercetin exhibited significant *exvivo* inhibitory activity indicating higher affinity for enzyme and permeability into brain.
Conclusion: Phytoconstituents of *D.gangeticum* showed significant AChEI and BChEI in both assays, also have proven antioxidant and anti inflammatory activity which is vital in prevention of Alzheimer's disease. These can be forwarded as leads for screening in *invivo* Alzheimer's models and possible mechanism to be studied further

[6]Department of Clinical Chemistry, University Medical Center Göttingen, Göttingen, Germany
Objectives: Proteins often use complex networks of interactions to produce a sophisticated signaling network. Deciphering the structure and dynamics of complex network of protein-protein interactions in AD is important for understanding many aspects of disease in depth. Our quest is for defining the functional interaction of AD brain proteins and the altered expression of interacting components in a complex using an ESI Q-TOF–MS/MS and Orbitrap approach.
Methods: The protein complexes were isolated from the autopsied human brain tissue cortical region (n=8 each) of Alzheimer's patients and Control subjects. Expression profiling was carried out on Blue Native (BN) PAGE in the first dimension followed by two-dimensional SDS-PAGE. Software analysis of differentially expressed proteins, Mass Spectrometric analysis and validation by western blotting were performed. The protein-protein interactions in a single complex were further confirmed by STRING and MINT databases.
Results: Thirteen protein complexes were isolated and separated on BN-PAGE gel. Each complex was further resolved into five to eight components on SDS-PAGE. A number of protein components in the second dimension were found to be differentially expressed between the AD and control brain. Mass spectrometric analysis in conjunction with protein-protein interaction database reveals significant interaction of proteins in a single complex that might be involved in the pathophysiology of the disease.
Conclusion: Current study expressed remarkable results that propose unique possibilities to investigate the interaction between protein in complexes in more detail with their modifications in AD for therapeutics and biomarker discovery.

[60]FULLERENE DERIVATIVE IS NEUROPROTECTIVE AGAINST AMYLOID-BETA PEPTIDE THROUGH MODULATION OF ADENOSINE AND METABOTROPIC GLUTAMATE RECEPTORS

J.L. Albasanz[1], D. Giust[2], T. da Ros[3], M. Martín[1]
[1]Inorganic Organic Chemistry and Biochemistry Neurochemistry Group, Castilla-La Mancha University, Ciudad Real, Spain
[2]Institut of Inflammation and Repair, University of Manchester, Manchester, United Kingdom
[3]Scienze Chimiche E Farmaceutiche, University of Trieste, Trieste, Italy

Amyloid-beta peptide (Aβ) is widely known as an important hallmark of Alzheimer's Disease (AD). It is aggregated into senile plaques which are responsible for neurodegeneration and cell death characteristic of AD. Although the mechanisms for its formation and toxicity are still unclear, Aβ is considered a potential target for therapeutic agents. [60]Fullerenes have been observed to be neuroprotective due to its antioxidant and radical scavenger properties. These effects have been associated to neurotransmitter receptor modulations. Some of these receptors, as adenosine and metabotropic glutamate receptors, have been shown to be affected in AD. mGlu receptors are significantly decreased in frontal cortex from AD brain in parallel to progression of disease. On the contrary, adenosine receptors are significantly increased in the same area even since early stages. The aim of the present work was to determine the possible neuroprotective effect of t3ss, a fullerene hydrosoluble derivative, and the role of adenosine and mGlu receptors in this neuroprotection. To this end, SH-SY5Y and SK-N-MC cells were treated with Aβ at different concentration and time exposure. Cell viability, radioligand and quantitative real time PCR assays were performed with treated and control cells. Results showed that Aβ caused a significant cell death affecting also adenosine and mGlu receptors expression. In addition, t3ss prevented the cell death elicited by Aβ and caused modulation of these receptors. These results suggest [60]fullerenes as neuroprotective nanoparticles against Aβ toxicity involving modulation of GPCRs and open new future perspectives to be considered in the treatment of AD.

ADPD5-0647

THE COMPARATIVE EFFICACY OF CHOLINESTERASE INHIBITORS IN PATIENTS WITH MILD TO MODERATE ALZHEIMER'S DISEASE: A BAYESIAN NETWORK META-ANALYSIS

H. Kobayashi[1], T. Ohnishi[1], R. Nakagawa[1], K. Yoshizawa[1]
[1]Medical Affairs, Janssen Pharmaceutical K.K., Tokyo, Japan

Objectives
To provide comparative evidences and hierarchies for efficacy between three cholinesterase inhibitors (ChEIs); donepezil, galantamine, and rivastigmine in patients with mild to moderate Alzheimer's disease (AD)

Methods
Article search was done using PubMed and The Specialized Register of the Cochrane Dementia and Cognitive Improvement Group. Previously published systematic reviews and meta-analyses were also manually reviewed. We included randomized, double-blind, placebo-controlled trials and head-to-head randomized trials evaluating the efficacy of ChEIs in AD patients. Comparisons evaluating high dose or low dose treatment were excluded. We examined Alzheimer's Disease Assessment Scale (ADAS-Cog), Neuropsychiatric Inventory (NPI), and Clinician's Interview-Based Impression of Change scale (CBIC+) as efficacy of treatment.

Results
We extracted data from 18 studies that provided sufficient data and met our inclusion criteria. Network meta-analysis was performed based on 7 arms of drug/dose treatment conditions, including donepezil 5mg & 10mg, galantamine 16mg & 24mg, rivastigmine 6-12mg, rivastigmine-patch 18mg, and placebo control. The analysis showed that all treatments were significantly more efficacious than placebo in cognitive improvement measured by ADAS-Cog. All treatments except rivastigmine-patch were significantly more efficacious than placebo in global assessment measured in CBIC+. Across all conditions, no significant efficacy was observed in behavioral improvement measured by NPI. Derived hierarchies in the efficacy of treatment conditions showed no consistency or clear-cut superiority in all 3 efficacy measures.

Conclusions
The Bayesian network meta-analysis incorporated direct and indirect comparisons. Our results suggested that the three drugs should have significant efficacies on cognition and global assessment, and these efficacies should be relatively similar.

TRANSCRIPT PROFILING OF NEUROPEPTIDES IN ALZHEIMER'S DISEASE: FOCUS ON THE GALANIN SYSTEM

S. Barde[1], A. Solarz[1], C. Morris[2], J. Attems[2], T. Harkany[3], T. Hokfelt[1]
[1]Neurovetenskap, Karolinska Institutet, Stockholm, Sweden
[2]Institute of Neuroscience, Newcastle university, Newcastle upon Tyne NE 4PL, United Kingdom
[3]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden

Objective. *The neuropeptide galanin (GAL) and its G-protein-coupled receptors (GALR1-3) are widely distributed in the mammalian brain and modulate several neurotransmitter systems. Less is known about AD and galanin but analysis of postmortem AD brains shows a marked galaninergic hyperinnervation of the cholinergic forebrain neurons. Several studies show that GAL levels increase throughout the cortex in AD and that GALR binding sites are amplified in various brain regions during the course of the disease.* ***Method****. In this study we aim to quantitate the transcript levels of galanin and its receptors in brain regions showing AD pathology using qRT-PCR. Brain regions including hippocampal formation (HiFo) and entorhinal cortex (EC) were analyzed to elucidate differential expression patterns related to region and degree of degeneration. In a preliminary study post mortem brain tissue of 10 cases each with Braak 0-II, Braak III/IV and Braak V/VI have been analyzed.* ***Results.*** *We found that galanin and GalR1/2 mRNA are expressed in both the HiFo and adjacent EC of controls and a significant but transient increase was observed in the EC for GalR1 (Braak III/IV), perhaps suggesting an attempt to counteract degeneration. Transcript levels for galanin, GalR2 and GalR3 were significantly elevated in Braak V/VI samples of the HiFo, and GalR2 from the EC, suggesting involvement of galanin system in severe AD in this region.* ***Conclusion.*** *We hypothesize that there are significant changes in the galanin system in AD and that further exploration in selectively vulnerable brain regions may help explore therapeutic possibilities.*

Background: Alzheimer's disease (AD) is the most common form of dementia and causes a progressive and irreversible neurodegeneration. The loss of cholinergic neurons leads to the progressive reduction of acetylcholine (ACh) in the brain and resulting cognitive impairment in AD. ACh is hydrolyzed by both acetylcholinesterase (AChE) and butirylcholinesterase (BuChE). It was found that in the course of the disease, levels of AChE in the central nervous system (CNS) decrease, inversely to BuChE levels, so both enzymes represent legitimate therapeutic targets for ameliorating the cholinergic deficit characteristic of AD.

Objective: Screen a library of new isoquinoline, indolinone and benzoazepinone derivatives for their ability to inhibit AChE and BuChE activities, using galantamine and rivastigmine as standards.

Methods: The enzyme activities and inhibition studies were carried out using spectrophotometric techniques, based on the Ellman's method, with acetylthiocholine (ATCI) and butirylthiocholine (BTCI) as substrates, for AChE and BuChE, respectively. The data were complemented with modeling to analyze the structure-activity relationship.

Results: Our results show that the tested compounds are competitive inhibitors for AChEs and BuChEs, as the benchmarks galantamine and rivastigmine. The isoquinoline and indolinone derivative compounds showed strong anti-cholinesterases activities, with IC50 values ranging from 0.4 to 400 micromolar.

Conclusions: The results presented are promising and provide a pathway for the design of new AChE and BuChE inhibitors.

NEUROPROTECTIVE EFFECT OF THYMOQUINONE AGAINST LIPOPOLYSACCHARIDE- INDUCED BEHAVIORAL AND NEUROTRANSMITTER ALTERATION IN AN ANIMAL MODEL

N. Sharaf[1], R. Mansour[1], N. Salah El Dine[1], L. Mahran[1]
[1]Pharmacology and Toxicology, German University In Cairo, Cairo, Egypt

Objectives: The aim of this study was to investigate the neuroprotective effect of Thymoquinone (TQ) against Lipopolysaccharide (LPS) induced cognitive impairment. Two positive controls were used Zileuton (Zil) and Deprenyl (Dep) as being anti-inflammatory and antioxidant compounds respectively.
Materials and Methods: 96 Sprague Dawley male albino mice (25-30 gm) were used. All the drugs were injected intraperitoneally once daily for 7 successive days after a single injection of 0.8mg/kg LPS. Animals were divided randomly into 8 groups: Negative controls (1%Saline, 1%DMSO and 1%Tween/ body weight), LPS (0.8mg/kg), Zil, Dep (10mg/kg), and TQ (2.5 and 5mg/kg). Animals were subjected to neurobehavioral tests including Y-maze test, Novel object recognition test and Open field test which assess spatial and recognition memories and locomotor activity respectively. Animals were sacrificed by cervical dislocation and the whole brains were isolated for the determination of Monoaminergic neurotransmitters Dopamine, Norepinephrine and Serotonin using High performance liquid chromatography with fluorescent detection.
Results: LPS altered animals' behavioral activity; it significantly reduced spatial and recognition memories and motor activity. Also, it significantly suppressed Dopamine, Norepinephrine and Serotonin levels. Both doses of TQ significantly improved spatial and recognition memories and motor activity as well as Dopamine, Norepinephrine and Serotonin levels. Moreover, TQ 5 mg/kg significantly improved animals' behavior and neurotransmitter levels not only when being compared to TQ 2.5 mg/kg, but also when being compared to the two positive controls.
Conclusion: TQ proved to be a promising neuroprotective agent in restoring memory and neurotransmitter levels owing to its antioxidant and anti-inflammatory properties.

DETECTION, EARLY DIAGNOSIS AND TREATMENT OF ALZHEIMER'S DISEASE

M. Bakhadirova[1], E. Mirdjuraev[1], A. Bakhadirova[2]
[1]Neurology, Tashkent institute of postgraduate medical education, Tashkent, Uzbekistan
[2]2nd Clinical Department, Tashkent Medical Academy, Tashkent, Uzbekistan

We have been observing 20 patients with Alzheimer's disease and 48 patients with vascular dementia of Alzheimer's type for 8 years. Setting the diagnosis of Alzheimer's disease, great attention was paid to the family anamnesis on the given disease, as well as to the arterial pressure, (hyper)lipemia, diabetes, overweight and hypodynamia

The main methods of the research were the tests, questionnaires, where the level of dementia has been revealed by the scale of Gamilton for revealing emotional and behavioral disorder, as well as objective research of neurological status, MRI of the brain were conducted.

In the process of the research it was revealed that 16 patients with Alzheimer's disease and 14 patients with vascular dementia were at the moderately severe stage and 4 patients had severe dementia.

With this aim the observation of the Alzheimer's disease has been conducted. For this purpose we prescribed the preparation Nitrendipine (Nitresan) in a dose of 10mg a day. For reducing the evidence of the main symptoms we have successfully used the preparations, which optimize synaptic transmission: inhibitor Donepezil (Alzepil) in a dose of 5- 10 mg. a day, as well as noncompetitive reversible antagonist – NCRA - glutamate receptor – memantin (carrier) 10-20 mg. a day.

As a result of detection, patients' diagnostics and treatment we were able to increase the quality of patients' life and prolong it; to reduce the cognitive deficiency and to reintegrate the patient to the family and society life in early stages.

IMPACT OF DONEPEZIL AND MEMANTINE ON BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS IN PATIENTS WITH ALZHEIMER'S DISEASE

P. Bago Rozankovic[1], *J. Badzak*[1]
[1]*Dpt of neurology, University Hospital Dubrava, Zagreb, Croatia*

Introduction: Behavioral and psychological symptoms of dementia (BPSD) are common in Alzheimer disease (AD). Donepezil and memantine are both used for the treatment of moderate AD. This study evaluated the efficacy of donepezil and memantine on BPSD in patients with moderate AD.
Methods: A prospective, longitudinal, randomized, 6-month clinical trial included 57 patients with moderate AD. The Neuropsychiatric Inventory (NPI) was performed to assess the prevalence and severity of BPSD at baseline and after 6-month treatment with memantine (n=29) and donepezil (n=28).
Results: .Baseline characteristics of participants including age, sex, mean length of education and disease duration were comparable. There was also no difference considering baseline Mini-Mental State Examination (MMSE) and Hachinski Ischemic Score (HIS) scores The NPI total scores improved from baseline to month 6 in both groups, with greater change in memantine group ($p<0.001$) comparing to donepezil group ($p=0.008$). Patients treated with memantine had significantly lower NPI final scores than patients treated with donepezil ($p=0.029$). Analyses of the NPI domains revealed that memantine treatment produced statistically significant improvement in agitation/aggression and anxiety NPI items ($p=0.01$; $p=0.03$ respectively).
Conclusion: The data suggest that specific drugs for AD, especially memantine, may be effective in treating BPSD in patients with moderate AD. The major benefits were observed on the symptoms of agitation/aggression and anxiety in memantine group

[3]Química Médica, Instituto de Química Médica (IQM-CSIC), Madrid, Spain

1. Objectives: Nowadays, novel AChE inhibitors are being designed to interact with both active and peripheral binding sites of AChE. It is known that the active site is responsible by acetylcholine hydrolysis and peripheral site is being related with the aggregation and deposition of the neurotoxic beta-amyloid peptide (Abeta), main cause of AD[1]. In this work, we reported the synthesis and biological evaluation of a key intermediate in the total synthesis of a new tacrine-donepezil hybrid, which was shown by preliminary studies of docking to be a potential AChE dual binding site inhibitor.

2. Methods: Synthesis of the key intermediate of tacrine-donepezil hybrid. Biological human AChE in modified Ellman's assay[2] and also Blood-brain barrier penetration using parallel artificial membrane permeability assay (PAMPA-BBB) [3].

3. Results: The key intermediate presented an IC_{50} 4.88±0.45 μM in Ellman's assay and also was able to cross the blood brain barrier.

4. Conclusions: The key intermediate of the total synthesis of tacrine-donepezil was performed and will be transformed into the designed hybrid in two steps. In addition, the biological assays will be carried out, including the Tioflavine T test to evaluate the capacity of the hybrid to avoid the beta amyloid aggregation induced by AChE peripheral site.

04m. Therapeutic Targets & Mechanisms for Treatment: wnt signalling

ADPD5-0444

WNT SIGNALING PREVENTS MITOCHONDRIAL MEMBRANE PERMEABILITY INDUCED BY AMYLOID-BETA OLIGOMERS, THROUGH THE PERMEABILITY TRANSTION PORE INHIBITION IN HIPPOCAMPAL NEURONS.

M.S. Arrázola[1], *N.C. Inestrosa*[1]

[1]*Center for Aging and Regeneration (CARE). Departamento de Biología Celular y Molecular. Facultad de Ciencias Biológicas., Pontificia Universidad Católica de Chile, Santiago, Chile*

Objectives: The canonical *Wnt* signaling, activated through its Wnt3a ligand, has been described as a neuroprotective pathway against A-beta toxicity, however the mechanism has not been explored. Mitochondrial permeability transition pore opening (mPTP) occurs under apoptotic agent exposure, such as A-beta. The aim of this work is to determine whether the protective effect of Wnt signaling pathway is mediated by the inhibition of mPTP opening in hippocampal neurons exposed to A-beta oligomers (ABo).

Methods: Live cell imaging was performed in hippocampal neurons treated with *Wnt3a*. ABo toxicity was evaluated measuring mitochondrial calcium levels (Rhod2-AM), mitochondrial membrane potential with Mitotracker Orange and mPTP opening with calcein-Co^{2+} labeling. Also, we carried out electron microscopy to observe structural changes and integrity of the mitochondrial membranes.

Results: *Wnt3a* prevents a cascade of mitochondrial events that leads to neuronal death induce by Abo, such as: (a) mitochondrial calcium increase, (b) mitochondrial membrane potetial loss, (c) cytochrome-c release, (d) the mPTP opening and (e) mitochondrial swelling, to finally prevents the cell death. We propose that this mPTP inhibition could be mediated by interaction of GSK3-beta with some of the mPTP protein components.

Conclusions: The activation of the canonical *Wnt* signaling protects neurons against ABo damage. Under ABo exposure mitochondria undergoes several changes, such as, dissipation of the membrane potential, release of apoptotic factors and membranes permeabilization through mPTP opening. We observed that these events were prevented by Wnt3a ligand, protecting mitochondria against ABo and therefore preventing cell death.

LONG-TERM TREATMENT WITH GINKGO BILOBA EXTRACT EGB 761 IMPROVES ALZHEIMER'S DISEASE-RELATED SYMPTOMS AND PATHOLOGY

X. Liu[1], L. Schnoeder[1], W. Hao[1], Y. Qin[1], Y. Decker[1], K. Fassbender[1], Y. Liu[1]
[1]Neurology, University of Saarland, Homburg, Germany

OBJECTIVES: Alzheimer's disease (AD) is a neurodegenerative disease characterized by extracellular deposits of amyloid beta peptide (Abeta) and microglia-dominated neuroinflammation. The therapeutic options for AD are still very few up to now. In this study, we aimed to investigate preventive or therapeutic effects and underlying molecular mechanisms of *Ginkgo biloba* extract EGb 761 in TgCRND8 AD mice. METHODS: We fed APP-transgenic mice with EGb 761 as a supplement in the diet for 2 or 5 months. Neuronal function, neuroinflammatory activation and Abeta pathology are investigated in this AD mouse model. RESULTS: We observed that the treatment of EGb 761 for 5 months but not for 2 months significantly improved cognitive function as demonstrated by the Barnes maze and attenuated the loss of synaptic structure proteins like PSD-95, Munc18-1 and SNAP25. Five- but not two-month EGb 761 treatment also inhibited microglial inflammatory activation in the brain. As a potential anti-inflammatory mechanism, EGb 761 could activate autophagy and thereby degrade NLRP3 inflammasome in microglia. Moreover, long-term EGb 761 treatments potentially reduced cerebral Abeta pathology through inhibiting BACE1-secretase activity and Abeta aggregation and even protect neurons via activating ERK1/2 and NF-kappaB signaling. CONCLUSIONS: Ginkgo extract EGb 761 as a nature-produced compound might efficiently prevent AD pathogenesis.

DASATINIB MODULATES M1/M2 POLARIZATION AND IMPROVES COGNITIVE DEFICITS IN A MOUSE MODEL OF NEUROINFLAMMATION

H. El-Sallab[1], R.M. Abdel-Kader[1], N. Hamdi[1]
[1]Pharmacology and Toxicology, German University In Cairo, Cairo, Egypt

Objectives: Alzheimer's disease (AD) is the most common age-related disorder which is characterized by cognitive deficit and neuroinflammation. Activated microglia produce a robust inflammatory response causing secondary neurodegeneration. Microglial activation has been classified into a classical proinflammatory M1 and an alternative neuroprotective M2 phenotype. LPS, a known proinflammatory stimulus, was shown to cause AD-like pathology. An *in vivo* LPS model was used in this study to investigate the effects of dasatinib, a tyrosine kinase inhibitor, on the cognitive functions and the microglial activation phenotypes.

Methods: Adult male Swiss albino mice were treated with intraperitoneal injection (i.p) of dasatinib (5 mg/kg) 1 hour prior to i.p administration of LPS (250 µg/kg). Four hours following LPS, the effects of dasatinib on spatial working and recognition memory were determined using Y-maze and novel object recognition tests respectively. The effect of dasatinib on mRNA levels of the M1 marker CD86 and the M2 marker arginase-1 was assessed in brain tissue using RT-qPCR.

Results: Behavioral tests showed that peripheral LPS challenge significantly impaired the cognitive functions, which was reversed by dasatinib pre-treatment. Moreover, LPS strongly upregulated both CD86 and arginase-1 gene expression with a higher induction of CD86. Dasatinib could significantly attenuate the LPS-mediated effect.

Conclusions: The present study shows for the first time that dasatinib modulates M1 and M2 microglial activation phenotypes in a mouse model of neuroinflammation. This correlates with a remarkable enhancement of the cognitive functions, suggesting a possible therapeutic role of dasatinib in controlling AD progression.

TUDCA TREATMENT AMELIORATES INFLAMMATION IN ALZHEIMER'S DISEASE (AD) MODELS

P. Dionísio[1], J.D. Amaral[1], M.F. Ribeiro[2], A.C. Lo[3], R. D'Hooge[3], C.M.P. Rodrigues[2]
[1]Cellular and Therapeutic Targeting,
iMed.ULisboa Faculty of Pharmacy Universidade de Lisboa, Lisbon, Portugal
[2]Cellular and Therapeutic Targeting,
iMed.ULisboa Faculty of Pharmacy Universidade de Lisboa, Lisboa, Portugal
[3]Laboratory of Biological Psychology, University of Leuven, Leuven, Belgium

Objectives:
Our aim was to evaluate the therapeutic effects of tauroursodeoxycholic acid (TUDCA) when administrated after the onset of amyloid pathology in APP/PS1 mice, focusing on neuroinflammation.

Methods:
We injected APP/PS1 mice and wild-type littermates 7 months old with 500 mg/kg body weight TUDCA intraperitoneally every 3 days for 3 months. One hemisphere of the brain was processed for immunohistochemistry (IHC) and immunostained for beta-amyloid (Abeta) and astrocytes or microglia markers. The other hemisphere was processed for RNA and protein extraction, and analyzed by qRT-PCR and Western blot (WB). To evaluate whether TUDCA specifically inhibits microglial pro-inflammatory response, we used microglia cell lines exposed to lipopolysaccharide (LPS) and Abeta species, followed by qRT-PCR and WB analysis.

Results:
TUDCA-treated transgenic mice brains presented reduced amyloidogenic proteolytic fragments of amyloid precursor protein (APP), along with decreased amyloid plaque burden and Abeta levels. Notably, gliosis was significantly decreased by TUDCA, as evaluated by IHC and WB, with a concomitant decrease in the expression of TNFalfa. Importantly, increased GSK3beta activity, an important event in glial activation, was strongly associated with Abeta accumulation and markedly abrogated by TUDCA. Finally, TUDCA-treated microglial lines exposed to LPS or Abeta presented reduced NFkappaB and GSK3beta activation.

Conclusion:
Overall our results suggest that TUDCA modulates microglial anti-inflammatory mechanisms in a pleiotropic manner, highlighting TUDCA as a potential therapeutic option for the treatment of neuroinflammation-related pathologies, including AD.

GLYCYRRHIZIN ATTENUATES OXIDATIVE STRESS AND NEUROINFLAMMATION: NOVEL APPROACH TARGETING ALZHEIMER'S DISEASE

N. Sharaf[1], R. Mansour[1], N. Salah El Dine[1], L. Mahran[1]
[1]Pharmacology and Toxicology, German University In Cairo, Cairo, Egypt

Objectives: Alzheimer's disease (AD) pathogenesis is still intangible but substantial facts demonstrate that oxidative stress and neuro-inflammation are the most prominent features of AD. The aim of this study was to explore the effect of Glycyrrhizin (Gly) on oxidative damage and neuro-inflammation induced by Lipopolysaccharide (LPS). Zileuton (Zil) a 5-lipoxygenase (5-LOX) enzyme inhibitor and Deprenyl (Dep) a potent antioxidant drug were used as positive controls.
Methods: 96 Sprague Dawely male albino mice (25-30 gm.) were randomly divided into 8 groups: Negative controls: Saline and DMSO (1%/ body weight), LPS (0.8 mg/kg), Zil and Dep (10mg/kg), and Gly (5, 10 and 20 mg/kg). Drugs were administered once per day via intraperitoneal route for 7 successive days after single injection of LPS. Lipid peroxidation end product thiobarbituric acid reactive substances (TBARS), reduced glutathione (GSH) levels and superoxide dismutase (SOD) activity were determined biochemically. 5-LOX level was determined by ELISA technique. Amyloid beta (Aβ) deposition in the dentate gyrus of the hippocampus and the cerebral cortex were determined by immunohistochemistry.
Results: LPS significantly increased TBARS & 5-LOX levels, and suppressed GSH levels and SOD activity. Also it stimulated the accumulation of Aβ in the two different brain areas. Gly elevated significantly the levels of TBARS & 5-LOX and increased GSH levels and SOD activity. Moreover, Gly prevented the accumulation of Aβ.
Conclusion: Gly might be an auspicious drug for the control of memory insult and neuronal aging due to its anti-inflammatory & antioxidant properties.

NEUROPROTECTIVE EFFECTS OF AMINOPROCALCITONIN INHIBITION IN EXPERIMENTAL MODELS OF ALZHEIMER'S DISEASE

E. Tavares[1], D. Antequera[2], F.J. Minano[1], E. Carro[2]
[1]Clinical and Experimental Pharmacology Research Unit, Valme University Hospital, Seville, Spain
[2]Neuroscience, Instituto de Investigacion Hospital 12 de Octubre (i+12), Madrid, Spain

Background: Neuroinflammation, a prominent feature in neurodegenerative disorders, has been associated with Alzheimer's disease (AD). Growing evidence suggests that inflammatory responses cause brain atrophy and play a prominent and early role in the progression of AD. Recent findings show that aminoprocalcitonin (NPCT), a neuroendocrine peptide produced in the periphery and in the brain, plays a critical role in the development of systemic inflammatory response, sepsis and multiple organ dysfunction syndrome. However, the presence, possible function, regulation and mechanisms by which NPCT could be involved in AD neuropathology remain unknown.
Objective: The aim of this study was to explore the expression of NPCT and its interaction with amyloid-b (Aβ), pro-inflammatory, and neurogenic effects.
Method: We used *in vitro* (neuronal cultures) and *in vivo* (brain autopsy samples from AD patients, and APP/PS1 transgenic mice) approaches to explore our objectives.
Results: We found Ab-induced NPCT up-regulation in cortical and hippocampal brain areas of APP/PS1 mice and AD patients. Additionally, Ab-induced cytotoxicity was blocked by anti-NPCT treatment, accompanied by reduced levels of pro-inflammatory cytokines. Remarkably, anti-NPTC therapy resulted in a significant improvement in behavioral status of APP/PS1 mice.
Conclusions: Our results indicate a central role of NPCT in the pathogenesis of AD and suggest this protein as a potential diagnostic and therapeutic target for this disease.

GAMMA-LINOLENIC ACID ACTS ON AB25-35-INDUCED INFLAMMATORY RESPONSES MODULATING NF-KAPPA B SIGNALING PATHWAY IN PC12 CELLS

M. Jun[1], *K. Youn*[1]

[1]*Food science & nutrition, Dong-A University, Busan, Korea*

Objectives: Alzheimer's disease (AD) is a neurodegenerative disorder initiated by the aggregation of amyloid beta (Aβ) peptide. The activation of the nuclear factor kappaB (NF-κB) is one of the signaling pathways through which Aβ exerts its neurotoxicity. The present study investigated the effect of gamma-linolenic acid (GLA) on $A\beta_{25-35}$-induced inflammatory damage and their underlying molecular mechanism of neuroprotective action

Methods: The cells were treated with GLA at different doses for 1 h and then added by $A\beta_{25-35}$ for another 24 h. Subsequently, the expressions of the TNF-α, iNOS, COX-2, NF-κB, IκB, p38, ERK and JNK were determined by Western blotting and the NO and PGE_2 were examined by ELISA.

Results: GLA attenuated levels of NO, PGE_2 and TNF-α, and induced down regulation of COX-2 and iNOS protein expression. GLA suppressed NF-κB p65 and IκB, and reduced the activation of JNK and ERK MAPK, whereas no changes in the activation of p38 could be observed.

Conclusion: This is the first report proving that GLA attenuates $A\beta_{25-35}$-stimulated neuroinflammation *via* inhibition of the NF-κB signaling pathway.

ADPD5-0228

EDARAVONE AMELIORATES STREPTOZOTOCIN (STZ) - INDUCED COGNITIVE IMPAIRMENT IN SPORADIC MODEL OF ALZHEIMER'S DISEASE IN RATS

R. Kh[1], Y.K. Gupta[1]
[1]Department of Pharmacology, All India Institute of Medical Sciences, Delhi, India

Objectives:

This study evaluates the effect of edaravone (3-methyl-1-phenyl-2-pyrazolin-5-one), a neuroprotective, in a sporadic model of Alzheimer's disease in rats.

Methods:

Male Wistar rats were divided into four groups: (i) Control wherein no treatment was given nor any procedure was done; (ii) Sham animals were injected artificial CSF intracerebroventricularly (i.c.v.); (iii) Streptozotocin (STZ) group wherein STZ (3 mg/kg, dissolved in artificial CSF) was injected i.c.v. (0.8 posterior, 1.5 mm lateral from bregma, and 3.6 mm ventral to dura) and (iv) STZ plus edaravone wherein edaravone (3 mg/kg, oral) was administered for 28 days after STZ. Cognitive impairment was evaluated using Morris water maze (MWM), elevated plus maze (EPM) and passive avoidance tests (PAT) on days 0, 14 and 28 after STZ injection. Rat brain malondialdehyde (MDA), reduced glutathione (GSH), nitric oxide (NO), superoxide dismutase (SOD), acetylcholinesterase (AChE) and butylcholinesterase (BuChE) were estimated at the end of 28 days.

Results:

STZ caused significant impairment of learning and memory as assessed by MWM, EPM, and PAT compared to control. Edaravone ameliorated the cognitive deficits induced by STZ. GSH level and SOD activity decreased while levels of MDA and NO increased significantly in STZ rats. Edaravone restored their levels towards normal. Edaravone attenuated the significantly higher AChE and BuChE levels in STZ group. There were no differences between control and sham groups in any of the studied parameters.

Conclusion:

Edaravone protects against STZ-induced cognitive impairment in sporadic model of Alzheimer's disease in rats probably by modulating cholinergic status and reducing the oxidative stress.

THYMOL FROM ZATARIA MULTIFLORA BOISS. PREVENTS NEUROTOXICITY INDUCED BY AMYLOID BETA IN PC12 CELLS

Z. Azizi[1], N. Majlessi[1], S. Choopani[1], A. Amanzadeh[2]
[1]Physiology & Pharmacology, pasteur Institute of Iran, Tehran, Iran
[2]Cell Bank, pasteur Institute of Iran, Tehran, Iran

Objective: Essential oil of Zataria multiflora Boiss. (ZM), a member of Lamiaceae family, has been shown ability to reduce symptoms of Alzheimer's disease (AD) and affect the disease mechanism in animal and cellular models of AD. In this study, the effect of thymol as a major constituent of ZM essential oil on amyloid β (Aβ)-induced toxicity in cultured rat pheochromocytoma (PC12) cells was investigated.
Methods: PC12 cells were incubated with $A\beta_{25-35}$ (50 µM) in the presence or absence of thymol (10, 20, 50 µM). The activity of cells was measured by methyl thiazolyl tetrazolium (MTT) method. Flurospectrophotometer was employed to observe intracellular reactive oxygen species (ROS) production.
Results: The results showed that after incubation with $A\beta_{25-35}$, the cell viability was decreased; in contrast, the level of ROS was increased in PC12 cells. Co-incubation of thymol prevented the cytotoxicity induced by $A\beta_{25-35}$ in cells and attenuated intracellular ROS.
Conclusions: In conclusion, thymol significantly protects the PC12 cell from Aβ-induced injury through the mitochondria dysfunction and oxidative damage. It seems that antioxidant activity of thymol might contribute to its beneficial effects in this model. Our findings suggest that thymol may be a potentially valuable source of natural therapeutic agents for the treatment of AD. However, further investigations are necessary to establish its efficacy and potential toxicity in clinical trials.
Key Words: Alzheimer's Disease; Amyloid β; Thymol; Antioxidant Activity.

TOTAL OLIGOMERIC FLAVONOID FRACTION OF CYPERUS ROTUNDUS AMELIORATES AMYLOID BETA 25-35 INDUCED ALZHEIMER'S DISEASE PATHOGENESIS IN SH-SY5Y HUMAN NEURONAL CELLS

K. Hemanth Kumar[1], *F. Khanum*[1]
[1]*Biochemistry and Nanosciences Discipline, Defence Food Research Laboratory, Mysore, India*

Abstract

Objectives

The objective of the study is to determine the protective effect of TOF fraction of *Cyperus rotundus* against amyloid peptide induced neurotoxicity in SH-SY5Y human neurons.

Methods

The amyloid beta 25-35 induced toxicity in SH-SY5Y cells and the protective activity of TOF was evaluated by MTT assay and LDH assays. The ROS and MMP were evaluated by spectrofluorometer assays. The antioxidant enzymes levels and lipid peroxidation was evaluated by spectrophotometer method. Further, the gene expression of apoptotic marker proteins such as Bcl-2 and Bax and neuronal markers such as BDNF and TH were evaluated by qRT-PCR analysis.

Results

The pretreatment of SH-SY5Y cells with total oligomeric flavonoid fraction (TOF) of CR effectively inhibited cell damage. TOF effectively inhibited amyloid beta 1-35 induced LDH leakage and neuronal DNA damage. TOF also regulated antioxidant activity and restored the antioxidant enzymes levels such as such as SOD, CAT, GPx, GR and glutathione and inhibited ROS generation. The TOF pretreatment also restored amyloid beta 1-35, induced cellular and mitochondrial damage and also restored the expression of BDNF.

Conclusion

TOF pre-treatment effectively inhibited amyloid beta 25-35 induced neurotoxicity in SH-SY5Y cells. Taken together, our findings suggest that TOF might be developed as an agent for neurodegeneration prevention or therapy.

Keywords: Alzheimer's disease, Amyloid beta peptide, *Cyperus rotundus*, neuroprotection, SH-SY5Y neurons, total oligomeric flavonoid fraction.

PLASMA VITAMIN C LEVELS ARE ASSOCIATED WITH INCREASED RISK OF GROWING INTIMA-MEDIA THICKNESS IN AGED SUBJECTS

P. Mecocci[1], C. Ruggiero[1], T. Raichi[1], R. Cecchetti[1], M.F. Croce[1], S. Ercolani[1], F. Mangialasche[2], M.C. Polidori[3]
[1]Geriatrics, University of Perugia, PERUGIA, Italy
[2]ARC, University of Stockolm and Karolinska Institute, Stockolm, Sweden
[3]Geriatrics, University of Cologne, Cologne, Germany

Objective: To explore the relationship between plasma levels and activities of the major antioxidant molecules and the carotid intima-media thickness (IMT) in a consecutive sample of healthy older subjects.
Methods: 192 subjects aged 65 years and older consecutively presenting to a Geriatrics Department for routinary check-up were admitted in this study. All patients underwent high-resolution B-mode ultrasonography for IMT measurement of the carotid artery. Plasma levels of vitamins A, C, E, of uric acid as well as activities of the plasma antioxidant enzymes superoxide dismutase (SOD) and glutathione peroxidase (GPx) were measured in all patients by HPLC with electrochemical detection (vitamin C and uric acid), HPLC with UV detection (vitamins A and E) and by spectrophotometry (SOD and GPx activity).
Results: Plasma levels of only vitamins C and E significantly decreased among participants from the first to the fourth IMT quartile, with a linear slope only for vitamin C. Results were independent of age, gender, smoking habit, hypertension, CVD, stroke, diabetes, antiplatelet treatment and uric acid levels. Compared to participants in the lowest vitamin C quartile, the probability to have IMT>1.2 mm significantly decreased among persons from the second to the fourth quartile independent of confounders. This could not be shown for the other compounds measured.
Conclusions: Vitamin C plasma levels but not of other antioxidant micronutrients and enzymes appear to be selectively associated with the risk of growing IMT. An adequate vitamin C status might be particulalrly important for protection against the clinical manifestations of vascular and cognitive ageing.

NEUROPROTECTIVE EFFECTS OF DIARYLPROPIONITRILE AGAINST BETA-AMYLOID PEPTIDE-INDUCED NEUROTOXICITY IN RAT CULTURED CORTICAL NEURONS

N. Suwanna[1], W. Thangnipon[1], R. Soi-ampornkul[2]
[1]Research Center for Neuroscience Institute of Molecular Biosciences, Mahidol University, Nakhonpathom, Thailand
[2]Department of Biochemistry Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Alzheimer's disease is a major cause of dementia in the elderly that involves a β-amyloid peptide (Aβ)-induced cascade of an increase in oxidative damage and inflammation. The present study demonstrated the neuroprotective effects of diarylpropionitrile (DPN), a non-steroidal estrogen receptor β selective ligand, against 10 μM $A\beta_{1-42}$-induced oxidative stress and inflammation in primary rat cortical cell culture. Pre-treatment with 1-100 nM DPN significantly decreased neuronal cell death by increasing cell viability through a significant attenuation in the reactive oxygen species level, downregulation of pro-apoptotic activated caspase-3 and Bax, and upregulation of anti-apoptotic Bcl-2, thereby mitigating apoptotic morphological alterations. DPN pre-treatment decreased the expression levels of pro-inflammatory cytokines IL-1β and IL-6 through attenuation of $A\beta_{1-42}$-induced phosphorylation of mitogen-activated protein kinases JNK and p38. In addition, DPN enhanced ERK1/2 and Akt phosphorylation depressed by $A\beta_{1-42}$. These findings suggest that DPN protects neurons from $A\beta_{1-42}$-induced neurotoxicity through a variety of mechanisms, ranging from anti-oxidation, anti-apoptosis, through to anti-inflammation.

CURCUMIN/MELATONIN HYBRID AS NEUROPROTECTANT FOR AD

S. Zhang[1], K. Liu[1], J. Chojnacki[1], J. Saathoff[1], G. Lopetegi[2], H. Lee[2]
[1]Medicinal Chemistry, Virginia Commonwealth University, Richmond, USA
[2]Pathology, Case Western Reserve University, Cleveland, USA

In our effort to develop effective neuroprotectants as potential treatments for Alzheimer's disease (AD), hybrid compounds of curcumin and melatonin, two natural products that have been extensively studied in various AD models, were developed. A lead hybrid compound was discovered to show significant neuroprotection with nM potency (EC_{50} = 27.60 ± 9.4 nM) in MC65 cells, a cellular AD model. Mechanistic studies demonstrated that this lead compound might interfere the interactions of AβOs within the mitochondria. Furthermore, this lead compound was confirmed to cross the blood-brain barrier (BBB) and deliver a sufficient amount to brain tissue after oral administration. In vivo studies in APP/PS1 mice after three months treatment demonstrated that this lead compound reduced Aβ plaques by 20%. it also reduced the oxidative stress as demonstrated by the reduction of 8OHG and HNE staining. More importantly this lead compound enhanced the mitochondria complex I activities, which is consistent with our in vitro mechanistic results. Collectively, these results strongly support the hybridization approach as an efficient strategy to help identify novel scaffolds with a desired pharmacology, and strongly encourage further optimization of this lead compound to develop more potent neuroprotectants for AD.

[6]Drug Development & Discovery, Ever Neuro Pharma, Oberburgau, Austria

Concussive head injury (CHI) is quite frequent in Military personnel during combat operation. CHI induced breakdown of the blood-brain barrier (BBB) causing brains to be more vulnerable to peripheral toxins and other adverse reactions. Thus, this is likely that CHI may induce brain damage leading to enhanced reaction with additional amyloid beta peptide (AbP) exposure causing adverse Alzheimer's Disease (AD) pathology. This hypothesis was tested in this investigation.

AD like pathology was induced by AbP infusion (50 ng/10 µl, i.c.v. daily for 4 weeks) in control and CHI rats. CHI was inflicted by an impact injury (0.224 N) on the right skull without fracture to simulate clinical conditions.

We found that ABP infusion in CHI cases results in 8 to 12 fold higher deposition of ABP in various brain areas and accumulation of tau proteins. A significantly higher increase in CSF tau proteins was also seen in CHI group than normal rats induced with identical AbP. In these groups of animals BBB and blood-CSF barrier (BCSFB) was also broken down for Evans Blue albumin. Brain edema, neuronal injuries, activation of astrocytes closely corresponds to the tau protein concentrations in the brain. Interestingly TiO2 nanowired delivery of cerebrolysin, a balanced composition of neurotrophic factors and peptide fragment (2.5 ml/kg, i.v. daily for 3 weeks after 1 week of AbP infusion), resulted in marked neuroprotection in CHI induced exacerbation of AD pathology. This indicates that CHI aggravates AD pathology and nanowired cerebrolysin has a therapeutic value, not reported earlier.

[2]Russian Academy of Science, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russia

P75 neurotrophin receptor (p75) may induce opposing effects depending on co-receptor partners and associated ligands. The p75 is a well known mediator of β-amyloid (Aβ) neurotoxicity and neuronal apoptosis induced proNGF, i.e. two agents implicated in Alzheimer's disease (AD). Elucidation of the mechanisms that modulate p75-mediated signaling in AD can be useful tool for target therapy.
To create a functional map p75 extracellular domain to normal state and AD, we blockaded the different parts of p75 by binding with antibodies, and investigated the effects of immunization on spatial memory and morphology of neurons in a chronic AD mouse model – bulbectomized (OBE) mice and sham-operated (SO) animals. The mice were immunized with synthesized eight potentially immunogenic fragments of the extracellular domain of p75.
We showed that immunization with two fragments (III and IV) was effective in preventing impairment of spatial memory in OBE mice. Aβ reduction in the brains of these animals until to a level in SO mice was found after immunization by peptide III. . Peptide IV was effective protector against destruction of neurons in the cortex and hippocampus , but was not much visible impact on level of Aβ. Other fragments did not restore the spatial memory in OBE mice. In contrast to OBE mice the immunization with fragments I- IV reduced the neuronal density and impaired spatial memory in SO mice.
Our results provide new insights into the functions of different parts of this enigmatic receptor in normal and pathological state.

APOJ/CLUSTERIN PEPTIDE AS A NOVEL THERAPEUTIC AGENT FOR ALZHEIMER'S DISEASE

D. Chernick[1], D. Hottman[1], S. Cheng[1], R. Omtri[2], K. Kandimalla[2], L. Li[1]
[1]Experimental and Clinical Pharmacology, University of Minnesota, Minneapolis, USA
[2]Pharmaceutics, University of Minnesota, Minneapolis, USA

Objectives: Apolipoproteins are essential structural components of lipoproteins and mediate a variety of biological functions. ApoJ (a.k.a. clusterin) is an apolipoprotein associated with high density lipoproteins (HDL) in the plasma and brain. Recent genetic studies identified the gene of apoJ (CLU) as one of the top-ranking loci associated with late-onset Alzheimer's disease (AD) after apoE4, a primary genetic risk factor for AD. ApoJ is a multifunctional protein; it binds amyloid-beta protein (abeta), inhibits abeta aggregation, promotes abeta clearance across the blood-brain barrier (BBB), and modulates inflammatory and immune functions in the brain. A 10-amino acid peptide derived from an integral sequence of apoJ, apoJ[113-122], mimics the properties of apoJ. It reduces atherosclerosis in apoE-null mice and improves anti-inflammatory properties of plasma HDL in monkeys. The present study was designed to investigate the therapeutic potential of apoJ[113-122] for AD.
Methods and Results: ApoJ[113-122] was used for several studies in vitro. Our results show that apoJ[113-122] inhibits the aggregation of abeta, protects neuronal cells from abeta-induced toxicity, and reverses abeta-induced disruption of microtubule dynamics in neuronal cells. In addition, apoJ[113-122] treatment enhances synaptic plasticity in hippocampal slices from wild-type mice and promotes anti-inflammatory activity of HDL in the plasma of APP/PS1 mice, a model of AD. Moreover, apoJ[113-122] effectively crosses the BBB in an in vitro model.
Conclusions: Our findings render apoJ[113-122] a promising therapeutic agent for AD. Animal experiments are underway to test its ability to mitigate cognitive impairment and neuropathology in the APP/PS1 mouse model of AD.

[3]Research, Toronto Western Research Institute, Toronto, Canada
[4]Chemistry, Treventis, Toronto, Canada
[5]Biology, Treventis, Toronto, Canada

Objectives: Aberrant protein aggregation of both beta-amyloid *and* tau is often implicated in the development of AD. The clinical presentation of AD is heterogeneous (e.g. extrapyramidal symptoms in some people with AD and dementia symptoms in some people with PD). The clinical overlap amongst neurodegenerative disorders implies that AD is more of a syndrome than a disease and that the suppression of other aberrantly misfolded protein may afford additional therapeutic benefits. Accordingly, we are seeking to design and develop brain-penetrable small molecule new chemical entities as anti-protein misfolding agents targeting both beta-amyloid and tau. Based upon extensive in silico modelling a family of novel compounds has been identified. A representative compound is TRV 101.
Methods: Efficacy of TRV 101 was measured in a variety of *in vitro* assays including biotin- beta-amyloid and biotin- tau oligomerization assays. TRV 101 binding to beta-amyloid and tau 4NR2 was measured by Surface Plasmon Resonance (SPR). Additionally, in vitro ADMET data along with mouse pharmacokinetics/ bioavailability (plasma and brain) was collected.
Results: TRV 101 showed anti-oligomerization activity against both beta-amyloid and tau. TRV has optimum drug like properties, demonstrating favourable in vitro ADMET, high brain penetrance and oral bioavailability, and benign in a 44-receptor panel test.
Conclusions: We have developed a new class of compounds capable of inhibiting oligomerization of both beta-amyloid and tau proteins. Our small molecules have appropriate pharmacokinetic profiles and able to reach the target tissue. Our compounds are currently being tested in animal models of both beta-amyloid and tau pathologies.

04s. Therapeutic Targets & Mechanisms for Treatment: misfolding and chaperones

ADPD5-1224

INHIBITION OF ABETA AGGREGATION AND TOXICITY BY BRICHOS IN A DROSOPHILA MODEL

J. Presto[1], E. Hermansson[1], H. Poska[2], J. Johansson[1]
[1]Neurobiology Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden
[2]Department of Natural Sciences Institute of Mathematics and Natural Sciences, Tallinn University, Tallinn, Estonia

Objective

The BRICHOS domain is present in several protein families associated with respiratory distress, amyloid disease, dementia and cancer. It has been suggested that BRICHOS domains bind to aggregation-prone regions in their respective precursor protein, and thereby protect them from misfolding. The BRICHOS domains of Bri2 (associated with dementia) and proSP-C interact with other amyloid forming peptides like Aβ (associated with AD). Both proSP-C and Bri2 BRICHOS delay the amyloid fibril formation of Aβ40 and Aβ42 *in vitro*, even at sub-stoichiometrical amounts of BRICHOS.

Methods

To further examine the effect of BRICHOS on Aβ *in vivo*, we have developed two *Drosophila* models, one expressing proSP-C BRICHOS and the other expressing Bri2 BRICHOS. By crossing the BRICHOS flies with Aβ42 transgenic flies, and driver flies for expression in the neurons or in the fly eye, we can analyze the toxic effect of Aβ42 with or without BRICHOS co-expression.

Results

Neuronal expression of Aβ42 alone in flies results in peptide aggregates detectable with confocal microscopy, reduced life-span and decreased locomotor activity, while expression of BRICHOS alone causes no detectable effects. Co-expression of both proSP-C and Bri2 BRICHOS with Aβ42 increases life-span and improves locomotor activity. Expression of Aβ42 in the eyes leads to degeneration of the ommatidia, and co-expression of BRICHOS efficiently decreases the toxicity seen in the eyes by Aβ42.

Conclusions

This strongly suggests that the proSP-C and Bri2 BRICHOS domains, decrease Aβ42 induced toxicity *in vivo,* which holds promises for targeting this chaperone as a treatment for AD.

CRTC1 OVEREXPRESSION RESCUES BETA-AMYLOID-INDUCED HIPPOCAMPAL-DEPENDENT MEMORY DEFICITS IN MICE

C.A. Saura[1], A. Parra-Damas[1], L. Enriquez-Barreto[1], M. Chen[1], J. Valero[1], J. Rodriguez-Alvarez[1]

[1]Institut de Neurociències Centro de Investigación Biomédica en Red Enfermedades Ne urodegenerativas (CIBERNED), Universitat Autònoma de Barcelona, Barcelona, Spain

Objectives: Cognitive decline is associated with gene expression changes in the brain, but the specific gene programs and transcriptional mechanisms underlying memory impairments in cognitive disorders are largely unknown. We aim to elucidate relevant transcriptional mechanisms responsible for early synaptic dysfunction and memory loss in Alzheimer's disease (AD).

Methods: To elucidate transcriptional mechanisms relevant for memory loss in AD we performed extensive pathological, behavioral, transcriptome and biochemical analyses in control and mutant β-amyloid precursor protein ($APP_{Sw,Ind}$) transgenic mice during aging.

Results: Genome-wide transcriptome analysis revealed deregulation of a gene network related with neurotransmission, synaptic plasticity, and learning/memory in the hippocampus of $APP_{Sw,Ind}$ mice after spatial memory. $APP_{Sw,Ind}$ mice show changes on a transcriptional program dependent on the CREB-regulated transcription coactivator-1 (CRTC1). Interestingly, synaptic activity and spatial memory induces CRTC1 dephosphorylation and nuclear translocation leading to CRTC1-dependent transcription in the hippocampus, and these events are impaired in $APP_{Sw,Ind}$ mice at early pathological and cognitive decline stages. Adeno-associated viral-mediated CRTC1 expression in the hippocampus of $APP_{Sw,Ind}$ mice efficiently reversed Aβ-induced spatial learning and memory deficits by restoring a specific subset of CREB/CRTC1 target genes. We are currently applying similar gene therapy approaches targeting CRTC1 in other faithful mouse models of brain diseases.

Conclusions: Our results reveal a critical role for CRTC1-dependent transcription on memory processing in normal and pathological conditions and provide evidence that targeting CRTC1 can reverse memory loss in AD.

ADPD5-1839
TARGETING GANGLIOSIDES FOR NEUROPROTECTION, COGNITIVE ENHANCMENT, AND REDUCTION OF AMYLOID AND ASSOCIATED NEUROPATHOLOGY

M.P. McDonald[1], T.J. Flanigan[1], S.K. Rao[1], P. Maiti[1], J.M. Ross[1]
[1]Neurology and Anatomy & Neurobiology,
University of Tennessee Health Science Center, Memphis, USA

1. Objectives. Given evidence showing a critical role for gangliosides in Abeta aggregation and apoptosis, we sought to understand their role *in vivo*. We summarize here five translational studies and present new data using treatments chosen to decrease levels of the neurotoxic GD3 ganglioside, increase the neuroprotective GM1 ganglioside, and reduce gangliosides that serve as high-affinity substrates for Aβ aggregation (GD1b & GT1b).
2. Methods. We first cross-bred GD3 synthase (GD3S) knockouts with APP/PSEN1 transgenics and assessed cognition and neuropathology. We then examined shRNA-mediated knock-down of GD3S in 5xFAD transgenics. We then infused sialidase (VCS) from *v. cholerae* intraventricularly in aged 5xFAD transgenics over an 8-week period. We followed this by creating a recombinant adeno-associated viral (rAAV) vector encoding the ganglioside-specific Neu3 sialidase, injected intrahippocampally in 4-month-old 5xFAD transgenics. Finally, we administered the milk protein glycomacropeptide (GMP) through the diet for 7 months to 5xFAD transgenics.
3. Results. Knockout and knock-down of GD3S both improved memory and reduced Aβ aggregation, and rAAV.GD3S.shRNA prevented neuronal loss in the 5xFAD transgenics. VCS did not significantly improve memory in aged transgenics, but reduced neuronal loss and Aβ on the ipsilateral (infused) side. VCS also significantly reduced Aβ on the contralateral side, but to a lesser extent. Assessment of the effects of rAAV.Neu3 are ongoing. Dietary GMP improved memory and dramatically reduced soluble and insoluble Aβ. Assessment of neuronal loss is ongoing.
4. Conclusions. Altering brain ganglioside profiles can improve memory and reduce Alzheimer-related neuropathology, and warrants further investigation as a novel therapeutic strategy.

ADPD5-0609

LITHIUM MICROEMULSION OF LOW DOSE RESTORES NEUROPLASTICITY, NEUROGENESIS, AND RESCUES COGNITIVE DEFICITS IN A TRANSGENIC RAT MODEL OF ALZHEIMER'S DISEASE

E.N. Wilson[1], M.F. Iulita[1], S. Do Carmo[1], S. Allard[1], A. Ducatenzeiler[1], A. Marks[1], D.T. Jia[1], A.C. Cuello[1]

[1]Pharmacology & Therapeutics, McGill University, Montreal, Canada

Objectives

Lithium, a drug often prescribed for bipolar disorder, has disease-modifying properties in patients at risk for developing Alzheimer's disease. However, the exact mechanisms underlying these effects are poorly understood. In addition, conventional lithium therapy has many serious side effects that make it inappropriate for long-term treatment.

Methods

We evaluated a new lithium water-in-oil microemulsion of low dose on transgenic rats with AD-like amyloid beta pathology. Separate cohorts of McGill-R-Thy1-APP transgenic rats, representing pre and post-plaque stages of the amyloid beta pathology, received either vehicle or low-dose lithium for 2 and 4 months, respectively. After treatment, animals were assessed on learning and memory tasks and for markers of synaptic plasticity and inflammatory processes.

Results

We found that lithium-treated transgenic rats showed significant recovery in cognitive performance, including on the Morris water maze, novel object recognition, and fear conditioning. The new lithium microemulsion reduced soluble levels of human Abeta42 peptides, but did not affect soluble human Abeta40. Insoluble human Abeta42 was undetectable at this age. Neurogenesis, which was significantly reduced in transgenic compared to wild type rats, was restored to wild type levels after treatment. These changes occurred in parallel with a modulation of inflammatory processes. Most importantly, the present preparation, dosage and administration route did not provoke any adverse effect.

Conclusion

The new lithium microemulsion of low-dose allows delivery of significantly lower, yet pharmacologically active, amounts of lithium. These results show that this new formulation of lithium has a therapeutic effect in transgenic rats with AD-like amyloid beta pathology.

04v. Therapeutic Targets & Mechanisms for Treatment: synaptic plasticity and repair

ADPD5-0876

A BLOOD-BASED GLUTAMATE SCAVENGER, OXALOACETATE, ABROGATES ABETA-MEDIATED HIPPOCAMPAL SYNAPTIC PLASTICITY DISRUPTION IN VIVO

D. Zhang[1], *M.J. Rowan*[1]
[1]*Pharmacology and Therapeutics, Trinity College Dublin, Dublin, Ireland*

Abeta-mediated inhibition of long-term potentiation may be caused by triggering an increase in brain extracellular glutamate concentration, possibly by inhibiting glutamate uptake or promoting its release.

Objectives:

Determine the ability of intravenous administration of a blood-based glutamate scavenger to abrogate LTP disruption caused by Abeta or by an excitatory amino acid transporter inhibitor, DL-*threo*-beta-benzyloxyaspartic acid.

Methods:

Electrically evoked field EPSPs were recorded in the CA1 area of the dorsal hippocampus of urethane (1.5 g/kg, i.p.) anaesthetized adult male Wistar rats. A cannula was inserted in the lateral ventricle. LTP was induced by repeated-200 Hz high frequency stimulation.

Results:

Intracerebroventricular injection of either protofibril-enriched Abeta1-42 (350 pmol) or TBOA (6 nmol) 1 h prior to the conditioning stimulation inhibited LTP (117.3±4.2% n=5; 111.5±3.7% n=5, $P<0.05$ compared with vehicle 133.1±1.3% n=5). In contrast, Abeta no longer inhibited LTP in rats pretreated 1 h (132.8±2.8% n=5), but not 2 h (114.7±2.1% n=5), with oxaloacetate (35 mg/kg, i.v.), a dose that on its own did not affect control LTP. Indeed i.v. administration of oxaloacetate 45 min after Abeta also abrogated the inhibition of LTP by Abeta (131.8±6.9% n=5, $P>0.05$ compared with vehicle). Furthermore, post-injection of oxaloacetate i.v. similarly prevented the synaptic plasticity disruptive effect of TBOA (136.5±3.2% n=5, $P>0.05$ compared with vehicle).

Conclusion:

These findings indicate that reducing blood glutamate concentration can abrogate the synaptic plasticity disruptive effects of Abeta or TBOA in the brain within a defined time window. Oxaloacetate appears to promote rapid glutamate homeostasis across the blood-brain barrier.

04v. Therapeutic Targets & Mechanisms for Treatment: synaptic plasticity and repair

THE RATIONALE TO TEST A SPECIFIC NUTRITION COMBINATION IN THE LIPIDIDIET CLINICAL STUDY1 IN PRODROMAL ALZHEIMER'S DISEASE

P.H. Scheltens[1], T. Hartmann[2], H. Soininen[3]
[1]Department of Neurology, Alzheimer Center VU University Medical Center, Amsterdam, Netherlands
[2]Department of Neurodegeneration and Neurobiology,
Deutsches Institut für Demenzprävention, Homburg, Germany
[3]Department of Neurology, University of Eastern Finland and Kuopio University Hospital, Kuopio, Finland

Objectives:
The LipiDiDiet study in prodromal AD (Dubois 2007) investigates the long-term effects of a specific nutritional intervention (Souvenaid) targeting the formation and function of neuronal membranes and synapses. The rationale for this study is based on effects of specific nutrient enrichment in basic science models and clinical trials in AD.
Methods:
Synaptic loss has been recognized as strongest structural correlate with memory impairment in AD and is apparent already early in the disease, including MCI. Synapses largely consist of neuronal membranes which are mainly composed of phospholipids. Phospholipid synthesis depends on the availability of rate limiting nutritional precursors and cofactors. Basic science studies indicate that their increased intake enhances synaptogenesis. However, lower plasma levels of these nutrients are widely observed in AD, eg lower levels of uridine and docosahexaenoic acid are found in early AD patients compared with controls.
Results:
Recent preclinical studies in the LipiDiDiet project confirmed beneficial effects of the intervention on cognitive performance and neuroimaging markers in a mouse model (APP/PS1) of AD. The clinical studies so far in AD demonstrated that the nutritional intervention is safe and improved memory performance in mild, but not moderate, AD and improved EEG measures of functional connectivity.
Conclusions:
Mechanistic and clinical studies suggest potential utility of increasing intake of specific nutrients in the earliest stages of AD. The LipiDiDiet study is designed to test the hypothesis that the investigational intervention Souvenaid improves cognitive outcome and disease markers in prodromal AD.

[4]Neurology and 6Anatomy & Neurobiology,
University Tennessee Health Science Center, Memphis, USA
[5]R & D, Oncosynergy Inc, San Francisco, USA

Objectives. Inhibition of heat-shock protein Hsp90, such as via pharmacological inhibitors, is being investigated as a treatment option for neurodegenerative diseases such as Alzheimer's disease (AD) and tauopathies**.** However**,** a pharmacologically feasible Hsp90 inhibitor with CNS permeability and safety is lacking.
Methods. Using a combination of experimental approaches of biochemical, cell biology, electrophysiology and animal models, we tested a CNS-permeable compound in AD-related functions.
Results. We recently discovered that a commercial Hsp90 inhibitor 17-AAG not only elicits a heat shock-like response but also upregulates several presynaptic and postsynaptic proteins, such as synapsin I, synaptophysin, and PSD95 via transcriptional activation in neurons. We now demonstrate that a proprietary Hsp90 inhibitor compound (NXD30020, NXD) displays similar actions on HSPs and on synaptic protection as 17-AAG. Chronic treatment with NXD completely rescues memory deficits induced by soluble amyloid β-peptides Abeta as well as in symptomatic Tg2576 AD mice without causing systemic toxicity. Despite the short shelf-life of NXD in mouse brain, a single intraperitoneal injection of NXD induces rapid and long-lasting (2-3 days) nuclear activation of the heat shock transcription factor HSF1, and increases expression of synaptic proteins including BDNF, most prominently in the CA1 of hippocampus. Furthermore, we found that this master stress response regulator HSF1 is crucial for the initial memory consolidation in contextual fear test.
Conclusions. The activated HSF1 may largely mediate the beneficial effects of Hsp90 inhibitors on synapses and cognition. Taken together, this work implicates a previously unappreciated role of HSF1 in synaptic functions and memory.

PRESENILIN-1 FAMILIAL ALZHEIMER'S DISEASE MUTATION ALTERS HIPPOCAMPAL NEUROGENESIS AND MEMORY FUNCTION IN CCL2 NULL MICE

T. Kiyota[1], C.M. Morrison[1], M.E. Kurczy[2], J. Ivanisevic[2], G. Zhang[1], A.A. Epstein[1], M.D. Boska[3], G. Siuzdak[2], H.E. Gendelman[1]

[1]Pharmacology and Experimental Neuroscience, University of Nebraska Medical Center, Omaha, USA

[2]Chemistry, The Scripps Research Institute, La Jolla, USA

[3]Radiology, University of Nebraska Medical Center, Omaha, USA

1. Objectives

Familial Alzheimer's disease (FAD)-linked presenilin 1 (PS1) mutations affect adult neurogenesis. However, how neurogenesis is affected is a point of conflict. Some studies show impaired cell proliferation and survival while others demonstrate increased cell proliferation. We sought to define the mechanisms underlying FAD PS1 mutations in hippocampal neurogenesis by engaging multidisciplinary behavioral, molecular and biochemical approaches.

2. Methods

PS1 FAD mutant (M146L)-overexpressing mice were crossed with a CC-chemokine ligand 2 knockout (CCL2KO) to generate double transgenic (Tg) PS1/CCL2KO mice. Non-Tg, single Tg mice (PS1 and CCL2KO) were used as controls. Morris water maze tasks were utilized to assess learning and memory function. Immunohistological and biochemical assays were employed on brain tissues and neural progenitor cells, respectively to uncover pathways of neural dysfunction.

3. Results

PS1/CCL2KO mice developed age-dependent deficits in learning and memory, impaired hippocampal neurogenesis, altered expression of synaptic plasticity-related molecules and reduced non-canonical ErbB4 processing. Associated increases in hippocampal N-acetyl-glutamic acid and ornithine were observed in the PS1/CCLKO mice implicating a role for altered ammonia metabolism through urea cycle activation.

4. Conclusions

The findings show that CCL2 affects both chemotaxis and cell fate for hippocampal neurogenesis. These act in concert with PS1 FAD mutations. In parallel, the PS1/CCL2KO mice serve as a model of hippocampal degeneration in AD and for other neurodegenerative disorders.

BEYOND DRUG DELIVERY TO THE BRAIN: THE EFFECTS OF MRI-GUIDED FOCUSED ULTRASOUND ON BRAIN PLASTICITY

A. Isabelle[1]

[1]*Brain Sciences Biological Sciences, Sunnybrook Research Institute, Toronto, Canada*

Objective: The use of transcranial MRI-guided focused ultrasound (MRIgFUS) is known for the delivery of therapeutics to targeted areas of the brain. Here, we evaluated the effects of FUS on brain plasticity, particularly with regards to the stimulation of adult neurogenesis and dendritic complexity.

Methods: We used non-transgenic rodents, and a transgenic mouse model of amyloidosis. Animals were anesthetized and secured in the FUS system. The hippocampus was located by MRI and targeted with the ultrasound. MRI images were capture to detect the increase in permeability of the blood-brain barrier due to FUS in presence of microspheres. One of the best known modulator of adult neurogenesis is exercise. As such, we compared the impact of FUS with running on adult neurogenesis. The impact of these treatments was evaluated on cognitive functions, neural and vascular plasticity.

Results: Transcranial MRIgFUS efficiently reduced amyloid load in transgenic animals, even at advance stages of the pathology. In both non-transgenic and transgenic animals, MRIgFUS significantly increases adult neurogenesis and dendritic complexity, similarly to what was observed with exercise. Furthermore, MRIgFUS was found to improve cognitive functions.

Conclusions: FUS applications can reduce amyloid pathology, increase neural plasticity and improve cognition. MRIgFUS has the potential to fulfill the long sought-after goal of non-invasive drug delivery to the brain and, in addition, inducing brain plasticity.

BEXAROTENE INCREASES NEURONAL DIFFERENTIATION IN VITRO AND IN VIVO

A. Mounier[1], K. Nyon Nam[1], D. Georgiev[1], N. Fitz[1], A. Cronican[1], R. Koldamova[1], I. Lefterov[1]

[1]Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, USA

Retinoid X receptors (RXRs) are ligand-activated transcription factors that bind to DNA as homodimers, or heterodimers with other nuclear receptors. We and others have shown that RXR ligand Bexarotene improves memory in mice expressing human apolipoprotein E (APOE).

To identify direct RXR targets genome-wide we applied chromatin immunoprecipitation followed by massive sequencing (ChIP-seq). We chose mice expressing endogenous APP to avoid possible effects of A-beta pathology on transcription factor binding. Since we were particularly interested in determining the effect of RXR binding in APOE4 and APOE3 expressing mice we chose 6 months old *APOE* targeted replacement mice (WT/E4). The result from Functional Annotation revealed that “neuronal differentiation” category was significantly enriched in samples from Bexarotene treated animals. RXR binding to select genes related to neuronal differentiation was validated using ChIP-QPCR in brain samples and cells.

To determine how Bexarotene affects mRNA levels and gene expression in brain, we applied mRNA-seq. GO categories “behavior” and “neuron differentiation”, were amongst the most significantly enriched. We validated the effects of Bexarotene on neuron differentiation/neurogenesis using QPCR in APOE4 mouse brain and in ES (embryonic stem) cells. We demonstrate that Bexarotene treatment increased neuronal lineage commitment in ES cells as well as their differentiation into mature neurons. Finally, we show that in response to Bexarotene there is enhanced maturation of postmitotic neurons in dentate gyrus of WT mice.

The study demonstrates the applicability of new and powerful sequencing technologies for research in Alzheimer's disease model mice and for addressing questions with significant therapeutic implications.

Objectives
Weak static magnetic fields (SMF) in the order of milliTesla (mT) strength cause distinct physiological effects on the human and animal body, however little is known about the way in which magnetic fields affect neuronal survival. The objective of this study was to determine whether SMF exerts neuroprotective properties in primary neuronal cultures.
Methodology
Primary cultures were prepared from cortex and hippocampus of day 1 rat pups and grown in neurobasal medium for 6 days in the presence or absence of 5 mT SMF, achieved by positioning a neodymium magnetic disc beneath each well of the 24-well culture plate. On DIV6, etoposide (12 microM) or beta-amyloid 1-42 (25 microM) was added for 24 h, and the percentage of apoptotic cells was determined using Hoechst 33342. Levels of free Ca2+ were determined on DIV7 without neurotoxin addition using Indo1.
Results
Exposure to SMF reduced the percentage of etoposide-induced apoptosis in cortical cultures by 57.1 ± 6.3%. Similarly, the percentage of beta-amyloid-induced apoptosis in hippocampal cultures was reduced by 59.0 ± 4.0%. Kinetic analysis using indo-1 showed that resting levels of intracellular free Ca2+ in primary cortical cultures, as well as the expression of voltage gated calcium channel proteins, were higher in the presence of SMF.
Conclusions
Constant exposure to SMF conferred significant neuroprotection in both cortical and hippocampal primary neuronal cultures. The mechanism behind this effect may be linked to an increase in free Ca2+ leading to enhanced release of neurotrophic factors, and activation of additional anti-apoptotic mechanisms.

[4]Laboratory of Physiology University of Coimbra,
Center for Neuroscience and Cell Biology University of Coimbra, Coimbra Portugal, Portugal

1. Objectives: Amelioration of brain insulin resistance upon glucagon-like 1 peptide (GLP-1) analogue treatment suggests that these drugs could be relevant in type 2 diabetes (T2D)-associated cognitive dysfunction, and in neurodegenerative diseases that share several common features with T2D (*e.g.* Alzheimer disease (AD)). Herein, we hypothesized that chronic peripheral liraglutide administration has neuroprotective effects in a mouse model of AD.
2. Methods: 11 month-old triple transgenic AD (3xTgAD) mice were given liraglutide (0.2mg/kg, once/day, 28 days) subcutaneously. Wild-type age-matched female mice were used as controls. Spatial memory was analyzed by the Morris watermaze (MWM) test. Blood and brain cortical homogenates were collected for several analyses.
3. Results: Liraglutide significantly decreased blood and brain glucose levels, peripheral hyperinsulinemia and insulin resistance, and slightly decreased glycated hemoglobin (HbA1C) in 3xTgAD females. Liraglutide also partially restored protein kinase A activity (a downstream kinase of the GLP-1 receptor-mediated signaling), decreased C-reactive protein (inflammatory marker) and thiobarbituric acid reactive substances and 8-hydroxy-2'-deoxyguanosine (lipid and protein oxidation markers, respectively). Liraglutide's ability to improve spatial memory for 3xTgAD female mice was accompanied by a decrease in amyloid-beta peptide and tau protein phosphorylation levels.
4. Conclusions: Chronic treatment with liraglutide ameliorates cognitive function and AD pathological hallmarks in 3xTgAD female mice. The improvement of peripheral and brain insulin sensitivity and glucose homeostasis, and decreased oxidative stress and neuroinflammation underlie the benefits of liraglutide.

TARGETING THE RETINOID X RECEPTOR: A NEW WAY FOR INVESTIGATION AND THERAPY IN ALZHEIMER'S DISEASE
M. Kuntz[1], Y. Lamartiniere[1], J. Saint-pol[1], P. Candela[1], L. Fenart[1], F. Gosselet[1]
[1]Blood-Brain Barrier laboratory, University of Artois-Faculty Jean Perrin, Lens, France
OBJECTIVES: By regulating brain cholesterol homeostasis, the anticancer drug bexarotene – an agonist of RXR - has been shown to restore cognitive functions and decrease the amyloïd brain burden in animal models of Alzheimer's Disease (AD). Nevertheless, its exact mechanism of action remains elusive. The main objective of this study is to find out the potential of RXR stimulation at the BBB level in therapy of AD.
METHODS: Transcriptional, protein and functional analyses of receptors and transporters involved in cholesterol and Aß exchanges between the blood and the brain compartments were undertaken on a human *in vitro* BBB model (fig.1), following 24h of bexarotene treatment.

RESULTS: Our preliminary results show that nanomolars concentrations of bexarotene, non-toxic for the BBB, increase the expression of ABC transporters (ATP-binding cassette) as ABCA1 and ABCB1, respectively involved in the brain cholesterol homeostasis and Aß clearance across the BBB. These preliminary data are in accordance with an increase in cholesterol exchanges between the blood and brain compartments. Consequences of ABCB1 up-regulation on Aß transport are currently being characterized.
CONCLUSIONS: These preliminary data could explain in part the beneficial effect of bexarotene in AD's models, and reinforce the interest of RXR stimulation in AD therapy. Moreover, these results highlight the importance to consider the BBB in pathophysiology and therapeutic research in AD.

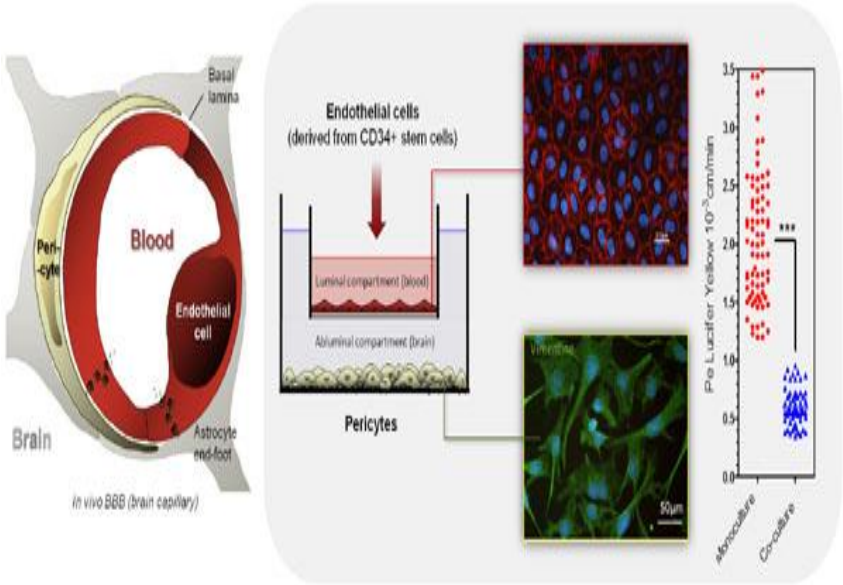

Fig 1. Human *in vitro* BBB model

Human cord blood CD34+ stem cells are differentiated into BBB endothelial cells by growing them on Matrigel-coated filters and cocultivating them with brain pericytes during 6 days (Cecchelli *et al.*, 2014).

PATTERNS OF LONGEVITY-ASSOCIATED SIRTUINS IN HUMAN DEVELOPING, DOWN SYNDROME AND AGING BRAIN

M.I. Lutz[1], I. Milenkovic[1], G. Regelsberger[1], G.G. Kovacs[1]
[1]Institute of Neurology 4J, Medical University of Vienna, Vienna, Austria

Objectives: Aging is a risk factor for neurodegenerative diseases such as Alzheimer´s disease (AD). AD-related pathology appears early in Down syndrome (DS). Recent studies suggest commonalities between the developing and aging brain. The sirtuin protein family was shown to be associated with longevity.
Methods: To evaluate a relation of sirtuin expression levels with the progression of AD we examined the highly vulnerable entorhinal cortex and compared with less affected regions in 45 cases grouped according to Braak stages of neurofibrillary degeneration. We applied morphometric immunohistochemistry and immunoblotting in subcellular fractions. In addition, we evaluated the distribution of SIRT1 and 3 in normal and Down developing brains by immunohistochemistry.
Results: Our studies revealed a subcellular redistribution of SIRT1 in aging brains suggesting a stepwise loss of neuroprotection. SIRT1 and 3 expression decreases during the progression of AD which is contrary to the increase of SIRT5. This increase associates with its appearance in activated microglial cells. In developing brains SIRT1 and 3 show strong positivity in the germinal matrix. The cellular distribution differs between DS and normal development.
Conclusions: The distinct pattern of sirtuin distribution in the developing and aging brain suggests a complex pathogenetic scenario, which should be considered when aiming sirtuins as therapeutic targets.

[5]Pharmacological and Biomolecular Sciences Center of Excellence on Neurodegenerative Diseases, Universita` degli Studi di Milano Milano Italy, Milan, Italy

Objectives Reduced neurosteroid levels have been reported in AD brain and thus increasing neurosteroid production may provide a novel therapeutic approach. Recently, the classic Translocator protein (TSPO) ligand, Ro5-4864, has been shown to increase neurosteroidogenesis and reduced cerebral beta amyloid deposition in an AD animal model. However, this ligand has limited clinical application due to low specificity and poor blood-brain barrier penetration. Here, we report three novel TSPO ligands : PBR175, PBR162, and CLINDE; that have favourable safety profiles on their effect on steroidogenesis and their ability to rescue against Aβ toxicity *in vitro*. **Methods** The three novel TSPO ligands based on substituted 2'-phenyl imidazopyridine structure and the acetamide side chain were shown to be non-toxic (10nM-100μM) by MTS and LDH release assay in M17 neuroblastoma and C6 glioma cell lines. Their neurosteroidogenic potency were assessed by measuring pregnenolone level by ELISA and neurosteroid levels were measured by LC-MS/MS in these cell lines. In addition, TSPO protein levels following TSPO ligands were measured by Western Blot. The ability to rescue against Aβ toxicity was also investigated by pre-treatment with the ligands following incubation with Aβ42 oligomers. **Results** These three novel TSPO ligands exerted a trend towards increasing levels of some (but not all) neurosteroid, with CLINDE being the most effective. However, they were not found to attenuate Aβ toxicity. **Conclusions** This study evaluates new generation TSPO imidazopyridine ligands as promising candidates that specifically target neurosteroid production for AD treatment.

USING MICRO-IMMUNOELECTRODES TO STUDY MECHANISMS OF RAPID AMYLOID-BETA CLEARANCE IN MICE

C.M. Yuede[1], C.Z. Li[2], J.R. Cirrito[1]
[1]Neurology, Washington University, St. Louis, USA
[2]Biomedical Engineering, Florida International University, St. Louis, USA

OBJECTIVES: Human studies strongly suggest that a key factor leading to Aβ accumulation in the brain is a defect in clearing the peptide. Aβ clearance from the brain occurs through multiple pathways, some of which may be fast-acting. The goal of this study was to use micro-immunoelectrodes (MIEs) to study the rapid removal of Aβ from the ISF.
METHODS: MIEs detect rapid changes in Abeta using an electrochemical approach (Prabhulkar et al., 2012). MIEs were implanted in the hippocampus of APP/PS1 mice, and baseline Aβ levels were measured. Mice were injected with a gamma secretase inhibitor (GSI) to block Aβ production, and the rate of Aβ clearance (elimination half-life) from the ISF was calculated. A second group of mice were pre-treated with a p-glycoprotein (Pgp) inhibitor to block active transport of Aβ across the blood-brain barrier. Clearance rates with and without PGP inhibitor treatment were compared to determine the relative impact of this clearance mechanism on Aβ halflife.
RESULTS: Baseline levels of Aβ40 before treatment are relatively stable and ISF levels begin to decline within 4 minutes of GSI injection. The elimination half-life of Aβ40 was calculated to be 38 minutes. Pre-treatment with a Pgp inhibitor resulted in a significant prolongation of Aβ40 half-life.
CONCLUSIONS: Inhibiting active transport slows clearance of Aβ, but does not completely block it, indicating multiple mechanisms are likely involved in Aβ clearance from the ISF.

[3]Molecular Pathology, UCSD, San Diego, USA

Alzheimer's disease (AD) pathology starts long before clinical symptoms manifest. It is likely that the earliest cognitive deficits are the result of high Aβ levels causing disrupted synaptic transmission leading to neuronal network dysfunction and depletion of calcium-dependent proteins, such as calbindin. Currently there is no therapy to treat, delay or prevent Alzheimer's disease. Recently we showed that rejuvenating the systemic environment of aged mice reverses age-related changes in synaptic plasticity and cognitive deficits. To investigate the possible therapeutic effects of young blood in the context of AD we used heterogenetic parabiosis, in which we joined young animals together with the Thy1-hAPPLond/Swe ($hAPP^{L/S}$) mouse model of AD. This resulted in a markedly increased expression of neuronal activity-related markers in the dentate gyrus of old heterogenetic APP parabionts restoring expression levels close to those observed in age-matched wild-type parabionts from isochronic pairs. Microarray analysis revealed that rejuvenating the systemic environment may restore several systems in the hippocampi of $hAPP^{L/S}$ mice, including calcium homeostasis. Together these transcriptional changes are indicative of a regenerated neuronal circuit, less neuronal cell death and improved cognition. Repeated intravenous injections of young plasma led to improvements in the memory of $hAPP^{L/S}$ mice and restored levels of neuronal activity related markers. Our data indicate that degenerative changes associated with AD pathology can be reversed by rejuvenation of the systemic environment, which opens the possibility for cognitive improvements in humans with AD.

TUDCA ATTENUATES ABETA LOAD IN APP/PS1 MICE BEFORE AND AFTER THE ONSET OF AMYLOID PATHOLOGY BY MODULATING ABETA CLEARANCE

M.F.C. Ribeiro[1], P.A. Dioníso[1], A.C. Lo[2], R. D'Hooge[2], J.D. Amaral[1], C.M.P. Rodrigues[1]
[1]Research Institute for Medicines (iMed.ULisboa),
Faculty of Pharmacy Universidade de Lisboa, Lisbon, Portugal
[2]Laboratory of Biological Psychology, University of Leuven, Leuven, Belgium

Objectives:
Our aim was to explore the neuroprotective mechanisms by which tauroursodeoxycholic acid (TUDCA) modulates amyloid-beta (Abeta) load in Alzheimer's disease (AD).

Methods:
We used 2 month-old APP/PS1 mice fed a diet containing 0.4% TUDCA, or no bile acid, for 6 months. Moreover, 7 month-old APP/PS1 mice were injected 500 mg/kg bw TUDCA i.p., or vehicle, every 3 days for 3 months. Wild-type littermates were used as controls. Brains were processed for Abeta immunohistochemistry; total proteins were prepared from dissected hippocampus and frontal cortex for Western blot (WB) and ELISA. Abeta clearance was evaluated using differentiated N2a cells treated with TUDCA before or after Abeta42 incubation, followed by ELISA and WB of cell lysates and supernatants. Finally, we analyzed the effect of TUDCA in intracellular Abeta levels, after wash-out procedures.

Results:
TUDCA significantly reduced amyloid plaque burden of APP/PS1 mice comparing to untreated controls. Importantly, this effect was observed in animals treated before amyloid deposition started, and in animals treated after the onset of amyloid pathology. Similar results were obtained by ELISA and WB analysis. *In vitro*, TUDCA treatment of differentiated N2a cells decreased both cell-associated and extracellular Abeta levels. Finally, we demonstrated that TUDCA still decreased Abeta intracellular levels after washing out Abeta from the culture medium. Therefore, TUDCA may influence not only the uptake of Abeta, but also Abeta intracellular degradation and/or exocytosis.

Conclusions:
Our data suggest TUDCA is a potential therapeutic alternative for prevention and treatment of AD-associated Abeta pathology, possibly by modulating intraneuronal amyloid clearance.

UNFOLDED PROTEIN RESPONSE (UPR) REGULATES THE ACCUMULATION OF AMYLOID BETA DEPOSITS IN EXPERIMENTAL MODEL OF ALZHEIMER'S DISEASE

C. Duran-Aniotz[1], S. Espinoza[1], A. Foley[1], V.H. Cornejo[1], G. Martinez[1], R. Vidal[1], C. Hetz[1]

[1]Program of Molecular and Cellular Biology,
Institute of Biomedical Sciences (ICBM) Faculty of Medicine University of Chil, Santiago, Chile

Introduction: Alterations of the protein homeostasis network have been extensively reported in Alzheimer's disease, in particular endoplasmic reticulum (ER) stress and the activation of UPR stress sensor IRE1 and its downstream target, the transcription factor XBP1. Importantly, a polymorphism in the XBP1 promoter was recently linked to AD, consistent with a global gene expression profile analysis that revealed XBP1 regulates a cluster of AD-related genes. Here we investigated the contribution of IRE1 to AD using a conditional knockout model in the context of AD and measured the impact on amyloid-beta aggregation/deposition.

Methods: We generated a brain specific knockout mouse for IRE1 and crossed it with an AD transgenic model termed 5xFAD. In order to evaluate the amyloid beta deposition, half of the brains of 6-month-old animals were processed for Abeta histological and biochemical analysis.

Results: We observed a reduced load of amyloid plaques in the brains of AD mice deficient for IRE1 measured by ThS staining and 4G8 specific antibody against amyloid beta. We also found that brain specific ablation of IRE1 significantly decreased soluble and insoluble forms of $Abeta_{42}$, as quantified by ELISA assay.

Discussion: IRE1 could modulate the processes affecting AD progression, offering new potential strategies for ameliorating AD pathology.

DBS VS RADIO-FREQUENCY ABLATIVE PROCEDURES : A COST EFFECTIVE ALTERNATIVE FOR MOVEMENT DISORDER FOR DEVELOPING COURTRIES

D. Ruikar[1], S. Jayalakshmi[1], M. Panigrahi[1], M. Surath[1]
[1]NEUROLOGY, KIMS HOSPITAL, HYDERABAD, India

Aim : To Study and to compare the outcomes following DBS and Pallidotomy/subthalamotomy procedures for movement disorders.

Material and Methods : radiofrequency ablative neurosurgery and DBS done for PD and dystonia at single center KIMS hospital, Hyderabad, India, presented here. UPDRS and UDRS scores used for preop and follow up clinical assessment. DBS done as standard protocols. Functional neurosurgery done by using sterotaxy and brainlab protocol for nucleus localization and lesion is created by radiofrequency probe which leads to thermocoagulation of the structure. Intraop stimulation of the target and neurological assessments were done by neurologist.

Results : At KIMS last 3 years there were 10 DBS procedures done One for Dystonia and 9 for parkinson's disease. 9 Ablative procedures done 5 for dystonia and 4 for parkinson's disease. Improvement noted in all the cardinal symptoms of the disease and functional status of patient on evaluation there was approximately more than 50% improvement in UPDRS and UDRS scales. Both the groups done well at the end of 1 year followup.

Discussion : Subthalamotomy and pallidotomy are seems tobe clinically effective procedures for patients having movement disorder. There were sustained clinical benefits by both the procedures. DBS is very costly and not available in most of centers in India.

For ablative neurosurgy cost of the procedure was significantly less [six times] than DBS. Ablative neurosurgery is affordable option in selected patient may return to the stage in Indian population but require further experience.

DIFFERENTIAL CONTRIBUTION OF CB1 AND CB2 CANNABINOID RECEPTORS TO THE PROGRESSION OF THE ALZHEIMER-LIKE PATHOLOGY IN APP/PS1 MICE

E. Aso[1], P. Andrés-Benito[1], M. Carmona[1], I. Ferrer[1]
[1]Institute of Neuropathology, IDIBELL, Hospitalet de Llobregat, Spain

Objectives: Growing evidence indicates that the pharmacological stimulation of the endogenous cannabinoid system represents a promising therapy to curb several neurodegenerative processes associated to Alzheimer's disease (AD). The aim of our study was to compare the specific contribution of CB_1 and CB_2 receptors, the main targets of the cannabinoid-based therapies, to the progression of AD-like pathology in an animal model.
Methods: Two new mouse strains were generated by crossing APP/PS1 mice, a transgenic model of AD, with CB_1 and CB_2 knockout mice. The cognitive performance as well as the cortical Abeta burden and gliosis were evaluated at different ages (3 and 6 months) in both colonies.
Results: The neonatal viability of APP/PS1/Cnr1$^{-/-}$ was drastically reduced and the few mutants that were born died before 2 months of age. APP/PS1/Cnr1$^{+/-}$ were viable but exhibited an accelerated cognitive impairment from 3 months of age. APP/PS1/Cnr2$^{-/-}$ developed normally and exhibited similar cognitive performance than CB_2 sufficient transgenic mice. However, higher Abeta burden and gliosis were observed in the cortex of APP/PS1/Cnr2$^{-/-}$.
Conclusions: CB_1 receptor plays a prominent role in the progression of AD pathology since its deficiency compromises the viability of APP/PS1 mice and accelerates their cognitive impairment. In contrast, CB_2 receptor deficiency does not alter APP/PS1 mice cognitive performance but exacerbates the Abeta-related pathology. In conclusion, a potential cannabinoid-based therapy against AD should target both CB_1 and CB_2 receptors in parallel in order to take advantage of the differential neuroprotective properties of these endogenous cannabinoid system components.

ADPD5-1914

RXR AGONIST CNX-013-B2 HAS A POTENTIAL TO REDUCE Aβ DEPOSITION, INCREASES CLEARANCE, ALONG WITH REDUCED NEURONAL DEATH IN BOTH N2A CELLS AND ASTROCYTES.

S. Baggavalli P[1], A. Tharappel M[1], S.K. Venkatesh[1], A. Mammen O[1], J. Madanahalli R[2]
[1]In Vitro Discovery, Connexios Life Sciences PVT LTD, Bangalore, India
[2]Cheif Scientific Officer, Connexios Life Sciences PVT LTD, Bangalore, India

Objectives: Alzheimer's disease (AD) is a neurodegenerative process involving amyloid-β (Aβ) peptide deposition, neuroinflammation, and progressive memory loss. Aβ accumulation leads to the deposition into plaques and is thought to initiate the pathologic cascade leading to neuronal death. Also cholesterol transport protein Apolipoprotein E along with ATP-binding cassette transporter A1 (ABCA1) play an important role in the clearance of Aβ from the brain. It is known that RXR/LXR functions as a sensor of cellular cholesterol concentration and mediates cholesterol efflux by inducing transcription of key cholesterol shuffling vehicles, ABCA1 and ApoE. In this study, we report impact of a potent and selective RXR agonist CNX-013-B2 on Aβ deposition, clearance, neuroinflammation/stress and neuroprotection in both neuronal cells and astrocytes.

Methods: N2a cells and mouse astrocytes were used to study the impact on the expression of markers of different mechanisms that regulate Aβ deposition, clearance, neuroinflammation/stress and neuroprotection after treating the cells with high cholesterol.

Results: Treatment with CNX-013-B2, a selective small molecule rexinoid with an EC_{50} of 48 nM towards human RXRa resulted in a significant increase in cholesterol efflux along with 3-5 fold increase in both ABCA1 and ABCG1 gene expression. CNX-013-B2 increases mitochondrial biogenesis and activity along with increased expression of NMDR, PGC1a and FOXO1 which are known as neuroprotective markers. CNX-013-B2 reduces ROS levels, MCP1 and IL1b expression along with decrease in caspase3 levels.

Conclusions: RXR activation with CNX-013-B2 can reduce Aβ deposition, neuroinflammation/stress, increase clearance and can be a neuroprotective agent.

REPEATED PERIPHERAL DELIVERY OF ADULT ISCHEMIC-TOLERANT MESENCHYMAL STEM CELLS LOWERS CEREBRAL ABETA AMYLOIDOSIS IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

T. Bolmont[1], N. Duthilleul[2], T. Lasser[2], N. Lukashev[1]
[1]Stemedica International, Stemedica International, Epalinges, Switzerland
[2]Biomedical Optics Laboratory, EPFL, Lausanne, Switzerland

Alzheimer's disease (AD) is a neurodegenerative disorder that represents one of today's major healthcare challenges. AD is neuropathologically characterized by the deposition of amyloid-beta (Abeta) peptides into extracellular senile plaques. The application of adult ischemic-tolerant mesenchymal stem cells (itMSC) for the treatment of AD is still not fully exploited. Therein we have evaluated the impact of repeated intravenous itMSC injections in a mouse model of AD.

Aged amyloid-depositing APPPS1 mice received a weekly intravenous itMSC injection for a total of 10 weeks. One injection consisted of a tail vein injection of 0.5 M itMSC in 150 ul of Lactated Ringers Solution (LRS). Repeated injections of LRS in aged-matched APPPS1 mice were performed as controls. One week after the last injection, APPPS1 animals were subjected to neuropathological examination. Biodistribution of itMSC in brains and peripheral organs was performed in different mice at several time-points after the intravenous delivery. The impact of itMSC on recovering brain dysfunction is being investigated using neuroimaging in living APPPS1 animals.

Our pre-clinical results indicate that repeated intravenous itMSC delivery in a mouse model of AD leads to significant reduction of cerebral Abeta amyloid plaques. The beneficial effect on plaques is accompanied by a significant diminution of neuroinflammation markers without appearance of cerebral amyloid angiopathy (CAA) or microhemorrhages. As revealed in the current study, the combination of safety and efficacy to remove amyloid plaques offered by itMSC, together with successfully completed safety phase I clinical trials, may put itMSC as a perspective candidate for treating AD.

RESULTS FROM A PHASE II STUDY TO ASSESS THE CLINICAL AND IMMUNOLOGICAL ACTIVITY, SAFETY AND TOLERABILITY OF AFFITOPE® AD02 IN PATIENTS WITH EARLY ALZHEIMER'S DISEASE

A. Schneeberger[1], S. Hendrix[2], F. Mattner[1], W. Schmidt[1], B. Dubois[3]
[1]Clinical Development, AFFiRiS AG, Vienna, Austria
[2]Statistics, Pentara Corporation, Salt Lake City, USA
[3]Department of Neurology, Salpetriere, Paris, France

Objectives: A multicenter, parallel group 18-month study was performed in both late MCI and mild AD subjects to assess the safety and efficacy of AFFITOPE® AD02, which is an *amyloid-beta (Aβ)-targeting vaccine*. AD04, an adjuvant control possessesing immune enhancing properties was originally designated as a placebo but appears to have disease-modifying activity.
Methods: The study enrolled 332 patients, randomly assigned to 5 groups: two formulations of AD04 (formulation 1 and 2), 25ug AD02 (in two different formulations) and 75ug AD02. Patients received 6 subcutaneous injections with final assessments at week 78. The efficacy analysis compared treatment groups on an Adapted ADAS-cog scale, Adapted ADCS-ADL and a Composite Scale.
Results: Dropout rates were similar across groups and exceptionally low for an 18 month study at 19.4% indicating good tolerance. A statistically significant difference in favor of AD04 (formulation 2) was found on the Composite Scale ($p=0.038$). Formulation 2 of AD04 showed statistically significant effects on several clinical outcomes: Adapted ADAS-cog, Adapted ADL, Composite, ADAS-cog, CDR-sb, and QOL-AD Caregiver as well as two biomarker outcomes: Right and Total Hippocampal volume (all $p<0.05$). 48% of patients in this group had no decline in the composite outcome over 18 months.
Conclusions: Primary efficacy outcomes in this phase 2 trial were significant in favor of AD04 over AD02. Exploratory analyses indicate potential treatment effects with the formulation 2 of AD04, supporting further studies of AD04. Clinical outcomes and biomarker evidence converged in favor of formulation 2 of AD04, consistent with a disease modifying effect.

ADPD5-0625

QUALITY OF LIFE IN ALZHEIMER'S DISEASE TRIALS: PRELIMINARY RESULTS AND FUTURE DIRECTIONS

K. Kahle-Wrobleski[1], Y.F. Chen[1], H. Liu-Seifert[1], E. Siemers[1], D. Henley[1]
[1]Lilly Research Labs, Eli Lilly and Company, Indianapolis, USA

Objectives: There is limited understanding in the ability of quality of life (QOL) scores to measure clinical impact of treatment effects in trials for disease-modifying agents of Alzheimer's disease (AD). This pre-specified secondary analysis explores the effects of solanezumab, a novel therapeutic, on QOL in patients with mild AD dementia.
Methods: Participants with mild AD dementia were drawn from two Phase 3 randomized clinical trials (EXPEDITION/2) that compared solanezumab with placebo. Patients and their caregivers completed the Quality of Life in AD (QOL-AD) scale (range 13-52) in addition to other outcome measures. Mixed-model repeated measures were used to estimate the change in QOL-AD over 18 months and compare the total QOL-AD scores for each treatment group.
Results: At baseline, QOL-AD mean scores were higher/better when self-reported compared with proxy-reported in both the placebo (37.88±6.00 versus 35.18±6.12) and solanezumab groups (37.73±6.10 versus 35.18±6.19). While there was numerically less decline in solanezumab-treated patients compared with placebo, there were no significant differences between the solanezumab and placebo groups for the change in self-reported total score (p=0.080) or the proxy-reported scores (p=0.434). Change in the self-report total scores declined less than the proxy-reported scores in the solanezumab group (-0.89 versus -1.95).
Conclusions: Although previous secondary analyses have demonstrated a significant benefit of solanezumab on cognition and function, the impact of treatment on QOL was limited. Trial duration, sample size and multiple non-treatment factors may have contributed to these findings. Self-reported and proxy-reported QOL measures may behave differently for patients with mild AD dementia.

PLANNING TRIALS WITH PRODROMAL AND MILD AD POPULATIONS: BASELINE AND PROGRESSION DATA FROM ADNI AND THE BAN2401 PHASE 2 STUDY

C. Swanson[1], V. Logovinsky[1], L. Xu[1], J. Wang[1], R. Lai[2], I. Do[1], M. Rabe[1], J. Luthman[1], A. Satlin[1]

[1]Neuroscience and General Medicine, Eisai Inc., Woodcliff Lake, USA

[2]Neuroscience, Eisai Ltd., Hatfield, United Kingdom

OBJECTIVES: Compare pre-dementia Prodromal AD and mild AD dementia subpopulations with regard to baseline characteristics and 12-month progression.

METHODS: Baseline clinical scores were summarized for Prodromal AD and mild AD subjects from the Alzheimer's Disease Neuroimaging Initiative (ADNI) (data collection and sharing funded by ADNI NIH Grant U01AG024904) and Study BAN2401-G000-201 (Study 201). Progression was assessed with 12-month follow-up ADNI data. Overlapping coefficients were calculated to quantify the degree of overlap between the prodromal AD and mild AD subpopulations.

RESULTS: Considerable overlap exists between Prodromal AD and mild AD baseline clinical scores in both ADNI and Study 201 (to date). For Study 201, the baseline clinical overlap between Prodromal AD and mild AD subjects ranged from 68% to 76%. Within ADNI, the baseline clinical overlap between the two subpopulations ranged from 43% to 60%, and persisted over 12 months of follow-up.

CONCLUSIONS: Baseline data from ADNI and Study 201 suggest there is no clear boundary between Prodromal AD and mild AD dementia based on clinical scores. Longitudinal ADNI data indicates that the lack of clear clinical score boundaries between the subpopulations persists over time, indicating similarity in disease progression. Prodromal AD and mild AD dementia subpopulations represent distinct clinical stages on the AD continuum that share common AD pathology. However, there exists a wide range of severity within each subpopulation, resulting in considerable overlap in baseline characteristics between them on common clinical tools. Collectively, these findings support the use of these two subpopulations as a single 'Early AD' population.

05b. Drug Development & Clinical Trials: antibody-based immunotherapy

EFFECTS OF HUMAN BRAIN PROTEIN EXTRACTS IMMUNODEPLETED WITH AN ANTIBODY AGAINST OLIGOMERIC AMYLOID BETA 1-42 INJECTED INTO THE ZEBRAFISH

M. Olsson[1], M. Offenbartl[2], H. Zetterberg[2], P. Kettunen[2]
[1]Biomedicine, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden
[2]Neuroscience and Physiology, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden

Alzheimer's disease (AD) is one of the most common diseases in elderly and will become even more prevalent with the constant increase in life expectancy. This will lead to increased suffering for patients and families, as well as elevated costs for society. However, there is currently no treatment for AD.

In this project we were interested in testing whether immunodepletion with ALZ-201, a monoclonal antibody 100% specific for amyloid-beta 1-42 ($A\beta_{1-42)}$ oligomers, removes toxic Aβ species from human brain protein extracts. Brain protein extracts from both controls and patients diagnosed with AD were immunodepleted with ALZ-201 (a generous gift from Alzinova AB). Then, the toxicity of the remaining brain extracts were tested in a zebrafish model for Aβ-mediated memory impairment and neurotoxicity.

Our preliminary results show that zebrafish embryos injected into the brain ventricle with brain extracts from control patients did learn. On the other hand, animals injected with brain extracts from AD patients failed to learn. However, when the AD brain extracts were immunodepleted with ALZ-201 prior to brain injection, embryos were able to learn. This data indicates that $A\beta_{1-42}$ oligomers are the most toxic form of Aβ in the AD brains, since ALZ-201 does not bind to monomeric or fibrillary $A\beta_{1-42.}$ In conclusion, our data supports that immunotherapy in the future could serve as preventive treatments for AD.

A HIGHLY SPECIFIC ASSAY FOR BACE1: CORRELATION OF BACE1 PROTEIN LEVELS WITH AGE AND TOTAL TAU IN CEREBROSPINAL FLUID

E. Vanmechelen[1], D. Jacobs[1], A. De Vos[1], S. Barão[2], B. De Strooper[2]
[1]Research, ADx NeuroSciences, Zwijnaarde, Belgium
[2]VIB Center for the Biology of Disease Department of Human Genetics and LIND, University of Leuven (KU Leuven), Leuven, Belgium

Objectives For all new drugs in clinical development, dose-finding is ultimately important. BACE1 is currently a prime drug target for Alzheimer's disease (AD) and even though explorative studies suggest that small changes in BACE1 protein levels are associated with pathological processes, so far only activity-based assays are widely available. A specific robust immuno-assay that determines the individual BACE1-levels and that is flexible enough to be combined with additional immuno-assays for target-engagement is not yet available. Therefore we present in this study the adaptation, according to the CSLI recommendations, of a previously reported research assay. As a first step towards clinical applications we also report age-dependent reference levels of BACE1 in CSF according to well-established guidelines.
Methods A research prototype ELISA was developed using monoclonal biotinylated antibodies, peroxidase conjugated streptavidin as reporter and recombinant human BACE1 as calibrator. CSF samples were picked from unselected diagnostic groups.
Results The analytical characteristics according to CSLI guidelines were: LOD 0,57 ng/ml; intra-assay and inter-assay variability 3% resp 12%, and cross-reactivity with human BACE2 was less than 5%. In more than 100 unselected CSF samples, a correlation between BACE1-levels and age was observed as well as a correlation with CSF tau.
Conclusion To our knowledge, this BACE1 assay is the only assay described today based on well-defined monoclonal antibodies, capable of measuring BACE1 levels in a wide range of CSF samples. The high specificity of this ELISA could complement the various activity-based BACE1 assays, enforcing BACE1 as a potential theranostic marker in clinical trials.

05d. Drug Development & Clinical Trials: gamma-secretase modulators

ADPD5-0249

ACTIVE SITES OF GAMMA-SECRETASE AND SPP ARE DISTINGUISHABLE WITH PHOTOREACTIVE PROBES

N. Gertsik[1], D. Chau[2], Y. Li[3]
[1]Biochemistry & Structural Biology, Memorial Sloan-Kettering Cancer Center, New York City, USA
[2]Clinical Genetics Unit, Universiti Putra Malaysia, Selangor, Malaysia
[3]Pharmacology, Memorial Sloan-Kettering Cancer Center, New York City, USA

Objectives
GSMs have been at the frontline of AD research since it was discovered that they can selectively reduce Aβ42 without affecting other Aβ species and Notch. While GSMs are therapeutically promising, little is known about their interactions with proteins other than gamma-secretase. Signal peptide peptidase (SPP), like gamma-secretase, is a multi-span transmembrane aspartyl protease that catalyzes RIP. We studied the effect of GSIs/GSMs on the active sites of gamma-secretase and SPP to determine whether SPP interacts with these compounds and how this interaction may impact SPP activity.
Methods
Active site-directed, photoreactive probes were employed to investigate differences in the active sites of gamma-secretase and SPP. Moreover, conformational changes in the active sites of both enzymes were studied upon GSI/GSM treatment.
Results
Comparison of the photolabeling profiles of SPP and gamma-secretase demonstrated that the active sites of these proteins are similar, yet some differences are apparent in specific active site sub-pockets. Furthermore, while GSIs block labeling of gamma-secretase and have no effect on or enhance SPP labeling, the opposite is true of GSMs, which block SPP labeling and have little effect on gamma-secretase labeling.
Conclusions
The structural similarity between the active sites of SPP and gamma-secretase indicated that SPP activity may be affected by GSIs/GSMs. In fact, photophore walking experiments suggest that GSIs enhance and GSMs reduce SPP activity. Reduction in SPP activity might result in undesirable side-effects for AD patients. Alternatively, the ability to target SPP with GSIs/GSMs may be therapeutically useful for SPP-dependent diseases, such as viral infections.

GAMMA-SECRETASE MODULATORS WITH IMPROVED DRUG-LIKE PROPERTIES FOR THE TREATMENT OF ALZHEIMER'S DISEASE

J.F. Blain[1], M.G. Bursavich[2], E.A. Freeman[1], L.A. Hrdlicka[1], H.E. Hodgdon[3], D.E. Costa[3], D.A. Murphy[3], T. Chen[3], B.A. Harrison[2], C. Tang[3], D.A. Burnett[2], H. Patzke[1], G. Koenig[1]
[1]Biology, FORUM Pharmaceuticals, Watertown, USA
[2]Chemistry, FORUM Pharmaceuticals, Watertown, USA
[3]DMPK, FORUM Pharmaceuticals, Watertown, USA

The therapeutic rationale of gamma-secretase modulators (GSMs) for Alzheimer's disease (AD) is based on genetic evidence of more than 160 distinct mutations in presenilin (PS) 1 and 2 leading to early onset familial AD. Some of these PS mutations decrease the processivity of the enzyme complex whereas GSMs increase it. This suggests that GSMs could potentially offset some of the effects of PS mutations thereby addressing the root cause of early onset AD. Unfortunately, the field has generated few, if any, molecules with good drug-like properties to enable proof-of-mechanism studies for GSMs. In our efforts to identify non-carboxylic acid GSMs (non-CA-GSMs), we designed, synthesized and screened over 50 different novel scaffolds (>1300 compounds). The current lead molecules demonstrate much improved drug-like properties, efficacy in rodent models and good in vivo-in vitro correlations. These new molecules, as opposed to CA-GSMs, increase the production of both Abeta38 and Abeta37. Here we report the screening strategy, properties, in vivo profile and the PKPD relationships of the current leads. We also show that changing the ratio of Abeta37/Abeta42 greatly reduces the aggregation properties of Abeta42 in vitro, a phenomenon that could further impact disease progression. In conclusion, these new GSM scaffolds combine good drug-like properties with in vivo efficacy to deliver GSMs that may soon be suitable for proof-of-mechanism studies in humans.

[3]F. Hoffmann-La Roche, F. Hoffmann-La Roche, Basel, Switzerland

[4]German Center for Neurodegenerative Diseases Munich Germany, DZNE, München, Germany

Objectives

γ-Secretase modulators (GSMs) are promising therapeutic agents by reducing generation of the aggregation prone Aβ42 species without blocking general γ-secretase activity. We now aimed to investigate the effects of a novel GSM [8-(4-Fluoro-phenyl)-[1,2,4]triazolo[1,5-a]pyridin-2-yl]-[1-(3-methyl-[1,2,4]thiadiazol-5-yl)-piperidin-4-yl]-amine (RO5506284) displaying high potency in vitro and in vivo on amyloid plaque burden and used longitudinal Aβ-microPET to trace individual animals.

Methods

Female transgenic APP-Swe mice aged 12 months were assigned to vehicle (N=12) and treatment groups (N=12), which received daily RO5506284 (30 mg/kg) treatment for six months. A total of 131 Aβ-PET recordings were acquired at 3 time points, whereupon histological analyses of Aβ were performed. Fibrillary β-amyloid plaques were stained with the fluorescent dye methoxy-X04, plaqueload, plaque density and histogram of the size of the plaques were determined.

Results

Plaque load in the TG-GSM mice was reduced by 42% relative to the TG-VEH group ($p<0.05$), while plaque density was 48% lower in the TG-GSM group compared to TG-VEH mice ($p<0.05$). Furthermore, histogram plotting of plaque size revealed differing distributions between groups of TG mice, showing fewer ($p<0.001$) small plaques (size<800 μm²) in TG-GSM animals. Individual plaque load assessed by PET remained nearly constant in the TG-GSM group during six months of RO5506284 treatment, whereas it increased progressively in the TG-VEH group.

Conclusions

We found clear attenuation of de novo amyloidogenesis upon prolonged treatment with a potent GSM in an AD mouse model. However GSM treatment was less effective in inhibiting the growth of pre-existing plaques.

05e. Drug Development & Clinical Trials: tau modifyers

ADPD5-1489

DEHYDROEVODIAMINE-DERIVATIVE AMELIORATES THE MEMORY IMPARIMENT AND PATHOLOGY OF ALZHEIMER'S DISEASE IN 5XFAD MICE

S. Ha[1], S. Lee[2], Y. Suh[3], K. Chang[1]
[1]Department of Pharmacology, Gachon University of Medicine and Science, Incheon, Korea
[2]Neurosurgery, Boramae Medical Center, Seoul, Korea
[3], Korea Brain Research Institute, Daegu, Korea

Objectives: Dehydroevodiamine(DHED), derived from *Evodia rutaecarpa*, has been known to improve memory impairments and decrease Alzheimer's disease(AD)-related pathology including amyloid plaque and hyperphosphorylated tau. However, it showed low water solubility in human gastrointestinal tract. Carboxy-DHED(cx-DHED), derivative of DHED, has high solubility in water so it is expected that cx-DHED has better therapeutic effects on AD with its increased bioavailability. In the present study, we investgated whether cx- DHED could improve memory deficits and modulate posttranslational modification of tau in 5xFAD, AD model mice.
Methods: Cx-DHED or donepezil (1mg/kg/day) was administered to 4month–old mice intraperitoneally for 2 months. To evaluate the cognitive impairment, the Y-maze and passive avoidance tests were performed. At the end of the behavior experiments, brains were collected and analysed histology and molecular mechanism.
Results: Cx-DHED treated–Tg mice exhibited significantly higher spontanuous alteration in the Y maze test than did the Tg-vehicle mice. In the passive avoidance test, the latency time was significantly increased by cx-DHED treatment compared to vehicle treatment. We also found that AD-related pathologies were reduced in the brains of Cx-DHED treated–Tg mice.
Conclusions: Cx-DHED, derivative of DHED with a high water solubility, significantly rescued memory deficits and ameliorated pathology in 5xFAD, AD model mice. These results suggest that Cx-DHED also has therapeutic effects on AD and it might be a potential candidate for AD treatment.

MOLECULAR EVOLUTION OF COMPOUNDS WITH POTENTIALLY THERAPEUTIC EFFECTS AGAINST PROTEIN MISFOLDING DISEASES

I. Matis[1], D. Delivoria[1], V. Mavroeidi[2], N. Papaevgeniou[1], M. Pelecanou[2], N. Chondrogianni[1], G. Skretas[1]
[1]Institute of Biology Medicinal Chemistry and Biotechnology, National Hellenic Research Foundation, ATHENS, Greece
[2]Institute of Biosciences and Applications, National Center for Scientific Research "Demokritos", ATHENS, Greece

It has now been widely recognized that many age-associated and very serious human diseases, such as Alzheimer's disease, Parkinson's disease, certain forms of cancer etc., are initiated by a common mechanism: the misfolding of specific proteins. Pharmacological chaperones, i.e. compounds with the ability to specifically bind to these proteins and rescue their misfolding, are valuable potential therapeutic agents for this type of disorders. In this work, we describe the application of molecular evolution approaches for the discovery of pharmacological chaperones for misfolding-prone proteins (MisPs) associated with protein misfolding diseases (PMDs). First, *Escherichia coli* cells are genetically engineered so as to biosynthesize very large libraries of test compounds exhibiting high levels of structural diversity. Then, the same cells are modified further so that the rare clones producing molecules with the ability to correct the folding of the target MisPs can be rapidly identified by high-throughput genetic screening. Lead compounds identified in this manner are subsequently subjected to more detailed evaluation by biochemical and biophysical methods of protein analysis, and their ability to inhibit MisP-induced pathogenicity is tested using appropriate human cell assays or *in vivo* models of the PMD of interest. We will describe our efforts to identify such "pharmacological chaperones" against the misfolding of the amyloid β (Aβ) peptide and of certain carcinogenic misfolded variants of human p53, with the aim of developing potentially therapeutic compounds against Alzheimer's disease and certain forms of cancer, respectively.

THE EFFECT OF APPLE AND HAWTHORN IN CHANGING THE STRUCTURE OF AMYLOID BETA OLIGOMERS AND THEIR MEMBRANE ATTACHMENT

M. Ferdousi[1], H. Jiang[2], K. Wilcox[2], M. Kamalinejad[3], M. Habibi Rezaei[1], W. Klein[2]
[1]School of Biology College of Sciences, University of Tehran, Tehran, Iran
[2]Department of Neurobiology, Northwestern University, Evanston, USA
[3]Department of Pharmacogenosy,
Faculty of Pharmacy Shahid Beheshti University of Medical sciences, Tehran, Iran

It has been elucidated that accumulation of amyloid beta oligomers (named ADDLs) in CNS is strongly the cause of AD. As a result, compounds capable of changing the structure and relative constituents of these ADDLs would be potential AD therapeutics. Nowadays natural compounds are of specific interest in AD treatment that some have been found to change the oligomer structure and cytotoxicity.

In this study we used the whole extract of two natural compounds (apple as MPG and hawthorn as CD) on preformed ADDLs to see their effects on the structure of the ADDLs. We also investigated the change in ability of the ADDLs in synaptosome binding after the addition of the compounds.

ADDLs were made according to Klein's Lab. protocol and were incubated with different concentrations of compounds (0.5, 1, 2, and 3 mg/ml in F12) in 4°C and 37°C for 6, 24, and 48 hours.

It was found that compounds were able to change the structure and MW distribution of ADDLs. According to western blot results when assayed with conformation specific antibody (NU2), in comparison with control ADDLs, CD showed a downward where MPG resulted in an upward shift in MW, the later caused a ladder-like distribution of SDS-stable ADDLs' subspecies. In synaptosome binding assay, CD showed a dramatic reduction in bADDLs attachment but not the MPG.

These results indicated that the whole extract of apple and hawthorn are capable of altering the oligomerization state of ADDLs where the later protected the synaptotoxicity effects of them.

[4]Karolinska Institutet Alzheimer Disease Research Center, Stockholm, Sweden

[5]Serenus Biotherapeutics, Inc., San Francisco, CA, USA

ALZ-801 is a novel, orally available small molecule prodrug of tramiprosate with improved pharmaceutical properties. ALZ-801 has an improved oral absorption profile, gastrointestinal tolerability and pharmacokinetic properties. Compared with oral tramiprosate in a single dose Phase 1 study, ALZ-801 pharmacokinetic variability was reduced by ~50% with an extended terminal t1/2 of 14.9 hours, allowing once-daily dosing. Oral tramiprosate was advanced to a 2,000 patient Phase 3 program which completed in 2007 with inconclusive results due to Alzheimer's disease misdiagnosis, which reached ~30% of the subjects. Post-hoc analyses of subjects with at least one e4 allele of apolipoprotein E gene (ApoE4 positive) in the North American Phase 3 study (n=599), showed that tramiprosate produced a clinically meaningful improvement in cognition (ADAS-cog) and function (CDR-SB) through 18 months, on top of treatment with acetylcholinesterase inhibitors and/or memantine (tramiprosate 150 mg BID, n=183; ADAS-cog: slope vs. placebo p

OPTIMIZATION OF POTENTIAL D-ENANTIOMERIC PEPTIDES BY CHEMICIAL MODIFICATIONS FOR THE TREATMENT OF ALZHEIMER´S DISEASE

T. Ziehm[1], O. Brener[1], T. van Groen[2], I. Kardish[2], M. Tusche[1], D. Willbold[1]
[1]ICS-6, Forschungszentrum Jülich, Jülich, Germany
[2]Department of Cell Developmental and Integrative Biology, University of Alabama at Birmingham, Birmingham, USA

1. Objectives

Alzheimer's disease (AD) is a neurodegenerative disorder, which is the most common cause of dementia. However, there is no drug available for causal treatment of AD. We developed D-enantiomeric peptides which target the cytotoxic amyloid beta (Abeta) oligomer species and optimized them by chemical modifications according to their ability to remove Abeta oligomers *in vitro*.

2. Methods

To investigate the efficacy of the chemically modulated D-enantiomeric peptides, several *in vitro* methods were used. The affinities of the potential drugs to various Abeta species were determined using surface plasmon resonance spectroscopy (SPR). Furthermore, the potency to remove cytotoxic Abeta oligomers was examined as well as the cytotoxicity of the Abeta-ligand-complex to neuronal cells. Finally, the efficacy of the optimized D-enantiomeric peptide was tested *in vivo* using a transgenic AD mouse model.

3. Results

By adding several chemical modifications, the affinities of the D-enantiomeric peptides to Abeta oligomers were improved. Additionally, an increased potency of cytotoxic Abeta oligomer removal was shown, resulting in decreased cytotoxicity of the Abeta-ligand-complex to neuronal cells. *In vivo* experiments showed that the treatment of transgenic AD mice with the optimized peptide leads to enhanced cognition in the animal model.

4. Conclusions

By introducing several chemical modifications to Abeta binding D-enantiomeric peptides, the *in vitro* efficacy of cytotoxic Abeta oligomer removal was successfully optimized. *In vivo* studies of transgenic AD mice yielded reduced cognitive impairments after the treatment.

05f. Drug Development & Clinical Trials: amyloid clearance

ADPD5-2113

PHARMACOKINETIC AND PHARMACODYNAMIC (PK/PD) ASSESSMENT AND COVARIATE ANALYSIS OF BIIB037 IN A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PHASE 1B STUDY IN PATIENTS WITH PRODROMAL OR MILD ALZHEIMER'S DISEASE

Y. hang[1], P. chiao[1], J. sevigny[1], L. williams[1], M. xiaopeng[1], J. o'gorman[1], J. ferrero[1]
[1]Clinical Pharmacology and Pharmacometrics, Biogen Idec, Cambridge, USA

Background: BIIB037, a fully human IgG monoclonal antibody that binds preferentially to aggregated forms of Aβ, is being investigated in a Phase 1b study as a disease-modifying treatment in patients with prodromal or mild AD.

Objectives: To assess the pharmacokinetic and pharmacodynamic (PK/PD) relationships and the possible covariate effects for amyloid removal following 6 months of treatment of BIIB037 in a Ph1b study.

Methods: In a staggered, parallel-group design, the treatment doses were: 1, 3, up to 10 mg/kg, and placebo. Sparse samples in the multiple ascending dose study and intensive samples from an earlier single ascending dose study were combined to construct a Population PK model. Cumulative AUC up to month 6 was estimated for each individual and used as the exposure variable for the assessment of PK/PD relationship. The relationship between BIIB037 exposure, SUVR change from baseline, and other covariates were evaluated with the Analysis of Covariance (ANCOVA) method.

Results: Cumulative BIIB037 exposures and baseline SUVR levels were found to be correlated with SUVR change from baseline. APOE4 carrier status (carriers vs non-carriers), stage of AD (mild vs prodromal), sex and age were not found to be correlated with change in SUVR.

Conclusions: BIIB037 treatment for 6 months resulted in a dose dependent removal of brain amyloid in AD patients. In addition, there was a significant correlation between BIIB037 exposures and degree of change in SUVR. The BIIB037-dependent change in SUVR was not significantly different in APOE4 carriers versus non-carriers or in prodromal versus mild AD patients.

05f. Drug Development & Clinical Trials: amyloid clearance

ADPD5-2136

CHARACTERIZATION OF A NOVEL D-ENANTIOMERIC PEPTIDE THAT IS ABLE TO ELIMINATE ABETA OLIGOMERS

A. Klein[1], T. Ziehm[1], M. Tusche[1], J. Kutzsche[1], D. Willbold[1]
[1]ICS-6, Forschungszentrum Jülich, Jülich, Germany

Objective:

Although Alzheimer's disease (AD) is the most prominent neurodegenerative disease and the sixth-leading cause of death, until now there is no causal therapy available. The accumulation of amyloid-beta (Abeta) aggregates is a key feature of AD. Especially small neurotoxic oligomers of Abeta are thought to be responsible for the development and progression of the disease and their elimination will therefore be a promising objective for therapy.

Methods:

We screened for new d-enantiomeric peptide derivatives of the compound D3 with enhanced specific binding to Abeta42 monomers and oligomers and characterized them for their Abeta42 oligomer elimination potential. Various biophysical and biochemical methods were used, like SPR, BLI, ThT assay, MTT assay, TEM (transmission electron microscopy) to characterize their potentials.

Results:

One of the newly identified peptides binds to Abeta42 monomers and oligomers with submicromolar affinity. Furthermore it was shown that it efficiently eliminates toxic Abeta42 oligomers *in vitro*. It inhibits Abeta42 self-aggregation to fibrils and reduces Abeta toxicity *in vitro*.

Conclusions:

By further modification of D3, it was possible to identify a new compound, which proved to eliminate toxic Abeta42 oligomeric species highly effective. *In vivo* results will show, whether the new compound's *in vitro* properties can translate into enhanced therapeutic potential in AD animal models.

05f. Drug Development & Clinical Trials: amyloid clearance

Fundacion ACE. Instituto Catalan de Neurociencias, Barcelona, Spain
[3]School of Medicine and Dentistry, University of Rochester, Rochester, USA
[4]Clinical Development, Transition Therapeutics, Toronto, Canada
[5]Alzheimer Disease Center & Gerontopole, University of Toulouse, Toulouse, France

Objectives: Agitation and Aggression are among the most disruptive neuropsychiatric symptoms (NPS) in AD. ELND005 (Scyllo-inositol) is being evaluated in an ongoing global clinical trial of Agitation and Aggression in AD (Study AG201; NCT01735630).
Methods: The study is a 12-week, double-blinded, placebo-controlled 2 arm study. Patients with AD are eligible if screening and baseline NPI- Agitation/Aggression score is ≥ 4 (at least moderate severity and frequency). Primary outcome measure is summed Agitation and Aggression scores from the expanded NPI (NPI-C), which separates Agitation and Aggression into distinct domains (De Medeiros et al., 2010).
Results: Baseline data from the first 260 AD patients was analyzed: mean age 75 years, 53% female, and 89% Caucasian. Patients mean baseline MMSE was 14.8 (range 0-28), NPI-total was 48.6 (range 4-144), NPI Agitation/Aggression score was 7.3 (range 4-12), and NPI-C Agitation and Aggression summed score was 18.8 (range 2-56). Baseline mean scores of depression, anxiety, apathy, irritability, and aberrant motor behavior were > 4. Distribution of NPI-C scores amongst mild, moderate and severe AD was similar.
Conclusions: The inclusion criteria in this study, as applied by clinical investigators, include AD patients who exhibit at least moderate levels of Agitation and Aggression requiring pharmacologic intervention. These patients also have high prevalence of anxiety, depression, apathy, and aberrant motor behaviors. Patient characteristics of the HARMONY-AD study are similar to the citalopram study (CitAD, Porsteinsson et al., 2014), and consistent with the recently published provisional criteria for Agitation and Aggression in AD (Cummings et al., 2014).

ADPD5-2284

DEVELOPMENT OF "COGNITIVE CLARITY": A UNIQUE DIETARY SUPPLEMENT FOR REDUCTION OF BRAIN "PLAQUES AND TANGLES" AND ENHANCEMENT OF MEMORY, FOCUS AND CONCENTRATION

A.D. Snow[1], G. Castillo[1], J. Cummings[1], T. Lake[1], Q. Hu[1], L.A. Esposito[1], K.L. Hanson[1], T.A. Chong[1], J. Cam[1]

[1]Neuroscience, ProteoTech Inc., Kirkland, USA

Beta-amyloid and tau are key proteins identified in the aging and Alzheimer's brain that are linked to memory loss and cognitive decline. There is currently no pharmaceutical drug that has been approved that can reduce and remove both beta-amyloid protein-containing "plaques" and tau protein-containing "tangles" in the brain. Cognitive Clarity may be the first nutraceutical product with the potential to reduce both brain "plaques and tangles", two pathological hallmarks of brain aging, memory loss and cognitive decline. Cognitive Clarity is a specific polyphenol-enriched combination of 1) a proprietary extract derived from the Amazon woody vine *Uncaria tomentosa* (cat's claw), and 2) a specific oolong tea extract identified after screening for direct activity against "plaque and tangles". A number of *in vitro* studies including Thioflavin T fluorometry, Congo red binding, Congo red and Thioflavin S staining, circular dichroism spectroscopy, and negative stain electron microscopy all demonstrated that Cognitive Clarity (and its major components) are effective reducers/disaggregators of beta-amyloid and tau protein "plaques and tangles". Transgenic "amyloid plaque" mouse model studies demonstrate that Cognitive Clarity's main plant extract ingredients cause a reduction and clearance of brain beta-amyloid protein and plaques, leading to marked improvement in memory (as assessed by water maze testing and probe trials). A randomized, double-blind, placebo-controlled human trial is currently underway to confirm the effects of Cognitive Clarity on improving memory, concentration and focus in subjects with age-associated memory impairment.

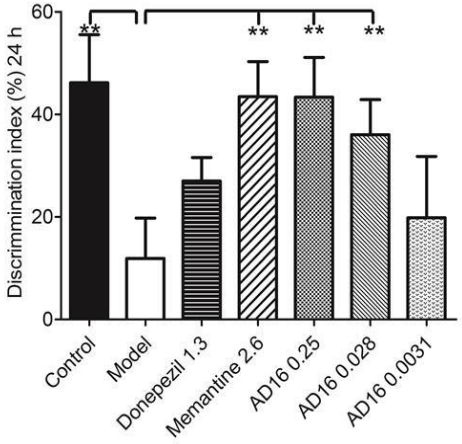
[4]Department of Pharmacy, The First Affiliated Hospital of Gungzhou Medical University, canton, China

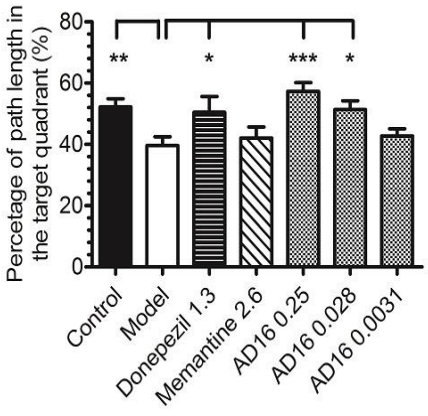
Objective: Phenotypic screening is making its renaissance in drug discovery as an alternative to target-focused approaches. Alzheimer's disease is a complex neurodegenerative disorder characterized by progressive impairment of memory and cognition. Since unclear aetiology of Alzheimer's disease and absence of validated therapeutic protein targets, it makes anti-AD drug discovery challenging in target-based approaches.

Methods: We employed microglia-based phenotypic screening to identify small molecules that can modulate the phenotype of detrimental neuroinflammation in Alzheimer brain.

Results: A novel pharmacological inhibitor (AD16, 0.25 mg/kg, oral) of neuroinflammation was discovered and showed comparable effect of cognitive impairment relief as donepezil (1.3 mg/kg, oral) and memantine (2.6 mg/kg, oral) did in both β amyloid-induced and *APP/PS1* double transgenic Alzheimer murine models. It exhibited desired safety properties and pharmacokinetic profiles of excellent blood-brain barrier penetration ability and acceptable half-life.

Conclusion: Our studies not only provide a potential drug candidate for further anti-AD drug development but also strongly support the concept that inhibition of neuroinflammation might be alternative strategy for combating AD.





Druglikeness	Lipinski's Rule of Five	None violation
	Clog*P*	2.163
Pharmacodynamic properties	Activity *in vitro*	LPS-stimulated microglia IL-1β inhibition IC_{50} = 3.4 nM
	Activity *in vivo*	Therapeutic effect was comparable to that of donepezil and memantine in 2 AD models
Pharmacokinetic properties	BIoavailability in rat	74.9%
	Half-life in rat	4.32 h
	BBB penetration	AUC(Brain/Plasma) = 0.21
	Metabolism stability	76% remains in 4 h in human liver microsome
Safety	*h*ERG	IC_{50} > 100 μM
	Acute toxicity	Maximum tolerance dose > 2000 mg/kg

[5]IN- CNR- via Vanvitelli 32 Milan, IRCCS Istituto Clinico Humanitas, Milan, Italy

Aim: Based on the evidence that microvesicles (MVs) shed from Bone -Marrow Mesenchymal Stem Cells (BM-MSCs) can play an immunomodulatory role, protecting the injured tissue, we aimed at assessing the possible anti-inflammatory effects of BM-MSCs-deriving MVs in microglia cultures exposed to hAbeta 1-42.

Methods: MVs were isolated by ultracentrifugation from mouse BM-MSCs and then characterized by FACS analysis. MVs were then incubated with primary microglia in the presence of human Abeta 1-42 peptide. The expression of different inflammatory or anti-inflammatory markers was investigated by ELISA, FACS, RT-PCR and immunocytochemistry.

Results: Microglial cells assume an amoeboid phenotype, changing its morphology and releasing anti-inflammatory cytokines, such as IL10, without significantly affecting the release of the pro-inflammatory cytokines TNFa and IL6. Also, MVs lead to the decrease in the expression of markers like MHC II, which is associated with a pro-inflammatory phenotype.

Conclusions: BM-MSC MVs down-regulate the inflammatory processes induced by exposure of microglia to h 1-42 Abeta peptide *in vitro*. The involved molecular mechanisms are under investigation.

A NEW ANTI-INFLAMMATORY DRUG WITH NEUROPROTECTIVE ACTIVITY IN THE OLIGOMERIC Ab25-35 PEPTIDE-INDUCED ALZHEIMER'S DISEASE MOUSE MODEL

F. Mourlane[1], V. Villard[2], T. Maurice[2], S. Laruelle[1], C. Laruelle[1]
[1]Résidences Panoramiques, 1093 Chemin des Plateaux Fleuris, 06700 Saint Laurent du Var, France
[2]2196 bd de la Lironde, 34980 Montferrier-sur-Lez, France

Objectives: Epidemiological and clinical studies have established the role of pro-inflammatory cytokines in the pathophysiology of Alzheimer's disease (AD). Anti-inflammatory agents like anti-TNF biologics have emerged as therapeutic alternatives for AD patients. AMYLZEN® is a nonapeptide analog of thymulin with potent analgesic and broad anti-inflammatory action that crosses the BBB. AMYLZEN® is safe and well tolerated in humans. We set out to evaluate the pharmacological activity of AMYLZEN® in a preclinical non-transgenic mouse model of AD.
Methods: has been tested in a validated mouse model where the intracerebral injection of Ab25-35-peptide (ABP) induces neuroinflammation, neurotoxicity and behavioral impairment. Cytokine levels, lipid peroxidation and formation of b-amyloid plaques were measured in hippocampus of ABP-injected mice 5 to 7 days post treatment. Two functional tests were used to evaluate spatial working (spontaneous alternation performance in the Y maze) and contextual long-term memory (passive avoidance test).
Results: Coinjection of AMYLZEN® at a low dose (5 ug/kg, intracerebral) with ABP completely blocked the overproduction of TNFa and IL-1b. Oxidative stress and formation of neurotoxic b-amyloid plaques were significantly reduced. AMYLZEN® had a protective effect on ABP-induced learning deficits. Systemic treatment with AMYLZEN® (1 to 10 mg/kg, intraperitoneal during 7 days) had protective effects similar to Donepezil (0.5 mg/kg, intraperitoneal), one of the few approved symptomatic treatment.
Conclusions: The encouraging neuroprotective activity demonstrated in a validated preclinical mouse model together with the excellent pharmacological, safety and toxicological profile of AMYLZEN® favorably position this compound as a new candidate for clinical investigation in AD patients.

[5]Clinical and Experimental Therapeutics, University of Southern California, Los Angeles, USA
[6]Neurology, University of Southern California, Los Angeles, USA

Objectives:
Regenerative therapeutics hold the promise of self-renewal and repair. While ageing and age-associated neurodegenerative diseases are marked by decline in these functions, capacity for regeneration is retained. Discovery research demonstrated that the neurosteroid, allopregnanolone (ALLO), induced neurogenesis in brain and restored cognitive function while simultaneously reducing AD pathology burden. Objectives of this program of research is to develop the neurosteroid, allopregnanolone (ALLO), as regenerative therapeutic for Alzheimer's disease.
Methods: Phase 1b clinical trial to establish safety and maximally tolerated dose.
Results: Outcomes of discovery and translational research led to an NIA funded Phase 1b clinical trial of Allo in persons with MCI and early Alzheimer's. Primary safety objectives are to determine maximally tolerated dose and incidence and severity of treatment emergent adverse events. Exploratory safety and feasibility analyses of cognitive function and MRI-based biomarkers relevant to regeneration will be conducted. Trial outcomes will provide: 1) an estimated safe and well-tolerated dose of Allo; 2) parameter estimates for cognitive efficacy to advance to a Phase 2 proof of concept trial of Allo; and 3) parameter estimates for MRI-based biomarkers.
Conclusion: Allopregnanolone as a regenerative therapeutic is based on a strong foundation of well defined mechanistic targets for neurogenesis and disease modification, dosing requirements, optimal treatment regimen, route of administration and the appropriate formulation necessary to advance to Phase2 proof of concept clinical studies to determine efficacy of allopregnanolone as a regenerative and disease modifying therapeutic for Alzheimer's disease.

NEUROPROTECTIVE EFFECTS OF HARMINE ALKALOIDS ON SODIUM NITRITE-INDUCED HYPOXIA AND ETHANOL-INDUCED NEURODEGENERATION IN ANIMAL MODELS RELEVANT TO ALZHEIMER'S DISEASE

H. Joshi[1], *S.M. Biradar*[1]

[1]*neuropharmacology, sarada vilas college of pharmacy KM puram Mysore, Mysore, India*

Background: Cognitive impairment is a multidimensional and complicated concept that subsumes the attention, concentration, learning, memory, problem-solving ability, visuospatial abilities, mental flexibility, psychomotor efficiency and manual dexterity.
Objective: To study the effects of harmine alkaloids from the seeds of Peganum harmala on cognitive deficit mice.
Methods: Harmine alkaloids were screened for Sodium nitrite induced hypoxia and Ethanol induced neurodegeneration using behavioral models such as rotarod, Passive shock avoidance paradigm, special water bottle case model, elevated plus maze and Morris water maze. HM (5, 2.5 and 1.25 mg/kg p.o.) were administered to the mice. Acquisition, retention, Transfer latency (TLT), Time spent in target quadrant (TSTQ), Step down latency (SDL) and Escape latency (ELT) and biochemical parameters such as AChE, MAOA, TBARS, epinephrine, 5 HT were determined. DNA fragmentation studies were conducted which were compared with donepezil.
Results: HA (5, 2.5 and 1.25 mg kg(-1) p.o.) significantly ($p < 0.001$) protected the Sodium nitrite induced memory impairment by decreasing the time require to find the water bottle in special water bottle case model. HA improved acquisition and retention memory significantly ($p < 0.001$) by decreasing the Transfer Latency Time (TLT), escape latency time, TSTQ and increased the Step Down Latency (SDL. HA inhibited Acetylcholinestrase ($p < 0.01$) activity, increased GSH,decreased TBARS and inhibited MAOA activity. Reduced the metabolism of epinephrine, 5-HT. HA (5 mg kg(-1)) protected the DNA fragmentation of frontotemporal cortex from hypoxic effects.
Conclusion: Harmine alkaloids are beneficial in the management of Neurodegenerative disorders particularly for Alzheimer's disease.

DEVELOPMENT OF NOVEL CURCUMINOIDS FOR THE TREATMENT OF ALZHEIMER'S DISEASE AND OTHER NEUROCOGNITIVE DISORDERS

A. Kulkarni[1], N. Kumari[2], M. Hipolito[2], S. Nekhai[2], E. Nwulia[2]
[1]Pharmaceutical Sciences, Howard University, Washington DC, USA
[2]College of Medicine, Howard University, Washington DC, USA

Curcumin, a *bis*-phenolic compound isolated from the rhizomes of *Curcuma longa* is known for its potent antiretroviral, anticancer, anti-diabetic, anti-inflammatory, and memory-improving properties. However, in spite of its impressive biological activity, curcumin is not used in therapeutics because of its poor oral absorption, short plasma half-life and facile conversion into its glucuronide and/or hydrogenated metabolites that are devoid of the biological activity. We have systematically and covalently altered the chemical structure of curcumin to furnish a focused library of curcumin-inspired compounds referred to as curcuminoids. Initially, we replaced the 1,3-diketone moiety in curcumin with a monoketone moiety. We then synthesized conformationally-restricted analogs of curcumin by the addition of a carbocyclic or heterocyclic ring. We also synthesized lipophilic analogs of curcumin via the replacement of one of the phenolic moieties in curcumin with strategically placed fluoro-substituents. The effect of the parent compound curcumin and the synthetic curcuminoids was analyzed on neuroprotective genes, AKT1, MAP Kinase, and Brain-derived Neurotrophic Factor (BDNF). The data shows that the pretreatment of one of our synthetic analogs resulted in the upregulation of mRNA as well as the protein levels of all three genes investigated. The most dramatic impact was observed on with BDNF. These studies indicate a novel application for these analogs in the treatment of neurocognitive disorders, such as the Alzheimer’s disease. Our recent findings on the plausible mechanism(s) of action of these analogs will also be presented.

Histaminergic H3 inverse agonists, by stimulating central histamine release, represent attractive drug candidates to treat cognitive disorders. The present studies aimed to describe the mechanistic profile of S 38093 a novel H3 receptors inverse agonist.
S 38093 displays a moderate affinity for rat, mouse and human H3 receptors (Ki = 8.8, 1.56 and 1.2 µM, respectively) with no affinity for other histaminergic receptors.
In cellular models, the compound was able to antagonize mice H3 receptors (KB = 0.65 µM) and to suppress cAMP decrease induced by an H3 agonist via human H3 receptors (KB = 0.11 µM). The antagonism properties of the compound were confirmed by electrophysiological studies on rat hippocampal slices (from 0.1 µM). In cells expressing a high H3R density, S 38093 behaved as a moderate inverse agonist at rat and human H3 receptors (EC50 = 9 and 1.7 µM, respectively).
S 38093 was rapidly absorbed in mouse and rat (Tmax= 0.25-0.5h), slowly in monkey (2h), with a bioavailability ranging from 20 to 60% and t1/2 ranging from 1.5h to 7.4h. The compound was widely distributed with a moderate volume of distribution and low protein binding. The brain distribution of S 38093 was rapid and high.
In mice, S 38093 significantly increased *ex vivo* N-tele-Methylhistamine cerebral levels from 3 mg/kg p.o. and antagonized R-alpha-Methylhistamine-induced dipsogenia from 10 mg/kg i.p..
Taken together, these data suggest that S 38093, a novel H3 inverse agonist, is a good candidate for further *in vivo* evaluations, in particular in animal models of cognition.

[2]Neuropsychiatry Research and Development, Servier, Suresnes, France
[3]Preclinical, Pharmaness, Pula, Italy
[4]Preclinical, Biotrial, Rennes, France

S 38093, a novel inverse agonist at histamine H3 receptors, was tested in a series of neurochemical and behavioral paradigms designed to evaluate its procognitive and arousal properties.

In intracerebral microdialysis studies performed in rats, S 38093 dose-dependently increased histamine extracellular levels in the prefrontal cortex and facilitated cholinergic transmission both in prefrontal cortex and hippocampus of rats after acute and chronic administration (10 mg/kg i.p.).

Oral administration of S 38093 at 0.1 mg/kg significantly improved spatial working memory in rats in the Morris water maze test. The compound also displayed cognition enhancing properties in the two-trial object recognition task in rats, in a natural forgetting paradigm at 0.3 and 1 mg/kg p.o. and in a scopolamine-induced memory deficit situation at 3 mg/kg p.o.. The property of S 38093 to promote episodic memory was confirmed in a social recognition test in rats at 0.3 and 1 mg/kg i.p..

Arousal properties of S 38093 were assessed in freely moving rats by using electroencephalographic recordings: at 3 and 10 mg/kg i.p., S 38093 significantly reduced slow wave sleep delta power and induced at the highest dose a delay in sleep latency. S 38093 at 10 mg/kg p.o. also decreased the barbital-induced sleeping time in rats.

Taken together these data indicate that S 38093, a novel H3 inverse agonist, displays cognition enhancing at low doses and arousal properties at higher doses.

S 38093 is currently in clinical trial (Phase II) for the symptomatic treatment of mild to moderate Alzheimer's disease.

PROTECTION OF RADIAL GLIAL-LIKE CELLS IN THE HIPPOCAMPUS OF APP/PS1 MICE: A NOVEL MECHANISM OF MEMANTINE IN THE TREATMENT OF ALZHEIMER'S DISEASE

X. Fan[1], D. Sun[2], J. Chen[2], X. Bao[3], L. Gao[2], H. Xu[2]

[1]Department of Histology and Embryology, Third Military Medical University, Chongqing, China

[2]Southwest Hospital/Southwest Eye Hospital, Third Military Medical University, Chongqing, China

[3]Department of Anesthesiology Xinqiao Hospital, Third Military Medical University, Chongqing, China

The failure of adult neurogenesis in the hippocampal dentate gyrus (DG) is closely correlated with memory decline in Alzheimer's disease (AD). Radial glial-like cells (RGLs) localized to the adult DG generate intermediate progenitor cells and immature neurons and thus contribute to adult hippocampus neurogenesis. Memantine (MEM) has been indicated to dramatically increase hippocampal neurogenesis by promoting the proliferation of RGLs. In this study, MEM significantly improved the nest building scores of APPswe/PS1dE9 transgenic (APP/PS1) mice at 9 and 13 months of age .We further found that MEM could enhance hippocampal neurogenesis and increase the number of RGLs in the DG subgranular zone (DG-SGZ) of both APP/PS1 and WT littermates at 9 and 13 months of age compared to saline-treated age-matched APP/PS1 and WT mice. Moreover, MEM decreased amyloidogenesis in 13-month-old APP/PS1 mice and protected cultured radial glia cells (RGCs, L2.3 cells) from apoptosis induced by the β amyloid peptide (Aβ). Additionally, MEM inhibited microglial activation in a vertical process in DG-SGZ and retinas of APP/PS1 mice and induced the reduction of RGLs and Müller cells. Reelin is involved in the proliferation of RGLs in the hippocampus, which was typically upregulated in the hippocampus of APP/PS1 mice by MEM and thought to be an active signaling pathway associated with the MEM-induced increase in RGLs. Our data suggest MEM can enhance hippocampal neurogenesis in APP/PS1 mice by protection of RGLs within the adult DG-SGZ through inhibition of microglial over-activation and enhancing reelin expression.

THE 5-HT6 RECEPTOR ANTAGONIST IDALOPIRDINE FACILITATES NEURONAL OSCILLATIONS AND NEUROTRANSMISSION IN BRAIN REGIONS THAT MEDIATE COGNITION.

I.E.M. de Jong[1], K.F. Herrik[1], L. Helboe[1], M.A. Foraster[1], N. Richard[1], A. Mørk[1]
[1]Neurodegeneration, Lundbeck A/S, Valby, Denmark

Objectives
The 5-HT_6 receptor is a promising target for cognitive disorders. Idalopirdine is a selective 5-HT_6 receptor antagonist in development for the symptomatic treatment of Alzheimer's Disease (AD) as adjunctive therapy to acetylcholinesterase inhibitors. We investigated the effects of idalopirdine on neuronal oscillations and neurotransmission in the rat hippocampus and cortex and studied the neuronal substrates for these effects.
Methods
In situ hybridization was used to study cellular expression and co-localisation of 5-HT_6 receptor mRNA with a range of neuronal and interneuronal markers. Acetylcholine and glutamate levels were measured in dorsal hippocampus and frontal cortex of freely-moving male Sprague Dawley (SD) rats by microdialysis. Local field potentials were recorded in anesthetized SD rats with tungsten electrodes during electrical stimulation in the nucleus pontis oralis. Recordings were Fast Fourier transformed to yield the power of oscillatory activity.
Results
The 5-HT_6 receptor was located postsynaptically, co-localising mainly with glutamatergic and less frequently with GABA-ergic markers. In the frontal cortex, idalopirdine increased extracellular levels of glutamate and transiently increased gamma oscillations. Furthermore, idalopirdine potentiated and prolonged the effects of donepezil on acetylcholine efflux, theta- and gamma oscillations in the dorsal hippocampus and frontal cortex.
Conclusion
Idalopirdine potentiates the effects of donepezil on acetylcholine efflux and neuronal oscillations and facilitates glutamatergic signaling in areas critical to memory and executive function such as the hippocampus and frontal cortex. These effects are likely to be mediated via glutamatergic and GABA-ergic systems, in which the 5-HT_6 receptor was demonstrated to be expressed.

[3]UNICAEN Normandie University GMPc, Groupe Mémoire et Plasticité comportementale, Caen, France
[4]CNRS UMR 7259 NICN Aix-Marseille University, Neurobiologie des Interactions Cellulaires et Neurophysiopathologie, Marseille, France

Objectives: Complex pathologies such as Alzheimer's disease (AD) would benefit from a combination of actions targeting, in the same time, several molecular causes implied in the pathogenesis. Our aim was to design a multi target-directed ligand (MTDL) gathering two properties: acetylcholinesterase (AChE) inhibition and 5-HT_4 receptor activation. AChE inhibition is the action mechanism of donepezil, the current available drug for AD. Activation of 5-HT_4 receptors promotes the non-amyloidogenic cleavage of the amyloid precursor protein (APP) and the release the neuroprotective soluble APPα fragment. Moreover, we have demonstrated that chronic administration of 5-HT_4R agonists delays amyloid pathology and prevents cognitive deficits in a mouse model of AD.
Methods: Combining a dual-binding site pharmacophore of AChE inhibitors with a pharmacophore of 5-HT_4R ligands, we isolated a candidate compound and performed pharmacomodulation of this hit to optimize its properties.
Results: We selected donecopride as a druggable lead able to inhibit AChE (IC_{50} = 16 nM) and to induce sAPPα release (EC_{50} = 11.3nM) upon 5-HT_4R activation (K_i = 10.4 nM; 48.3% of serotonin response). *In vivo* properties of this new compound in the 5XFAD mouse model of AD (acute and chronic administration) will be presented.
Conclusions: Donecopride is an innovative MTDL for AD, which combine symptomatic properties (restoration of cholinergic transmission) with disease-modifying actions (sAPPα release, decrease of Aβ accumulation and aggregation).

DISCOVERY OF DONECOPRIDE A NOVEL MULTI-TARGET DIRECTED LIGANDS FOR ALZHEIMER'S DISEASE

C. Rochais[1], C. Lecoutey[1], T. Freret[2], C. Ballandonne[1], V. Bouet[2], P. Giannonni[3], F. Gaven[3], S. Clayesen[3], M. Boulouard[2], P. Dallemagne[1]
[1]CERMN, Université de Caen Basse Normandie, Caen, France
[2]GMPc, Université de Caen Basse Normandie, Caen, France
[3]Institut de Génomique Fonctionnelle, CNRS UMR-5203, Caen, France

Objectives

Targeting more than one molecular cause implied in the pathogenesis of Alzheimer's disease (AD) with a sole drug is considered a promising challenge, because it may address the numerous failures that recently occurred during clinical trials that were conducted in this area. In this aim we decided to develop such peiotropic compound associating acetylcholinesterase inhibition and 5-HT_4R activation which could lead to symptomatic and disease modifying properties.

Methods

Starting from an *in silico* high throughput screening and a rational drug design strategy we have identified that RS67,333, a reference 5-HT_4R partial agonist, possess moderate AChE inhibition properties. Pharmacomodulation of this hit and rapid evaluation of *in vitro* biological activities against both targets as well as drugability led to the identification of a novel family of pleiotropic ligands.

Results

These efforts allowed us to select donecopride[1] as a valuable dual (h)5-HT_4R partial agonist (Ki = 10.4 nM)/(h)AChEI (IC_{50} = 16 nM) that further promotes sAPPα release (EC_{50} = 11.3nM). Donecopride could improve memory performances at 0.3 and 1 mg/kg on the object recognition test. In vivo results obtained in the 5XFAD mouse model of AD will be for the first time presented.

Conclusion

On the basis of these in vitro and in vivo activities, donecopride seems to be a promising drug candidate for AD treatment.

ADPD5-0259

EVALUATION OF NOVEL POLYAMINE AND MEMANTINE-DERIVATIVE COMPOUNDS TARGETING NMDA RECEPTORS FOR ALZHEIMER'S DISEASE TREATMENT

I.F. Abu[1], M. Rosini[2], I.R. Mellor[1]
[1]School of Life Sciences, University of Nottingham, Nottingham, United Kingdom
[2]Department of Pharmaceutical Sciences, University of Bologna, Bologna, Italy

Objectives: To evaluate novel compounds as potential treatment for Alzheimer's disease targeting *N*-methyl-D-aspartate receptor (NMDAR). These ionotropic glutamate receptors are highly permeable to Ca^{2+}, thus are implicated with excitotoxicity in neurodegenerative disorders.
Methods: The *Xenopus laevis* oocyte expression system was employed in this study where cRNAs for NMDAR subunits were injected into the oocytes and responses to NMDA/glycine and channel blockers were recorded using two-electrode voltage clamp. Three novel polyamine compounds (CR) and eight memantine-derivatives (MAB) incorporated with antioxidant groups (alpha-tocopherol, lipoic acid, melatonin and methoxyphenol) were tested on GluN1/2A NMDAR subunits at -60 mV and compared with Mg^{2+} and memantine.
Results: All spermine-derived CR compounds proved to be highly effective in blocking the NMDAR channel; CR18, CR8 and CR24 recorded IC_{50}s of 0.692, 2.214 and 2.352 µM respectively, all significantly lower than Mg^{2+} (IC_{50} = 10.08 µM). MAB compounds were much less potent; MAB22, MAB30, MAB14 and MAB7 recorded the lowest IC_{50}s (26.90, 38.19, 43.09 and 55.92 µM respectively) versus memantine (IC_{50} = 3.178 µM) while the rest were all higher than 100 µM. This suggests the loss of memantine functionality due to attachment of the antioxidant structure to its amine group. All compounds were also found to act through a voltage-dependent manner assessed via the Woodhull model.
Conclusions: Our data suggests that the CR compounds particularly CR18 (spermine polyamine incorporated with alpha-tocopherol) has the potential for development of Alzheimer's disease treatment which not only can inhibit excitotoxicity, but also suppresses oxidative stress and beta-amyloid plaques.

[4]Neurofit, Illkirch, Switzerland

[5]Biotrial, Rennes, France

[6]Pôle Expertise Recherche et Biopharmacie, Institut de Recherches SERVIER, Surennes, France

S44858 presents unique and innovative mechanism of action, as it both potentiates glutamate AMPA receptors and blocks glutamate NMDA receptors. The aim of the present work was to characterize its mechanism of action and pharmacological properties.

In vitro, S44858 did not present affinity towards glutamate binding sites on AMPA, kainate and NMDA receptors nor towards glycine and PCP binding sites. A low affinity for the ifenprodil binding site was detected. On oocytes injected with rat cortex or human hippocampal mRNA, S44858 increased AMPA responses, did not affect kainate responses and decreased NMDA responses. S44858 displayed selectivity toward NR1/NR2B subunits both on murine and human NMDA receptors. The inhibition was neither competitive nor voltage-dependent. S44858 protected cultured rat brain neurons towards glutamate and NMDA toxicity and increased AMPA-mediated BDNF expression.

In vivo, S44858 (30 mg/kg ip) both increased the synaptic response and its Long-Term Potentiation in the dentate gyrus of the hippocampus on anaesthetized rats. S44858 (0.3-1 mg/kg po) improved episodic-like memory in a novel object recognition test in rats. No effect on general behaviour, body temperature, spontaneous locomotor activity or occurrence of epileptic seizures was noticed after acute administration in mice and rats (10-100 mg/kg po).

Taken together, these results indicate that S44858 is neuroprotective against glutamate excitotoxicity, it enhances synaptic plasticity and cognition in the absence of side effects in rodents after acute administration. S44858 may therefore be of interest for the treatment of various CNS diseases in which dysfunctions of glutamatergic pathways have been implicated.

[3]Biomedical Research Centre, University Hospital, Hradec Kralove, Czech Republic

Objectives – The aim of the project is to develop novel therapeutic agents against Alzheimer's disease by targeting a mitochondrial enzyme termed the Amyloid Binding Alcohol Dehydrogenase (ABAD).

Methods – Two therapeutic approaches appear to hold merit in treating Alzheimer's disease, firstly to inhibit the interaction between the ABAD enzyme and amyloid beta peptide oligomers and secondly, to inhibit the ABAD enzyme directly. Initially, we are pursuing the second approach.

Results – We have developed a novel series of compounds, derived from the immunosuppressant Frentizole molecule, and have shown two of them, compounds K690 and K691, to be relatively potent inhibitors of the ABAD enzyme with IC_{50} values in the low micro-molar range. We have also characterised the mechanism of inhibition utilised by these two inhibitors using an enzyme kinetics based approach.

Conclusions – We have shown that through a few small modifications the parent, non-inhibiting, Frentizole molecule can be turned into a relatively potent inhibitor of the ABAD enzyme, offering a novel scaffold for the development of subsequent generations of compounds with improved pharmacological properties.

Although the aetiology of AD is still unknown, the build-up of amyloid β-peptide (Aβ) is considered to play a central role in the pathogenesis of the disease. It is well established that the intracellular accumulation of Aβ is associated with AD and increasing evidence suggests that mitochondria may be an important target for intracellular Aβ to exert its neurotoxic effects.

Amyloid-binding alcohol dehydrogenase (ABAD) is to date the most characterized Aβ-binding intracellular protein. Direct interaction of this mitochondrial enzyme with Aβ was confirmed by many different methods. Aβ binding to ABAD triggers a series of events leading to mitochondrial dysfunction characteristic for AD. Thus this interaction may represent a target for treatment strategy against AD.[1-4]

The benzothiazolyl analogues related to known immunosuppressant frentizole were synthesized and *in vitro* evaluated for their capability to inhibit ABAD. Several prepared compounds showed ability to inhibit ABAD *in vitro* on low μM or nM scale or conversely activation of the enzyme.[5] These promising compounds are going to be further tested on inhibition/influence of Aβ-ABAD interaction.

This work was supported by project OP VaVpI (no. CZ.1.05/3.1.00/10.0213).

The early and substantial degeneration of basal forebrain cholinergic neurons (BFCNs) in Alzheimer's disease (AD) patients is the key factor in cognitive decits associated with the disease, implying that BFCNs hold potentials in developing stem cell-based therapy for AD. However, the mechanisms underlying BFCN generation *in vivo* are not well characterized and there is therefore a lack of knowledge on how to direct BFCNs generation from pluripotent stem cells (PSCs) *in vitro*. To date, the direct differentiation of BFCNs from mouse PSCs has not been achieved, and it was still unknown if PSC-derived BFCNs can restore cholinergic function and alleviate cognitive deficits in AD model mice. Here, we show that cholinergic neurons with a basal forebrain regional identity can be efficiently derived from both mouse and human pluripotent stem cells in a serum-free system. The PSC-derived cholinergic neurons exhibit BFCN-like features, including gene expression and acetylcholine secreting, and possess abilities to fire action potentials and form synapse *in vitro*. After transplanted into the basal forebrain of AD model mice, the PSC-derived basal forebrain progenitors predominantly differentiate into mature cholinergic neurons that functionally integrate into the endogenous basal forebrain cholinergic projection system. The AD model mice grafted with both mouse and human BFCNs exhibit significant improvements in the spatial learning and memory abilities. These results suggest that PSC-derived BFCNs may contribute to ameliorate the cognitive decline of AD mice, and may be a promising tool for the development of stem cell-based therapies for the treatment of AD.

EXAMINING THE ROLE OF CXCR4 IN THE DIFFERENTIAL MIGRATION OF ESC-DERIVED AND FETAL-DERIVED HUMAN NEURAL STEM CELLS.

E.M. Abud[1], B.L. Chen[1], C.H.H. Nguyen[1], W. Chen[1], J.L. Davis[1], M.M. Blurton-Jones[1]
[1]Neurobiology and Behavior, University of California Irvine, Irvine, USA

Objectives

Many studies have begun to examine neural stem cell (NSC) transplantation in animal models of neurodegeneration. Yet, disorders such as Alzheimer's Disease (AD) involve multiple brain regions and thus successful use of NSCs may depend on the ability of these cells to migrate large distances. Our lab has found that fetal-derived NSCs (f-NSCs) migrate far greater distances than pluripotent -derived NSCs (p-NSCs). However, p-NSCs offer several advantages including scalability and potential use of a patient's own iPS cells. To determine why these two NSC populations exhibit such different migration we examined a gene expression database and found that f-NSCs typically express higher levels of CXCR4 than p-NSCs. As CXCR4 is implicated in cell migration, we hypothesized that overexpression could be used to increase the migratory capacity of p-NSCs.

Methods

H9-derived NSCs were modified to stably overexpress CXCR4 via lentiviral transduction. In vitro chemotaxis in response to CXCL4 was then examined. Cells were also transplanted into [M1] xenotransplantation-compatible AD transgenic mice (Rag-5xFAD) generated in our lab to assess the effects of CXCR4 on migration in vivo.

Results

Migration assays revealed that CXCR4-p-NSCs migrate greater distances than control p-NSCs. CXCR4-p-NSCs also engraft well in Rag-5xFAD and ongoing analysis will determine the effect of CXCR4 overexpression on migration in vivo.

Conclusions

CXCR4 appears to play an important role in the differences between p-NSC and f-NSC migration. Increasing CXCR4 expression may also provide a novel approach to bolster the migratory capacity of p-NSCs and their potential application for neurodegenerative disorders such as AD.

ADPD5-0282

REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION ENHANCED ATTENTION AND PSYCHOMOTOR SPEED IN PATIENTS WITH EARLY ALZHEIMER'S DISEASE

L. Anderkova[1], I. Eliasova[1], R. Marecek[2], I. Rektorova[1]
[1]Applied Neuroscience Research Group, CEITEC MU, Brno, Czech Republic
[2]Multi-modal and Functional Neuroimaging, CEITEC MU, Brno, Czech Republic

Objectives
Repetitive transcranial magnetic stimulation (rTMS) is a promising tool to study and modulate brain plasticity. The aim of this study was to investigate the effects of high-frequency rTMS over the right inferior frontal gyrus (IFG) and the right superior temporal gyrus (STG) on cognitive functions in patients with mild cognitive impairment (MCI) and early stages of Alzheimer's disease (AD).
Methods
Twenty patients (11 women, 9 men; age 73.0 ± 6.9 years; 12 mild AD, 8 MCI) participated in the placebo-controlled study. Each patient received 3 sessions of 10 Hz rTMS (2250 stimuli per session at 90% of resting motor threshold) applied over the IFG, STG and vertex (a control stimulation site) in a randomized order. The Trail making test (TMT) and the Stroop test (ST) were used to evaluate attention prior to and immediately after the each session.
Results
Significant improvement in the Word part of the ST was found after the stimulation over IFG and STG (Wilcoxon paired test; p=0.023 and 0.033, respectively), while the IFG stimulation induced additional enhancement in the TMT A and B (Wilcoxon paired test; p = 0.002 and 0.005, respectively). When controlling for placebo effects, the improvement in the ST (Word part) remained significant after both IFG and STG stimulation.
Conclusions
rTMS of the right IFG and the right STG enhanced psychomotor speed and attention in patients with MCI and early AD and may thus have a therapeutic potential that should be subjected to the further research.

A NEUROREHABILITATION CLINIC FOR PATIENTS WITH ALZHEIMER'S DISEASE: AN ITALIAN INITIATIVE FOR A NEW THERAPEUTIC PARADIGM

C. Muscio[1], P. Tiraboschi[2], D. Rossi Sebastiano[3], C. Miniussi[4], C.A. Defanti[1]
[1]Fondazione Europea Ricerca Biomedica (FERB) Centro Eccellenza Alzheimer, Ospedale Briolini, Bergamo, Italy
[2]Division of Neurology V/Neuropathology, Fondazione IRCCS Istituto Neurologico "Carlo Besta", Milano, Italy
[3]Department of Neurophysiopathology, Fondazione IRCCS Istituto Neurologico "Carlo Besta", Milano, Italy
[4]Cognitive Neuroscience Section, IRCCS Centro San Giovanni di Dio-Fatebenefratelli, Brescia, Italy

Objectives.To date, there are only few promising data (Lefaucher et al., 2014) supporting a beneficial effect of the application of repetitive transcranial magnetic stimulation (rTMS) on patients with Alzheimer's disease (AD), especially in an integrative approach with cognitive rehabilitation (shortly: "neurorehabilitation"). Thus, the level of evidence is currently insufficient to warrant any recommendation for a therapeutic use. The main issues are: limitation of placebo-controlled studies and lack of harmonized procedures (stimulation parameters, methodology, patient selection), as well as small sample and effect sizes. Aims of the present project are to implement harmonized procedures for neurorehabilitation and to define an optimal protocol at two Italian centres of excellence for AD care.
Methods.Firstly, the project will develop harmonized procedures for neurorehabilitation and clinical outcome evaluation, qualifying both centres. Secondly, 200 AD patients will be enrolled and the efficacy of high-frequency rTMS or computer-assisted cognitive rehabilitation or a combination of the two will be assessed. Finally, to enable the replication of our results, the protocol agreed upon at the two centres will be disseminated.
Results.Exclusion/inclusion criteria, a sufficiently large sample size and common procedures for neurorehabilitation and clinical outcomes evaluation have been defined. Moreover, common methods have been detailed: the project will be longitudinal, randomized, placebo-controlled, single blinded, with a multiple-baseline and adaptive design.
Conclusions.Standardized procedures for the first multi-centric study on "neurorehabilitation" for AD have been defined by two Italian clinical centres. This innovative project will contribute to the field in the attempt to surmount its current controversial issues.

NOVEL DRUG CANDIDATE FOR THE TREATMENT OF ALZHEIMER'S DISEASE RESTORED DISINHIBITED BEHAVIOR AND IMPROVED LEARNING AND MEMORY DEFICITS IN 5XFAD-MICE

B. Fischer[1], S. Azran[1], O. Shimon[1], H. Segal[2], Y. Barhum[2], D. Offen[2]
[1]Chemistry, Bar Ilan University, Ramat Gan, Israel
[2]Neuroscience Laboratory,
Felsenstein Medical Research Center Sackler Faculty of Medicine Tel-Aviv University Rabin Medical Center, Petah Tikva, Israel

Objectives: Design and in-vitro and in-vivo evaluation of a multi-functional drug candidate, SSA37, for the treatment of Alzhiemer's disease (AD) based on a naturally occurring molecule.
Methods: Synthesis; pharmacological evaluation at G-Protein-Coupled-Receptors; evaluation of antioxidant and neuroprotective activity; in-vivo studies in transgenic mice (5xFAD).
Results: We found that SSA37 is a most potent P2Y1-R agonist (EC50 2.6nM) and shows no activity at P2Y11-R. SSA37 inhibited Fenton reaction (IC50 37microM) acting mainly as Fe(II)-chelator, and inhibited reactive oxidative species production in PC12 cells (IC50 40nM), possibly through P2Y12-R. SSA37 potently rescued cortical neurons from cell death caused by FeSO4 (EC50 40nM), and from Abeta42 toxicity. Co-application of 5microM SSA-37 with 50microM Abeta42 for 48h to a primary neuron culture resulted in almost 80% protection (IC50 0.5microM). Next, we treated 6 weeks old 5xFAD mice with SSA37A by daily injection (IP, 1 mg/kg) for 7.5 weeks (male n=8-9 and female n=6-8). We demonstrated that SSA37 treatment markedly restored disinhibitied behavior in the elevated plus maze both in male and female mice, as indicated by a 85% decrease in time spent in the open arms ($p<0.05$). SSA37-treated female mice also showed improvement in learning and memory, represented by a 32% reduction in the number of days required for learning in the water T maze assay ($p=0.07$).
Conclusions: SSA37 is a biocompatible multifunctional drug candidate, which showed high efficacy using behavioral and biochemical parameters in models of AD. We believe that this compound may delay or slow down the progression of AD in patients.

DESIGN AND SYNTHESIS OF MULTITARGET-DIRECTED DIALLYL DISULFIDE DERIVATIVES: A BIOCHEMICAL, MOLECULAR MODELLING AND BEHAVIOURAL STUDY

A. Manral[1], *M. Tiwari*[1]
[1]*Dr.B.R. Ambedkar Center for Biomedical ResearchUniversity of Delhi, Dr.B.R. Ambedkar Center for Biomedical Research, Delhi, India*

Objective: Designing drugs with a specific multi-target profile is a promising approach against multifactorial illnesses as Alzheimer's disease. Diallyl disulfide (DADS), an active principle of garlic, has been reported to prevent APP processing in AD. But its use is restricted due to its volatile and unstable nature. Based on the above understanding, novel DADS derivatives with greater stability were synthesized and tested to assess their potential as anti-Alzheimer's agents.
Methods: Diallyl Disulphide derivatives were synthesized by a novel scheme. *In vitro* Aβ anti-aggregation studies were carried out using ThT -florescence assay. The oxygen radical absorbance capacity assay using ORAC-FL was performed to determine antioxidant activity of compounds. *In vivo* assessment of cognitive deficits, associated to Alzheimer's disease, induced by scopolamine was performed on male wistar rats. Molecular docking studies with targets such as $A\beta_{1\text{-}40}$ and Acetylcholinesterase (AChE) were carried out using Discovery studio 2.1
Results: Biochemical evaluation of synthesized DADS derivatives indicated that most of the target compounds exhibit significant inhibition of self-induced and Cu^{2+}-induced β-amyloid (Aβ) aggregation, acted as potential antioxidants and AChE inhibitor. Molecular docking studies and ADMET analysis have further confirmed their activities and drug like properties. Furthermore*, in vivo* behavioural studies with best active derivative **compound 4f** showed attenuation of scopolamine-induced amnesia in a dose-dependent manner, as revealed by the elevated plus maze and passive avoidance test.
Conclusion: Taken together, our data indicate that DADS derivatives emerges as an interesting anti-Alzheimer's lead compound with potent anti- Aβ aggregatory, antioxidant, metal chelating and cognition enhancing effects.

[4]Biomedical Research Center, University Hospital Hradec Kralove, Hradec Králové, Czech Republic

We report the identification of multitarget anti-Alzheimer compounds designed by combining a naphthoquinone function and a tacrine fragment. *In vitro*, **12**-**29** displayed excellent acetylcholinesterase (AChE) inhibitory potencies and interesting capabilities to block amyloid-*β* (A*β*) aggregation. The X-ray analysis of AChE-**20** complex allowed rationalizing the outstanding activity data (IC_{50} = 0.72 nM). Selected compounds **16** and **20** showed negligible toxicity in immortalized mouse cortical neurons Neuro2A and primary rat cerebellar granule neurons.

However, only **16** was less hepatotoxic than tacrine in HepG2 cells. In T67 cells, **16** and **20** showed antioxidant activity, following NQO1 induction. Furthermore in Neuro2A, they were able to completely revert the decrease in viability induced by A*β*. Importantly, they crossed the blood-brain barrier, as demonstrated in *ex vivo* experiments with rats. When *ex vivo* results were combined with *in vitro* studies, **16** and **20** emerged to be promising multitarget lead candidates worthy of further pursuit.

[1]Institute of Chemistry, Faculty of Science P. J. Safarik University, Kosice, Slovakia
[2]Biomedical Research Center, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic

A series of novel tacrine derivatives and tacrine-coumarin heterodimers were designed, synthesized, and biologically evaluated for their potential inhibitory effect on both acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE). Of these compounds, tacrine-coumarin heterodimer 7c and tacrine derivative 6b were found to be the most potent inhibitors of human AChE (hAChE), demonstrating IC50 values of 0.0154 and 0.0263 μM. Ligands 6b, 6c, and 7c exhibited the highest levels of inhibitory activity against human BuChE (hBuChE), demonstrating IC50 values that range from 0.228 to 0.328 μM. Docking studies were performed in order to predict the binding modes of compounds 6b and 7c with hAChE/hBuChE.

[2]Lille University, Inserm UMR-S1172, LILLE Cedex, France
[3]Neuroprotectants for Alzheimer's Disease, AlzProtect, LILLE Cedex, France

Objectives.
The amyloid precursor protein (APP) plays a central role in Alzheimer's disease (AD). Preventing deregulated APP processing by inhibiting amyloidogenic processing of carboxy-terminal fragments (APP-CTFs), and reducing the toxic effect of amyloid beta (Aβ) peptides remains an effective therapeutic strategy. Chloroquine was shown to modulate processing of APP-CTFs and production of Aβ peptide. Our objective was to evaluate the effect of piperazine-containing compounds derived from chloroquine on APP metabolism.
Methods.
Chloroquine or related heterocycles were functionalized with piperazine-containing amino side chain to improve the ability to accumulate into acidic cell's compartments. All compounds were tested for their potential interference with APP processing in SY5Y-APP^{wt} cell lines. Cytotoxicity, APP fragments and Aβ levels were determined. Acute administration (po) was performed on naive mice.
Results.
Compounds which retained alkaline properties and high affinity for acidic cell compartments were the most effective. The present study demonstrates that (1) the amino side chain of chloroquine can be efficiently substituted by a bis(alkylamino)piperazine chain, (2) the quinoline nucleus can be replaced by a benzyle or a benzimidazole moiety, and (3) pharmacomodulation of the chemical structure allows the redirection of APP metabolism toward a decrease in Aβ peptide release, and increased stability of APP-CTFs and amyloid intracellular fragment.
Conclusions.
Benzimidazole derivatives increases APP-CTFs *in vivo* and shows promising activity by the oral route. This family of compounds retains a lysosomotropic activity which inhibits lysosome-related Aβ production, and is likely to be beneficial for therapeutic applications in AD.

[4]INSERM UMR-995, Lille University Pharmacy Faculty, Lille, France
[5]CERMN EA 4258, Caen University Pharmacy Faculty, Lille, France

Objectives.
Alzheimer's disease (AD) is by far the most prevalent cause of dementia. The complexity of this disease weight on the strategic choice for the discovery of new drug candidate. The development of multi-target compounds is one of this possible strategy. In this way, we have developed new family of multitarget compounds. These compounds are characterized by a combination between N,N'-disubstitued piperazine (MSBD), discovered in our lab to be active on the amyloid precursor protein metabolism (APP), and acetylcholinesterase inhibitors (AChEI).
Methods.
Among available AChEI we chose tacrine and rivastigmine because their structure are the most prone to respect the SAR established in the MSBD family. Target compounds were synthesized and evaluated for both AChE inhibition and *in vitro* modulation of APP metabolism (SY5Y cells).
Results.
This novel family of mixed compounds modulates APP metabolism by selectively reducing the secretion of Aβ peptides and by increasing several APP metabolites including the gene regulatory fragment of APP (AICD). Moreover, these multitarget compounds displayed improved affinity with respect to known AChEI.
Conclusions.
We discovered a series of multitarget compounds displaying high AChE inhibition along with a good ability to modulate APP metabolism. These results underline the interest to develop multitarget compound for the treatment of AD.

05v. Drug Development & Clinical Trials: structure-activity relationships

ADPD5-1326
THE STRUCTURE FUNCTION RELATIONSHIP OF SCYLLO-INOSITOL AND ALZHEIMER'S DISEASE

J. McLaurin[1], M. Nitz[2], C. Hawkes[3]
[1]Biological Sciences, Sunnybrook Research Institute, Toronto, Canada
[2]Chemistry, University of Toronto, Toronto, Canada
[3]Pathology, University of Southampton, Southampton, United Kingdom

Objective: Determine the mechanism of action of *scyllo*-inositol that leads to improvement in cognitive function in a mouse model of Alzheimer's disease.
Methods: To better understand the structure-function relationships of amyloid-beta peptide assembly in the presence of *scyllo*-inositol, we utilized a reliable and high-throughput method for screening *scyllo*-inositol derivatives, a novel electrospray ionization mediated high throughput mass spectrometry-based platform to address the role of various small molecules in modulating the dynamic assembly of amyloid-beta peptide and atomic force microscopy. The data from these in vitro studies, lead us to investigate whether the same was recapitulated *in vivo*, using the TgCRND8 mouse model of Alzheimer's disease. Biochemical and pathological examination of disease-bearing mice after 30 days of treatment with *scyllo*-inositol were analyzed.
Results: We found that two *scyllo*-inositol molecules bound to one amyloid-beta peptide, that the hydrophobic faces and hydrogen-bonding hydroxyl groups were necessary for interaction and inhibition of peptide assembly. We further demonstrate *in vivo* that alterations to the structure of *scyllo*-inositol greatly diminishes the beneficial effects of treatment. This latter effect was not dependent on the effective drug dose within the CNS.
Conclusions: *scyllo*-inositol is the most effective compound so far identified for the amelioration of cogntive deficits in mouse models of Alzheimer's disease.

APPROACHES TO IMPROVING RATER ACCURACY IN EARLY/PRODROMAL ALZHEIMER´S DISEASE CLINICAL TRIALS

J.L. Marsh[1], M. García-Valdecasas Colell[2], J. Sedway[3]
[1]Rater Training Services, Inventiv Health Clinical, Florida, USA
[2]Rater Training Services, Inventiv Health Clinical, BARCELONA, Spain
[3]Rater Training Services, Inventiv Health Clinical, N-Carolina, USA

A total of 698 raters from 23 countries conducting assessments in 3 Early/Prodromal AD studies were included in this survey. Data regarding professional background, experience with the study populations, and familiarity with the study-specific rating scales were gathered as part of formalized rater qualification programs for each study. Once trained and approved, raters submitted in-study assessments for central review, which were then evaluated for administration and scoring errors. Raters were divided into two groups based on type of assessments performed (Psychometric versus Global role). Means and standard deviations of years of experience by dementia indication and rating scale experience were calculated. Pooled results of central rating review findings were examined to determine trends in rater performance over time as a measure of the effectiveness of an enhanced rater training program.

Raters reported different levels of indication experience depending upon the type of assessments they conducted in the trial, with psychometric raters reporting relatively less Early AD study scale experience. In-study rater performance, as measured by the number of errors found per visit in an enhanced training program including central rating review, improved over time.

Raters' reported experience both with the Early/Prodromal population and the scales most sensitive to change in Early/Prodromal AD calls into question the assumption that these qualifications are functionally equivalent across types of clinical trials. Augmenting traditional rater training programs is one strategy to improve the accuracy of raters at all levels of experience with the assessment of emergent symptoms of the early phases of the disease.

BENEFICIAL EFFECTS OF HYPERBARIC OXYGEN THERAPY ON THE PATHOPHYSIOLOGY OF ALZHEIMER'S DISEASE MOUSE MODELS

R. Shapira[1], D. Frenkel[1], R. Vassar[2], B. Solomon[3], U. Ashery[1]
[1]Neurobiology, Tel Aviv University, Tel-Aviv, Israel
[2]Cell and Molecular Biology, Northwestern University, Chicago Illinois, USA
[3]Molecular Microbiology and Biotechnology, Tel Aviv University, Tel-Aviv, Israel

Background. Hypoxia is intimately entwined in the pathogenesis of Alzheimer's disease(AD). Reduced cerebral perfusion starting early in the disease can lead to cerebral hypoxia, which contributes to the accumulation of A-Beta, hyperphosphorylation of tau and degeneration of neurons. Hyperbaric Oxygen Therapy (HBOT), the medical administration of 100% oxygen at environmental pressures greater than 1 atmosphere absolute (ATA), has recently been used successfully in the treatment of other hypoxia-related neurological conditions such as strokes and traumatic brain injury.
Objective. Elucidating the mitigating effects of HBOT on the early and late stages of AD pathology in the 3xTg and 5XFAD mouse models.
Methods. 17month-old 3xTg mice were exposed to HBOT at 1 ATA for 60 minutes daily for 14 days. In addition, 4 month-old 5xFAD and wt mice were exposed to HBOT at 1 ATA for 60 minutes daily, 5 days a week for 1 month (20 treatments). Subsequently to HBOT in both sets, a behavioral test battery including nest building test, rotarod, y-maze, open field and object recognition test, was performed.
Results. HBOT improved the performance of 3xTg treated mice in the Y-maze, open field test and object recognition test. HBOT-treated 5xFAD mice travelled more distance and in higher velocity than controlsin the open field test, and similarly to 3xTg, showed improved performance in the Y-maze.
Conclusions. HBOT ameliorated cognitive deficits of old 3xTg mice andpromoted improvement in performancein cognitive tasks in 5xFAD mice.These findings suggest that HBOT may present a novel therapeutic intervention of AD.

LOW DOSE WHOLE BRAIN IRRADIATION (LDWBI) AS A POTENTIAL TREATMENT FOR ALZHEIMER'S DISEASE (AD)

J. Fontanesi[1], D.B. Michael[1], A.A. Martinez[2], G. Wilson[3], S. Bowen[4], B. Marple[3]
[1]Neurosurgery, Oakland University William Beaumont School of Medicine, Royal Oak, USA
[2]radiation oncology, 21 st Century Oncology, Royal Oak, USA
[3]radiation biology, William Beaumont Hospital, Royal Oak, USA
[4]neuropsychology, Wayne State University School of Medicine, Detroit, USA

Objective:
To determine if LDWBI can retard the memory disturbance progression in a genetically altered AD mouse
Methods:
16 month B6.Cg-Tg (APPswePSEN1dE9) 85Dbo/J mice were given LDWBI (5 x 200 cGy (n=19)) and compared to untreated animals (n=14). Neurocognitive testing utilized the Morris Water Maze with a Noldus Etho Vision video tracking system. Testing was completed pre treatment and then 8 weeks after treatment at which time the animals were then sacrificed.
Mice were trained with 3 trials/day (90 second maximum) with a 30 minute intra-trial interval for 5 consecutive days.
At sacrifice amyloid count , volume , synaptophysin along with other stains were completed
Results:
Latency period for controls pre treatment were 58 secs (SD +/- 23s) and 48 secs (SD +/- 15s) for 'to be treated' animals (p=.39). At 8 weeks post treatment the control animals latency period was 60 secs (SD +/- 15s) and for the treated animals it was 31secs(SD+/- 17s) (p=0.03)
The treatment group located the platform significantly faster than the control animals on the final day of testing. This finding was not attributed to baseline learning the groups did not differ in latency to find the platform pre treatment
Treatment animals had statistically lower amyloid plaque numbers and trended towards significance in volume of residual plaques
Conclusions:
This data confirms our previous hemi brain irradiation data but documents improved memory performance when LDWBI is utilized. Based on this data we have been granted FDA approval to initiate a Ph I human clinical trial using LDWBI

VARIOUS OUTCOMES OF CHOLINESTERASE INHIBITOR TREATMENT INFLUENCE SURVIVAL OF PATIENTS WITH ALZHEIMER'S DISEASE

C. Wattmo[1], E. Londos[1], L. Minthon[1]
[1]Clinical Memory Research Unit Department of Clinical Sciences Malmö, Lund University, Malmö, Sweden

Objectives: Various outcomes of cholinesterase inhibitor (ChEI) therapy have been observed in Alzheimer's disease (AD). It is not clear whether the duration of treatment, type of ChEI, or dose affect mortality. We aimed to investigate the association between ChEI therapy and patient survival.
Methods: The Swedish Alzheimer Treatment Study (SATS) is a prospective, observational, multicentre study to evaluate long-term treatment with ChEIs in clinical practice. This study included 1021 outpatients with a clinical diagnosis of mild-to-moderate AD (Mini-Mental State Examination score, 10–26) at the start of ChEI treatment (shortly after diagnosis). The date of death of participants was recorded.
Results: After up to 16 years of follow-up, 841 (82%) of the patients in the SATS had died. The mean ± standard deviation time from diagnosis of AD to death was 6.0 ± 2.9 years, and differed between individuals with varying durations of ChEI treatment in the study, from 7.2 ± 2.5 years (3-year completers) to 4.9 ± 2.9 years (<1 year) (P<0.001). Patients who received a higher mean dose of ChEIs during the study had a longer lifespan than those who received a lower dose (6.4 ± 2.9 vs 5.5 ± 2.8 years; P<0.001). The median cutoff values were donepezil 6.9 mg, rivastigmine 6.0 mg, and galantamine 15.0 mg. No difference in mortality between the types of ChEIs was found after adjusting for sex, age, and disease severity.
Conclusions: Longer survival can be expected for AD patients who receive and tolerate higher ChEI doses and a longer duration of treatment.

[7]Family Medicine, Carolinas Health Care System, Charlotte, USA

[8]School of Medicine and Dentistry, University of Rochester, Rochester, USA

Objective: The treatment of AD with disease-modifying drugs is believed to require intervention at the earliest possible stage of the illness. These studies were conducted to evaluate the utility of a telephone screening methodology to identify subjects with cognitive impairment from among individuals reporting subjective memory complaints in primary care networks.

Methods: Two non-interventional, observational studies were completed in the UK (1 site) and US (3 sites). In these studies, participants with subjective memory complaints were identified through the CHARIOT registry (UK), or by self-report, caregivers/informants, or PCPs (US). Participants were administered the Alzheimer's Disease-8 (AD8) questionnaire and Rey Auditory Verbal Learning Test (RAVLT) through a telephone contact center.

Results: A total of 18/82 (22%) UK subjects and 54/191 (28%) US subjects who completed telephone assessments were determined to have abnormal cognition. Data suggested that informants were more accurate than patients in identifying cognitive dysfunction. 10/18 (56% UK) and 54/54 (100% US) individuals indicated they would consider enrollment into a hypothetical clinical trial for AD. With various recruitment approaches ranging from targeted clinical screening to mass mailings, the study identified ~1 individual with abnormal cognition per week per network. No one method appeared superior in identifying prospective treatment study subjects.

Conclusions: Compared with or combined with traditional patient recruitment tools such as print or web-based advertisements, telephone based cognitive assessment of individuals with subjective memory complaints is a relatively efficient means of identifying potential early-stage AD subjects for recruitment into clinical trials. Recruiting strategies should be tailored to each site.

German Center for Neurodegenerative Diseases (DZNE), Munich, Germany

Alzheimer's disease (AD) is a progressive neurodegenerative brain disorder and the most frequent cause of dementia. To date, there are few approved drugs for AD, which show little or no effect on disease progression. Impaired intracellular calcium homeostasis is believed to occur early in the cascade of events leading to AD. Here we examined the possibility of normalizing the disrupted calcium homeostasis in the endoplasmic reticulum (ER) store as an innovative approach for AD drug discovery. High-throughput screening of a small-molecule compound library led to the identification of tetrahydrocarbazoles, a novel multifactorial class of compounds that can normalize the impaired ER calcium homeostasis. We found that the tetrahydrocarbazole lead structure, firstly, dampens the enhanced calcium release from ER in HEK293 cells expressing familial Alzheimer's disease (FAD)-linked presenilin 1 mutations. Secondly, the lead structure also improves mitochondrial function, measured by increased mitochondrial membrane potential. Thirdly, the same lead structure also attenuates the production of amyloid-beta (Aβ) peptides by decreasing the cleavage of Amyloid Precursor Protein (APP) by β-secretase, without notably affecting α- and γ-secretase cleavage activities. Considering the multiple modes of action of tetrahydrocarbazoles in addressing three key pathological aspects of AD, these compounds hold promise for development of a potentially effective AD drug candidate.

THE EARLY EFFICACY OF BRIGHT LIGHT THERAPY FOR DEMENTIA OF THE ALZHEIMER TYPE; A PRELIMINARY STUDY

H. Sekiguchi[1], Y. Matsumoto[2], M. Oshige[2], S. Kumamoto[2], Y. Fukaya[2], S. Iritani[3], K. Fujita[2]

[1]Psychiatry, Misatopia Ogura Hospital, Azumino, Japan

[2]Psychiatry, Okehazama Hospital Fujita Mental Care Center, Toyoake, Japan

[3]Psychiatry, Nagoya University, Nagoya, Japan

(Introduction)

It is expected that bright light therapy for the patient with dementia may improve sleep disturbance and night wondering. This non-pharmacological therapy is in the process of comprehending recently. However, in according to the recommended protocol, the patient must be forward dazzling light box, during fixed time every day, in several weeks, so it is actually difficult to carry out precisely. Nevertheless, the some cases respond by intervention of 1 to2 weeks. We investigate to eliminate the declined level of cognitive function of dementia of the Alzheimer type (AD) to respond in a short term.

(Method)

The hospitalized AD with sleep disturbance and/or night wondering were assigned and treated 5000lux bright light therapy every from 9 to 10 o'clock in two weeks. The effect was assessed by sleep-awareness chart and Neuro-psychiatric inventry.

(Result)

Six AD cases were treated. Three cases showed improvement for sleep disturbance and reduction of care burden within from 7 to 10 days although the therapy has not taken sufficient time because of incorporative attitude.

(Discussion)

The effective cases of AD were shorter morbidity period or at from mild to moderate dementia state. As melatonin neuronal system conducting circadian rhythm reduces as aging or deterioration for AD, it was expected that the sleep disturbance in early and middle stage of AD can be responded by blight light therapy. As this presentation was a preliminary data, more objects would be needed.

ADPD5-1773

EFFECTS OF ADD-ON MEMANTINE ON DAILY FUNCTIONING IN PATIENTS WITH MODERATE TO SEVERE ALZHEIMER'S DISEASE RECEIVING STABLE DONEPEZIL TREATMENT

S. Hendrix[1], N. Ellison[1], V. Pejovic[2], V. Otcheretko[3]
[1]Statistics, Pentara Corporation, Salt Lake City, USA
[2]Medical Writing, Prescott Medical Communications Group, Chicago, USA
[3]Medical Affairs, Forest Research Institute, Jersey City, USA

Objectives: Previous post hoc analyses of the total ADCS-ADL_{19} score, an assessment of daily functioning, suggested that add-on memantine treatment in moderate to severe Alzheimer's disease (AD) may result in significant improvement versus placebo in patients with ≥24 months of stable donepezil pretreatment. This analysis examined the effects of add-on memantine on individual ADCS-ADL_{19} items.
Methods: Patient-level data (ITT population) were pooled from two randomized, placebo-controlled, 24-week trials of add-on memantine in individuals with moderate to severe AD (MMSE range: 3-16) receiving stable treatment with donepezil (MEM-MD-02; n=384) or any cholinesterase inhibitor (MEM-MD-50, donepezil subset only; n=444). Placebo/donepezil and memantine/donepezil groups were compared based on the covariate duration of donepezil monotherapy, using a mixed model (main effects: α=0.05, two-sided; interaction effects: α=0.10, two-sided).
Results: Overall, duration of donepezil pretreatment (mean ± SD) was 20.8 ± 17.7 months. The memantine/donepezil group significantly outperformed the placebo/donepezil group on the items of grooming, conversing, and finding belongings in patients pretreated with donepezil for ≥12 months and on the items of toileting, bathing, watching TV, and turning the light off in those pretreated with donepezil for ≥24 months. The placebo/donepezil group was superior on the items of walking and travelling outside the house in patients receiving donepezil pretreatment for 0-12 months.
Conclusions: In patients with moderate to severe AD, adding memantine to stable donepezil treatment of ≥12 months may be associated with improvements in both basic and instrumental daily functions.

METHODOLOGICAL ASPECTS OF A PHASE II STUDY TO ASSESS THE CLINICAL AND IMMUNOLOGICAL ACTIVITY, SAFETY AND TOLERABILITY OF AFFITOPE® AD02 IN PATIENTS WITH EARLY ALZHEIMER'S DISEASE

S. Hendrix[1], S. Stanworth[1], N. Ellison[1], F. Mattner[2], W. Schmidt[2], A. Schneeberger[2], B. Dubois[3]

[1]Statistics, Pentara Corporation, Salt Lake City, USA

[2]Clinical Development, AFFiRiS AG, Vienna, Austria

[3]Department of Neurology, Salpetriere, Paris, France

Objective: AD02 and AD04 were evaluated in a multicenter, parallel group study in early AD, including 332 prodromal and mild AD patients randomized to 5 groups. The statistical methodology used in this study was specialized for a mixed stage early AD population.

Methods: Partial least squares models were fit to historical data to identify an optimally weighted cognitive (adapted ADAS-cog), functional (adapted ADCS-ADL), and cognitive/functional composite. The Adapted ADAS-cog scale combined ADAS-cog items, Neuropsychological test items and CogState items, the Adapted ADCS-ADL included a subset of the ADCS-ADL items, and the composite combined these. The positive signal in one of the placebo groups resulted in the need for accurate historical estimates of placebo decline. Pooled ADNI mild and ADCS study data was used for this.

Results: Heavily weighted cognitive items were Word Recall, Word Recognition, and Orientation. Delayed Word Recall and Digit Cancellation were among those excluded due to ceiling or floor effects. Heavily weighted ADL items were telephone use, traveling, preparing a meal/snack, selecting clothing, shopping and using appliances. Excluded items were primarily basic ADLs such as eating, walking, toileting and bathing. Adapted scales showed improved sensitivity over traditional scales. Historical analyses supported a strong treatment effect for AD04.

Conclusions: To our knowledge, this is the first completed early AD study combining prodromal MCI and mild AD subjects. It is also the first to prospectively use optimized composites as primary endpoints and to demonstrate their superior power in early disease. Historical analyses added to interpretability of the results.

D-PEPTIDES DEVELOPED TO BE THERAPEUTICALLY ACTIVE AGAINST BETA-AMYLOID OLIGOMERS SHOW PROMISING PHARMACOKINETIC PROPERTIES

L.H.E. Leithold[1], N. Jiang[1], J. Post[1], J. Kutzsche[1], D. Jürgens[1], K.J. Langen[2], A. Willuweit[2], D. Willbold[1]
[1]Structural Biochemistry, Forschungszentrum Jülich GmbH, Jülich, Germany
[2]Medical Imaging Physics, Forschungszentrum Jülich GmbH, Jülich, Germany

Objectives: To date, no treatment exists to cure Alzheimer's disease (AD). Aggregation of beta-amyloid (Abeta) plays an important role in the pathology of AD. Currently, Abeta oligomers are thought to be the most toxic species. D3, a D-enantiomeric peptide (D-peptide), was developed that specifically eliminates Abeta oligomers in vitro and has been shown to improve cognition and reduce plaque load and inflammation in transgenic Alzheimer's mice. D-peptides have several advantages over L-peptides since they are less immunogenic and more protease-resistant. Therefore, they are thought to remain longer in the body providing more time to be therapeutically active. Here, we show pharmacokinetic studies of some derivatives of D3 in mice and estimate their plasma protein binding.
Methods: Radioactively labelled peptide was administered via several administration routes and organs were harvested at different time points post injection. The amount of radioactive D-peptide in the organ homogenate was measured by liquid scintillation counting. Furthermore, binding to plasma proteins as well as brain membranes was determined, also using radioactively labelled peptide as indicator.
Results: Results show that all D-peptides indeed reach the brain where they may exhibit their therapeutic activity. Furthermore, the peptides show small elimination constants and long half-lives of more than a day in plasma as well as a high bioavailability after i.p., s.c. or p.o. administration.
Conclusions: Promising pharmacokinetic properties confirm that D-peptides may be very potent AD-therapeutic agents on their way to clinical studies.

ANTI-INFLAMMATORY EFFECTS OF ARN14494, A NEW SERINE PALMITOYLTRANSFERASE INHIBITOR, IN AN IN VITRO MODEL OF ALZHEIMER'S DISEASE.

T. De Vita[1], C. Albani[1], M. Migliore[1], A. Cavalli[1]
[1]Drug Discovery and Development, Istituto Italiano di Tecnologia, Genoa, Italy

Objectives: Alzheimer's disease (AD) is a neurological disorder that present a progressive loss of memory, neuronal death, inflammation and a debilitation of intellectual capacity. Neuronal death in the brain play a key role in AD progression and is directly linked to neuroinflammation. Recent evidences has suggested a link between ceramides and AD showing that these sphingolipids are increased in AD patients. Activation of serine palmitoyltransferase (SPT), increases ceramide levels. The aim of this work is the development of a new SPT inhibitor, ARN14494, that have shown promise in vitro by attenuating glial activation. **Methods:** Studies of Ceramide measurement by LC/MS analyses, Serine palmitoyltransferase Assay, Quantitative reverse transcription-polymerase chain reaction (PCR), Enzyme-linked immunosorbent assay (ELISA), Western Blot, Nitrite measurement, SiRNA transfection were performed in Neuronal cell line (N2a, CCF-STTG1) and Primary astrocytes culture. **Results:** Results demonstrated that ARN14494 treatment exerted potent anti-inflammatory action by inhibiting the production of Nitric Oxide, Inteleukin-1β (IL1β) and tumor necrosis factor alpha (TNFα). Moreover, significantly suppressed the expression of cyclooxygenase 2 (COX2) and inducible nitric oxide synthase (iNOS) at protein and mRNA levels. In addition reduce ceramide levels and SPT activity, by using mouse astrocytes cultures stimulated with beta amyloid 1-42. **Conclusions:** These results suggest that ARN14494 can reduce neuroinflammation and the regulation of neuroinflammatory processes might be a practical strategy for the treatment of AD.

VISUAL RATING OF POSTERIOR ATROPHY AS A MARKER OF PROGRESSION TO DEMENTIA IN MILD COGNITIVE IMPAIRMENT PATIENTS: A PRELIMINARY STUDY

Y. Park[1], J. Jang[2], S. Park[1], M. Wang[1], M. Baek[1], S. Kim[1]
[1]Department of Neurology, Seoul National University Bundang Hospital, Seong-nam si Gyounggi-do, Korea
[2]Department of Neurology, Kangwon National University Hospital, Chuncheon si Kangwon-do, Korea

Objectives
We evaluated whether posterior atrophy (PA) could be a useful marker of progression to dementia in patients with mild cognitive impairment.
Methods
We retrospectively identified 148 patients with mild cognitive impairment who underwent a coronal MRI and were followed up for a mean of 21.17 months (range, 11 to 36 months) in Clinical Neuroscience Center of Seoul National University Bundang Hospital. Medial temporal atrophy (MTA) and PA were rated visually using a 5-point and 4-point rating scale, respectively. Cox regression analysis was used with follow-up time as time variable and conversion to dementia as status variable.
Results
At follow-up, 47 (30.5% of 148) patients fulfilled criteria for dementia. MTA and PA were significantly associated with dementia at follow-up with a hazard ratio (HR) of 3.194 ($p < 0.001$) and 2.583 ($p = 0.002$) for the presence of atrophy, respectively. Including both MTA and PA ratings as covariates, MTA remained independently predictive of progression (HR, 2.634, $p = 0.004$) and PA also remained statistically significant (HR, 1.922, $p = 0.044$). The predictive accuracy of MTA and PA was independent of age and *APOE* **ε**4 allele.
Conclusions
Visual assessment of PA is a useful predictor of progression to dementia, together with MTA, in mild cognitive impairment patients.

ADPD5-0437
AUTOMATIC PREDICTION OF RAPID COGNITIVE AND FUNCTIONAL DECLINE IN AN ELDERLY POPULATION

R. Guerrero[1], R. Wolz[2], M. Austin[2], K. Gray[2], D. Rueckert[1]
[1]Computing, Imperial College London, London, United Kingdom
[2]Imaging, IXICO, London, United Kingdom

Objectives: Identifying subjects with rapid cognitive or functional decline (RCD or RFD) in MCI and dementia patients as well as in elderly subjects is a relevant task in care planning and management. We present an approach to predict cognitive and functional decline from structural imaging and baseline clinical assessment.
Methods: 647 healthy (217), AD (114) and MCI (316) subjects recruited in the ADNI I/II/GO studies (www.adni-info.org) that had MR imaging, MMSE and FAQ scores at baseline, month 12 and 24 were included. Subjects were classified as RCD and RFD if the rate of decline was >= 8 MMSE points or 10 FAQ points over 2 years respectively. Using baseline MRI, volumes were automatically extracted with LEAP for the hippocampus, amygdala, temporal horn and the lateral ventricle. Individual volumes were aggregated into a weighted atrophy index (WAI), combined with baseline MMSE or FAQ score, and used as 2D-features for Gaussian mixture population estimation. The difference between progressing and non-progressing (cognitively or functionally) populations was modelled as a sigmoid function in order to obtain a class-likelihood index.
Results: Class-likelihood indices derived from both WAI-MMSE and WAI-FAQ were used to predict RCD and RFD subjects. Prediction accuracies of 75% and 80% were respectively obtained. This compares to 68% (WAI) and 72% (MMSE) for RCD, 69% (WAI) and 74% (FAQ) for RFD, when using individual measurements alone.
Conclusion: Class-likelihood indices derived from structural imaging and baseline clinical assessment (MMSE/FAQ) give a good indication as to whether a subject is likely to be an RCD/RFD.

ADPD5-0469

MAGNETISATION TRANSFER CONTRAST IMAGING REVEALS WHITE MATTER PATHOLOGY IN THE APP/PS1 MOUSE MODEL OF AMYLOIDOSIS.

J. Praet[1], C. Bigot[1], J. Orije[1], M. Nayaert[1], M. Verhoye[1], A. van Der Linden[1]
[1]Bio-Imaging Lab, University of Antwerp, Antwerp, Belgium

Objectives: While no definitive cure for Alzheimer's disease exists yet, current treatments would benefit greatly from an early diagnosis. We have previously shown that Magnetisation Transfer Contrast imaging (MTC) is able to detect amyloid β plaques in old APP/PS1 mice [1]. In the current study we investigated if MTC is also able to visualize early amyloid-induced pathological changes.

Materials and methods: In a cross-sectional study, we used wild type (n=61) and APP/PS1 mice (n=76) [2] of 2, 4, 6, 8 and 24 months of age. Mice were imaged at the respective ages and sacrificed thereafter for histological analysis. MTC was acquired using a 7T Pharmascan MRI system (Brucker, Germany) using a Turbo Spin Echo sequence with an off-resonance pulse at -16875 Hz.

Results: We first validated our previous results using 24 month old mice as, compared to our previous study, we acquired the MTC images using a different sequence and a lower field strength MRI scanner. We observed an increased MTC ratio in grey matter regions of APP/PS1 mice, validating our previous results. Next we observed that in young mice, MTC is unable to consistently visualize amyloid β-induced grey matter pathology. Instead, we consistently observed decreased MTC ratios in the splenium of 4, 6 and 8 month old APP/PS1 mice. Histology is currently ongoing and will allow to correlate our MTC values to various histological markers.

Conclusion: MTC is able to visualize early pathological changes in the splenium of APP/PS1 mice.

DEVELOPMENT OF VOLUMETRIC PROGRAM FOR FAST EVALUATION OF REGIONAL BRAIN ATROPHY

D. Yang[1], E. Lim[1], J. Cho[1], Y. Shim[2], B. Yoon[3], Y.J. Hong[4], K.C. Kwak[5], J.M. Lee[5]
[1]Neurology, Seoul St. Mary's Hospital, Seoul, Korea
[2]Neurology, Bucheon St. Mary's Hospital, Bucheon, Korea
[3]Neurology, Konyang University College of Medicine, Daejeon, Korea
[4]Neurology, Asan Medical Center, Seoul, Korea
[5]Biomedical Engineering, Hanyang University, Seoul, Korea

Introduction: Brain atrophy is one of the reliable markers for the evaluation of neurodegenerative change of brain and severity of dementia. FreeSurfer and other surface morphology based volumetric programs took much time, require high performance computer system.

Aims: We developed a volumetric analysis program that can measure 26 regional volumes of brain with high feasibility for health professionals to use in clinical practice.

Methods: Based on SPM8 and MATLAB, we made a tool box to measure the 26 regional brain volumes in both hemispheres with segmented masks. The regions were frontal (anterior, antero-medial, dorso-lateral, dorso-medial, inferior, orbital), temporal (anterior, lateral, medial), parietal (medial, lateral), occipital and central. We also calculated ventricle volume, brain volume and total intracranial volume (TIV). We validate the program with T1 high resolution 3D MRI data from 25 AD and 36 normal control subjects.

Results: The average running time for single data analysis was 5 minutes and 36 seconds. Test-retest reliability of this program was perfect, ICC=0.999. AD patients showed decreased brain volume and increased ventricle volume compared to normal controls (p

Discussions: This automatic brain volumetric program was reliable and feasible for the researchers in clinical practice who require fast and reliable results. We will obtain more brain volume data of normal controls with different age and sex to complete normative data set.

ADPD5-0525

DISTRIBUTION ANALYSIS OF CEREBRAL MICROBLEEDS IN ALZHEIMER'S DISEASE AND STROKE WITH SUSCEPTIBILITY WEIGHTED MR IMAGING

M.Y. Park[1], H.J. Park[1], D.S. Shin[1], J.S. Ha[1]

[1]Neurology, Yeungnam UniversitySchool of Medicine, Daegu, Korea

Cerebral microbleeds (CMBs) is an important finding in cerebral amyloid angiopathy and hypertensive arteriopathy. A few studies showed that these two disorders have different patterns in CMBs distribution on the brain. The aim of this study is determining different patterns in CMBs distribution on the brain in AD and stroke by susceptibility weighted imaging (SWI) which is known to be a sensitive magnetic resonance technique in detecting microbleeds.

Seventy-one patients presenting at our neurology department were included and 1.5 Tesla SWI was used to image. Thirty AD patients and 21 patients who had recent ischemic stroke. Remnant 20 patients was classified with healthy control with subjective memory complaint.

The Microbleed Anatomical Rating Scale (MARS) was used to localize each CMB (lobar versus basal ganglia/thalamus (deep), and infratentorial). Incidence, and numbers of microbleeds in each anatomical division were counted and statistically compared each other.

Total CMBs were revealed a preference for the lobar and basal ganglia/thalamus (deep) regions. There were significance that CMBs in patients with AD had higher incidence of CMBs in lobar region and showed predominant distribution of CMBs in lobar brain area than infratentorial region significantly. In stroke patients, had higher incidence of CMBs in basal ganglia/thalamus (deep) region and showed significant predominance in basal ganglia/thalamus (deep) region than infratentorial region. And there were statistical significance for predominant distribution of CMBs in ganglia/thalamus (deep) region in stroke patients compared with AD and controls. But there is no statistically significant difference of distribution predominance between AD and controls.

ADPD5-0664

DIFFUSION TENSOR IMAGE FOR EARLY DIAGNOSTIC TOOL FOR SUBJECTIVE COGNITIVE DECLINE AND RELATIONSHIP OF BASELINE MEMORY SCORE

E. Lim[1], D. Yang[1], K. Jung[1], H.O.N.G. Yun jung[2], Y. Shim[1], B.O.R.A. Yoon[3]
[1]Neurology, Catholic University, Seoul, Korea
[2]Neurology, Asan medical center, Seoul, Korea
[3]Neurology, Konyang University, Seoul, Korea

Background and purpose Recent study showed subjective cognitive decline(SCD) may be the first symptomatic stage AD. The SCD is very heterogeneous state and identification who will converte to dementia is very important. We investigated microstructural changes of brain using DTI in SCD patients and compared DTI parameters between SMI Patients with normal memory scores and with abnormal memory scores in MMSE. **Methods** We enrolled 60 subjects who visited the neurology department of Seoul St. Mary's hospital from Jan, 2009 to May, 2013. We defined SCD who have self-reported memory impairment, but with normal cognitive performance in neuropsychological test.There were 20 normal people, 40 SMI patients and among SCD patients, 15 patients have abnormal recall scores in MMSE. We measured the FA and MD of bilateral entorhinal cortex, hippocampal head and body by using the program Volume-One and dTVII. **Results** There were significant differences of MD values of left entorhinal cortex and FA value of bilateral hippocampal head between normal and SCD groups. And there were significant differences of FA values of bilateral hippocampal head between SCD Patients with normal recall scores and with abnormal recall scores. **Conclusion** This study showed that early microstructural changesoccur in SCD patients and low baseline recall scores in MMSE are related to DTI value change in hippocampus head. This result suggest the possibility DTI can be used as a useful tool to detect microscopic brain changes of SCD patients with low baseline recall scores in MMSE.

ADPD5-0711
CORTICAL THICKNESS IN INDIVIDUALS WITH SUBJECTIVE MEMORY IMPAIRMENT: MEMORY CLINIC VERSUS HEALTH PROMOTION CENTER BASED POPULATION

N. Jung[1], J. Chin[1], J. Yang[2], J. Lee[2], H. Kim[1], Y. Kim[1], H. Shin[3], D.U.K.L. Na[1], S. Seo[1]
[1]Department of Neurology, Samsung Medical Center, Seoul, Korea
[2]Department of Biomedical Engineering, Hanyang University, Seoul, Korea
[3]Center for Health Promotion, Samsung Medical Center, Seoul, Korea

Background
Subjective memory impairments (SMI) without objective memory deficits are quite common among older adults, but their clinical impact remains unclear. We hypothesized that health-seeking behavior may predict the causes or prognosis of SMI. We aimed to determine whether there is difference in cortical thickness between SMI who visited a memory clinic for concern of their memory problem and those who visited health promotion center for disease-preventive medical check-up.
Methods
We consecutively recruited 387 SMI individuals (cSMI), who had no objective cognitive impairments, in memory clinic from September 2008 to June 2012. We also recruited 2155 individuals who had no dementia in health promotion center during the same period. According to the question 'Do you have memory complaints?', 771 individuals were classified into SMI (hpSMI) and 1384 individuals were classified into normal control (NC).
All participants underwent magnetic resonance imaging (MRI), including three-dimensional volume images. Automated surface-based analyses of the MRI data were used to measure cortical thickness. Analysis of covariance analysis was performed after controlling for age, sex and intracranial volume.
Results
Relative to NC, cSMI showed cortical thinning predominantly in the left frontal, temporal, bilateral parietal and occipital regions. Relative to hpSMI, cSMI showed cortical thinning predominantly in the left temporal, bilateral parietal and occipital regions. However, there were no differences in the mean cortical thickness between NC and hpSMI groups.
Conclusions
Our findings revealed that cSMI, but not hpSMI, had cortical thinning compared to NC, suggesting that health seeking behavior reflects early marker for neurodegeneration.

[2]Department of Neurology, Hospital Universitario Marqués de Valdecilla, Santander, Spain
[3]Department of Radiology, Hospital del Mar, Barcelona, Spain
Objectives: To study the relationship between cerebrospinal fluid (CSF) biomarkers of Alzheimer's disease (AD) and their interactions on brain structure in a cohort of cognitively normal subjects (CN).
Methods: Eighty CN subjects underwent structural 3T magnetic resonance imaging and lumbar puncture. We measured Abeta42, total tau, phospho-tau (p-tau) and the marker of inflammation YKL-40 in CSF by enzyme-linked immunosorbent assay. Cortical thickness (CTh) was measured by Freesurfer. Subjects were classified as Abeta42+ (below 550pg/ml) or Abeta42- (above 550pg/ml). CTh difference maps were derived from group, correlation and interaction (by Abeta42 status) analyses.
Results: 9/80 (11.25%) participants were Abeta42+. There were no differences in age or gender between subgroups. The Abeta42+ group showed cortical thickening in AD-related areas compared to Abeta42- subjects (Fig 1A). The interaction analysis showed that the relationship of CTh with YKL-40 is modified by Abeta42 status (Fig 1B). In the stratified correlation analyses YKL-40–dependent thinning was found in Abeta42+ subjects only (Fig 1C). Similar results were obtained with p-tau, but these did not survive family-wise error correction.
Conclusions: Our results support the importance of considering interactions between biomarkers in preclinical AD. According to our results, there is a cortical thickening in relation to decreasing CSF Abeta42 in CN subjects. Atrophy would develop in the presence of a synergistic effect of p-tau and YKL-40-associated inflammation.

PHARMACOLOGICAL EFFECTS OF DONEPEZIL AS A DISEASE MODIFIER

A. Ishiwata[1], S. Mizumura[2], K. Kimura[3]
[1]Department of Neurology, Nippon Medical School Musashi-kosugi Hospital, Kawasaki, Japan
[2]Department of Radiology, Toho University Omori Medical Center, Tokyo, Japan
[3]Department of Neurological Science,
Graduate School of Medicine Nippon Medical School, Tokyo, Japan

Objectives: Donepezil is an acetylcholinesterase inhibitor used to treat Alzheimer's disease (AD) and has recently been proven to have a neuroprotective effect. In this study, we used a Voxel-Based Specific Regional Analysis System for AD (VSRAD) to analyze hippocampal volume and to assess the pharmacological effects of donepezil as a disease modifier.
Methods: 185 patients with AD underwent MRI, 120 (43 men and 77 women, 77.8±7.1 years) without treatment of donepezil and 65 (29 men and 36 women, 78.4±6.0 years) with treatment of donepezil. VSRAD was compared between both groups and against a database from 80 normal subjects. The Z-score was used to assess the degree of hippocampal atrophy.
Results: No siignificant difference between the groups was found for age, sex, or Z-scores, but a significant difference was found for mean Mini-Mental State Examination (MMSE) scores (p=0.02, Student's t-test). In single regression analysis, there was no significant association between Z-score and the MMSE score in the treated group (p=0.494), whereas there was significant association between the Z-score and the MMSE score in the untreated group (p=0.001**).** This implies that the MMSE score becomes lower when the Z-score is higher in untreated patients, whereas there is no significant trend in the treated group.
Conclusion: Donepezil affects the relationship between hippocampal volume and cognitive function. Donepezil, therefore, has a pharmacologic effect as a disease modifier, affecting the disease pathogenesis. This effect may be caused by the involvement of donepezil in hippocampal neurogenesis and its interaction with the sigma-1 receptor for neurite outgrowth.

WHAT DO WE ASSESS USING MEMORY TESTS? A VOLUMETRIC MRI STUDY OF THE FCSRT AND DMS48

N. Philippi[1], V. Noblet[2], M.L. Seux[3], B. Cretin[1], E. Duron[3], C. Martin-Hunyadi[4], X. De Petigny[4], C. Demuynck[4], O. Hanon[3], F. Blanc[1]

[3]Gerontology, Broca Hospital Assistance Publique-Hôpitaux de Paris, Paris, France
[4]Gerontology, University Hospital of Strasbourg, Strasbourg, France

We explored the neuro-anatomical correlates of two memory tests used to assess verbal and visual anterograde memory in order to determine whether they relied on the medial temporal lobe (MTL), and could be predictive of Alzheimer's disease (AD).
We analysed data from a cohort of 140 right-handed patients with mild cognitive impairment (MCI) participating in the longitudinal multicentric clinical research study BALTAZAR. Verbal memory was assessed using the Free and Cued Selective Reminding Tests (FCSRT) and visual recognition memory using a computerized forced-choice task, the DMS-48, among a larger cognitive baseline. Performances in verbal and visual recognition memory using the two tests were correlated to local gray matter atrophy via structural MRI using Voxel Based Morphometry.
Our results confirmed the involvement of the MTL prominently on the left for the FCSRT and on the right for the DMS-48 in the whole group of MCI patients. Interestingly, MTL remained implied only in the subgroup of patients who had deficient scores on the cued recall or recognition, but not on the free recall phase of the FCSRT. For the DMS-48, MTL remained implied only for the group of patients whose performances degraded between Set 1 and Set 2.
The FCSRT and the DMS-48 are able to detect specific features of memory loss due to MTL damage, under the condition that the cued recall or delayed recognition scores are deficient. These results have significant clinical implications with regards to the clinical diagnosis of the underlying etiologies of MCI, such as Alzheimer's disease.

MYELIN BASIC PROTEIN AND ALZHEIMER'S DISEASE IN DOWN SYNDROME

E. Head[1], L. Jutras[1], J. Hilal[1], C. Freeman[1], M. Thacker[1], D. Wilcock[1], F. Schmitt[1]
[1]Sanders-Brown Center on Aging, University of Kentucky, Lexington, USA

Objectives: Virtually all adults with Down syndrome (DS) over the age of 40 years have Alzheimer Disease (AD) neuropathology. We previously showed that white matter (WM) integrity was reduced in clinically demented adults with DS by magnetic resonance imaging and measures of fractional anisotropy. We hypothesized that losses in WM integrity in our cohort was associated with reduced myelin basic protein (MBP) in the frontal cortex.

Methods: To test this hypothesis, we used a separate set of autopsy cases and immunohistochemistry with a rat monoclonal antibody to MBP. MBP levels were compared in the frontal cortex from cases with DS (n=16, 8-25 years), DS with AD (n=41, 50-55 years), sporadic AD (>70 years, n=13, 71-85 years), and age-matched controls (n=35, 15-90 years). Image J was used to quantify the % area occupied by positive immunolabeling for MBP.

Results: An unexpected positive linear relationship between MBP and age in non-DS samples was observed with sporadic AD cases having the highest percent immunolabeling for MBP. Interestingly, there is an exponential increase in MBP immunolabeling and age in DS samples with a rapid rise occurring at approximately 30 years of age.

Conclusions: We had predicted the MBP levels would drop with age and the presence of AD neuropathology in DS. Higher MBP immunolabeling in AD and in DS with AD may reflect increased expression of MBP as a compensatory response. However, higher MBP levels in DS with AD may also be due to reduced degradation and aggregation, and/or accumulation of posttranslationally modified MBP.

ADPD5-0965

IMPROVED AD DISEASE CLASSIFICATION USING STRUCTURAL VOLUMES OF THE WHOLE BRAIN

C. Ledig[1], R. Wolz[1], M. Austin[1], K. Gray[1], D. Rueckert[2], D.L.G. Hill[1]
[1]Science, Ixico plc., London, United Kingdom
[2]Computing, Imperial College London, London, United Kingdom

Objectives

We automatically segment 366 T1-weighted MR brain scans from the ADNI1 database into numerous structures. We investigate the potential of structural volumes to differentiate between AD, MCI and healthy control subjects (N=84/179/103). Comparing to an established technique, we analyse the diagnostic value of individual structures and their joint potential.

Methods

We calculate whole-brain segmentations using MALP-EM, which infers 134 structural labels from manually annotated images. For comparison, we employed volumes of 6 structures calculated with an established technique, LEAP. MALP-EM compensates for incorrectly aligned reference segmentations using intensity information and parcellates the whole brain. LEAP improves the alignment itself in predefined regions and yields single structure segmentations.

Results

Hippocampus and temporal horn perform similar for both methods (cf. Table 1). Amygdala segmentations calculated with LEAP have higher predictive value. Combining all available volumes in a single classifier substantially improves the results for MALP-EM.

MALP-EM	AD/HC	HC/MCI	AD/MCI
All 134 structures	**85.6%**	**71.9%**	**69.1%**
Hippocampus R/L	76.4%/79.9%	70.9%/66.5%	64.4%/59.4%
Amygdala R/L	74.8%/75.0%	58.0%/61.5%	63.7%/64.6%
Temporal Horn R/L	68.0%/66.1%	57.7%/55.7%	64.5%/62.2%
+ 128 other structures			

LEAP	AD/HC	HC/MCI	AD/MCI
All 6 structures	80.7%	70.2%	66.2%
Hippocampus R/L	74.4%/77.7%	71.0%/68.5%	63.3%/63.2%
Amygdala R/L	79.3%/78.3%	63.6%/66.7%	66.2%/61.8%
Temporal Horn R/L	64.0%/66.5%	56.9%/58.7%	63.6%/64.8%

Table 1: Classification accuracy using cross validation.

Conclusions

MALP-EM allows the analysis of many distinct structures and their combination improves classification results. Combining LEAP (improved alignment) and MALP-EM (intensity-based refinement) can potentially further increase the diagnostic value.

[2]Cerebral Imaging Centre, Douglas Mental Health University Intitute, Montreal, Canada

[3]Institute of Neuroradiology, University of Zurich, Zurich, Switzerland

Objectives

Potential treatments and interventions for Alzheimer's disease (AD) may be most effective in prodromal stages, referred to as mild cognitive impairment (MCI). However, there is heterogeneity among MCI, with only some patients progressing to AD. Thus, the establishment of biomarkers that accurately identify future converter to AD is crucial.

Methods

We applied recently developed analyses techniques to investigate differences in subcortical shape and volume changes (thalamus, striatum) in patients with stable MCI (MCIsbl, n=23), future converter at baseline (MCIcbl, n=10) and at time of conversion (MCIctc, n=10) compared to age/gender matched cognitively normal subjects (CNS). Improved analyses techniques were used to further confirm cortical thinning and of the volume of the hippocampus and its subfields as key magnetic resonance imaging-based markers for AD.

Results

Apart from striatal volume reductions ($p<.05$), MCIsbl revealed no morphometric alterations in any of the investigated structures. In contrast, we identified shape alterations using FDR at $q<.10$ in striatal (caudate head and body, ventral lateral putamen) and thalamic regions (anterior and medial dorsal thalamus) paralleling AD like patterns of morphometric changes (cortical thinning in medial temporal regions using FDR at $q<.10$; hippocampal total and subfield atrophy $p<.05$) in MCIcbl and MCIctc.

Conclusions

Based on the ability to distinguish MCIcbl and MCIctc from CNS, our results evidence the value of early thalamic and striatal shape alterations to act as potential markers for the early detection of AD. Our results further confirm the key role of cortical thinning and hippocampal atrophy in the early detection of AD.

[9]Psychiatry Warneford Hospital, University of Oxford, Oxford, United Kingdom
[10]Institute of Psychiatry, King's College London, London, United Kingdom

Objectives. Atrophy in medial temporal, frontal, and posterior cortex can be measured with visual rating scales such as MTA, GCA-F, and PA, respectively. However, practical cut-offs are urgently needed especially now that different presentations of Alzheimer's disease (AD) are included in the revised diagnostic criteria. Our aim was to generate a list of practical cut-offs for MTA, GCA-F, and PA, both for AD diagnosis and MCI prognosis, and to evaluate the influence of key demographic and clinical factors.
Methods. AddNeuroMed and ADNI cohorts were combined, comprising 1147 participants (345 controls, 480 MCI patients, 322 AD patients). MTA, GCA-F, and PA scales were applied and a broad spectrum of cut-offs was evaluated.
Results. MTA showed better diagnostic and predictive performance than GCA-F and PA. Age, ApoE ε4 status, and age at disease onset influenced all three scales. For each of the age ranges 45-64, 65-74, 75-84, and 85-94 years, the following cut-offs should be used: MTA (≥1.5, ≥1.5, ≥2, ≥2.5), GCA-F (≥1, ≥1, ≥1, ≥1), PA (≥1, ≥1, ≥1, ≥1), with an adjustment for early-onset ApoE ε4 non-carriers AD patients: MTA (≥2, ≥2, ≥3, ≥3), GCA-F (≥1, ≥1, ≥2, ≥2).
Conclusions. If successfully validated in clinical settings, the list of practical cut-offs proposed here might be beneficial for clinical practice. This will also foster research on atrophy subtypes, increasing our understanding of different presentations of AD, improve diagnosis and prognosis and aid clinical trials.

Alzheimer's disease (AD) is clinically heterogeneous. Studying AD subtypes based on structural atrophy patterns could help understanding of the different presentations of the disease. Here we aimed to characterize AD subtypes based on visual rating scales of medial temporal (MTA), frontal (FA) and posterior (PA) atrophy.

Regional visual rating scales were applied to 322 AD patients (AddNeuroMed and ADNI). Eight AD subtypes were defined: no atrophy, atrophy exclusively in one region: MTA, PA, FA, and multi-region atrophy: MTA+PA, MTA+FA, PA+FA, MTA+PA+FA. Orthogonal projection to latent structures (OPLS) was utilized to characterize subtypes based on demographic and clinical aspects, cognitive performance and CSF biomarkers. Subtypes were also quantitatively validated with analyses of cortical thickness and subcortical volumes.

OPLS models based on demographic and clinical variables were able to discriminate the typical MTA AD group from other AD groups including frontal atrophy: MTA+FA (Q^2_Y=0.156), PA+FA (Q^2_Y=0.139) and MTA+PA+FA (Q^2_Y=0.102). Demographic and clinical variables could discriminate patients with and without frontal atrophy (Q^2_Y=0.118), with the frontal atrophy group older, demonstrating later disease onset and showing higher CDR sum of boxes memory scores. CSF measures were able to discriminate atypical AD subtypes (no medial temporal atrophy) with and without frontal atrophy, where subjects with frontal atrophy had lower level of Amyloid-beta.

MTA, FA and PA visual rating scales helped to discriminate clinically different AD subtypes. This could be useful to improve diagnostic and predictive methods and aid population selection and enrichment for clinical trials, and, as a central goal, improve clinical care.

[5]Laboratory of Epidemiology and Neuroimaging, IRCCS Fatebenefratelli, Brescia, Italy

Objectives Understanding the metabolic and structural changes during Alzheimer's disease (AD) is a task of major relevance since it would allow identifying clinical biomarkers suitable for an early diagnosis. Within the IMI-PharmaCog European Consortium (Grant Agreement n°115009, www.alzheimer-europe.org), we performed a longitudinal MRI and MRS analysis in two different transgenic mice.

Methods With a 7T Bruker Biospec high-res (146x117x146 µm voxel) in vivo MRI and MRS (PRESS sequence TR/TE=2500/10ms) in two single voxels (~4mm^3) positioned in the dorsal hippocampus and striatum were acquired. We followed from 4 to 24 months double (TASTPM) and triple (APP/PS2/Tau) transgenic mice.

Results Already at 4 months TASTPM showed a pronounced atrophy (-20%) not age-related whereas in APP/PS2/Tau hippocampal volume progressively decreased with age (-32%). Also the striatal area was affected by a progressive age-dependent atrophy in both Tg (APP/PS2/Tau -30%; TASTPM -27%). We observed: a progressive reduction of Glutamate (Glu) (TASTPM -20%; APP/PS2/Tau -10%) in the hippocampus; a reduction of N-acetylaspartate (NAA) at 4 months in TASTPM (-16%) although not progressive; a progressive increase of Myo-Inositol (mIns) starting from 12 months reaching a 2 fold increase in elderly TASTPM mice. Also in the striatum of double Tg mice a progressive reduction of Glu reaching about ~40% was detected.

Conclusions Changes observed in these transgenic mice are partially reminiscent of the cerebral alterations in familial AD. This non-invasive analysis could be adopted in preclinical investigation of therapeutic approaches: we are now addressing whether these alterations are modified as a result of amyloid lowering treatment.

ADPD5-1342

COGNITIVELY NORMAL SUBJECTS WITH LOW BETA-AMYLOID LEVELS IN CEREBRAL SPINAL FLUID HAVE FASTER AGE-RELATED HIPPOCAMPAL ATROPHY

O. Lindberg[1], E. Stomrud[1], J. Lätt[2], P. Thompson[3], K. Blennow[4], K. Nägga[1], O. Hansson[1]
[1]Clinical Memory Research Unit Department of Clinical Sciences Malmö, Lund University, Malmö, Sweden
[2]Department of Diagnostic Radiology, Lund University, Lund, Sweden
[3]Laboratory of Neuro Imaging, Keck School of Medicine of University of Southern California, Los Angeles, USA
[4]Department of Psychiatry and Neurochemistry Institute of Neuroscience and Physiology , University of Gothenburg, Göteborg, Sweden

Objectives.
Several studies have shown that the volume of the hippocampus (HC) is reduced with age. However the underlying causes for this are not fully understood.
We investigated the association between levels of β-amyloid (Aβ42) and phosphorylated tau (P-tau) in the cerebral spinal fluid (CSF) and age-related hippocampal volume decline in 252 cognitive normal participants (65-87 years) from the prospective Swedish BioFinder study.

Methods.
Volumetric hippocampal data were acquired from structural 3D magnetic resonance images using the machine learning algorithm 'AdaBoost' (www.loni.usc.edu) with a training set produced by 'Harmonized hippocampus protocol' initiative (www.hippocampal-protocol.net). CSF Aβ42 and P-tau were quantified using Innotest ELISA.

Results.
A linear regression analysis including CSF measures and age as dependent variables revealed that only age (Beta=-0.29) was associated with right hippocampal volumes, while age (Beta = -0.35, $p<0.001$) and levels of Aβ42 (Beta = 0.12, $p=0.04$) were associated with left hippocampal volume.
The correlation between age and HC volume in whole cohort was $r= -0.47$ (left HC) and $r= -0.38$ (right HC). In 76 participants with pathologic levels of CSF Aβ42, we found an increased age-associated HC atrophy (left HC, $r=-0.60$; right HC, $r= -0.44$ right HC) compared to those with normal levels of Aβ42 (Left HC, r=-0.39; right HC, -0.35).

Conclusions.
These results reveals that the levels of CSF Aβ42, but not P-tau, have a modest association with HC volume in cognitively healthy subjects. Increased amyloid burden in the brain may enhance age-related HC atrophy particularly on the left side.

ADPD5-1383

ANALYSIS OF CALLOSAL ATROPHY IN ALZHEIMER'S BRAIN MR IMAGES USING NON-LINEAR DIFFUSION FILTER AND EDGE BASED LEVEL SET METHOD

A. Kilpattu Ramaniharan[1], S. Chinnaswamy Manoharan[1], R. Swaminathan[2]
[1]Electronics and Communication Engineering, Anna University, Chennai, India
[2]Applied Mechanics, Indian Institute of Technology Madras, Chennai, India

Objective: Alzheimer's Disease (AD) is a complex neurodegenerative disorder that results in the atrophy of gray and white matter structures and whole brain shrinkage. In this work, callosal reduction in sagittal view MR images is analyzed using anisotropic diffusion filter based level set method. Anisotropic diffusion filtering is a non-linear diffusion process, which performs region specific smoothing on images while preserving edges.
Methods: Images for this study are obtained from OASIS, a public domain database. Non-linear anisotropic diffusion filtering is used to enhance the intensity variations and feature boundaries. Level set method without re-initialization is used to segment corpus callosum from the sagittal view MR images. The penalty term added in the level set evolution overcomes reinitialization problem.
Results: It is found that the level set method is able to segment Corpus Callosum (CC) in both the normal and Alzheimer conditions. The edges obtained using non-linear anisotropic diffusion filtering is found to be distinct with less discontinuity. Consequently, edges of CC are preserved. The geometric features such as area, minor axis and convex area are found to be highly significant ($P < 0.001$) in differentiating the pathology. The morphometry of CC is apparently affected in AD subjects.
Conclusions: In this work, an attempt has been made to segment CC using anisotropic diffusion based level set method. The features extracted from the segmented CC are able to differentiate normal from Alzheimer conditions. Thus atrophy analysis of CC could be useful in the prognosis and diagnosis of AD.

ADPD5-1395

FORMULATION OF MINKOWSKI BASED RATIO METRIC INDEX IN ALZHEIMER'S MR BRAIN IMAGES USING LOCALIZED REGION BASED LEVEL SET

M. Kayalvizhi[1], G. Kavitha[1], C.M. Sujatha[2], S. Ramakrishnan[3]
[1]Electronics, MIT campus AnnaUniversity, Chennai, India
[2]Electronics and communication, CEG campus AnnaUniversity, Chennai, India
[3]Applied Mechanics, IIT Madras, Chennai, India

Objectives: Alzheimer's disease (AD) is a chronic brain disorder characterized by behavioral change and most common cause of dementia. The analysis of the hippocampus and ventricle in structural MR brain images helps in diagnosis of Alzheimer's disease.In this work, an attempt is made to analyze hippocampus and ventricle based on localized region based level set method and Minkowski based ratio metric index for severity detection.
Methods: The normal and abnormal images considered in this work are obtained from MIRIAD database. The T1 weighted sagittal images (N=120) are considered. The hippocampus and the ventricles are segmented using multi-object localized region based level set. This method formulates the curve evolution with multiple signed distance functions using advance and retreat components. The analysis of the segmented hippocampus and ventricle are carried using Minkowski functionals. The prominent Minkowski feature, hippocampus to ventricle ratio is correlated with the Mini-Mental State Examination (MMSE) score. The longitudinal analysis of the proposed index is also carried out and the results are analyzed.
Results: Results show that multi-object localized region based level set is able to delineate the boundary of the hippocampus and ventricle. It is observed that the Minkowski area of segmented regions helps in better discrimination of normal and pathology conditions. The correlation of ratio metric index with MMSE score is found to be 0.83, 0.44, 0.91 and 0.94 for normal, mild, moderate and severe respectively.
Conclusion: The longitudinal analysis shows that index could be used as a biomarker in Alzheimer like disorders.

[2]Laboratory of Neuro Imaging Institute for Neuroimaging and Informatics, Keck School of Medicine of University of Southern California Los Angeles CA, Los Angeles, USA

[3]Department of Psychiatry and Neurochemistry Institute of Neuroscience and Physiology Sahlgrenska Academy at the University of Gothenburg, Göteborg, Sweden

Objectives

We aimed to study the brain atrophy pattern associated with episodic memory decline in healthy elderly individuals with or without brain beta-amyloid (Aβ) pathology.

Methods

In the prospective Swedish BioFinder study we compared the association between memory performance, hippocampal volume and cortical thickness in cognitively healthy elderly (65-87 years) with (N=76) or without (N=176) pathologic levels of cerebrospinal fluid (CSF) Aβ42. CSF Aβ42 was measured using Innotest ELISA and memory performance using ADAS-cog item 3 (wordlist delayed recall). Structural 3D magnetic resonance images were analyzed using "AdaBoost" (www.loni.usc.edu) with a training set produced by "Harmonized hippocampus protocol" initiative (www.hippocampal-protocol.net) and Freesufer 5.3 (http://freesurfer.net).

Results

In participants with normal levels of Aβ42 we found a strong correlation between memory performances and decreased hippocampal volumes and cortical thickness in several regions of the medial temporal lobe (including entorhinal cortex). Interestingly, hippocampal volumes and left temporal cortical structures were not significantly correlated with memory performance in participants with low levels of Aβ42 in the CSF. Instead we found strong correlations between episodic memory decline and the left and right superior frontal gyrus as well as the right precentral gyrus.

Conclusion

Episodic memory performance in cognitively healthy elderly with Aβ pathology is more strongly associated with frontal areas compared to cases without Aβ pathology where memory performance is more strongly associated with hippocampal volumes.

[9]Radiology, Mayo Clinic, Rochester, USA

Background: Hippocampal atrophy is the most established structural imaging biomarker for Alzheimer's disease (AD) to date. European AD Consortium and ADNI investigators recently developed a Harmonized Protocol for Hippocampal Segmentation (EADC-ADNI HarP). EADC-ADNI HarP has not been pathologically validated.
Methods: The temporal lobes of 9 AD and 7 cognitively normal subjects (NC) were scanned post-mortem on a 7T Bruker Biospec MRI scanner. Pathologic diagnosis of AD was based on Braak and Braak and CERAD criteria. Hippocampal volumes were obtained with the EADC-ADNI HarP. 6µm-thick hippocampal slices were stained for amyloid beta (Aβ1-40), tau and cresyl violet. The demarcations of each hippocampal subfield were manually drawn with Aperio ImageScope® CS on the digitally scanned stained tissue. Subfield margins were identified based on cytoarchitectonic features. Neuronal counts, Aβ and tau burden for each hippocampal subfield were obtained.
Results: Mann-Whitney comparison of medians showed significant differences between the two groups for total hippocampal tau and Aβ burden and trend difference for neuronal count. Significant median differences were seen in all subfields for tau, in the subiculum, CA1, CA3 and CA4 for Aβ, and in the CA1 and subiculum for neuronal count. We found significant correlations between hippocampal volume and fresh brain weight, Braak and Braak staging, tau, Aβ burden and neuronal counts. Subfield-wise significant association were found for Aβ and neuronal count in CA1 and subiculum, and for tau in CA2-4.
Conclusions: The observed associations provide pathologic validation for the EADC-ADNI HarP and pathologic confirmation of hippocampal morphometry as a valid AD biomarker.

[5]Department of Neurology, Seoul Bukbu Hospital, Seoul, Korea

Introduction: Encoding failure with poor recognition is characteristic of memory impairment seen in AD patients. We think that the pattern of WM alterations in aMCI patients with retrieval deficit (aMCI-R) is somewhat different from that of AD. Methods: We selected subjects diagnosed with aMCI-R (n=7). The control subjects were recruited from general population (n=7). MRI was performed on a 3.0-T MR system equipped with an 8-channel head coil. For the DTI data, a single shot spin-echo EPI sequence was used. FA and trace maps for each subject were obtained with DTIstudioV2 software. Further imaging processing was performed with the statistical parametric mapping-version 5 (SPM5) program. We compared the DTI indices of aMCI-R with that of normal control. Results: FA in aMCI-R was reduced in WM of the bilateral cingulate and the middle frontal gyri, and the right superior frontal gyrus (p

STRUCTURAL CHANGES IN MIDDLE-AGED ADULTS WITH SUBJECTIVE MEMORY COMPLAINTS

E. Rolandi[1], E. Cavedo[2], G.B. Frisoni[3], S. Galluzzi[1]
[1]LENITEM - Laboratory of Epidemiology Neuroimaging and Telemedicine, IRCCS Centro San Giovanni di Dio Fatebenefratelli, Brescia, Italy
[2]Institut de la Mémoire et de la Maladie d'Alzheimer (IM2A) & Institut du Cerveau et de la Moelle épinière (ICM), Sorbonne Universités Université Pierre et Marie Curie, Paris, France
[3]Memory Clinic and LANVIE - Laboratory of Neuroimaging of Aging, University Hospitals and University of Geneva, Geneva, Switzerland

Objectives. Aim of the present study is to compare whole brain gray matter volumes between cognitive intact middle-aged individuals with subjective memory complaints (SMC+) and without (SMC-).
Methods. 134 middle-aged cognitive intact individuals (49.2±5.6 years, MMSE 29.1) underwent clinical, neuropsychological evaluation and T1-weighted volumetric MRI. Subjects were considered SMC+ if they believed to have some memory disturbances (yes/no question). MRI images were pre-processed using DARTEL tool in SPM8 to perform Voxel-Based Morphometry analysis. Whole brain gray matter volumes differences between groups were computed using an analysis of variance model with age, gender, education and depressive symptoms as covariates, after correction for total intracranial volume. Comparison of clinical data between groups were performed using independent sample t-test or chi-square test when appropriate.
Results. SMC+ (N=78) compared to SMC- (N=56) were more female (68% vs 37% $p<0.001$), had lower education (10.0±4.0 vs 12.3±3.9 $p=0.001$) and showed more depressive symptoms at Brief Symptoms Inventory (6.3±4.6 vs 3.9±3.2 $p=0.001$). No significant differences in vascular and genetic (Apolipoprotein E4 allele) risk factors and neuropsychological performance were found between groups. SMC+ show significant lower gray matter volumes than SMC- in caudate nuclei and right superior medial frontal gyrus (FWE correction, $p<0.05$). SMC- did not show any voxel with significantly reduced grey matter density.
Conclusions. This is the first study aimed to assess cortical changes in middle-aged individuals complaining about memory problems. Follow-up studies should clarify whether structural differences found between groups are normal inter-individual genetically-based features or pathological abnormalities predisposing to the development of Alzheimer's disease.

APOE-BY-SEX INTERACTIONS ON BRAIN METABOLISM AND STRUCTURE

E. Vilaplana[1], F. Sampedro[2], D. Alcolea[1], V. Montal[1], J. Pegueroles[1], J. Clarimon[1], M.V. Camacho[2], R. Blesa[1], A. Lleo[1], J. Fortea[1]

[1]Neurology, Institut de Recerca Biomèdica - Hospital de Sant Pau, Barcelona, Spain

[2]Nuclear Medicine, Institut de Recerca Biomèdica - Hospital de Sant Pau, Barcelona, Spain

Objective: To assess the APOE4-by-sex interaction on brain structure and metabolism in healthy controls (HC).

Methods: Cross-sectional study. HC from the Alzheimer´s Disease Neuroimaging Initiative (ADNI) underwent structural 3T-MRI (n=146) and/or a FDG PET (n=242) and lumbar puncture. Cerebrospinal fluid (CSF) beta-amyloid-1-42 (AB1-42) and phospho-tau (p-tau) levels were measured by Luminex. Cortical thickness (CTh) was measured by Freesurfer and FDG was analyzed by SPM8. CTh and FDG difference maps were derived from interaction and group analyses. Clusters from the interaction analysis were isolated to analyze the directionality of the interaction in an ANCOVA.

Results: There was a significant APOE4-by-sex interaction for brain structure and metabolism. ApoE4 carriers had lower CSF AB1-42 and higher CSF p-tau values with respect non-carriers. Hypometabolism was found only in ApoE4-carrier females. CTh was increased in ApoE4-carrier males and decreased in ApoE4-carrier females (Figure). The stratified group analyses by gender confirmed these results.

Interpretation: The impact of APOE4 on brain structure and metabolism is modified by gender. Females APOE4 carreriers show greater hypometabolism and atrophy than males. This APOE4-by-sex interaction should be considered in current clinical trials in pre-clinical AD in which APOE4 status is a selection criteria**.**

Figure. Clusters with APOE4-by-sex interaction on CTh (A1) and metabolism (B1). Box-and-whisker plots illustrate individual CTh (A2) or FDG-uptake (B2) values in the most significant cluster.

[5]Queensland Institute of Medical Research, Queensland Institute of Medical Research, Brisbane, Australia
[6]Neurology Psychiatry Pediatrics Engineering Radiology and Ophthalmology, Keck University of Southern California School of Medicine, Los Angeles, USA

1. Objectives

We previously reported that the C677T variant (MAF=0.245) in the methylene-tetrahydrofolate reductase (*MTHFR*) gene was associated with smaller regional brain volumes in two independent elderly cohorts. This variant causes a reduction in the function of the MTHFR enzyme. Here, we tested if the effects of C677T on brain volumes could be consistently detected across the life span.

2. Methods

At each voxel in the brain, we used tensor-based morphometry to examine whether regional volume differences were associated with carrying the risk allele, and compared findings between two large cohorts of elderly (N=738, average age 75.52 years) and young (N=578, average age 23.80 years) individuals.

3. Results

After FDR correction for multiple comparisons, young carriers of the risk variant showed small reductions in localized brain regions and also showed slightly larger volumes in the medial occipital lobes. Elderly subjects showed extended areas of brain atrophy, especially in the thalamus, frontal lobes, temporal lobes, and cingulate gyrus. These effects were twice as pronounced in the elderly. Each risk allele was associated with a 1-2 % change in local brain volumes in the young sample, and with a 2-4% variation in elderly individuals.

4. Conclusions

These findings suggest that carriers of the C677T variant have differences in brain structure, which may vary over the lifespan. Previous reports have shown that the effects of this variant could be modulated by dietary folate, which may influence the onset or rate of progression of brain aging and neurodegeneration in carriers of this polymorphism.

[4]Clinical Research, BarcelonaBeta Brain Research Center, Barcelona, Spain

APOE e4 carriers, specially the homozygous ones, are at increased risk for developing AD. Healthy late-middle aged APOE4 carriers show alterations such as decreased glucose metabolism, reductions in cortical thickness and alterations in task-related and default mode network activity in brain regions known to be affected by AD. Conversely, there is controversy on whether, at these ages, asymptomatic APOE4 carriers display reduced hippocampal volumes, even though this is a characteristic feature by the time AD symptoms occur. In this work, we aimed at determining APOE4-associated structural changes in cognitively healthy late-middle age subjects in the whole brain and, specifically, in the hippocampus.
Within the ALFA project, 238 subjects aged 45-65 were recruited (107 noncarriers, 100 heterozygous and 31 homozygous). Cerebral 3D-T1 weighted MRIs were submitted to VBM-SPM and Freesurfer analyses ($p<0.001$) of APOE4 additive effects after correcting for intracranial volume, age and sex. Additionally, the hippocampal formation was further segmented into 8 subfields which were subsequently analyzed ($p<0.05$).
The VBM analysis revealed a cluster of APOE4-associated volumetric decrease in the right hippocampus. No reductions could be detected either in the volumes of the whole hippocampus or in the hippocampal subfields in either hemisphere. No significant changes in cortical volume could be detected in the VBM-SPM analysis. However, cortical thickness was bilaterally reduced in the precuneus, among other brain regions, in a dose dependent manner.
Our results indicate that cognitively healthy late-middle aged APOE4 carriers show subtle cerebral morphological alterations in key regions in the development of AD pathology.

LONGITUDINAL CORTICAL THICKNESS CHANGES ASSOCIATED TO AMYLOID-BETA DEPOSITION IN COGNITIVELY HEALTHY SUBJECTS

J.D. Gispert[1], A. Tucholka[1], C. Falcon[1], L. Rami[2], J.L. Molinuevo[2]
[1]Neuroimaging, BarcelonaBeta Brain Research Center, Barcelona, Spain
[2]Alzheimer's Disease and Other Cognitive Disorders Unit Neurology Department, Hospital Clínic i Provincial de Barcelona, Barcelona, Spain

The characteristic progressive memory impairment in AD is related to a pattern of mesial temporal and temporoparietal atrophy. However, Amyloid-β (Aβ) deposition begins many years before symptoms appear. Indeed, several recent studies have shown that Aβ is associated with changes in cortical thickness prior to the development of cognitive impairment. In this regard, increases in cortical thickness have been reported in temporopariteral regions which might undergo neuronal hypertrophy and/or inflammation. In this work, we report the longitudinal changes in cortical thickness of cognitively healthy subjects associated to baseline CSF Aβ.

Forty-seven healthy subjects underwent MRI and lumbar puncture. Two years later, MRI was repeated on the same individuals. Freesurfer was used to calculate longitudinal cortical thickness changes. In a temporopariteral ROI that showed cortical thickening, we performed a nonparametric regression against CSF Aβ. Based on this, subjects were divided into three groups according to their baseline CSF Aβ values (over 800 pg/mL, between 400 and 800 pg/mL, and under 400 pg/mL) and, then, longitudinal cortical thickness changes were compared between them.

Subjects with higher CSF amyloid concentrations showed a moderate cortical thickening in this ROI that reversed in subjects with transitional amyloid values. The lower CSF Aβ group showed significantly lower baseline thickness (-0.215 mm; p=0.020) but minor longitudinal changes. Only the middle group showed a significant variation over time (0.025 mm/year; p = 0.049).

Our results support that Aβ deposition is associated with a subtle yet complex pattern of cerebral structural changes prior to the development of cognitive impairment.

BETWEEN COHORT TRANSFERABILITY OF ALZHEIMER'S DISEASE CLINICAL TRIAL ENRICHMENT WITH AMYLOID IMAGING, HIPPOCAMPAL VOLUME AND APOE-4 GENOTYPE

R. Wolz[1], K.R. Gray[1], D.L.G. Hill[1]
[1]R&D, IXICO, London, United Kingdom

Background: Biomarkers and genetics are proposed to enrich populations in MCI / AD clinical trials. Amyloid burden and structural neurodegeneration have both been qualified by the EMA as enrichment markers. The transferability of these biomarkers between cohorts has not yet been well characterized. Here, the performance of these biomarkers are assessed individually and in combination on the ADNI I/II MCI cohorts and compared to enrichment with ApoE-4 status.
Methods: Included are the 260 MCI subjects from ADNI I/II for which an Amyloid marker and clinical follow-up with MMSE/CDR-SB after 24 months is available. We calculated required sample sizes per arm and trial cost for a hypothetical 2-year trial based on the 24 month change in MMSE/CDR-SB [1]. Hippocampal volume was extracted using LEAP [1]. Compared where enrichment performance of the three markers individually and combined. Marked-benchmarked values were used to estimate trial costs [1].
Results: Presented are sample sizes and trial cost ($m) for different enrichment strategies and different clinical endpoints in both cohorts.
Conclusions: Sample size and trial cost can be significantly different across cohorts and clinical endpoints. Individual and combined enrichment cannot just help to reduce required sample sizes and trial cost, but can also help to significantly reduce this variability across cohorts and clinical endpoints.

NEURO-IMAGE GUIDED INVESTIGATION OF EARLY WHITE MATTER ALTERATIONS IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

F. Kara[1], A. Van der Linden[1], A. Alia[2]
[1]Bio-imaging lab, Antwerp University, Antwerp, Belgium
[2]Leipzig University, Institut für Medizinische Physik und Biophysik, Leipzig, Germany

The corpus callosum (CC) plays an important role in interhemispheric transfer of cognitive information and has been shown to be susceptible to Alzheimer's disease (AD). There is an emergent need for new in vivo non-invasive studies to monitor CC changes longitudinally in order to clarify how and when the integrity of CC alters in AD. The aim of this study was to probe *in vivo* T_2 relaxation time changes longitudinally in the CC (Fig.1) of the Tg2576 (Tg) and wild-type (WT) mice with age and to investigate potential biological mechanisms contributing alterations in the CC. The major finding of our longitudinal study was a significant prolongation of the T_2 in the CC, reflecting significant microstructural changes in Tg mice compared to WT mice at and above 10 months of age ($P < 0.0031$) (Fig. 2A). These changes may be related with activated glial cells, increased vacuole formation, increased demyelination and Aβ plaque load (Fig. 2B,C &D). To our knowledge, this is the first longitudinal *in vivo* T_2 study assessing microstructural changes in the CC of the Tg2576 mice. Our results suggest that inflammatory pathology accompanied by demyelination may lead to prolonged T_2 which can be mark as an early event during AD progression in this animal model.

Acknowledgment: This work was partially supported by grants from Alzheimer Forschung Initiative e.V. (AFI, Grant Nr 13810), Stichting Alzheimer Onderzoek (SAO-FRA, Grant Nr 13026). Firat Kara is a Postdoctoral Fellow of the Research Foundation-Flanders (FWO) from University of Antwerp.

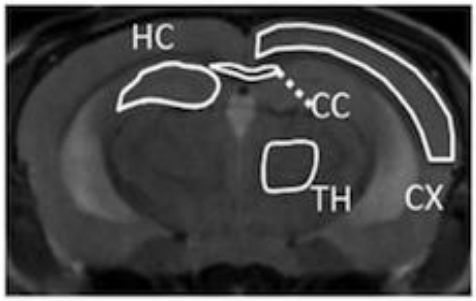

Fig. 1. T2-weighted image of a mouse brain. Corpus callosum (CC), hippocampus (HC), cortex (CX) and thalamus (TH).

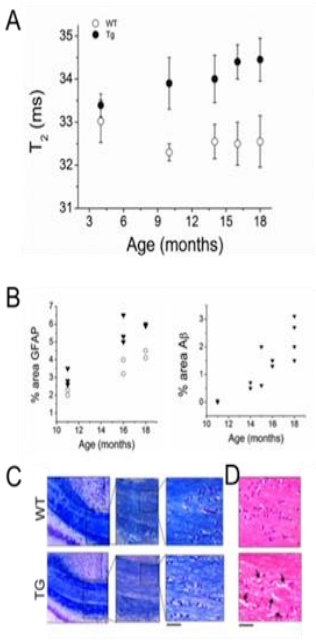

Fig. 2. (A) Age-dependent *in vivo* T_2 changes of the CC region of the wild-type (WT) and Tg2576 (TG) mice. Values are expressed as mean T_2 in ms ± SD (error bars) (95% C.I.). Two tailed student t- test show significant difference between wild type and Tg2576 mice at the age of 10 months ($P < 0.00313$), 14 months ($P < 0.00063$), 16 months ($P < 0.00063$) and 18 months ($P < 0.00063$). No significant difference was observed between WT and TG mice at the age of 4 months ($P > 0.05$). (B) Quantitaive analysis of GFAP stained area and Aβ load in the CC with age in Tg2576 (▼) and control mice (○). (C) Histological section of the brain of a WT and a Tg mouse, stained with the Klüver-Barrer method, which stains the myelin in blue, and standard H&E stain (D). Demyelination and vacuolation in the CC region of Tg mouse (C and D, lower layer) is more prominent compared to the WT mouse (C, D upper layer) as can be clearly seen (arrows) in the magnified subsampled areas. Scale bars: 500 μm.

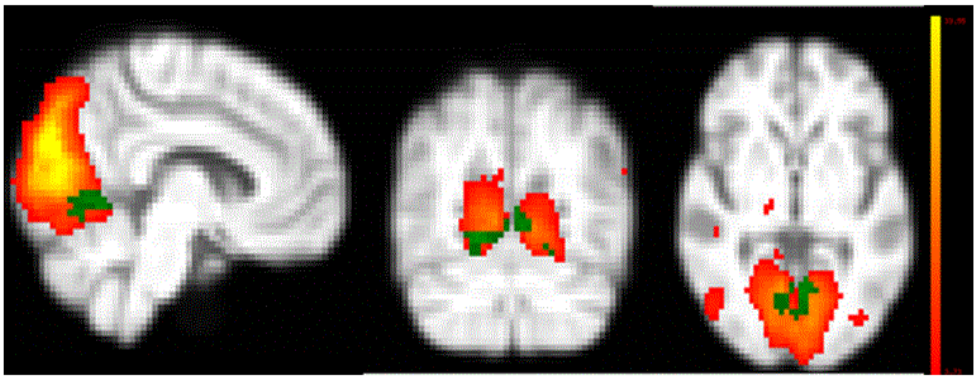
Objectives: Alzheimer's disease (AD) is a neurodegenerative disorder characterised by disconnection within and between various brain networks along with diffuse neuropsychological impairment. Pathology in the visual association areas has been documented in pre-clinical AD and therefore we aimed at examining the relationship between brain connectivity and visuo-spatial (V-S) cognitive deficits in AD.

Methodology:
Patients with AD (N=23; females=8) diagnosed according to NIAAA criteria and of mild illness severity (CDR=1) were recruited after obtaining informed consent. The study was approved by institutional ethics committee of NIMHANS. Tests for V-S working memory, episodic memory and construction were administered as part of comprehensive neuropsychological assessment using NIMHANS Neuropsychological Battery for Elderly. Resting state fMRI (rsfMRI) and high resolution structural T1 images were acquired as per the standard protocols. Based on the severity of V-S impairment, the sample was sub-divided into those with severe (N=12;F=4) and mild (N=11;F=4) deficits. Between-group differences in resting state functional connectivity (rsFC) were examined by performing independent component analysis (ICA) and dual regression analysis in FSL, correcting for age, gender, age of illness onset, and total brain volume.

Results:
Patients with AD having severe V-S deficits exhibited significantly increased rsFC in medial occipital area of the visual network and right paracingulate region of executive network compared to patients with mild V-S deficits.

Conclusion:
Increased rsFC in visual and executive networks in patients with more severe V-S deficits might be considered as a functional neuroimaging biomarker reflecting an attempt to compensate for the progressive visuo-spatial neurocognitive impairment in

early AD.



Group resting state visual network is represented by voxels in red-yellow (threshold between 3.73 – 33.55 respectively) Green voxels shows clusters of significantly increased functional connectivity in patient with severe visuo-spatial cognitive deficits compared to patients with mild visuo-spatial cognitive deficits ($p<0.05$, family wise error (FWE) corrected). A NOVEL COGNITIVE FMRI TASK TO ASSESS BRAIN MECHANISMS UNDERLYING VISUAL PROCESSING AND ATTENTION IN EARLY ALZHEIMER'S DISEASE

N. Elfmarková[1], R. Marecek[1], S. Rapcsak[2], I. Rektorová[1]
[1]Brain and Mind Research Programme, CEITEC MU, Brno, Czech Republic
[2]Department of Neurology, University of Arizona, Tucson, USA

Objectives
Visual processing deficits can be found in early Alzheimer's disease (AD). We aimed at developing a visual cognitive task to study brain mechanisms underlying visual processing in early AD using functional MRI (fMRI). To achieve our goal we developed a novel visual object matching task using conventional and unconventional (spatially rotated) views of object pairs. Here we present the fMRI results of a pilot study performed in healthy subjects (HS).

Methods
Twenty-two right-handed HS (11 men; age 25.3±2.8 years) performed a visual cognitive task in a 1.5T MR scanner. fMRI data were processed using SPM8 and the standard pipeline. The significance level was set to $p<0.05$ FWE corrected.

Results
At the group level, we found major activation of bilateral temporo-occipital areas, precuneus and inferior frontal gyri during the conventional conditions as compared to the control task. The unconventional conditions revealed additional activation of the posterior parietal areas including the superior parietal lobule and intraparietal sulcus as compared to the conventional conditions.

Conclusions
In the visual object matching task with conventional views of objects we observed major engagement of the ventral visual pathway. The task with spatially unconventional views of objects revealed additional recruitment of the dorsal visual pathway and the dorsal attentional network which is involved in the top-down attentional control of visual processing. Our fMRI paradigm shows promise for investigating the functional integrity of the ventral and dorsal visual pathways and for assessing task-dependent attentional modulation of visual processing in early AD.

[2]Biomedical Engineering, Hanyang University, Seoul, Korea

Backgrounds: Amnestic mild cognitive impairment (AMCI) is regarded as an early clinical stage of dementia, especially Alzheimer's disease (AD). Memory impairment is also common in Parkinson's disease (PD) patients with cognitive impairment (PDMCI). We aimed to find the changes in functional connectivity in patients with AMCI with PD (AMCI-PD+) and those without PD (AMCI-PD-) using resting-state functional MRI (rs-fMRI).

Methods: A total of 65 patients with AMCI (AMCI-PD-, n = 33, AMCI-PD+, n = 32) and 29 subjects with normal cognition (NC) underwent rs-fMRI. We analyzed the resting-state functional connectivity from seed region of interest in precuneus, posterior cingulate cortex (PCC), substantia innominata (SI), and caudate in patients with AMCI-PD- and AMCI-PD+ relative to NC group.

Results: Seed-based analyses with precuneus and PCC seeds showed that, patients with AMCI-PD+ had a decreased functional connectivity mainly in the posterior cortical regions including bilateral occipital, lateral parietal, and temporal lobes, while patients with AMCI-PD- had an increased connectivity in the medial temporal, frontal, and parietal lobes, insular cortex, and thalamus. Both AMCI groups exhibited an increased connectivity from the SI in widespread cortical regions including the frontal, temporal, and parietal lobes. Seed-based analyses with caudate seed showed that patients with AMCI-PD+ had a decreased cortical and cerebellar functional connectivity; however, no areas of decreased cortical functional connectivity were observed in the AMCI-PD- group.

Conclusion: The pattern of changes in cortical functional connectivity from the PCC/precuneous and striato-cortical connectivity differ between AMCI-PD- and AMCI-PD+, which may reflect different neuropathological basis of memory dysfunction.

COURSE PREDICTION FOR ALZHEIMER DISEASE BY DIFFUSION TENSOR PARAMETERS OF UNCINATE FASCICLES.

T. Taoka[1], M. Sakamoto[1], T. Miyasaka[1], F. Yasuno[2], K. Kichikawa[1]
[1]Radiology, Nara medical university, kashihara, Japan
[2]Psychiatry, Nara medical university, kashihara, Japan

Purpose: The purpose of the current study is to access the feasibility of diffusion tensor parameters for predicting the prognosis of Alzheimer disease (AD). We made analysis for correlation between diffusion tensor parameters and the MMSE.
Subject and Methods: Subjects were 29 AD cases in which annual follow up of diffusion tensor study and clinical study including MMSE score were made for more than two years. Diffusion tensor image were acquired and tractographies were made to measure apparent diffusional coefficient (ADC) and fractional anisotropy (FA) of uncinate fascicles. We evaluated following points. 1) FA, ADC vs MMSE of the same year, 2) FA, ADC vs MMSE of the next year, 3) ΔFA, ΔADC vs ΔMMSE of the same interval, and 4) ΔFA, ΔADC vs ΔMMSE of the next interval.
Results: 1) ADC and FA of showed statistically significant correlation with the MMSE of the same year. 2) ADC and FA showed correlation with the MMSE of the next year (Figure). 3),4)ΔFA and ΔADC did not show correlation with changes in MMSE of the same interval nor the next interval.
Conclusion: ADC and FA of uncinate fascicles can be used in prediction for the severity of Alzheimer disease.

[2]Inserm-EPHE-UCBN U1077 CHU de Caen, Cyceron, Caen, France

The posterior cingulate cortex (PCC) is a major hub connecting sub-systems of the default mode network which are functionally impaired in early Alzheimer's disease (AD). The PCC can be subdivided into ventral (vPCC) and dorsal (dPCC) regions. We aimed at identifying relationships between cognitive impairment and ventral and dorsal PCC functional connectivity (FC) disruptions in amnestic Mild Cognitive Impairment (aMCI) and AD patients.

Forty-one healthy old controls (HC), 26 aMCI and 25 AD patients underwent neuropsychological tests and resting-state functional MRI. FC maps from vPCC and dPCC were obtained. In HC, the maps were compared to each other and correlation analyses were carried out with neuropsychological performances to identify ventral and dorsal networks. In patients, connectivity disruptions were investigated by comparing with HC networks.

In HC, the ventral network implied the hippocampus and temporo-parietal regions, whereas the dorsal network held the precuneus, supramarginal, anterior temporal and dorso-medial prefrontal regions. The ventral network FC correlated with autobiographical memory, while the dorsal network FC correlated with visual mental imagery. In aMCI, the dorsal network FC was preserved, while the ventral network FC was altered in the bilateral hippocampus. In AD, ventral network FC disruptions spread into the left supramarginal region and the dorsal network FC was also affected in the right inferior middle temporal region.

In aMCI, only the vPCC network FC may be disturbed, which could be related to episodic memory impairment. In AD, FC disruptions in both ventral and dorsal networks could be related to additional cognitive disruptions arising lately.

SELF-REPORTED PHYSICAL EXERCISE AND DEFAULT MODE NETWORK

C.V.L. Teixeira[1], M. Weiler[1], B.M. Campos[1], M.H. Nogueira[1], L.F.L. Pegoraro[1], B.P. Damasceno[1], F. Cendes[1], M.L.F. Balthazar[1]

[1]neurology, Faculty of Medical Sciences, Campinas, Brazil

Introduction: The default mode network (DMN) is a set of brain regions that typically deactivate during performance of cognitive tasks. The DMN is detectable using task-free functional connectivity MRI and has been implicated in episodic memory processing. Some studies have shown that physically active people show better DMN connectivity when compared to sedentary. Objective: We aimed to investigate if self-reported physically active elderly present better DMN functional connectivity than sedentary elderly. Methods: 42 cognitive preserved elderly (mean age 68.4, SD=7.2, mean schooling years of 12.12, SD=6.8), with average MMSE score of 28.4 out of 30 (SD=0.9), were divided into two groups: 20 self-reported physically active (A) and 22 sedentary elderly (S). It was considered physically active those subjects who reported practicing physical exercise at least 3x per week for 30 minutes each session. Functional neuroimaging measures were collected in resting state, no task involved. *UF²C* software was used to perform FC analysis and the posterior cingulate cortex (0,-51,15) was settle as seed region. The resultant individual statistical maps were used as input of a second level analysis (group inference), by using *SPM8* (Statistical Parametric Mapping). Results: Two Sample *t*-test ($p<0.005$ cluster with at least five voxels) did not show any difference in DMN functional connectivity between groups. Conclusion: It was not possible to observe DMN functional connectivity difference between self-reported activity elderly, we may consider the fact self-report may not be the best way of assessing physical activity level, since it does not represents fitness level per se.

[4]Department of Psychiatry and Neurochemistry Institute of Neuroscience and Physiology , University of Gothenburg, Gothenburg, Sweden
[5]Clinical memory research unit clinical sciences, Lund University, Malmö, Sweden

OBJECTIVE
CSF levels of β-amyloid (Aβ42) has emerged as a powerful predictor of subsequent development of AD in subjects with Mild Cognitive Impairment (MCI). In the present study we investigate the changes in interregional connectivity in MCI patents with pathologic CSF Aβ42 levels.
METHODS
We included 105 cognitively healthy controls with normal CSF Aβ42 levels (>550ng/l) and 55 patients with amnestic MCI with pathologic CSF Aβ42 levels (<550ng/l) from the Swedish BioFinder study. CSF Aβ42 was analysed with Innotest ELISA. The whole-brain functional connectivity was gauged by resting-state fMRI (Siemens Trio 3T, 6min gradient-echo EPI TR/TE=2000/30ms).
RESULTS
Relative controls, patients with aMCI exhibit reduced interregional connectivity (reduced correlation between regional BOLD time-series) in a very large network component, highly focused on a hub region involving thalamus, caudate and putamen, also including key regions, e.g. hippocampus (see Fig. 1 and 2). Several interconnected networks are affected: the basal ganglia, frontal executive, visual and default mode network.
CONCLUSIONS
These findings are in accordance with the hypothesis of cognitive decline following a global disconnection syndrome and failing hub connectivity. Furthermore, we aim to elucidate a progression line ranging from amyloid pathology in healthy elderly, subjective cognitive decline to aMCI and AD.

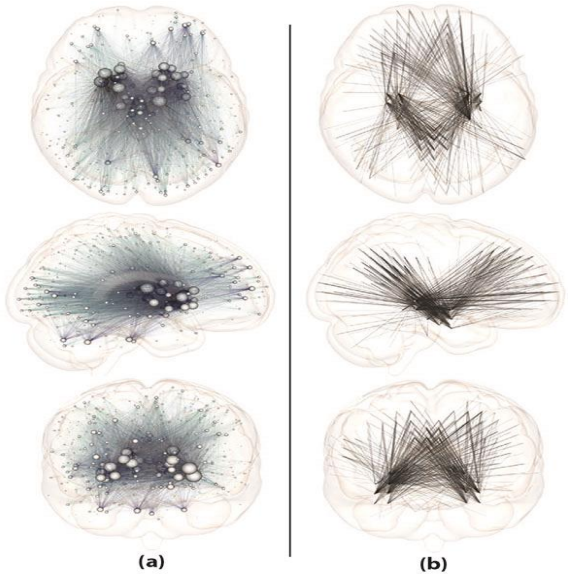

Figure 1. (a) Network component with reduced functional connectivity in aMCI relative controls (Sphere-size represents number of connected links (degree), links colored by end-point degree). (b) Part of high-resolution component involving hippocampus reveals links with default mode and executive networks.

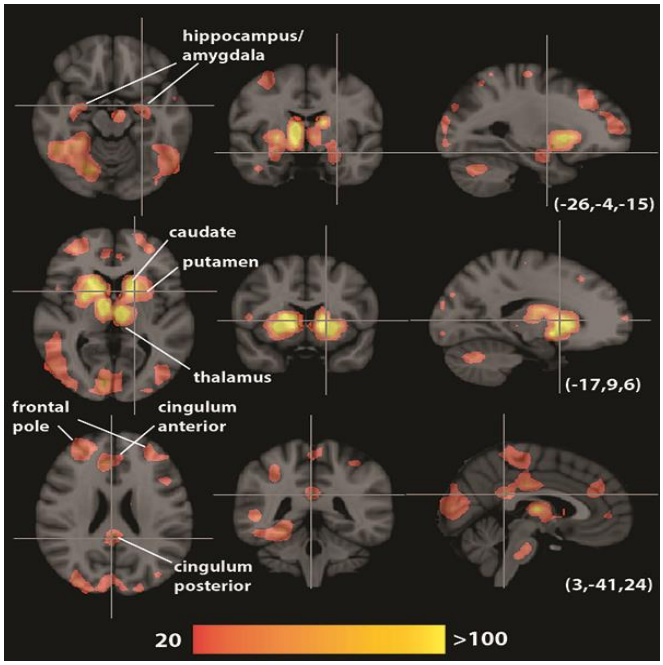

Figure 2. Representative slices of reduced connectivity network component degree.

[5]Functional Architecture of Memory Unit, Ruhr University, Bochum, Germany

[6]Institute of Cognitive Neuroscience, University College, London, United Kingdom

In the medial temporal lobe there are domain-specific pathways that support two different types of memory - memory of object/item (PRC-LEC) and spatial/context information (PHC-MEC). The dentate gyrus and CA3 of the hippocampus might be the regions where the information coming from these two domains is integrated. The aim of this study was to investigate these pathways during a memory task that poses high demands on the precision of recognition memory and pattern separation of similar appearing stimuli.

We used 3T functional magnetic resonance imaging (fMRI) to investigate the precision of recognition memory for object and scene stimuli. During the fMRI session, 44 young and 44 healthy elderly subjects discriminated original stimuli from similar appearing lures. The stimuli were quasi-realistic images of indoor objects and spatial scenes. Older individuals were specifically impaired in detecting lures compared to young individuals, but there was no dissociation between the accuracy to detect object and scene lures. FMRI data showed that there were reduced novelty responses within the hippocampus of elderly subjects for both types of stimuli. However, whereas novelty responses were evident for similar appearing scene lures, they were diminished for object lures.

Elderly subjects show a drop in precision of recognition memory in object and scene stimuli, which is accompanied by functional differences in the processing of object lures. This selective functional impairment is compatible with the possibility that object-processing pathways (PRC-LEC) are affected early by tau pathology.

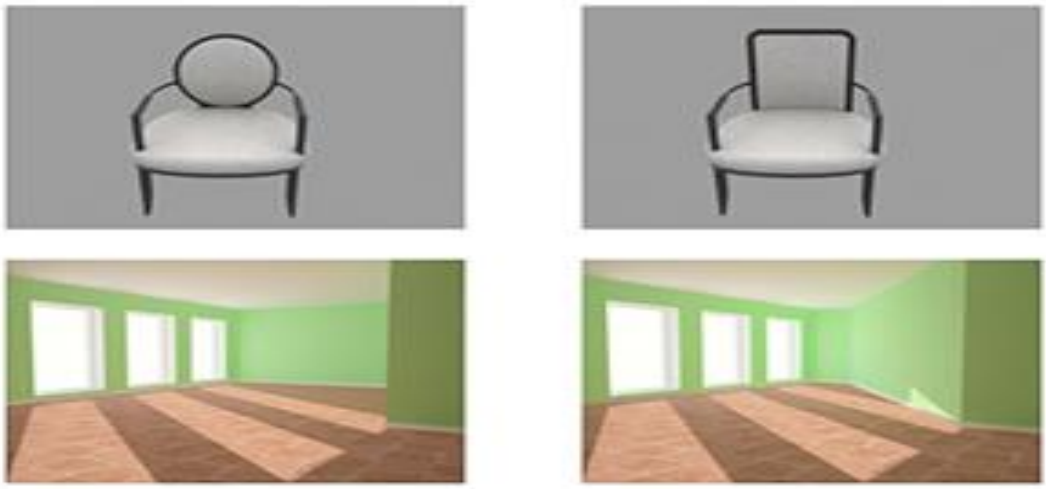

Figure 1: Original and similar appearing lure stimuli for the object and scene condition.

IN VIVO IMAGING TECHNIQUES FOR PRECLINICAL TESTS IN NEURODEGENERATIVE DISEASE

T. Lee[1], D. Kim[1], H. Kim[1], Y.O.N.G. Jung[2], C. Kim[1]
[1]Laboratory Animal Center, Daegu-Gyeongbuk Medical Innovation Foundation, Daegu, Korea
[2]Bio and Brain Engineering, KAIST, Daegu, Korea

In vivo imaging is wildly used to investigate disease mechanisms in both humans and animals since disease progression can be easily monitored repeatedly in the same subject. Specifically, MRI is a very powerful tool to acquire high resolution anatomical images and functional scans. Further, the introduction of smart MRI sensor can provide a way to detect molecular signalling in the brain. Here I present a novel dopamine mapping technique to possibly study Parkinson's disease using functional MRI. In addition, MRI technique is applied to study animal model of dementia.

Dopamine mapping was performed in the rat brain using dopamine sensitive MRI sensor. The sensor was slowly infused into the nucleus accumbens area and dopamine release was measured while the medial forebrain bundle was periodically stimulated. A series of T1 images were acquired in Bruker 9.4T magnet and processed to obtain dopamine concentration. The highest concentration was measured in the nucleus accumbens core. The spatial dopamine release was mapped in real-time. This result can be applied to study dopamine related disease such as Parkinson's disease, drug addiction, etc.

MRI technique was also applied to study Alzheimer's disease and vascular dementia in mice. Their brain was repeatedly scanned to obtain anatomical images, angiography and diffusion tensor imaging. Neuronal atrophy appeared in the hippocampus of 5XFAD mouse over 6 months. Bilateral common carotid artery stenosis in C57BL/6 mice also developed hippocampal damages 2~3 months after surgery. In conclusion, various MRI techniques are essential to study neurodegenerative disease in vivo.

ADPD5-2139

DEFAULT MODE NETWORK FUNCTIONAL CONNECTIVITY IN THE EARLY AND LATE MILD COGNITIVE IMPAIRMENT: RESULTS FROM THE ALZHEIMER'S DISEASE NEUROIMAGING INITIATIVE

E.S. Lee[1], K. Yoo[2], Y.B. Lee[2], J. Chung[2], J.E. Lim[2], B. Yoon[3], Y. Jeong[2]
[1]Graduate School of Medical Science and Engineering,
Korea Advanced Institute of Science and Technology, Daejeon, Korea
[2]Department of Bio and Brain Engineering,
Korea Advanced Institute of Science and Technology, Daejeon, Korea
[3]Department of Neurology, Konyang University Hospital, Daejeon, Korea

Neuroimaging studies have identified a breakdown of functional connectivity in the default mode network (DMN) in individuals with Alzheimer's disease or mild cognitive impairment (MCI). However, no studies have investigated DMN connectivity at different stages of MCI, such as early MCI (EMCI) and late MCI (LMCI). Therefore, the aim of this study was to investigate the patterns of breakdown of DMN connectivity occurs using a quantitative index of functional connectivity among cognitively normal (CN), EMCI, and LMCI subjects. Resting state functional magnetic resonance images and neuropsychological test scores from 130 subjects (CN = 43, EMCI = 47, LMCI = 40) were obtained from the Alzheimer's Disease Neuroimaging Initiative. Functional connectivity in the DMN of each subject was computed using independent components analysis. DMN connectivity maps were compared among groups. Functional connectivity in the precuneus, right medial frontal, right parahippocampal, and right middle temporal gyrus was decreased in the EMCI and LMCI compared with CN subjects. When the two MCI groups were directly compared, LMCI subjects exhibited decreased functional connectivity in the precuneus, right medical frontal, left parahippocampal, left middle temporal, and left superior frontal gyrus. Conversely, LMCI presented increased connectivity in the right superior temporal gyrus and left superior parietal lobule. Mean DMN *z*-scores correlated well with measures of cognitive performance. These findings indicate that DMN connectivity is in a continuum going from CN to LMCI. Even in the EMCI state, functional connectivity in the precuneus and medial prefrontal gyrus is decreased.

[2]Radiology, Harvard Medical School Massachusetts General Hospital, Boston, USA

Cross-sectional functional magnetic resonance imaging (fMRI) studies using a memory task in mild cognitive impairment (MCI) patients have produced discordant results, with s studies reporting increased hippocampal activity -consistent with findings in genetic at-risk populations- and other studies reporting decreased hippocampal activity, relative to normal controls. However, previous MCI studies have not included markers of amyloid-β (Aβ), which may be particularly important in prediction of progression along the Alzheimer's disease continuum. Here, we examine the contribution of Aβ deposition to cross-sectional and longitudinal measures of hippocampal fMRI activity, hippocampal volume, global cognition and clinical progression over 36 months in thirty-three patients with MCI (Figure 1). Aβ-status was examined with positron emission tomography imaging using Pittsburg compound-B, hippocampal fMRI imaging activity was assessed using an associative face-name memory task, and hippocampal volume was quantified with structural MRI. Finally, global cognition was assessed using the Mini Mental State Exam (MMSE) and clinical progression using Clinical Dementia Rating (CDR) sum of boxes. At baseline, Aβ+MCI patients showed increased hippocampal activation, smaller hippocampal volumes, and a trend towards lower MMSE and higher CDR scores compared to Aβ-MCI patient. Longitudinally, Aβ+MCI patients continued to show high levels of hippocampal activity, despite increasing rates of hippocampal atrophy, decline on the MMSE and faster progression on the CDR. When entered simultaneously into the same linear mixed model, Aβ status, hippocampal activation, and hippocampal volume independently predicted clinical progression. These results indicate that Aβ+MCI patients are more likely on a path towards Alzheimer's disease dementia than Aβ-MCI patients.

APATHY IS ASSOCIATED WITH INCREASED SEGREGATION OF BRAIN NETWORKS IN ALZHEIMER'S DISEASE

S. Tumati[1], J.B.C. Marsman[1], S. Martens[1], P.P. De Deyn[2], A. Aleman[1]
[1]Department of Neuroscience, University Medical Center Groningen (UMCG), Groningen, Netherlands
[2]Department of Neurology, University Medical Center Groningen (UMCG), Groningen, Netherlands

Objectives: The development of apathy in the course of Alzheimer's disease (AD) increases the risk of disease progression. Using connectivity measures based on graph theory, we investigated changes in brain networks associated with apathy in healthy older individuals and those at different stages of AD (subjective memory complaints (smc), mild cognitive impairment (MCI) and AD).
Methods: Resting state MRI scans from 142 individuals (healthy=31, SMC=24, MCI=61, AD=26) (data from the Alzheimer's Disease Neuroimaging Database (ADNI); see adni.loni.usc.edu) were assessed. Following standard preprocessing steps, data was additionally processed to remove volumes with excessive motion and signal variation to reduce motion related effects. Graph theoretical measures of modularity and global efficiency were assessed over a range of thresholds in those with and without apathy across all subjects. We further assessed whether differences in network measures between the groups were influenced by age, gender, diagnostic category or apolipoprotein E status (ApoE) using analysis of covariance.
Results: Modularity, measuring the extent of segregation in brain networks, differed significantly across those with and without apathy. This effect was independent of the changes associated with diagnostic category, age, gender and ApoE status. Further, global efficiency, a measure of functional integration of brain networks, did not differ significantly between the groups.
Conclusions: Apathy is associated with increased segregation of brain networks suggesting that apathy appear to be related to disconnectivity between brain regions. Such alterations in brain networks may underlie the development of apathy in AD

ADPD5-0768

UPREGULATION OF MGLUR5 AT EARLY AGE IN MOUSE MODEL FOR ALZHEIMER'S DISEASE VISUALISED WITH [11C]ABP688 PET.

X. Fang[1], J. Eriksson[2], D. Sehlin[1], L. Cato[1], U. Yngve[2], G. Antoni[2], S. Syvänen[1]
[1]Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden
[2]Uppsala University Hospital PET-center, Uppsala University, Uppsala, Sweden

Objectives: Amyloid-beta (Aβ) oligomers act as co-receptors for the metabotropic glutamate 5 receptor (mGluR5); forming a complex that mediates increases of intracellular calcium in neurons, and leads to dendritic spine loss. Aβ also upregulates astrocytic mGluR5 receptor expression; and mGluR5 antagonism reverses learning, memory and synapse density deficits. In a transgenic mouse model (tg-ArcSwe) for Alzheimer's disease, with enhanced intraneuronal Aβ aggregation starting before 4 months of age, we investigated mGluR5 characteristics using the [^{11}C]ABP688 PET tracer for mGluR5.

Methods: Mice expressing the Arctic (E693G) and Swedish (KM670/671NL) APP mutations (tg-ArcSwe), and C57/Bl6 control littermates of different ages were PET-scanned in a Triumph trimodality PET/SPECT/CT scanner using mGluR5 ligand [^{11}C]ABP688. Mice were sacrificed after scanning, followed by brain extraction. Soluble Aβ protofibrils and mGluR5 concentrations were determined in brain tissue using ELISA, and the amount of mGluR5 protein in brain was also assessed using Western immunoblotting.

Results: PET data and *ex vivo* measurements indicated a tendency of higher mGluR5 concentrations in 4-month-old tg-ArcSwe compared with control mice and this observation was supported by ELISA and Western blot analyses. The mGluR5 ELISA also revealed increased mGluR5 at 8 months of age in tg-ArcSwe mice compared with controls. At these ages, tg-ArcSwe mice also had increased levels of soluble Aβ protofibrils.

Conclusions: Upregulation of mGluR5 occurs before formation of insoluble Aβ plaques. Aβ oligomers can possibly cause toxic effects through the mGluR5 receptor, and [^{11}C]ABP688 could be an early biomarker for Alzheimer's disease.

THE MRC UK DEMENTIAS PLATFORM: ACCELERATING DEMENTIA RESEARCH
J. Gallacher[1], *N. UKDP study group*[1]
[1]*Primary Care and Public Health, Cardiff University, Cardiff, United Kingdom*
Objective:
UKDP is a £53M dementia dedicated 'big-data' platform created to provide closer synergy between epidemiology and experimental medicine (EM) through the re-purposing of epidemiologic cohorts for trials readiness.
Methods:
Data from 2M intensively phenotyped participants from 22 cohorts will enable the rapid testing of complex hypotheses across multiple independent datasets. Population and familial disease cohorts will enable unique and common mechanisms across the dementias to be identified. Data access will be through a single informatics portal (figure).
Results:
Integration of the research environment, linking strategic resource cohorts and methods development programs to specialist PET/MR, informatics and iPSC networks will support an in-depth EM programme of discovery studies and early phase trials. Initial EM foci include innate and acquired immunity, synaptic function, and vascular risk factors with other programmes to be developed.
Readiness cohorts will include 10,000 UK Biobank participants with 2 year repeat 3T brain MRI, cognitive phenotyping and bio-sampling; providing a step-change in the size and phenotypic detail of trials ready cohorts.
UKDP is a PPP bringing together a broad range of academic and industry expertise. Linking molecular pathology at the cellular level with biological systems impact and in-depth phenotyping of outcomes, will powerfully enable new therapeutics development.
Conclusions:
UKDP brings many opportunities for accelerating dementia research and the development of new treatments and welcomes collaborative proposals.

[3]Clinical Sciences Division of Diagnostic Radiology, Skåne Unviversity Hospital, Lund, Sweden

[4]Clinical Sciences Clinical Memory Research Unit, Skåne Unviversity Hospital, Malmö, Sweden

Objectives

Chronic brain hypoperfusion has been suggested to play a causative role in the development of beta-amyloid deposition in Alzheimer's disease.

We hypothesize that cerebral hypoperfusion due to a unilateral internal carotid artery (ICA) occlusion may increase beta-amyloid deposition in the affected regions.

Methods

We plan to include 10 non-demented patients with unilateral ICA occlusion, or other asymmetric vascular pathology on an atherosclerotic basis and 5 patients with occlusion due to ICA arterial dissection. Major brain infarction on the affected side is an exclusion criterion. The patients will undergo clinical assessment, neuropsychological testing, brain MRI including: structural MRI sequences, MR-angiography, MR-perfusion, and 18F-Flutemetamol-PET. Based on MR perfusion sequences cortical ROIs will be evaluated for 18F-Flutemetamol binding. A contralateral, normally perfused, region will be used as an internal control for amyloid deposition.

Results

So far 7 patients have been recruited (4 right ICA, 2 left ICA, and one with bilateral occlusions and a 50% left middle cerebral artery-stenosis). Age ranges from 51-77 years, MMSE 27-30. Atherosclerotic cardiovascular disease, smoking and hypertension are the causes for vessel occlusion in the patients recruited so far. In one patient radiation due to ear-nose-and throat carcinoma is a probable contributor to vessel occlusion.

Conclusions

We have designed a small scale study to address the hypothesis that cerebral hypoperfusion may cause beta-amyloid deposition. Recruitment is currently ongoing. MRI and PET data will be presented at the meeting.

[3]-, Roche, Basel, Switzerland
[4]ICM, Hôpital de la Pitié-Salpêtrière, Paris, France
[5]MIRCen/ URA CEA-CNRS 2210, CNRS, Fontenay aux Roses, France

Objective: Few methods have been developed to detect amyloid plaques by MRI but they always required an invasive process to open the blood brain barrier (BBB). Camelids heavy chain only antibody fragments (VHH), because of their small size and their basic isoelectric point, can cross the BBB. Hence, in order to detect amyloid plaques by MRI, we developed anti-Abeta VHHs. Alexa-Fluor488 or Gadolinium (Gd) were conjugated to VHHs and the resulting contrast agents were evaluated by multi-photon imaging or MRI.
Methods: Experiments were performed on PS2APP mice with VHH conjugates. *In vivo* multi-photon experiments were realized after intravenous injections of VHH-AlexaFluor488. MRI acquisition were recorded following three different protocols 1) *in vitro* incubation of the brain with VHH-DOTA/Gd overnight 2) *in vivo* injection followed by post-mortem imaging, 3) Gd-staining, a reference technique to reveal amyloid plaques by soaking the brain in a Gd-solution.
Results: Live multi-photon imaging showed gradual extravasation of the fluorescent VHHs from blood vessels and penetration in brain parenchyma with an exquisite tropism for amyloid plaques. MR images obtained after *in vitro* incubation or *in vivo* administration with VHH-DOTA/Gd showed numerous hypointense spots in the cortex. Several hypointense spots were colocalised with amyloid plaques revealed by the reference technique of Gd-staining.
Conclusion: VHHs cross the BBB, label amyloid plaques *in vivo* and can be detected by MRI following conjugation with a contrast agent. VHHs thus appear as promising tools with translational value for *in vivo* detection of amyloid deposits by MRI.

Background: Early-onset Alzheimer's disease (EOAD) has a different pathologic burden and clinical features compared with late-onset Alzheimer's disease (LOAD). We examined the effects of age-at-onset on the burden and distribution of β-amyloid in patients with EOAD in whom well-characterized mutations associated with Alzheimer's disease (AD) were absent. **Methods:** We genotyped *ApoE, APP, PSEN1* and *PSEN2* in 23 patients with AD; after application of exclusion criteria, our study contained 9 patients with EOAD (age < 65), 11 with LOAD (age > 70), and 8 normal controls (NCs), all of whom had undergone ^{11}C- labeled Pittsburgh compound B (PiB)-positron emission tomography (PET) imaging. Statistical parametric mapping (SPM) analysis was used to compare distributions of PiB deposition in three groups. **Results:** Patients with EOAD exhibited a similar topographical distribution of PiB deposition compared with patients with LOAD; however, patients with EOAD exhibited higher z-scores and larger cluster sizes. Furthermore, patients with EOAD retained higher levels of PiB in the bilateral thalamus and in some parts of the globus pallidus, compared with patients with LOAD ($p < 0.05$, FDR). **Conclusion:** Distribution of amyloid deposition in EOAD outside the context of genetic mutations differs topographically from that in LOAD, a finding that is consistent with a previous study on familial EOAD.

A BIOMARKER PANEL TOWARDS THE EARLY DIAGNOSIS, PREDICTION AND MONITORING OF ALZHEIMER'S DISEASE: AUSTRALIAN IMAGING BIOMARKERS AND LIFESTYLE STUDY OF AGING COHORT

V. Gupta[1], S. Pedrini[1], E. Hone[1], J. Doecke[1], R. Martins[1], A.I.B.L. Research Group[1]
[1]School of Medical Sciences, Edith Cowan University, Perth, Australia

Objectives: To study Alzheimer's disease (AD) related changes in the peripheral body fluids such as blood plasma.
Methods: Mesoscale Discovery platform was utilised to measure protein biomarkers in plasma of Australian Imaging Biomarkers lifestyle (AIBL) study of aging cohort. The biomarkers tested belonged to endocrine, vascular injury, inflammatory, coagulation cascade, apoptotic and lipoprotein pathways consisting of a 4-plex, 5-plex and a 6-plex. Generalized Linear model (GLM) was used to assess the potential of these proteins as biomarkers for AD.
Results: GLM results show that biomarkers such as Thrombopoietin (TPO), Fatty acid Binding protein 3 (FABP3), Pancreatic polypeptide Y (PPY), chemokine 309 (I309), soluble vascular cell adhesion molecule (sVCAM), beta 2 microglobulin (B2M), adiponectin and apolipoprotein J differ significantly between healthy controls (HC) and AD patients ($p<0.005$). Biomarkers such as FABP3, sVCAM, B2M, adiponectin and apoJ specifically differentiate between HC and Mild cognitively impaired (MCI) participants ($p<0.05$), however only I309 was able to differentiate between MCI and AD patients ($p=0.001$). We also classified participants based on their progression towards the severity of the disease into non-transition and transitional categories and found that markers such as TPO, FABP3, PPY, I309, sVCAM and adiponectin significantly differentiate between non-transition and transitional categories ($p<0.005$). These biomarkers also showed a significant correlation with the brain amyloid beta deposition obtained from brain imaging using Positron Emission tomography. **Conclusion:** The findings from this study suggest that these set of biomarkers could be used to assess cognitive decline and monitor changes in periphery during the progression of the AD.

CATIONIZATION OF AN ABETA PROTOFIBRIL SELECTIVE ANTIBODY FRAGMENT INCREASES BRAIN UPTAKE IN APP TRANSGENIC MICE

S. Syvänen[1], D. Edén[1], C. Möller[2], L. Lannnfelt[1], D. Sehlin[1]

[2]Bioarctic Neuroscience AB, Bioarctic Neuroscience AB, Stockholm, Sweden

Objectives: Antibodies and antibody fragments are, because of high selectivity for their targets, considered as potential therapeutics and biomarkers for several neurological disorders including Alzheimer's disease. However, due to their large molecular size, antibodies/fragments do not easily penetrate the blood-brain-barrier. The aim of the present study was to improve the brain uptake of an Abeta protofibril selective $F(ab')_2$ fragment ($F(ab')_2$-158) via adsorptive-mediated transcytosis to be used as a radioligand.
Methods: $F(ab')_2$-158 fragment was cationized to different extents with the polyamine putrescine and its specific and unspecific binding was studied with ELISA. Next, cationized $F(ab')_2$-158 was labelled with ^{125}I and its brain distribution and pharmacokinetics was studied in wild type and APP transgenic mice (tg-ArcSwe) with single-photon emission computed tomography (SPECT) imaging.
Results: Cationization did not alter the *in vitro* binding to amyloid-beta protofibrils, but increased the unspecific binding somewhat. *Ex vivo* experiments revealed a doubling of brain concentrations compared to unmodified $F(ab')_2$-158 and *in vivo* SPECT imaging showed that the cationized $F(ab')_2$-158, but not the unmodified $F(ab')_2$-158 could be visualized in the brain.
Conclusions: To conclude, cationization is a means to increase brain concentrations of antibodies or antibody fragments and may enable their use as imaging biomarkers in the brain.

TRANSFERRIN RECEPTOR MEDIATED TRANSCYTOSIS OF AN ANTIBODY BASED PET RADIOLIGAND FOR IN VIVO QUANTIFICATION OF SOLUBLE ABETA AGGREGATES

D. Sehlin[1], X.T. Fang[1], L.M. Cato[1], G. Hultqvist[1], G. Atoni[2], J. Fälting[3], L. Lannnfelt[1], S. Syvänen[1]

[2]Medicinal Chemistry Preclinical PET Platform, Uppsala University, Uppsala, Sweden
[3]Immunology and Pharmacology, Bioarctic Neuroscience AB, Stockholm, Sweden

Objectives: Positron emission tomography (PET) [^{11}C]PIB imaging detects amyloid plaques formed early in the Alzheimer's disease (AD) pathogenesis. However, plaque pathology does not correlate well with disease progression or outcome of therapeutic interventions. This project aims to develop a PET radioligand based on an antibody (mAb158) that binds selectively to soluble Abeta protofibrils, which may correlate better with disease severity than amyloid plaques. Brain uptake of the antibody was increased with transferrin receptor (TfR) mediated transcytosis (Figure).

Methods: A F(ab')$_2$ fragment of mAb158 was chemically fused with a TfR antibody (8D3) and the fusion protein was analyzed with ELISA for retained binding to Abeta and TfR. Brain uptake of ^{125}I radiolabelled fusion protein was studied *ex vivo* in wild type and APP transgenic (tg-ArcSwe) mice and correlated to brain levels of Abeta protofibrils. Brain distribution of ^{124}I labelled fusion protein was studied with PET.

Results: The fusion protein had retained binding properties and displayed a near ten-fold higher brain uptake compared to F(ab')$_2$-158 three days post injection. Brain retention increased with age, correlating closely with brain levels of soluble Abeta protofibrils and a clear difference between tg-ArcSwe and wt mice was seen with PET.

Conclusions: This fusion protein has the potential to become an important tool for *in vivo* PET-imaging of soluble Abeta aggregates in AD patients.

[5]Department of Health Sciences, University of Milano-Bicocca, Milano, Italy

Objectives

Our aim was to evaluate novel functionalized ^{18}F-labelled nanoliposomes (NLs) as PET imaging agents. The NLs were tailored for Alzheimer's disease treatment by functionalization with phosphatidic acid alone (PA-^{18}F-NL) or with an additional peptide derived from Apolipoprotein-E receptor-binding domain (PA-mApoE-^{18}F-NL).

Methods

Pharmacokinetic properties of ^{18}F-NLs were studied in FVB/N mice with dynamic 60 min PET/CT scans and the results were verified with ex vivo tissue counting at 15, 60 and 90 min after ^{18}F-NL injection. Brain uptake and distribution was evaluated from coronal cryosections at 15 and 60 min using digital autoradiography. ^{18}F-NL binding to beta-amyloid deposits was studied in transgenic APP23 mice at 60 min with methods mentioned above.

Results

PA-^{18}F-NL and PA-mApoE-^{18}F-NL had different distribution in mice; 90 min after PA-^{18}F-NL injection high ^{18}F-radioactivity was seen in blood, spleen and liver. Additional mApoE functionalization resulted in 7-fold decrease in mean blood ^{18}F-radioactivity and in 2-, 4- and 70-fold increase in mean ^{18}F-radioactivity in spleen, liver and lungs. Total brain uptake at 90 min was low with PA-^{18}F-NL and PA-mApoE-^{18}F-NL and brain-to-blood -ratios were 0.02 and 0.05, respectively. High ^{18}F-radioactivity "hot spots" were seen in APP23 brain tissue autoradiographs, however, no co-localization with thioflavin stained beta-amyloid deposits was observed.

Conclusions

PA-^{18}F-NLs and PA-mApoE-^{18}F-NLs had different biodistribution in mice. Brain uptake of both functionalized ^{18}F-NLs was low but additional mApoE functionalization increased the brain-to-blood –ratio. Specific binding to beta-amyloid was not detected at 90 min.

The research received funding from the European Community's 7th framework Programme (FP7/2007-2013, nº212043).

Center for Radiopharmaceutical Sciences of ETH-PSI-
USZ Institute of Pharmaceutical Sciences ETH Zurich, Zurich, Switzerland

Objective:

Alterations in cerebral glucose metabolism and blood flow were consistently described in individuals at risk of Alzheimer's disease (AD), e.g.: Apo-E-epsilon-4-allele carriers, family history of AD or amnestic MCI. Early regional [11C]-PiB-uptake (0-6 minutes; ePiB) estimates regional cerebral blood flow (rCBF) while late [11C]-PiB-uptake measures cerebral beta-amyloid deposition. We made use of both signals in a dynamic PET study in elderly subjects without cognitive impairment (HCS) and patients with mild cognitive impairment (MCI). **Methods:**

Dynamic 11-C-PiB-PET early and late frame measurements in MCI (n=23) HCS (n=85) in six bilateral volumes of interest: posterior cingulate (PCC), hippocampus (Hip.), temporoparietal region (TR), superior parietal (SPG), parahippocampal (Parahip.) and inferior frontal gyrus (IFG).

Results:

13 MCI and 11 HCS were classified PiB-positive. Subjects with MCI showed lower ePiB signal as compared to HCS in the following regions: left PCC (p<0.001), left IFG (p<0.001), left (p<0.001) and right Hip ($p=0.004$). Effects were strongest in MCI above the age of 70 years with high cortical PiB binding.

We observed no difference in rCBF in the total population between PiB-positive and PiB-negative subjects. There was a moderate negative correlation of ePiB with age in bilateral SPG (p=0.004), bilateral TR (p=0.007), right IFG (p=0.003), right PCC (p=0.004) and left Parahip. (p=0.001) in PiB positive subjects but not in the PiB-negative group.

Conclusions:

rCBF apparently declines with age in the presence of AD pathology and contributes to cognitive impairment. On the other hand, normal CBF in amyloid negative subjects may be a characteristic feature of healthy aging.

[7]Department of Neurology, University of Eastern Finland, Kuopio, Finland

Background: FINGER study is a randomized 2-year multidomain lifestyle intervention study in subjects at increased risk of cognitive decline.[1,2] A sub-group of the study population participate in a PET study to investigate brain metabolism and amyloid deposition at baseline and at the end of intervention. At present, data from the baseline [11C]PIB scans is available and the association of PIB data to baseline characteristics and cognition are reported.
Methods: 48 elderly subjects underwent a [11C]PIB PET scan, brain MRI and neuropsychological examination. Subjects were divided into two groups (PIB+ and PIB-) based on a visual PET scan analysis. Hippocampal atrophy and brain vascular changes were visually graded according to Scheltens and Fazekas scores. Between-groups differences in the cognitive function were analyzed.
Results: Twenty subjects (42%) were PIB positive. PIB- group performed better in executive functions than PIB+ group (Z-score difference p = 0.02). PIB+ group showed a trend to higher amount of white matter lesions and hippocampal atrophy (Fazekas score 2-3: 50% in PIB+ vs. 29% in PIB-; Scheltens score 1-3: 40% right, 45% left in PIB+ vs. 29% and 21% in PIB-).
Conclusions: The high percentage of PIB positive subjects provides evidence of a successful recruitment process of the at-risk population in the FINGER trial. The results suggest an association between early brain amyloid accumulation and decline in executive functions, as well as a trend of increased vascular changes and hippocampal atrophy in amyloid positive subjects.

[5]Food and Nutrition Flagship, CSIRO, Melbourne, Australia
[6]National Ageing Research, Institute, Melbourne, Australia
[7]The Florey Institute, University of Melbourne, Melbourne, Australia

Objectives: We investigated if longitudinal Aβ imaging with ^{18}F-flutemetamol (Flute) PET can show change over time in Aβ burden as previously shown with ^{11}C-PiB in non-demented participants in the AIBL study .
Methods: Flute-PET was performed in 187 non-demented AIBL volunteers who had not previously had Aβ imaging, 50 with Mild Cognitive Impairment (MCI; 74.5±5.7 yo) and 137 healthy controls (HC; 74.5±5.6 yo). To date, a repeat scan at 18 months has been obtained in 76 participants. SUVR was calculated using the pons as reference region. Change was expressed as the yearly SUVR %change from baseline.
Results: At baseline, 54% of MCI and 23% of HC showed high Flute retention. At 18-month follow-up, increases in Flute SUVR were observed in 38/68 (56%) of HC and 6/7 (86%) of MCI. The increase for the whole cohort (accumulators & non-accumulators) was 1.8% (P=0.06). The prevalence of Aβ accumulators was similar in those HC who presented with either high or low Aβ burden at baseline (60% and 56%, respectively). The average change for Aβ accumulators was 2.6% per year, the same as we have reported for PiB accumulators. SUVR %change was the same for HC and MCI. Finally, despite presenting with an almost 40% greater prevalence of positive scans, the differences between HC accumulators with and without memory complaints were not significant.
Conclusions: With a relatively small sample size, there is a clear trend for an increase in Flute binding over time, similar to that observed with PiB in another AIBL cohort. Follow-up data collection continues.

[2]Maastro Clinic, MUMC+, Maastricht, Netherlands
[3]Department of Nuclear Medicine, MUMC+, Maastricht, Netherlands
[4]Nuclear Medicine and PET Research, VU University Medical Centre, Amsterdam, Netherlands

Background: Recent advances in PET imaging tracers have provided means to diagnose AD patients, but still have drawbacks such as a short half-life, and misdiagnosis. Our results show that it might be feasible to use antibodies as a diagnostic tool.
Methods: Bapineuzumab (hu-IgG1) or isotype controls were labeled with ^{89}Zr. 100 µg antibody (3.7 MBq) was injected intraperitoneally in 5xFAD or wild type (WT) littermate controls. Mice were subsequently scanned for 0.5 hour using a microPET over a period of up to 10 days. Activity in brain was measured using a gammacounter, and autoradiography of brain slices was performed for validation of the PET imaging data.
Results: 1 day after injection a specific binding could already be detected in 5xFAD mice injected with bapineuzumab. The signals remained stable over a period of 10 days. No difference between 5xFAD and WT animals was found in the isotype control group. While difference between 5xFAD and WT animals could readily be detected at 6 months of age, this difference increased at 9 months of age.
Conclusion: This study shows the first proof of principle that anti-Aβ antibodies accumulate in the brain in vivo, and this within one day after injection using PET. The longer half-life of ^{89}Zr compared to other isotopes also allows this method to be used in more clinics around the world for diagnosis of AD. Furthermore, this new technique holds great promise for the further study of AD, by using for instance antibodies directed against different forms of Aβ.

[18F]FLORBETABEN-PET IMAGING IN CLINICAL ROUTINE CASES – BENEFIT OF EARLY ACQUISITION

A. Rominger[1], S. Daerr[1], M. Brendel[1], D. Oestreicher[1], C. Zach[1], M. Patt[2], A. Danek[3], H. Barthel[2], O. Sabri[2], P. Bartenstein[1]

[1]Dept. of Nuclear Medicine, University of Munich, München, Germany

[2]Dept. of Nuclear Medicine, University of Leipzig, Leipzig, Germany

[3]Dept. of Neurology, University of Munich, München, Germany

Objectives

In the last few years [^{18}F]-labelled amyloid PET radiotracers have been developed and recently received clinical approval. We now report on our experience with a heterogenous patient cohort undergoing [^{18}F]Florbetaben (FBB) PET. A major goal was to investigate the benefit of additionally performed early post injection acquisition of the FBB-PET.

Methods

All subjects for amyloid imaging were recruited in a clinical setting. Aside from undergoing a detailed neuropsychiatric test battery, collection of biomarkers (MRI, CSF, FDG-PET) was performed as well. Furthermore 300 MBq [^{18}F]Florbetaben were injected i.v. and PET scans were routinely acquired 90 min p.i., and an early acquisition starting just after injection was performed in a subset of patients.

Results

A total of 89 patients (mean age 70.1 ± 9.5y) were scanned. In a subset of 40 patients an early acquisition of the FBB-PET could be performed, in 35/40 patients the individual FDG-PET was available. In 12/35 cases the regularly acquired amyloid PET was read negative. When the early acquired FBB-PET was assessed in 3D-SSP and compared to a normative database, the visual interpretation resembled the interpretation of the individual FDG-PETs, irrespective of the amyloid-status of the late FBB-scans.

Conclusions

We report on the clinical use of Florbetaben-PET in a non-selected patient cohort. Early [^{18}F]Florbetaben acquisitions closely resembled FDG-PET characteristics. These findings need to be further investigated in a larger patient cohort but could potentially substitute an additional FDG-PET scan in the future.

[4]Deparment of Psychiatry,

Hospital Universitari Vall d'Hebron. CIBERSAM. Universitat Autònoma de Barcelona, Barcelona, Spain

Objectives: To assess the usefulness of cognitive function composites (CFC) to discriminate between healthy aging, non-Alzheimer's Mild Cognitive Impairment (MCI), and prodromal Alzheimer's disease (AD).

Methods: A sample of 59 subjects, > 64 years old, recruited from Recercalia project, divided in 39 healthy controls (HC) (20 men; 19 women) and 20 amnestic mild cognitive impairment (aMCI)(12 man; 8 woman) with storage memory impairment, and without comorbidities that could explain their cognitive impairment. All subjects received an extensive neuropsychological assessment, including CFC sensitive to: language, memory, praxis, visual gnosis and executive functions. A PET-PIB scanner, was administered at baseline, and subjects were divided in PiB+ or PiB- with a cutoff value of PIB=1.5, that is, HC+(n= 2), HC- (n=37), aMCI+ (n=12), aMCI- (n=8). The HC+ group was excluded from the analysis due to the sample size.

Results: Verbal delayed recall on memory, executive and language CFCs showed as the highest values to discriminate between, HC-, aMCI- and aMCI+ groups. Verbal learning and recognition on memory CFC did significantly discriminate between HC and aMCI whole groups, but not between aMCI+ or aMCI- groups. Although some differences could be appreciated between all three groups on visual gnosis and praxis CFCs , they were not enough discriminative.

Conclusions: A brief neuropsychological battery comprising tests sensitive to fronto-temporal functions, such as memory, language and executive functions may be useful to discriminate between healthy aging, non-AD MCI and prodomal AD, as PET-PiB measurements and applied CFCs showed.

METABOLOMIC CORRELATES OF AMYLOID-BETA RELATED COGNITIVE DECLINE IN NON-DEMENTED ELDERLY SUBJECTS
P.G. Unschuld[1], A. Gietl[1], S. Spoerri[1], A. Kaelin[1], L. Kulic[1], S. Leh[1], S.J. Schreiner[1], J.M. van Bergen[1], A. Buck[2], R.M. Nitsch[1], C. Hock[1]
[1]Division of Psychiatry Research and Psychogeriatric Medicine, University of Zurich, Zurich, Switzerland
[2]Division of Nuclear Medicine, University of Zurich, Zurich, Switzerland
Background: The current study aims to investigate whether information embedded in the peripheral metabolome may be used for inferences on Amyloid-beta (A-beta) deposition associated cognitive decline in non-demented elderly subjects.
Methods: 115 non-demented elderly subjects were randomly split into a discovery (n=58) and replication sample (n=57). Regional extent of A-beta-deposition was measured non-invasively by Pittsburgh Compound-B amyloid imaging (PiB-PET). Blood was drawn for metabolomic assessment (Biocrates Absolute-IDQ P180 Assay). Learning and memory performance over time was assessed by performing neuropsychological testing at two time points. After preprocessing and quality control, metabolites were administered to a multivariate analysis, including independent component analysis (ICA) based linear model building in the discovery sample and validation of predictive precision in the replication sample.
Results: 139 Metabolites representing 33 amino acids, biogenic amines and hexoses, 11 Acylcarnitines, 11 Lysophophosphatidylcholines, 70 Phosphatidylcholines, 14 Sphingomyelins could be quantified at high quality and attributed to 15 independent components by using ICA-decomposition. By applying a stepwise-regression linear fit algorithm (MatLab V8.4, statistics toolbox V9.1), a linear model for cognitive decline in association with high A-beta-plaque density could be identified for the discovery sample and replicated with >75% predictive accuracy in the second sample (coefficients of determination: r2 sample#1=0.57; r2 sample#2=0.50). Major predictive weights resulted for measures derived from the Phosphatidylcholine group.
Discussion: Our data indicate that A-beta associated cognitive decline in the elderly is associated with specific patterns of peripheral metabolomic measures, which may be used for stratification of prospective A-beta-targeted early interventional clinical trials.

ADPD5-2118
AMYLOID PET-POSITIVE, POSTERIOR VARIANT ALZHEIMER'S DISEASE
C. Wu[1]
[1]*Neurology, Texas Tech University Health Sciences Center, Lubbock, USA*
Objectives:The causes of posterior cortical atrophy (PCA) are diverse. A portion of PCA patients have underlying Alzheimer's pathology. Since 2012, an amyloid tracer has been first utilized in USA to clarify Alzheimer's diagnosis in patients with atypical presentation. In this study, patients with PCA according to the diagnostic criteria are investigated based on the positive findings of the amyloid PET. **Methods**: The medical records of PCA patients followed at a specialty clinic from January 1st 2011 to December 31st 2014 were collected and reviewed. Five PCA patients were diagnosed with probable Alzheimer's disease based on the amyloid PET study. Clinical features, neuroimaging findings and their impression with the PET study would be reported. **Results**: One man (age 64) and four women (age 54, 58, 60, 77) all took about two years before the diagnosis of PCA was made. They previously had been wrongly diagnosed with either a refraction disorder or anxiety, despite progressive visuospatial symptoms. The 77-year-old woman even became "blind" and displayed visual hallucinations. One man and three women exhibited marked cortical atrophy of bilateral parietal lobes in brain MRI studies. One woman had reduced metabolism of parieto-occipital regions shown by the FDG PET. Interestingly, the amyloid PET study demonstrated cortical deposition of neuritic plaques prominently in both frontal and temporal lobes. All patients received standard treatments. The fact that the amyloid PET would provide a certain diagnosis satisfied all patients and their family members. **Conclusions**: The amyloid PET can definitely enhance clinicians' ability to treat patients properly.

Comparison of clinical diagnosis and biomarker constellation in AD in a clinical setting

H.J. Gertz[1], D. Weise[1,2], S. Tiepolt[3], C. Awissus[1], K.T. Hoffmann[4], D. Lobsien[4], T. Kaiser[5], H. Barthel[3], O. Sabri[3]
[1]Department of Psychiatry, University of Leipzig, Leipzig, Germany
[2]Department of Neurology, University of Leipzig, Leipzig, Germany
[3]Department of Nuclear Medicine, University of Leipzig, Leipzig, Germany
[4]Department of Neuroradiology, University of Leipzig, Liebigstr. 20, 04103 Leipzig, Germany
[5]Tel. +49-341-97-17410 Institute of Laboratory Medicine,
Clinical Chemistry and Molecular Diagnostics, University of Leipzig, Leipzig, Germany

Objectives: The diagnosis of Alzheimer's disease (AD) can be made with reasonable accuracy using neuropsychological assessment and MRI. CSF and PET biomarkers have been incorporated in diagnostic criteria for AD. The biomarker results are thought to confirm or exclude the diagnosis of AD.
Methods: A cross-sectional observational study of 54 (mean age 72.1 ± 7.8y, 23 women) patients. Without knowledge of biomarker results 40 cases were diagnosed as AD, 14 cases as non AD. As biomarkers tau and Aβ 1-42 concentrations in the CSF and amyloid-targeting PET using either Pittsburgh Compound-B ([11C]PIB, n=25) or Florbetaben ([18F]FBB, n=29) were used.
Results: Four biomarker constellations were observed: 1. Completely congruent biomarkers (pathological/non-pathological), 2. at least one pathological degeneration and one pathological Aß marker, 3. at least one pathological Aß (CSF and/or PET), but normal degeneration marker (MTA and CSF), 4. pathological degeneration (MTA and/or tau), but no pathological Aß marker (CSF and PET). The percentage of inconsistent findings was high. In only one third of cases AD diagnosis was fully confirmed. In a minority of cases it seemed justified to switch the clinical diagnosis due to biomarker interpretation.
Conclusions: Biomarkers are no simple support or confirmation of the diagnosis of AD. Interpretation of AD biomarkers is complicated by multiple biomarker constellations. They may reflect different aspects of the pathological process. The design of this study does not allow to address the question of diagnostic accuracy since no gold standard in terms of neuropathological verification is available.

18F-FDG PET IN EARLY DIAGNOSIS OF ALZHEIMER'S DISEASE

I. Lupanov[1], V. Lobzin[1], A. Emelin[1], I. Boykov[2]
[1]nervous diseases, Military-medical academy n.a. S.M. Kirov, St-Petersburg, Russia
[2]radiology, Military-medical academy n.a. S.M. Kirov, St-Petersburg, Russia

Investigation of the possibilities of functional neuroimagingin early diagnostics of cognitive impairment is one of the most actualdirections in neurology.
The aim was to investigate the cerebral metabolism inpatients with amnestic MCI type (aMCI) and Alzheimer's disease (AD) using18F-FDG PET.
The study involved 18 persons aged 64 to 76 years withaMCI, and 9 persons with non-amnestic MCI matched by age as a control group (6persons without cognitive decline). Evaluation of cognitive status wasconducted using a set of validated neuropsychological tests.
Analysis of the results showed that aMCI group wascharacterized by the formation of zones of bilateral hypometabolism in thefrontal, parietal and temporal regions, in cingulate cortex and hippocampuswith prevalence in the dominant hemisphere. The most expressed decrease inmetabolism was determined in the hippocampal and parietal-temporal regions.With progression joined violations in the orbitofrontal cortex. However, one ofthe earliest domain involved in the pathological process in patients with aMCIwas the posterior cingulate cortex. When comparing with the results ofneuropsychological assessment it was revealed a relationship between theseverity of hypometabolism in hippocampal, parietal-temporal regions, posteriorcingulate cortex and the results of verbal memory tests. These results are consistentwith the identified pattern of metabolic disorders and literature data on thepathological changes in the brain (including amyloid deposits) in AD.
Thus, the use of18F-FDG PET in clinical practice can significantly improve early diagnosticaccuracy of AD.

Objectives: It is generally assumed that cognitive reserve can compensate for cerebral changes in prodromal Alzheimer´s disease (AD) and mild AD. Therefore we compared cerebral changes between patients with a low vs. high cognitive reserve who consulted our memory clinic.

Methods: Up to now 22 patients with prodromal AD (mean age: 72.30; SD: 6.85), 17 patients with mild AD (mean age: 74.06; SD: 5.51) and 8 cognitive normal controls (mean age: 67.38; SD: 6.48) were included. Years of school education were used as a proxy for cognitive reserve and the Mini Mental State Examination (MMSE) was applied. ^{18}F-fluoro-deoxy-glucose positron emission tomography (FDG-PET) scans were analyzed by using SPM8. In the low vs. high cognitive reserve comparison MMSE scores were entered as a covariate.

Results: When contrasted with the controls the prodromal AD patients presented a significantly reduced glucose uptake in the posterior cingulate and the middle frontal gyrus. Within the prodromal AD group, patients with a high cognitive reserve showed a significantly lower glucose uptake in the right frontal and inferior parietal lobe, the posterior cingulum and the middle occipital gyrus than those with a low reserve. Similar differences were found between mild AD patients with a high vs. a low cognitive reserve.

Conclusions: The results of our ongoing study support the hypothesis that cognitive reserve can compensate brain changes in both prodromal and mild AD. This mechanism should be considered in clinical practise especially when establishing clinical diagnosis in ambiguous cases.

BILINGUALISM AS A CONTRIBUTOR TO COGNITIVE RESERVE? EVIDENCE FROM CEREBRAL GLUCOSE METABOLISM IN MILD COGNITIVE IMPAIRMENT AND ALZHEIMER`S DISEASE

M.E. Kowoll[1], *A. Küntzelmann*[2], *J. Schröder*[3]
[1]*Section for Geriatric Psychiatry, University of Heidelberg, Heidelberg, Germany*
[2]*Department of Psychiatry and Psychotherapy, University Hospital Leipzig, Leipzig, Germany*
[3]*Section for Geriatric Psychiatry/Institute for Gerontology, University of Heidelberg, Heidelberg, Germany*

Background
Growing epidemiological evidence suggests that bilingualism could be one factor contributing to 'cognitive reserve' (CR) (e.g. Bialystok et al., 2014). Therefore we analysed differences in cerebral glucose metabolism between bilinguals and monolinguals with mild cognitive impairment (MCI) and Alzheimer´s disease (AD) using [^{18}F]fluorodeoxyglucose (FDG) positron emission tomography (PET) under a resting condition.
Methods
30 patients (73.1 ± 7.4) with a diagnosis of MCI or probable AD received a physical examination, neuropsychological assessment, blood tests and a FDG-PET scan. 16 patients were classified as lifelong bilinguals following the criterion of Bialystok et al. (2007); groups were matched for age, gender and MMSE scores. SPM 8 was used for analyses utilising the whole brain as a reference region for intensity normalization and years of education as covariate.
Results
Compared to the monolingual patients, bilinguals with MCI and AD showed a substantially greater impairment of glucose uptake in frontotemporal and parietal regions (including Brodmann areas 9, 47, 40 and 21) and in the left cerebellum.
Conclusions
According to our findings bilingualism appears to increase the CR since the bilingual patients presented more severe brain changes than the monolinguals. The latter did not only comprise Brodmann areas relevant to speech and language but also structures typically involved in AD such as the temporal and the parietal cortex.

[5]Departement of Nuclear Medicine, University of Heidelberg, Heidelberg, Germany
[6]Department of Psychiatry and Psychotherapy and LIFE - Leipzig Research Center for Civilisation Diseases, University Hospital Leibzig, Leibzig, Germany

Objectives: Theory of Mind (ToM), the attribution of mental states to oneself and others interferes with cognitive decline, however, neuroimaging studies with regard to ToM are scarce. Therefore we presented first- and second-order-false-belief-tasks based on the concept of the bands-aid-task (Carlson & Moses, 2001) to patients with prodromal and mild AD of our memory clinic and compared their 18F-fluoro-deoxy-glucose positron emission tomography (FDG-PET) findings.
Methods: Up to now 27 AD patients and 8 cognitive normal controls were included. The patient group was splitted according to their results in the ToM-tasks. 11 patients with a deficit of ToM (mean age: 74.5; SD: 5.3), 16 patients with preserved ToM ability (mean age: 72.3; SD: 5.6) and 8 cognitive normal controls (mean age: 67.38; SD: 6.48) were compared with each other. FDG-PET scans were analyzed by using SPM8. In the ToM comparison MMSE scores were entered as a covariate.
Results: When contrasted with the controls the patients with prodromal and mild AD showed a bilaterally reduced glucose uptake in the superior and the right middle frontal gyrus and the precuneus. Patients with a preserved ToM presented a significantly higher glucose uptake in the cerebellum, the right superior temporal and the left cingulate gyrus than those with an absent ToM-ability.
Conclusions: The results of our ongoing study demonstrate that ToM in patients with prodromal and mild AD corresponds to cerebellar, temporal and cingulate brain regions. From a clinical perspective these deficits should be considered in the evaluation of patients with prodromal and mild AD.

ADPD5-1539

A NEW LOOK AT FDG PET LONGITUDINAL ANALYSES IN ALZHEIMER'S STUDIES USING A FREESURFER NATIVE SPACE METHOD

G. Klein[1], M. Sampat[1], D. Staewen[1], D. Scott[1], S. Landau[2], J. Suhy[1]
[1]Neuroscience, BioClinica Inc., Newark, USA
[2]Helen Wills Neuroscience Institute, University of California, Berkeley, USA

Objectives: We compare results of standard uptake value ratio (SUVR) analyses in the Alzheimer's Disease population using a native space compared to an SPM template method. While an SPM approach has shown metabolic differences between normal and AD subjects, the smoothing and deformable registration used for alignment may sacrifice information otherwise retained in a native space approach.
Methods: Freesurfer was used to obtain an ROI parcellation on T1 MRI data from 458 subjects (175 Normal, 92 EMCI, 153 LMCI, 39AD). FDG-PET data from two time points approximately 24 months apart were registered to the MRI data in T1 native space, and SUVR's were computed for 110 subregions. Eight reference regions including whole cerebellum and brainstem were evaluated. SUVR's were also computed in template space using SPM and a 'Meta-ROI' composite approach. Effect sizes between AD and Normal groups were evaluated using Cohen's d. Longitudinal change in SUVR was also compared.
Results: The native space approach showed largest differences between AD and normals in regions traditionally seen to be hypometabolic, including the precuneus and cingulate. Unique to the native space approach is that hippocampal regions also showed a very large effect size. Effects were largest using the whole cerebellum reference region. In a longitudinal analysis, the composite measure showed similar effect size but less variability than the template-based approach.
Conclusions: A native space approach shows promise in providing improved regional differentiation between normal and AD groups, and possibly reduced sample size requirements in clinical trials.

ADPD5-1804

EVALUATION OF THE CLINICAL VALUE OF FDG-PET IN MEMORY ASSESSMENT IN A TERTIARY CARE CENTER

E. Thalme[1], I. Savitcheva[2], A. Nordberg[3]
[1]Department of Geriatrics, Karolinska University Hospital, Stockholm, Sweden
[2]Department of Radiology, Karolinska University Hospital, Stockholm, Sweden
[3]Department of Neurobiology Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden

Objective: to investigate the usage and clinical value of FDG-PET in assessment of mild cognitive decline in a memory clinic. **Methods**: Patients were referred for cognitive symptoms and had undergone routine memory assessment including neurological examination, blood analysis (including APOE genotyping), CT or MRI imaging, CSF biomarker analysis and neuropsychological testing. When the diagnosis was uncertain PET-FDG was used. Regional SUVs and z-scores were extracted from the PET-FDG images. **Results**: Two hundred twenty patients, investigated in-between November 2012 and May 2014 were included. All patients had seen a physician prior to PET-investigation, and most (174 patients), had been followed-up after PET-FDG imaging. Patients were generally young (mean age=67.5 yrs.; SD=8.7) and high-functioning (mean MMSE=24.6; SD=5.3). The most common diagnoses before PET-investigation were: MCI (28%), non-AD dementia (18%) and AD (10%). In 43% of patients the diagnosis was changed after the PET-FDG scan (34% in MCI, 53% in non-AD dementia and 6% in AD). In MCI and non-AD dementia the diagnosis was predominately (62% and 65% respectively) changed to AD. The final diagnoses were: MCI 40%, non-AD dementia 21% and AD 28%. **Conclusions**: We have yet to demonstrate causality between FDG-PET investigation and change in diagnoses, however, z-scores are still to be analysed. Nonetheless, there is a large increase in AD diagnoses following PET-FDG investigation, many of which had previously been considered MCI patients. Furthermore, the majority of non-AD dementia patients received a changed diagnosis following PET-FDG evaluation, indicating the usefulness of PET-FDG in differential diagnosis of dementia.

[3]Institute of Chemistry and Biochemistry, Université Claude Bernard Lyon 1, Lyon, France

[4]R&D, Neurolixis, Dana Point, USA

[5]CERMEP-Imaging Platform, Lyon Neuroscience Research Center, Lyon, France

Objectives. PET imaging studies using 5-HT_{1A} receptor radiotracers show a decreased density of this receptor in hippocampi of patients with Alzheimer's disease (AD) at advanced stages. However, current 5-HT_{1A} receptor radiotracers used in neuroimaging are antagonists, thought to bind to 5-HT_{1A} receptors in different functional states (i.e., both the one which displays high affinity for agonists and is thought to mediate receptor activation, as well as the state which has low affinity for agonists). Comparing the PET imaging obtained using an agonist radiotracer, which binds selectively to functional receptors, with the PET imaging obtained using an antagonist radiotracer would therefore provide original information on 5-HT_{1A} receptor impairment during AD.

Methods. Quantitative autoradiography using ^{18}F-F13640 and ^{18}F-MPPF, a 5-HT_{1A} agonist and antagonist, respectively, was measured in hippocampi of patients with AD (n=26, at different Braak's stages) and control subjects (n=10). The specific binding of both radiotracers was determined by addition of WAY-100635 and the agonist binding of ^{18}F-F13640 was revealed by addition of Gpp(NH)p.

Results. The autoradiography distribution of both 5-HT_{1A} PET radiotracers varied across hippocampus regions. The highest binding density was in the pyramidal layer of CA1. The incubation with Gpp(NH)p, a non-hydrolysable analogue of GTP, reduced significantly ^{18}F-F13640 binding, confirming its specific binding to G-coupled receptors. ^{18}F-F13640 binding compared to ^{18}F-MPPF binding revealed specific modifications of the density of functional 5-HT_{1A} correlated to the Braak's stages.

Conclusions. These in vitro results support testing the concept of functional imaging using agonist radiotracers in future clinical studies.

[3]Radiopharmaceutical Chemistry Laboratory and Accelerator Laboratory, Turku PET Centre/Åbo Akademi, Turku, Finland

[4]Turku University Hospital, Turku PET Centre/University of Turku, Turku, Finland

Objectives

Decreased cannabinoid receptor 1 (CB_1) activity has been found in *postmortem* brains of the patients of Alzheimer's disease (AD). We aimed to study changes in CB_1 expression in a transgenic mouse model of AD with [^{18}F]FMPEP-*d2*, an inverse agonist of CB_1, and longitudinal PET imaging.

Methods

In vivo binding of [^{18}F]FMPEP-*d2* was studied using the Inveon Multimodality PET/CT scanner with 30 min static PET scans 90 min after tracer injection. Transgenic (Tg) APP/PS1-21 (n= 8) and wild type control mice (WT) (n= 8) were imaged at 6, 9, and 12 months of age. [^{18}F]FMPEP-*d2* binding in the brains of Tg (n= 4) and WT (n= 4) mice was also evaluated with *ex vivo* autoradiography. Radiometabolites of [^{18}F]FMPEP-*d2* were analyzed from plasma and brain homogenates.

Results

[^{18}F]FMPEP-*d2* demonstrated high binding to the CB_1-rich areas in mouse brain. The binding was significantly ($p<0.05$) lower in Tg mice at 9 months of age than in WT mice at 7 months of age. Metabolite analyses from plasma showed three radiometabolites, of which two were more polar than the parent compound. One more polar metabolite was found in the brain tissue.

Conclusions

Our preliminary studies with Tg mice demonstrated decreased CB_1 expression in transgenic animals; however additional longitudinal studies are needed with transgenic and age-matched wild-type animals in order to further confirm these results. This study was funded by the European Community's 7th framework programme (FP7/2007-2013) under grant agreement no. HEALTH-F2-2011-278850 (INMiND).

CHROMOSOMAL DNA DAMAGE MEASURED USING THE CYTOKINESIS-BLOCK MICRONUCLEUS CYTOME ASSAY IS SIGNIFICANTLY ASSOCIATED WITH COGNITIVE IMPAIRMENT IN SOUTH AUSTRALIANS

P. Thomas[1], S. Lee[1], M. Fenech[1], J. Hecker[2], J. Faunt[3]
[1]Food and Nutrition, CSIRO, Adelaide, Australia
[2]Internal medicine, Royal Adelaide Hospital, Adelaide, Australia
[3]General medicine, Royal Adelaide Hospital, Adelaide, Australia

Objectives
Loss of genome integrity may be associated with increased risk for neurodegenerative disease. The aim of this study was to investigate whether mild cognitive impairment (MCI) or Alzheimer's disease (AD) individuals have increased DNA damage relative to age and gender matched controls using the cytokinesis block micronucleus cytome (CBMN-Cyt) assay.
Methods
DNA damage was measured as micronuclei (MNi), nucleoplasmic bridges (NPB), and nuclear buds (NBUD) in once divided lymphocytes that are recognised by their binucleate appearance. The assay was performed on blood samples from 80 participants consisting of (i) MCI cases (N=20) and age and gender matched controls (N=20), and (ii) AD cases (N=20) and age and gender matched controls (N=20).
Results
There was a significant increase in MCI NBUD frequency (P= 0.006) relative to controls, which was also observed in male (P=0.03) and female (P=0.04) subgroups. For AD cases, there were no significant differences in assay biomarkers relative to controls. There was a significant negative correlation between Mini Mental State Examination (MMSE) and (i) MNi in all controls, (R=-0.3, P= 0.04), and AD cases (R=-0.4, P=0.03), (ii) NPB in all controls, (R=-0.4, P=0.006) and AD cases (R=-0.5, P=0.01), and (iii) NBUD in MCI cases (R=-0.5, P=0.007) and AD cases (R=-0.7, P=0.0002).
Conclusion
The results suggest that an increase in lymphocyte CBMN-Cyt DNA damage biomarkers maybe associated with cognitive decline.

[3]CEA Service hospitalier Frédéric Joliot, Institut d'imagerie biomédicale, Orsay, France
[4]Orion Pharma, Orion Pharma, Turku, Finland
[5]Turku PET Centre, Turku PET Centre University of Turku, Turku, Finland

Objective
We aimed to characterize the novel TSPO binding PET tracer [^{18}F]DPA-714 for *in vivo* and *ex vivo* detection of neuroinflammation in a mouse model Alzheimer´s disease (AD).
Methods
We used the APP/PS1-21 mouse model of AD. For 60 minutes *in vivo* PET-CT scans, groups of 6 mice were imaged at the ages of (1mo, 3mo, 6mo, 9mo and 12mo) with [^{18}F]DPA-714. For the *ex vivo* brain autoradiographic study, immediately after the *in vivo* scans, the mice were killed, the brain dissected, frozen and sliced (20 µm) with a cryostat, and then apposed to an imaging plate. Immunohistochemical and histological staining for amyloid and microglial activation were performed.
Results
In vivo PET results showed increase [^{18}F]DPA-714 uptake initially in cortex (3mo) and later in thalamus and striatum (6mo) of AD mice compared to the 1 month old mice used as baseline. Wild type mice (WT) were used as controls.
The *ex vivo* results demonstrated increasing cortex to cerebellum ratios from 3 months of age until 12 months. Cortex to thalamus and striatum ratios peaked at 3 months, and later slightly declined as mice aged and amyloid plaques and inflammation started to increase in the thalamus and striatum.
Conclusions
This preclinical study demonstrates the validity of the novel ^{18}F tracer [^{18}F]DPA-714 for the detection of neuroinflammation in a mouse model of AD, and could serve as an alternative to the widely used ^{11}C tracer [^{11}C]PK11195. Funding by: HEALTH-F2-2011-2788850 (INMiND)

ADPD5-1737

CAN RESULTS OF NEUROINFLAMMATION USING NOVEL TSPO TRACERS IN TSPO HAB/MAB SUBGROUP BE TRANSLATED TO THE ENTIRE AD COHORT

Z. Fan[1], D. Harold[2], G. Pasqualetti[1], J. Williams[2], D. Brooks[1], P. Edison[1]
[1]Neurology Imaging Unit, Imperial college London, London, United Kingdom
[2]MRC, Cardiff University, Cardiff, United Kingdom

Objectives: Neuroinflammation plays a significant role in Alzheimer's disease (AD). Novel TSPO PET imaging allows *in vivo* quantification of neuroinflammation, which is dependent on TSPO genotype, with 40-50% increase in BP in high affinity (HAB) compared to mixed affinity (MAB) binders; while low affinity binders (LAB) are unsuitable for evaluation. To translate the findings of neuroinflammation studies to the entire population, it is crucial to establish the influence of TSPO genotypes on AD course. Here we investigated whether different TSPO genotypes have influences on their cognitive function and amyloid load at baseline, and disease progression during follow up.
Methods: We evaluated 798 subjects (225 normal, 388 MCI and 185 AD) from ADNI cohort, who underwent TSPO genotyping (SNP rs6971), MRI, amyloid PET and neuropsychometric assessments with longitudinal follow-up.
Results: The prevalence of genotypes (Thr147Ala, Thr147Thr and Ala147Ala) was similar among AD, MCI and control groups; including sex, age, amyloid status, MMSE, ADAS 11, ADAS MOD and GDS. During the follow up, mean change of neuropsychometric test scores were similar in different genetic groups. The covariates showed that diagnostic group (normal, MCI, AD), ApoE4 status, and gender all had a significant effect on ADAS MOD decline but not age or TSPO genotype.
C**onclusion:** Our findings suggest that the efficacy of intervention studies and observational studies with an anti-glial agent in a TSPO genetic subgroup of high or medium affinity binders could, therefore, be translated to the entire AD and MCI population.

ADPD5-1806

EARLY ASTROCYTOSIS IN AUTOSOMAL-DOMINANT AND SPORADIC AD: A LONGITUDINAL MULTITRACER PET IMAGING STUDY

E. Rodriguez-Vieitez[1], S.F. Carter[1], L. Saint-Aubert[1], O. Almkvist[1], K. Farid[1], K. Chiotis[1], M. Schöll[1], S. Thordadottir[1], A. Wall[2], C. Graff[1], B. Långström[3], A. Nordberg[1]
[1]Neurobiology Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden
[2]Radiology Oncology and Radiation, Uppsala University, Stockholm, Sweden
[3]Department of Chemistry, Uppsala University, Uppsala, Sweden

Objectives: Early astrocytosis was reported from cross-sectional multitracer PET imaging in autosomal-dominant AD (ADAD) and sporadic-AD (sAD)[1]. Here we sought to validate the cross-sectional findings by a longitudinal follow-up investigation in a larger cohort, and investigate regional and temporal distributions of brain astrocytosis, amyloid deposition and glucose metabolism.
Methods: 52 baseline participants (26 followed-up at 2.8±0.6 years) included ADAD-carriers (n=11), non-carriers (n=16), sporadic-MCI (sMCI) (n=17) and sAD (n=8). Participants underwent baseline/follow-up PET-scans with ^{11}C-Deuterium-L-Deprenyl (^{11}C-DED), ^{11}C-PIB, and ^{18}F-FDG; and neuropsychological testing. Linear mixed models (LMMs) were applied to longitudinal PET data versus estimated years to symptoms onset (EYO).
Results: Increased ^{11}C-DED binding and ^{11}C-PIB retention were first observed in ADAD-carriers around EYO ≈ -20 years, and subsequently showed opposite time-courses. ^{11}C-DED binding in ADAD-carriers declined steadily, while ^{11}C-PIB retention showed increase rates, steepest in anterior/posterior cingulate and putamen (≈0.034 SUVR/year). LMMs of ADAD-carriers demonstrated both higher ^{11}C-PIB and lower ^{11}C-DED in symptomatic ADAD-carriers versus sMCI. Presymptomatic ADAD-carriers (EYO ≈ -12 years) showed incipient hypometabolism. ^{18}F-FDG decline rates were largest in caudate and parietal cortices (-0.022, -0.016 SUVR/year respectively) of ADAD-carriers, and in sMCI until 5-years after diagnosis. Hypometabolism was more pronounced in symptomatic ADAD versus either sMCI/sAD.
Conclusions: The longitudinal investigation demonstrated that PET data was reproducible after mean follow-up of 2.8-years, statistically strengthening cross-sectional findings. Early and declining astrocytosis, increasing amyloid-plaque deposition and decreasing glucose metabolism characterized AD evolution. The observed type of early astrocytosis might have downstream pathological consequences, potentially identifying a new therapeutic target.

FDG-PET CT BRAIN CHANGES IN MCI PARTICIPANTS CHARACTERISED BY COGNITIVE DOMAIN

E. Cunningham[1], A.P. Passmore[1], D. Watson[2], A. Crawford[3], B. McGuinness[1]
[1]Centre for Public Health, Queen's University Belfast, Belfast, United Kingdom
[2]Computational Neuroscience, University of Ulster, Belfast, United Kingdom
[3]Geriatric Medicine, Belfast Health and Social Care Trust, Belfast, United Kingdom

FDG-PET CT Brain Changes in MCI Participants Characterised by Cognitive Domain

Objectives

To compare FDG-PET CT brain findings in mild cognitive impairment (MCI) participants according to their cognitive domain classification.

Methods

Participants were recruited as a sub-study within a larger cohort. 36 patients underwent neuropsychological evaluation and PET images were acquired by 'Discovery ST' PET-CT equipment. Spatially normalised images were smoothed with an isotropic Gaussian kernel of 8 mm using the Statistical Parametric Mapping programme implemented in Matlab 7.8.

Groups were compared on a voxel-by- voxel basis using a two-sample t test (SPM8). Significant differences between groups (i.e. normal v deficit) were examined at $p<0.001$ for voxel height, uncorrected with a minimum cluster extent of 20 voxels. Deficits in all domains (memory, executive function, language and visuo-spatial processing) were tested in this manner.

Results

Mean age of participants was 73.4 years (sd7.7), 47% were female. Mean Addenbrooke's Cognitive Examination (ACE) score was 84.33 (sd7.0). Table 1 shows the areas of reduced activation on FDG-PET CT associated with specific cognitive deficits.

Conclusions

Results suggest fairly robust relationships between domains of cognitive impairment and specific regional changes. It would be of interest to continue this work in a larger cohort of participants.

Table 1 Summary of Findings from FDG-PET Analyses in MCI Participants

Normal/Impaired	Deficit	Areas of Reduced Activation
12/24	Memory	Occipital lobe; Sub-lobar, right lentiform nucleus and right thalamus
21/15	Executive function	Frontal lobe; Temporal lobe; Occipital lobe; Sub-lobar, R/L lentiform nuclei
29/7	Language	Frontal lobe
29/7	Visuo-spatial	Extensive multi-lobe deficits

[3]Klinik für Radiologie und Nuklearmedizin, Otto-von-Guericke-Universität, Magdeburg, Germany

[4]Auditory Learning & Speech, Leibniz Institute for Neurobiology, Magdeburg, Germany

Neuronal activity and membrane potential are coupled to transmembrane potassium (K^+)-turnover rates and intra- to extracellular K^+-gradients. We have recently shown, using histochemical methods in rodents, that the K^+-probe thallium (Tl^+) or the lipophilic chelate complex thallium diethyldithiocarbamate (TlDDC), respectively, can be used for mapping acute (stimulus-dependent) and chronic (disease related) changes in neuronal activity as well as a breakdown of neuronal K^+-gradients.

During development of cortical β-amyloidosis in the transgenic 5xFAD mouse model single cell resolution mapping of neuronal thallium uptake revealed that electrical activity of pyramidal cells breaks down throughout infragranular cortical layer V long before cell death occurs (Lison et al., 2014). We here show, in rodent models of neurodegenerative diseases, that pathological alterations in CNS K^+-metabolism can be imaged in vivo using ^{201}TlDDC single-photon emission computed tomography (SPECT).

In still ongoing preclinical studies validating the use of ^{201}TlDDC we found that ^{201}Tl-uptake and -redistribution are severely altered in focal cerebral ischemia and that ^{201}TlDDC-SPECT can be used to dynamically image the progressive breakdown of K^+-gradients as an early indicator of neuronal damage. Preliminary data indicate that uptake and redistribution patterns are altered in mouse models of dementia.

The close coupling of changes in K^+-metabolism and chronic up- or down-regulation of neuronal activity as well as cell death suggests the use of ^{201}TlDDC as a tracer for diagnosing and monitoring neurodegenerative diseases in preclinical and clinical studies.

[4]Department of Nuclear Medicine AD Center,
Charles University Third Faculty od Medicine University Hospital Kralovske Vinohrady, Prague, Czech Republic
[5]AD Center, National Institute of Mental Health, Prague, Czech Republic

Objectives
To develop simple regional semi-quantification of 3D brain perfusion using SPECT and use for of very early Alzheimer disease (AD) diagnostics.
Methods
We transformed SPECT examinations into 3D brains using NeuroGam^{TM}Segami software in 35 cognitively normal controls (NC) (Mini-Mental State Examination (MMSE) 29±1 points) and 33 patients with mild cognitive impairment (MCI) and mild dementia due to Alzheimer disease (AD) (MMSE 26±3 points). Each lobe convexity, cingulum, mediotemporal and frontobasal regions were rated 0,1 or 2 in both hemispheres and combined into a single bilateral score ranging from 0 (normal) to 3 (pathological on both sides).
Results
Since AD patients with MCI and dementia did not differ in age, gender, education, MMSE, any brain perfusion score, we merged them into one AD patient group. In comparison with the NC group, these patients had significantly higher scores of perfusion defects only in temporal and parietal convexity separately on each side and also bilaterally. All other regions including mediotemporal ones were similarly perfused in the patients and in the controls.
Conclusions
Visual rating of 3D Neurogam brain SPECT is a simple and convenient tool for routine clinical practice. Very early AD patients had already incipient perfusion alterations in temporo-parietal regions on both sides. Surprisingly, mild mediotemporal changes were common even in normal seniors and were indistinguishable from those found in AD patients. This unusual pattern for early diagnosis needs further exploration.
Supported by grant IGA NT 13183, PRVOUK 34/LF3 and DRO (PCP, 00023752).

DIFFERENCES IN THE EFFECTS OF VARIOUS DEMENTIA THERAPEUTIC DRUGS - COMPARISON USING ADAS-JCOG AND SPECT –

K. Kanaya[1], S. Abe[1], M. Sakai[1], H. Fujii[1], H. Hanyu[2], K. Koizumi[3]
[1]Geriatric medicine, Tokyo Medical University Hachioji Medical Center, Tokyo, Japan
[2]Geriatric medicine, Tokyo Medical University, Tokyo, Japan
[3]Radiology, Tokyo Medical University Hachioji Medical Center, Tokyo, Japan

[Purpose]
A comparative study was conducted based on changes in Alzheimer's Disease Assessment Scale (ADAS) and SPECT imaging in order to assess differences in the effects of various dementia drugs.
[Methods]
1. The subjects consisted of 274 cases of Alzheimer's disease (AD) being treated in out-patient. The subjects were comprised of 142 cases using Donepezil (Group D), 33 using Rivastigmine (Group R), 32 using Galantamine (Group G) and 14 using Memantine (Group M), and 53 as concomitant drug therapy. Mini Mental State Examinations (MMSE) and ADAS were performed prior to administration and six months after administration of each drugs, followed by a comparative study of changes in scores among each of the drug groups.
2. 226 of the above cases able to undergo SPECT imaging were similarly categorized into groups. 99mTc-ECD SPECT imaging was performed , and changes in cerebral blood flow (CBF) were compared using Statistical Parametric Mapping (SPM-8).
[Results]
1. Groups D and G demonstrated significant improvement with respect to "word recall", and with "following commands" in Group R among ADAS subscales ($p<0.05$).
2. Those sites where CBF increased consisted of the anterior cingulate in Group D, a wide range of the parietal lobe in Group G, the orbital gyrus, straight gyrus, and a portion of the thalamus in Group R, and the occipital lobe, in Group M.
[Discussion]
It`s interesting to note that ADAS subscale showed improvements in that differed among using drugs, and that there was a correlation with sites of improved cerebral blood flow.

IMAGING IN ALZHEIMER DISEASE (AD) TRIALS: IMPACT ON PATIENT RECRUITMENT, RETENTION AND LOGISTICS

K. Shamsi[1]
[1]*Principal, RadMD, New York, USA*

Background: MRI and PET is now extensively utilized in AD trials for patient eligibility, efficacy assessment efficacy, and safety evaluations.
Methods: Standardization of MRI and PET methodology across the sites is essential to acquire consistent data. This requires prospective site qualification, evaluation of phantom data, training and continuous monitoring. standardization is important for estimation of brain volumes and PET data.
Results and discussion:
Patient Eligibility: Many neurological diseases like vascular dementia, multiple sclerosis, vascular pathology, neoplasms have similar presentation as AD or could confound the assessment of drug therapy. Inclusion of wrong patients has ethical and legal issues and data could be excluded from the analysis. Eligibility evaluation and optimization of eligibility read process will be discussed.
Evaluation of Amyloid Related Imaging Abnormalities (ARIA): ARIA were observed in amyloid-β trials. MRI findings of ARIA include vasogenic edema (ARIA E), micro and macro hemorrhages (ARIA H) and superficial siderosis. FDA had mandated frequent MRIs in all AD trials putting burden on sites and patients. Our experience in ARIA evaluations in large phase III study at >350 sites will be presented.
Efficacy evaluation: MRI is utilized to evaluate various volumes of brain. FDG PET has been used to measure metabolic activity of brain. We will share our experience about site and central independent reads.
Conclusion: MRI and PET are used for patient eligibility, efficacy and safety assessments. Imaging must be prospectively planned including standardizing imaging methodologies, site selection process and selecting eligibility and efficacy criteria. Training should be transparently conducted and documented.

THE EFFECT OF NEURODEGENERATION ON THE ANATOMICO-FUNCTIONAL CIRCUITRY OF THE MEMORY NETWORK

H. Burianova[1], L. Marstaller[1], D. Reutens[1]

[1]The Centre for Advanced Imaging, The University of Queensland, Brisbane, Australia

1. Objectives

The objective of the study was to identify the critical alterations in the anatomico-functional circuitry of the memory network that mediate the transition from healthy ageing to Alzheimer's disease (AD). Specifically, we aimed to quantify pathological changes in white and grey matter integrity and relate them to the delineated functional connectivity patterns and measures of cognitive deterioration.

2. Methods

We used diffusion-weighted, structural, and functional magnetic resonance imaging to examine structural and functional changes in three groups of individuals: healthy older adults, adults with mild cognitive impairment (MCI), and patients in early stages of AD. We delineated the functional connectivity of the underlying memory network, modeled the relevant white matter pathways, and measured cortical and subcortical volume of the network's main nodes. We compared the delineated anatomico-structural changes across the three groups of participants.

3. Results

MCI and AD patients showed alterations in the functional connectivity of the memory network, especially in the connections to and from the medial temporal lobe structures, but also between parietal and prefrontal cortices. These changes were significantly more pronounced in AD patients and correlated with measures of cognitive ability. The functional alterations in the memory circuitry correlated with large-scale decreases in cortical volume, hippocampal atrophy, and white matter integrity.

4. Conclusions

Examination of neurodegenerative changes in both the structural integrity and functional connectivity of known networks in patient groups will help identify early signs of AD-related neuronal degeneration and successfully predict later development of dementia in healthy participants.

[2]Department of Neurology, Scientific Institute and University Hospital San Raffaele, Milan, Italy

[3]Department of Neuroradiology, Scientific Institute and University Hospital San Raffaele, Milan, Italy

Objectives. To investigate gray (GM) and white matter (WM) structural changes in Alzheimer's disease (AD) patients and the relationship between biological measures at baseline and their brain structural progressive changes over time.

Methods. T1-weighted and diffusion tensor (DT) MRI from 14 patients with probable AD were obtained at baseline and after a mean follow-up of 16 months. At baseline, CSF samples from patients and MRI from 37 controls were also acquired. Regional GM volume loss and DT MRI metrics from the interhemispheric and major long-association WM tracts were obtained. MRI metrics were compared between patients and controls, and changes over time were evaluated in patients.

Results. Compared to controls, patients showed GM atrophy in the medial temporal and inferior parietal regions, as well as WM damage of the corpus callosum (CC), bilateral cingulum, inferior (ILF) and superior longitudinal fasciculus (SLF), left corticospinal tract and uncinate fasciculus. At follow-up, additional damage was observed in CC, bilateral SLF, right cingulum, and left ILF. No further GM damage was detected. Patients with higher CSF total-tau levels presented greater WM damage over time in the right cingulum.

Conclusions. Although AD patients already presented GM volume loss and reduced WM integrity at baseline, considerable WM changes over time were detected. Interestingly, only WM changes over time in regions typically hit by the disease were related to the baseline high levels of CSF total-tau, suggesting the tau crucial role in predicting WM damage progression once the disease onsets.

ADPD5-1378

THE EFFECT OF GREY MATTER ATROPHY ON FUNCTIONAL ANALYSIS OF THE DEFAULT MODE NETWORK IN ALZHEIMER'S DISEASE AND AMNESTIC MILD COGNITIVE IMPAIRMENT

M. Balthazar[1], M. Weiler[1], B. Machado de Campos[1], T.J. Rezende[1], C.V.L. Teixeira[1], F. Cendes[1]

[1]Neurology, University of Campinas, Campinas, Brazil

Background: It is not completely known how grey matter (GM) atrophy influences the patterns of functional connectivity and activity analyses in Alzheimer's disease (AD) and amnestic Mild Cognitive Impairment (aMCI), especially in the Default Mode Network (DMN). We aimed to compare DMN's functional connectivity (FC) as well as amplitude of low frequency fluctuations (ALFF) measures among mild AD, aMCI and healthy elderly subjects considering GM values.

Methods: We evaluated 72 participants: 29 mild AD, 14 aMCI, and 29 controls in a 3T MRI. DMN was divided in 3 subparts: Frontal, Parietal and medial Temporal. We evaluated anatomical (regional and global cortical thickness and volume) and functional (FC and ALFF) aspects.

Results: AD patients were significantly more atrophic than aMCI and controls considering total GM volume and frontal and temporal DMN. Before atrophy correction, AD patients had lower ALFF values only in DMN's Parietal subpart. Also, AD showed lower FC in frontal and parietal DMN. Regarding aMCI, they were more atrophic than controls only in temporal DMN. Before atrophy correction, they presented higher ALFF values than AD and controls in Frontal DMN; no differences were found in FC in comparison with the other groups.

After GM correction, aMCI patients had lower ALFF value than controls in the temporal DMN. AD DMN's Frontal FC was no longer significantly lower than controls, while all other analysis did not change.

Conclusions: Atrophy did not account as much for the DMN FC analyses, but influenced, at some extent, ALFF measures in AD spectrum.

[3]Department of Radiology, Harvard Medical School, Boston, USA

[4]Institute for Biomedical Engineering, ETH Zurich, Zurich, Switzerland

Introduction: Postmortem neuropathology studies and in vivo MRI studies have demonstrated altered iron levels in both cortical and deep grey matter structures of late stage Alzheimer's patients. Since Abeta plaques start to form long before clinical symptoms occur, sensitive non-invasive in vivo techniques to detect these changes are required for early intervention. Quantitative Susceptibility Mapping (QSM) allows quantitative in vivo mapping of iron levels in the brain using MRI phase data and is more specific than other, e.g. relaxation based, iron measures. By acquiring QSM maps at 7T and Carbon-11 based Pittsburgh compound-B Positron Emission Tomography (PiB-PET) images in patients with mild cognitive impairment (MCI) and age matched controls, we want to confirm the AD biomarker potential of iron levels as detected by QSM.

Methods: 40 elderly study participants aged between 62 and 89 years (22 cognitively normal, 18 MCI), without evidence for significant medical illness, were recruited at our hospital. QSM maps were reconstructed using the phase images of a 3D multi-echo GRE sequence, acquired on a 7T MR scanner (figure shows a healthy control). PiB-PET images were acquired to determine regional Aβ load. Automated atlas based image segmentation and co-registration will be performed to select the regions of interest. Preliminary results will be presented on region based QSM iron levels and the correlation with Abeta load in MCI and controls.

[5]Taub Institute for Research on Alzheimer's Disease and the Aging Brain, College of Physicians and Surgeons Columbia University Medical Center, New York, USA

Introduction: Cerebral accumulation of amyloid-beta (abeta) is a pathological hallmark of Alzheimer's disease (AD), and begins prior to the clinical onset of AD. Abeta deposits can be assessed in vivo using Pittsburgh compound-B positron emission tomography (PiB PET), showing significant amyloidosis of the brain in up to 30 % of healthy elderly individuals. To study the effects of abeta on brain tissue integrity, the individual abeta load was correlated with regional intensities of fluid-attenuated inversion recovery (FLAIR) magnetic resonance imaging (MRI) in asymptomatic elderly subjects.
Methods: All participants (n=14; age=69±8; female/male=6/8) underwent neuropsychological assessment, PiB PET and MRI at high field strength of 7 Tesla including FLAIR and MPRAGE sequences. Volume-normalized signal intensities of PiB PET and FLAIR were calculated based on automated subcortical segmentation of PIB PET, FLAIR and structural MRI volumes. Regional associations between PiB PET and FLAIR signal intensities were investigated using spearman's rank correlation, followed by Holm-Bonferroni correction for multiple testing.
Results: All participants showed normal cognitive performance, and structural analysis indicated no significant brain atrophy. Three anatomical subregions demonstrated significant statistical dependence between volume-normalized PiB PET and FLAIR intensities: hippocampus (right: rho=0.86; left: rho=0.84), brain-stem (rho=0.85), left basal ganglia vessel region (rho=0.82).
Conclusions: We found significant associations between PiB PET and FLAIR MRI signals in the hippocampus and brainstem, suggesting abeta-associated brain tissue abnormalities such as edema in cognitively normal elderly individuals. Further studies are warranted to understand the significance of these results regarding preclinical detection and pathophysiology of neurodegenerative diseases such as AD.

ADPD5-0669

QUANTITATIVE EEG IN PATIENTS WITH ALZHEIMER ´S DISEASE, MILD COGNITIVE IMPAIRMENT AND HEALTHY CONTROLS BEFORE AND AFTER SHORT AND LONGTERM TREATMENT

A. Medvedeva[1]
[1]*Neurological department, First Moscow Medical University, Moscow, Russia*

Objectives. Patients with mild cognitive impairment (amnestic and vascular type) and Alzheimer·s disease (AD) are characterized by changes in spectral power and EEG-coherence, which could be visualized more with specific tests of fatigue.
The aim was to evaluate spectral power and EEG-coherence in MCI, AD patients and healthy elderly controls, to find their reactivity before and after standartized tests on fatigue before and after 3 months and after 2.9 years of treatment with memantine, galantamine and to determine correlations between EEG-changes, cognitive and neuropsychiatric impairments.
Materials and methods. 46 patients with AD, 36 patients with amnestic MCI, 42 patients with vascular MCI, 40 age-matched controls were examined using EEG -recordings, neuropsychological investigations and neuropsychiatric inventory (NPI).
Results. There was found significant increase of slow-wave activity in frontal,central and temporal regions and decreased alpha rhythm in the same regions in both MCI groups vs controls (<0.05), in AD vs controls , which become significantly stronger after tests on fatigue. Coherence in the same regions was significantly lower in both groups of MCI vs controls(p<0.05), AD vs MCI, AD vs controls.
We found significant positive dynamic in EEG-changes on short and longterm treatment after tests on fatigue (p<0.05).
Conclusions. EEG changes before and after tests on fatigue , cognitive and neuropsychiatric impairments have positive dynamic on short and longterm treatment. Significant positive dynamic in spectral power and EEG-coherence was visualized especially after standartized probe on fatigue, which could serve a specific indicator of the dynamic and efficacy of treatment patients with AD and both MCI types.

VIRTUAL ELECTRO-PHYSIOLOGICAL MARKER REFLECTING CHOLINERGIC ACTIVITY IN THE BRAIN : PROPERTIES IN VARIOUS DEMENTIAS AND PROGRESSION OF AD

K. Johnsen[1], G. Johannesson[1], M. Johannsson[1], N. Blin[1], A. Emilsdottir[1], J. Snaedal[2], T. Gudmundsson[2], B. Einarsson[2]
[1]Research and Development, MentisCura, Reykjavík, Iceland
[2]Geriatrics, Landspitali University Hospital, Reykjavík, Iceland

Objectives

Demonstrate and profile the properties of an EEG based AchIndex in an elderly population of both healthy controls and patients suffering from different stages and types of dementia.

Methods

An electroencephalography (EEG) based acetylcholine (Ach) index reflecting cholinergic activity in the brain was developed using data from a scopolamine challenge study. A data-driven approach incorporating statistical pattern recognition methods and a genetic algorithm was used to select the relevant features from the EEG. To demonstrate the applicability of the AchIndex its behaviour was comprehensively examined using EEG recordings from an elderly population of both healthy controls and patients suffering from various causes of cognitive decline (N=1054).

Results

The AchIndex showed a strong reduction in the severe stages of AD dementia ($p<0.001$), in which lower cholinergic activity was expected. A high correlation was also demonstrated between the Ach Index and cognitive function as estimated by MMSE ($r=0.52$, $p<0.001$) and DSST ($r=0.57$, $p<0.001$). The index was reduced in patients with MCI and prodromal AD ($p<0.001$), indicating decreased cholinergic activity and contradicting previous post-mortem findings.

Conclusion

The AchIndex provides a physiological means of virtually monitoring cholinergic activity. This has great potential for aiding diagnosis and patient stratification, for monitoring disease progression and treatment response, and for assisting further research into dementia.

ADPD5-1472

EEG SOURCE RECONSTRUCTION AND ASSOCIATIVE MEMORY TESTS FOR THE DETECTION OF ASYMPTOMATIC ALZHEIMER'S DISEASE

R. Jagger[1]

[1]*Psychology, University of Bolton, Bolton, United Kingdom*

The ability to differentiate between those people who will go on to develop Alzheimer's disease (AD) from normal ageing adults, at the earliest possible time point, is of primary importance. Episodic memory problems are a central feature of Alzheimer's disease. However, in the asymptomatic stage of AD, no explicit difference in memory performance can be observed, as it has been shown that compensatory activity within the episodic memory network, especially in the pre-frontal cortex, is initially successful in overcoming the pathological changes in medial temporal lobe areas. Recent advances in EEG techniques, including source reconstruction procedures, make it a good candidate for providing a simple biomarker for detecting these compensatory changes in neural activity. Furthermore, as task difficulty increases in certain types of memory test, it can be assumed that the compensatory activity will increase or breakdown. Our laboratory is designing a series of associative memory tasks that are completed whilst EEG recordings are taken. Advanced analysis including source reconstruction should theoretical allow for the detection of compensatory processes and be sufficient to differentiate between normal and pathological ageing.

Results will be presented from a healthy young adult sample to illustrate how this technique could be applied to detection of AD at the asymptomatic stage and how advances in EEG analysis could prove to be an important and cost-effective biomarker.

ADPD5-1521
THE CORRELATION OF QUANTITATIVE EEG AND MEDIAL TEMPORAL LOBE ATROPHY IN ALZHEIMER'S DISEASE
J.Y. Ahn[1], J.H. Heo[1], B.K. Kim[2]
[1]Neurology, Seoul Medical Center, Seoul, Korea
[2]Neurology, Eulji university hospital, Seoul, Korea
Backgrounds: The electroencephalogram (EEG) abnormalities in Alzheimer's disease (AD) have been widely reported, and medial temporal lobe atrophy (MTLA) is one of the hallmarks in early stage of AD. We aimed to assess the relationship between EEG abnormalities and MTLA and its clinical validity. **Materials and Methods:** A total of 18 patients with AD were recruited (the mean age: 77.83 years). Baseline EEGs were analyzed with quantitative spectral analysis. MTLA was assessed by a T1-axial visual rating scale (VRS). **Results:** In relative power spectrum analysis according to the right MTLA severity, the power of theta waves in C4, T4, F4, F8, and T5 increased significantly and the power of beta waves in T6, C4, T4, F8, T5, P3, T3, and F7 decreased significantly in severe atrophy group. In relative power spectrum analysis according to the left MTLA severity, the power of theta waves in T3 increased significantly and that of beta waves in P4, T6, C4, F4, F8, T5, P3, C3, T3, F3, and F7 decreased significantly in severe atrophy group. **Conclusions:** The severe MTLA group, regardless of laterality, showed more severe quantitative EEG alterations. These results suggest that quantitative EEG abnormalities are correlated with the MTLA, which may play an important role in AD process.

ADPD5-2013

GENDER DEPENDENT DIFFERENCES IN QUANTITATIVE NEURO-ELECTRIC ACTIVITY PATTERNS IN HEALTHY AND MILDLY COGNITIVELY IMPAIRED SUBJECTS: A RETROSPECTIVE ANALYSIS

M. Windisch[1], *W. Dimpfel*[2]
[1]*Clinical Pharmacology, NeuroScios GmbH, Graz, Austria*
[2]*Clinical Pharmacology, NeuroCode AG, Wetzlar, Germany*

Objective. Mild cognitive impairment (MCI) is regarded as a transitional stage in the development of Alzheimer disease. MCI can be recognized by changes in EEG. The present retrospective analysis of several clinical studies was undertaken in order to sort out if there are gender dependent quantitative differences in brain regions in healthy subjects in comparison to cognitively mildly impaired subjects older than 40 years.
Methods. EEG recordings were taken using the CATEEM®. Spectral power - averaged during recordings of 5 minutes duration – was compared during relaxed states “eyes open” as well as during different cognitive tests. Data from 90 male and female subjects were grouped and statistically compared for 102 parameters by Wilkinson- Mann-Whitney non-parametric statistical tests and fed into linear discriminant analysis.
Results. Recording in the relaxed state revealed increases in spectral power in the left occipital region in both genders, but decreases in spectral alpha2 and beta power in the left frontal and temporal lobe only in male MCI subjects in comparison to healthy controls. During performance of the d2-test only in males significantly less left frontal delta and theta spectral power was observed. During performance of a calculation test or the memory test only in male subjects (MCI) significantly higher spectral power was documented in the left occipital region but decreases in the temporal lobe on both genders. Gender dependent differences were confirmed by discriminant analysis.

CALPAIN INHIBITORS INCREASE THE RELEASE OF ACETYLCHOLINE AND RAPID EYE MOVEMENT (REM) SLEEP

K. Wicke[1], K. Drescher[2], A. Kling[3], W. Hornberger[4], A. Möller[4]
[1]Pharmacology, AbbVie Germany, Ludwigshafen, Germany
[2]Neuroscience, AbbVie Germany, Ludwigshafen, Germany
[3]Neurochemistry, AbbVie Germany, Ludwigshafen, Germany
[4]Biology, AbbVie Germany, Ludwigshafen, Germany

Calpains are a family of calcium-dependent cysteine-proteases that proteolyze a wide variety of cytoskeletal, membrane-associated, and regulatory proteins and are activated in pathologic processes in the CNS including neurodegenerative diseases like Alzheimer´s disease (AD). Today, inhibitors of acetylcholine esterase (AChEI) represent the AD standard treatment. Such compounds increase the extracellular levels of acetylcholine thereby stimulating cholinergic receptors.

Objectives: We have synthesized a series of calpain inhibitors which besides their neuroprotective effects increase extracellular ACh levels. We investigated whether calpain inhibitors similar to the effects of AChEIs increased extracellular ACh and thereby stimulate REM sleep in polysomnographic studies suggesting its use as translational biomarker for clinical studies.

Methods: In rats we investigated the effects of the prototypic calpain-inhibitor A-705253 (K_i=56 nM) on acetylcholine release in the frontal cortex and hippocampus by *in vivo* microdialysis. In a rat polysomnographic study we also analyzed the sleep EEG.

Results: A-705253 induced a dose-related increase of acetylcholine levels in both brain regions suggesting potential pro-cognitive effects. A-705253 also increased REM parameters without affecting total sleep time.

Conclusion: The calpain inhibitor-induced increase of extracellular acetylcholine translates into increased REM sleep. Such effects have been observed in healthy volunteers and AD patients after treatment with AChEIs. This suggests the usefulness of polysomnographic studies as translational biomarker for the clinical development of calpain inhibitors.

Disclosures: All authors are employees of AbbVie. The design, study conduct, and financial support for this research was provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the publication.

ADPD5-2147

LONG-TERM EEG IS NECESSARY FOR DETECTING EPILEPTIC EEG-SIGNS IN PATIENTS WITH DEMENTIA

A. Horváth[1], A. Szűcs[1], G. Barcs[1], A. Kamondi[1]
[1]Neurology, National Institute of Clinical Neurosciences, Budapest, Hungary

Objectives
Major neurocognitive disorders represent a serious socio-medical and economical issue. An elevated risk of seizures has been shown in conditions with dementia, especially in Alzheimer's disease (AD). Several studies highlighted the major impact of seizures and epileptic activity on the progression of cognitive decline. Electroencephalography (EEG) is the tool for detecting dementia-related epileptic signs and clarifying unnoticed seizures.
In the framework of the Alzheimer-Epilepsy Project of the National Brain Research Program of Hungary, we compared the sensitivity in detecting interictal and ictal epileptic EEG signs of 'routinely' applied 30 minutes EEGs and 24 hours' EEG recordings in patients with dementia.
Methods
We performed 24 hours portable EEGs in 5 AD patients clinically suffering from epilepsy. We segmented the recordings into 30 minute-long epochs. We calculated the proportion of epochs with no ictal or interictal epilepsy pattern in the whole recording. The sleep-related distribution of the epochs containing epilepsy signs as well as the epochs' relation with REM or non-REM sleep was analyzed and calculated.
Results
60 percent of the 30 minute-long epochs did not contain any epileptiform activity. The occurrence of epochs containing interictal or ictal EEG patterns was higher during non-REM sleep.
Conclusions
Interictal and ictal EEG patterns are missed in 60 percent of 30 minute-long 'routine' EEGs. Long-term EEG is significantly more sensitive in capturing epileptiform activity in AD patients with epilepsy. Sleep EEG is especially useful, significantly increasing the chance of detecting epilepsy.

[5]NVS department, Karolinska Institutet, Stockholm, Sweden
[6]Dept of Neurology, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark
[7]Dept of Geriatric Medicine, Deakoness Hospital, Copenhagen, Denmark

Background: The aim of the study was to examine the discriminatory power of the quantitative EEG (qEEG) applying the statistical pattern recognition (SPR) method to separate Alzheimer's disease (AD) patients from elderly persons without dementia and from other dementia patients.

Methods: Participants were recruited from six Nordic memory clinics, 372 unselected patient, mean age 71.7 (s.d. 8.6), 54 percent women and 146 healthy old people, mean age 66.5 (s.d. 7.7), 60 percent women. After a standardized and comprehensive assessment clinical diagnoses were made according to international accepted criteria by at least two clinicians. EEG was recorded in a standardized way and analyzed independently of the clinical diagnoses using the SPR method

Results: In receiver operating characteristic (ROC) analyses the qEEG separated AD from healthy old person with an area under the curve (AUC) of 0.90, representing sensitivity (SS) of 84 percent and specificity (SP) of 81 percent. The qEEG further separated patients with Lewy body dementia or Parkinson's disease dementia from AD with AUC of 0.9, SS 85 percent and SP 87 percent.

Conclusion: The qEEG using the SPR method could be a useful tool in the dementia diagnostic work-up.

1H-MRS CHANGES IN PATIENTS WITH MILD COGNITIVE IMPAIRMENT

I. Lupanov[1], V. Lobzin[1], S. Vorobyev[1], A. Emelin[1], V. Fokin[2], A. Sokolov[2]
[1]nervous diseases, Military-medical academy n.a. S.M. Kirov, St-Petersburg, Russia
[2]radiology, Military-medical academy n.a. S.M. Kirov, St-Petersburg, Russia

1H-MRS allows to reveal quantitative changes in brainmetabolites which reflects the violation of functional activity ofstrategically important areas preceding the development of structural damage.
The purpose of research was to investigate thecerebral metabolism in patients with mild cognitive impairment (MCI) using forfinding a reliable marker of the pathological process at early stages of thedisease.
The study involved 38 persons aged 62 to 74 years(mean age 68,6 ± 6,3 years) with MCI of alzheimer's and vascular etiology, and20 healthy volunteers as a control group. Region of interest was cingulategyrus.
Was found that Alzheimer's group characterized by the increaseof inositol, choline, lactate, as well as reduction of N-acetylaspartate,glutamate/glutamine and creatine, more expressed in the posterior part of thecingulate gyrus. Diagnostically significant was the increase in theratio Ins/Cr over 0,76 ± 0,31 and Cho/Cr over 1,47 ± 0,69.
In vascular MCI were identified an increase of choline,lactate and decreased N-acetylaspartate and creatine in all parts of thecingulate gyrus, in the absence of significant changes in inositol andglutamate / glutamine. Diagnostically significant was the increase in theratio Cho/Cr over 1,39 ± 0,36 at normal ratio of Ins/Cr.
Thus, the use of 1H-MRS may be effective in clinicalpractice for early diagnostic of cognitive impairment of neurodegenerative andvascular etiology.

[3]Department of Clinical Sciences, Lund University, Lund, Sweden

[4]Deparment of Psychiatry and Neurochemistry, The Sahlgrenska Academy, Gothenburg, Sweden

Objective: A potential biomarker for predicting onset and progression of Alzheimer's disease is proton magnetic resonance spectroscopy (MRS). We aimed to determine the correlation of MRS brain metabolite concentrations with Aβ deposition measured by positron emission tomography (PET), cerebrospinal fluid (CSF) markers and ApoE in cognitively healthy elderly participants and individuals with mild cognitive complaints.

Methods: Study participants (N_{CTL}=215, N_{MCI}=285) underwent MRS and CSF collection; ^{18}F-flutemetamol PET scans and ApoE status were available for a subset of patients. MRS was collected at 3 Tesla from a 2x2x2cm^3 voxel placed bilaterally in precuneus/posterior cingulate. Concentrations of N-acetyl-aspartate (NAA), myo-inositol (mI) and choline (Cho) were evaluated relative creatine (Cre). Study sample was divided into groups based on CSF Aβ42 levels (Aβ42 ≤ 530 ng/L was considered pathological). Subjects with mild cognitive complaints were also divided based on the nature of the cognitive impairment (subjective or objective).

Results: In controls with asymptomatic amyloidosis (CSF Aβ42 ≤ 530 ng/L), we found that tracer uptake in the precuneus was associated negatively with NAA/Cre (Spearman r_s = -0.42, p<0.001) and positively with Ins/Cre (r_s = 0.57, p<0.001), controlling for age, gender and spectral signal to noise ratio (SNR). In biomarker-positive controls and biomarker-negative MCI there were significant negative associations between CSF Tau and NAA/Cre. Healthy ApoE ε4 carriers had higher myo-inositol levels than non-carriers; interaction between age and carrier status significantly modulated Ins/Cre concentrations.

Conclusions: In preclinical AD, several changes in the MRS neurochemical profile are associated with known pathological processes such as Aβ42 deposition.

RED BLOOD CELL FATTY ACIDS ARE SIGNIFICANTLY ALTERED IN SOUTH AUSTRALIAN MILD COGNITIVE IMPAIRMENT AND ALZHEIMER'S DISEASE COMPARED TO CONTROLS

P. Thomas[1], S. Lee[1], M. Fenech[1], J. Hecker[2], J. Faunt[3]
[1]Food and Nutrition, CSIRO, Adelaide, Australia
[2]Internal Medicine, Royal Adelaide Hospital, Adelaide, Australia
[3]general Medicine, Royal Adelaide Hospital, Adelaide, Australia

Objectives
This study aimed to determine the red blood cell (RBC) fatty acid profile of newly diagnosed individuals with mild cognitive impairment (MCI) or Alzheimer's disease (AD) relative to each other and to age and gender matched controls.
Methods
Fatty acids were measured using the one step extraction and transesterification procedure
Results
There was a significant increase in palmitic acid ($p<0.0001$) for both MCI and AD cohorts. Further MCI saturated fats were significantly elevated including stearic acid ($p=0.0002$), arachidic acid ($p=0.0003$), behenic acid ($p=0.0003$), tricosanoic acid ($p=0.003$) and lignoceric acid ($p=0.0009$). The monounsaturated fatty acid elaidic acid was significantly elevated in both MCI and AD ($p=0.002$). N6 polyunsaturated fatty acids (n-6 PUFA) were significantly reduced in MCI including linolelaidic acid ($p=0.001$), γ-linolenic acid ($p=0.03$), eicosatrienoic acid ($p=0.01$), and arachidonic acid ($p<0.0001$). The n-3 PUFA Linolenic acid and docosahexaenoic acid were both significantly reduced in MCI and AD ($p<0.0001$). For MCI the area under the ROC curve (AUC) was >0.80 for eight fatty acids and for AD the highest AUC was 0.79 for elaidic acid and 0.75 for palmitic acid. Cross-correlation analysis between the Mini-mental state examination (MMSE) score and the RBC fatty acid analysis showed a positive correlation between MMSE score and nervonic acid in MCI ($r=0.54$, $p=0.01$) and a negative correlation with γ Linolenic acid in AD ($r=-0.43$, $p=0.05$).
Conclusion
Significant differences in RBC fatty acid profiles of MCI and AD individuals may prove to be useful potential biomarkers reflecting increased risk for dementia.

CYP2D6 GENE AND PLASMA CONCENTRATION OF S-DONEPEZIL AS BIOMARKERS TO PREDICT AND EVALUATE CLINICAL OUTCOME OF DONEPEZIL IN CHINESE ALZHEIMER'S DISEASE PATIENTS

J. Lu[1], L.L. Wan[1], Q. Yu[1], Y. Zhong[2], C. Guo[2]
[1]Department of Pharmacy,
Shanghai Jiaotong University Affiliated Sixth People's Hospital, Shanghai, China
[2]Department of pharmacy,
Shanghai Jiaotong University Affiliated Sixth People's Hospital, Shanghai, China

Donepezil (DNP) has been approved for the treatment for mild-to-moderate Alzheimer's disease (AD), but the therepeutic response rate varies from 20 to 60%. It lacks convenient and effective blood biomarkers to evaluate clinical outcome of DNP in early stage of medication. Our study is the first explored the target enzymes which is dominant in the metabolism of DNP *in vitro*, by clarifying the metabolism mechanism of DNP especially the effects of different types of cytochrome P450 enzymes on metabolism of two DNP chiral enantiomers .We identified CYP2D6 is the predominant P450 enzyme which has largest Clint in DNP liver metabolism , and CYP2D6 gene polymorphisms which have high variation rate in Chinese play different roles in metabolism of *S*-DNP and *R*-DNP. Secondly, we confirmed the *in vitro* experimental results n 64 Chinese AD patients, by separation and quantitation of pharmaco-effective *S*-DNP and genotyped CYP2D6 enzyme types (CYP2D6*1, CYP2D6*1*10, CYP2D6*10) ,in relation to clinical outcome of DNP. There is statistical correlations among effective *S*-DNP Cp/dose (steady-state plasma concentration/dose), CYP2D6 alleles (CYP2D6*1, CYP2D6*1*10, CYP2D6*10) and DNP clinical outcome. Conversely, there is no statistical difference in racemic DNP Cp/dose between responders and nonresponders, also no statistical difference n racemic DNP Cp/dose among the three CYP2D6 alleles .
Our results suggested that plasma concentration of *S*-DNP and CYP 2D6 gene (CYP2D6*1,CYP2D6*1*10 and CYP2D6*10) which exists the high mutation frequencies in Chinese, are potential blood biomarkers in early stage to predict and evaluate DNP clinical outcome in Chinese AD patients.

ADPD5-0508
PREPARATION AND STABILITY TESTING OF A QUALITY CONTROL MATERIAL FOR NEUROCHEMICAL DEMENTIA DIAGNOSTICS ASSAYS

P. Lewczuk[1], N. Lelental[1], J. Kornhuber[1]
[1]Psychiatry and Psychotherapy, Universitätsklinikum Erlangen, Erlangen, Germany

Objectives: (a) to prepare and test samples of different matrices to be used as quality control (QC) material for the Neurochemical Dementia Diagnostics (NDD); (b) to test short- and long-term stability of the NDD biomarkers (Amyloid β (Aβ) peptides and Tau/pTau proteins) in different matrices; (c) to test if antibacterial stabilizing component improves the stability of the samples and (d) to provide results enabling preparation of samples for an external quality control scheme (EQCS).
Methods: Large volumes of samples were prepared of: (a) human pooled cerebrospinal fluid (CSF), (b) artificial Aβ peptides dissolved in pre-diluted human plasma, and (c) Aβ peptides diluted in BSA/PBS. In addition to native material, samples containing antibacterial stabilizer were also tested. For a short term stability, the samples were stored for 1-14 days: (a) at room temperature, (b) refrigerated, and (c) under -20°C, following deep-freezing (isochronous method). All aliquots of a given matrix were then thawed and analyzed on one ELISA plate per biomarker to avoid the influence of inter-assay variability.
Results: In most cases, all the samples were be short-term stabile under all three conditions, with somehow better stability of the samples stored at -20°C. Addition of a stabilizer did not influence the stability of the biomarkers in any of the matrices.
Conclusions: Our results show that it is plausible to use a non-tailored, assay manufacturer-independent QC samples for controlling quality of the NDD assays performance. Currently, a project is running to test different matrices for their utility in an inter-center EQCS.

AMYLOID BETA 42/40 CSF CONCENTRATION RATIO WITH TWO NOVEL ASSAYS FOR AN EARLY DIAGNOSIS OF ALZHEIMER'S DISEASE

P. Lewczuk[1], J.M. Maler[1], N. Lelental[1], P. Spitzer[1], J. Kornhuber[1]
[1]Psychiatry and Psychotherapy, Universitätsklinikum Erlangen, Erlangen, Germany

Objectives: (a) to technically validate two novel assays (IBL International GmbH, Hamburg, Germany) specifically measuring Amyloid β (Aβ) 1-42 and Aβ1-40 in human cerebrospinal fluid (CSF); (b) to compare the diagnostic utility of Aβ42/40 Ratio and Aβ1-42 CSF concentration.
Methods: The novel Aβ1-40 and Aβ1-42 ELISA assays have been analytically validated considering their specificities, linearity, precision, repeatability of the standard curves, and recovery. In the clinical study, the hypothesis was tested if CSF Aβ42/40 concentration ratio gives better separation of AD and controls compared to the CSF Aβ42 concentration alone.
Results: The assays characterized with only marginal cross-reactivity (Aβ42 vs. Aβ40); recoveries were in the range of 85–100% for Aβ1-40, and 92–104% for Aβ1-42. For Aβ1-40, the intra-assay, the inter-assay, and the inter-lot imprecision were 2.1%, 4.4%, and 5.4%. For Aβ1-42, the numbers were 3.1%, 6.2%, and 6.9%, respectively. The imprecision of the optical densities of the standards (ten repetitions) was equal or less than 5% for all standards. Aβ1-42 showed the sensitivity and the specificity of 69.3 %, and 88.9%, respectively, Aβ42/40 ratio showed even better sensitivity and specificity of 93.3 %, and 100 %, respectively. The area under the ROC curve for Aβ42/40 (0.974) was highly significantly larger compared to the AUC of the Aβ1-42 concentration ROC curve (0.827, $p<0.0001$).
Conclusions: (a) the novel Aβ1-40 and Aβ1-42 ELISA assays characterize with very good analytical performance; (b) we reconfirm that the CSF Aβ42/40 concentration ratio shows significantly better diagnostic performance compared to the CSF Aβ1-42 concentration alone.

SEARCHING FOR A MOLECULAR SIGNATURE OF ALZHEIMER'S DISEASE IN DOWN SYNDROME PLASMA

M.F. Iulita[1], F. Caraci[2], A.C. Cuello[1]
[1]Pharmacology and Therapeutics, McGill University, Montreal, Canada
[2]IRCCS Associazione Oasi Maria S.S.,
Institute for Research on Mental Retardation and Brain Aging, Troina, Italy

Individuals with Down syndrome (DS) are at increased risk of developing Alzheimer's disease (AD) compared to the normal population. As a consequence of chromosome 21 trisomy, they progressively develop amyloid plaques, neurofibrillary tangles and CNS inflammation. Although the pathology of AD and DS is multifactorial, in both disorders there is a progressive degeneration of forebrain cholinergic neurons, which depend on nerve growth factor (NGF) to maintain a healthy phenotype. Notably, the proper maturation of the NGF precursor and the degradation of mature NGF are compromised in AD and DS brains.

Diagnosing AD in DS is challenging due to the underlying intellectual disability and cognitive decline associated with aging. Therefore, identifying novel biomarkers of an evolving pathology is a major unmet objective, with significant clinical impact.Toward this aim, we have obtained plasma samples from DS cases comprising the following subgroups: 1) young DS subjects (20-34 years), 2) older DS subjects without dementia and 3) DS with dementia (35-60 years); including age-matched controls. Amyloid-β peptides were quantified using a multiplex array (MesoScale Discovery, USA). $A\beta_{38}$ was detectable in only 40% of samples, with no apparent differences between control and DS subjects. Conversely, $A\beta_{40}$ was significantly elevated in DS, with the highest levels detected in plasma from adult DS subjects with and without dementia. Levels of $A\beta_{42}$ were higher in DS compared to controls but significantly elevated only in cases with dementia. Our long-term objective is to monitor these markers longitudinally, obtaining plasma from the same patients 9-12 months after the first blood draw.

IMPACT OF FREQUENT CSF SAMPLING ON CSF ABETA LEVELS: SYSTEMATIC APPROACH TO ELUCIDATE INFLUENCING FACTORS

B. Van Broeck[1], M. Timmers[2], J. Bogert[3], M. Mercken[1], J.R. Streffer[2]
[1]Neuroscience Drug Discovery, Janssen Research & Development, Beerse, Belgium
[2]Neuroscience Experimental Medicine, Janssen Research & Development, Beerse, Belgium
[3]Clinical Biostatistics, Janssen Research & Development, Raritan, USA

Objectives
Cerebrospinal fluid (CSF) Aβ peptides are core biomarkers for Alzheimer's disease and have been proposed as pharmacodynamic markers in amyloid-lowering therapies. This is challenging, as frequent sampling with catheterization technique results in increased CSF Aβ levels compared to baseline. We assessed the impact of sampling frequency, schedule and sample volume on CSF Aβ levels using continuous CSF sampling over 36 hours.
Methods
Healthy participants (55 to 85 years of age) were randomized into 1 of 3 cohorts (n=6/cohort). All 3 cohorts were subjected to high-frequency CSF sampling: Cohorts 1 and 3 sampling started immediately post-catheterization; Cohort 2 sampling started 6 hours post-catheterization. Cohort 3 received ibuprofen (800 mg) before lumbar puncture. In an additional cohort 4 (n=6) an optimized sampling scheme, based on interim data review from cohorts 1-3, was applied. CSF Aß1-37, Aß1-38, Aß1-40 and Aß1-42 levels were assessed.
Results
Increases and fluctuations in mean CSF Aß1-40 levels were noted in cohorts 1-3 at times of high frequency sampling. Inter-participant variability was noted in all cohorts regarding the increase in CSF Aß levels. The optimized sampling scheme in cohort 4 (lower frequency and volume) resulted in low fluctuation of CSF Aß1-40 on group and individual level.
Conclusions
Increases and fluctuation of CSF Aß levels are primarily dependent on sampling frequency and not the catheterization procedure. Optimized sampling scheme and volume results in reduced to no relevant increase of CSF Aß levels, which will improve the predictive value when using this technique as a pharmacodynamic marker for amyloid-lowering therapies.

ADPD5-0842
DEVELOPMENT OF NEW MASS SPECTROMETRY BASED ASSAYS FOR ANALYSIS OF HUMAN CEREBROSPINAL FLUID

G. Brinkmalm[1], A. Brinkmalm[1], F. Duits[2], P. Scheltens[2], C.E. Teunissen[3], W.M. van der Flier[2], H. Zetterberg[1], K. Blennow[1]
[1]Neuroscience and Physiology, University of Gothenburg, Mölndal, Sweden
[2]Alzheimer center & Department of Neurology, VU University Medical Center, Amsterdam, Netherlands
[3]Clinical Chemistry, VU University Medical Center, Amsterdam, Netherlands

Introduction:
Mass spectrometry (MS) is well suited for biomarker analysis, diagnosis, prognosis, and theragnosis of many neurological diseases, including Alzheimer's disease (AD). The MS based assays are flexible and can easily be adjusted.

Objective:
The objective was to develop MS based assays to monitor cerebrospinal fluid (CSF) proteins using relatively little CSF. The assays should be robust, sensitive, and fast enough to allow analysis of larger study sets.

Methods:
Three different panels were developed. Panel 1 consisted of six high-to-medium abundant proteins previously implicated in AD. Panel 2 contained seven proteins involved in synaptic functioning. Panel 3 was a single protein panel for investigation of potential differences in processing pattern of amyloid precursor protein.
A set of 120 CSF samples (40 controls, 40 mild cognitive impairment, and 40 AD) were selected from the Amsterdam Dementia cohort. Trypsinated CSF was analyzed using microflow liquid chromatography coupled to a high resolution mass spectrometer (Q Exactive).

Results:
The overall CV was <3% for all three panels. Of the proteins investigated neurosecretory protein VGF showed decreased levels in AD, while the remainder showed no or little difference between controls and AD. Interestingly several proteins showed increased levels in the MCI group; the reason for this is presently unclear and requires further investigation.
For complex samples high resolution instrumentation is advantageous because of the superior ability to handle signal interferences.

ADPD5-0843

AUTOMATION OF COMMERCIAL AMYLOID-BETA AND TAU ELISAS WILL LOWER INTER-LAB VARIABILITY

O. Schmidt[1], A. Matzen[2], G. Göttner[2], I. Lachmann[3]
[1]Product Managment, IBL International GmbH, Hamburg, Germany
[2]Product Development, IBL International GmbH, Hamburg, Germany
[3]R&D, AJ Robboscreen GmbH, Leipzig, Germany

Background:
Measuring Amyloid-beta 1-42, Amyloid-beta 1-40 and Total Tau in CSF becomes more and more accepted as diagnostic tools in the clinical work up of Alzheimer's disease patients. Yet, available Quality assessment schemes show a high variability between labs lowering the trust in these biomarkers. One reason amongst others for these high variations might be linked to lab-specific differences in working up manual assays (e.g. sample predilution, operator qualification). This source of variation can possibly be reduced using fully automated systems.
Methods:
IBL International deliberately developed its Amyloid-beta (1-42), Amyloid-beta (1-40) and Total Tau ELISAs with easy-to-use protocols and ready-to-use reagents allowing adaption on any type of open ELISA processors. The performance of our assays was done with IBL International's quality control sample panel, that is composed of pooled CSF samples spiked with recombinant peptide spanning the entire range of the assays. Performance criteria were inter-, intra- assay and intra-platform variability.
Results:
The reagent composition of IBL International's Amyloid-beta and Total Tau assays and the manual protocols are highly compatible to all used open ELISA processors, as there were Dynex DSX, Siemens BEP2000 and the Tecan EVOLyzer. All automated procedures highly correlated with the manual procedures and stabilized the already very good low manual variability.
Conclusion:
Automation of IBL International's Amyloid-beta and Total Tau ELISAs is easily achieved on different automation platforms thus biomarker measurements in different labs will become less error prone and will have reduced variability and therefore become more trustworthy.

ADPD5-0859
IDENTIFICATION OF SYNAPTIC PROTEINS DETECTABLE IN THE CEREBROSPINAL FLUID IN THE SEARCH FOR BIOMARKERS OF PRECLINICAL ALZHEIMER'S DISEASE

O. Belbin[1], G. Gomez-Giro[1], L. Muñoz[1], D. Alcolea[1], M. Colom-Cadena[1], M. Carmona-Iragui[1], J. Fortea[1], J. Clarimon[1], A. Bayés[2], A. Lleó[1]
[1]Memory Unit, Biomedical Research Institute Sant Pau (IIB-SantPau), Barcelona, Spain
[2]Molecular Physiology of the Synapse Laboratory,
Biomedical Research Institute Sant Pau (IIB-SantPau), Barcelona, Spain

Objectives: To identify and quantify synaptic protein levels in cerebrospinal fluid (CSF) in the search for biomarkers of synaptic loss at the preclinical stage of AD. **Methods:** The CSF proteome was constructed by performing a proteomic study of the CSF of 50 cognitively healthy controls and 10 age-matched AD patients (mean age=64 years). Samples were pooled, immunodepleted, digested, and analysed by liquid chromatography mass-spectrometry. The synaptic proteome was constructed by retrieving proteins from a systematic literature search of proteomic studies of mouse, rat or human synaptic fractions (n=16) and proteins annotated with a synaptic function in the Gene Ontology, Kegg and SynSysNet databases. **Results:** In total, CSF proteomic profiling identified 2,482 proteins (1,826 from control pools and 1,705 from the AD pool). Cross-referencing the CSF (n=2,482) and synaptic proteomes (n=3,359), resulted in 817 CSF proteins functionally and/or topographically related to the synapse. Proteins considered to be non-specific to the synapse (expressed at ≥moderate/medium levels in glia or neuronal soma and ≤moderate/medium levels in the neuropil of the human cortex according to the 'Human Protein Atlas' database) were subsequently removed leaving 192 proteins (8% of the CSF proteome). Quantification of these proteins in CSF from cognitively healthy controls, age-matched AD and preclinical AD cases using targeted mass spectrometry is currently underway. **Conclusions:** By performing a detailed characterization of the CSF and synaptic proteomes, we have identified 192 synaptic proteins detectable in the CSF, which, if confirmed as biomarkers of synaptic loss, could be invaluable for the diagnosis of preclinical AD.

Objective

To predict progression from Mild Cognitive Impairment (MCI) to Alzheimer's Disease (AD) by combining information from diverse groups of variables.

Methods

We combined variables from the AD Neuroimaging Initiative (ADNI) database including clinical, cognitive, proteomic, genomic, and imaging variables as well as demographics to build models that predict progression to AD 12-72 months from baseline assessments (n=94 MCI subjects). To that end, we performed joint variable selection and classification and compared performances of predictive models using variables from each data type independently and from the fully merged dataset.

Results

Signatures predicting mid-term progression (within 24 and 36 months) proved to be more robust in terms of sensitivity, specificity and stability than signatures for faster or slower progression. The best predictive model for progression from MCI to AD within 36 months (30 with stable MCI and 39 progressors to AD) involved a combination of 6 proteins measured in plasma and CSF (80% classification accuracy, 88% sensitivity, 70% specificity). These identified proteins are linked to AD-related biological processes. Interestingly, including imaging or cognitive variables in the model did not improve classification accuracy.

Conclusions

There is a clear need for developing better tests to identify individuals with early AD and a high risk to progress to AD in order to support clinical trials design and development of novel therapies. Our results suggest that combining different types of molecular biomarkers which represent different aspects of AD pathology can improve prediction of progression to AD.

RATIONAL DESIGN OF ENVIRONMENT SENSITIVE FLUOROPHORES FOR DETECTION OF AGGREGATED AMYOID PROTEIN BIOMARKERS IN NEUROLOGICAL DISEASES

K.J. Cao[1], K.M. Elbel[1], L. Fu[1], C.J. Sigurdson[2], E.A. Theodorakis[1], J. Yang[1]
[1]Chemistry and Biochemistry, University of California San Diego, La Jolla, USA
[2]Pathology, University of California San Diego, La Jolla, USA

Objectives

We describe the development of a class of environment-sensitive amino-aryl nitrile fluorophores that show an enhancement of fluorescence upon binding amyloid aggregates and the capability to discriminate amyloid-beta, prion, and alpha-synuclein species by their emission wavelengths. Utilizing this property, we seek to further investigate and characterize the amyloid basis of neural pathologies including Alzheimer's Disease (AD) and prion disease.

Methods

Fluorophore design was guided by a modified Lippert equation for solvatochromism where we model the relationship between probe fluorescence emission wavelength and the amyloid binding pocket microenvironment. We tuned fluorophores to improve both the sensitivity to different amyloid species as well as their biocompatibility. *Ex vivo* histological staining of neuronal amyloid-beta deposits from AD mice models and human AD cases, as well as prion plaques in innoculated mice models, were performed to evaluate our design features.

Results

By modifying the fluorophore core of the molecules, we developed a series of compounds with enhanced discrimination capabilities towards differentiating between amyloid-beta and prion plaques in hippocampal and cortical tissue. We have also improved biocompatibility by red-shifting emission towards the near-infrared and increasing their stability in biological environments. Finally, we generated a library of characteristic fingerprints for several amyloids associated with neurological disorders by their unique emission signatures.

Conclusions

We show the potential application of a new class of biocompatible amyloid-binding fluorophores with discriminatory properties as a diagnostic tool for the detection and identification of neurodegenerative amyloid biomarkers.

[7]Neurology, Dong-A University Medical Center, Busan, Korea
[8]Neurology, Inha University School of Medicine, Incheon, Korea

Objectives: The levels of plasma Aβ have been studied as a marker of Alzheimer's disease (AD), however the results were inconsistent. Recently accumulating evidences support the heterogeneity of AD. It is possible that the inconsistency is from the inhomogeneity of the subjects at least partly. We evaluate the validity of plasma levels of Aβ40, Aβ42, and their combined ratio in relation to AD including early onset AD without known AD mutations.
Methods: This study was conducted as a part of the Center for Dementia of South Korea study. We have consequently enrolled the clinical probable early-onset AD patients (EOAD) with positive AD biomarkers from February 2013 to June 2014. Plasma levels of Aβ40 and Aβ42 were measured using sandwich enzyme-linked immunosorbent assay.
Results: The plasma levels of Aβ40 and combined ratio of Aβ40/Aβ42 were significantly higher in sporadic EOAD patients compared with controls. According to the presence of APOE*ε4* allele the levels of Aβ40, Aβ42, and Aβ40/Aβ42 ratio were not altered. The integrity of blood-brain barrier (BBB) was disturbed in sporadic EOAD groups revealing higher cerebrospinal/plasma albumin ratio. Although there was a tendency of inverse correlation between Aβ40 level and BBB integrity, it did not reach statistic significance. On multivariate analysis considering various covariates, higher plasma Aβ40 levels and Aβ40/Aβ42 ratio were still found to be highly valuable in discriminating AD from controls.
Conclusions: We found that the plasma levels of Aβ40 and Aβ40/Aβ42 ratio have a high validity in discrimination of sporadic EOAD from age-matched controls.

[3]Old Age Psychiatry, Institute of Psychiatry Psychology and Neuroscience (IoPPN), London, United Kingdom

[4]Department of Psychiatry, University of Oxford, Oxford, United Kingdom

Objective

Expression of Clusterin has been shown to be significantly elevated in AD brain and several molecular forms of clusterin have been reported to correlate with AD progression. Clusterin contains six N-linked glycosylation sites, three in the α subunit (α^{64}N, α^{81}N and α^{123}N), and three in the β subunit (β^{64}N, β^{127}N, and β^{147}N) and because glycosylation plays an important role in the physiological functions of clusterin, we hypothesised that the detailed glyco-peptide profiling of plasma clusterin might reveal disease-relevant isoforms and enable a better understanding of clusterin structure-function relationships associated with AD.

Methods

Following immuno-precipitation and SDS-PAGE, the characterisation of glycosylated peptides from human plasma clusterin was performed by LC/MS/MS using an Orbitrap Fusion Tribrid mass spectrometer.

Results

Having comprehensively described 42 distinct clusterin glyco-peptides, we further hypothesised that the overall glycopeptide profile may be useful as a diagnostic tool, especially since the difference in glycosylation patterns associated with distinct glycosylation sites may prove relevant to disease status. To explore this possibility, we compared the clusterin glycoform distribution in plasma obtained from a set of low atrophy (n=13) and high atrophy (n=14) subjects attending the memory clinic.

Conclusions

We will present the results of this study and also describe the development of a targeted glyco-peptide Selective Reaction Monitoring (Glyco-SRM) assay to measure selected glycans specifically associated with β^{64}N. The Glyco-SRM assay now facilitates high throughput testing of β^{64}N Clusterin glycoforms within larger cohorts of clinical specimens.

[6]www.alzheimer-europe.org, United Kingdom

Objectives: Hippocampal subfields are differentially affected in Alzheimer's Disease. However, their volume reproducibility has never been investigated. We report the evaluation of the across-session test-retest reproducibility of the hippocampal subfields segmentations derived from FreeSurfer.

Methods: Five healthy local volunteers (55-90 ys) were enrolled in 13 3T MRI sites (Siemens, GE, Philips) across Europe and were scanned in two sessions a week apart. Hippocampal subfields segmentation was performed using the longitudinal pipeline of Freesurfer. For each site and ROI, volumes reliability was computed evaluating test-retest absolute differences relative to the mean (absolute error) and intraclass correlation coefficient (ICC).

Results: Analysis was focused on: Cornu Ammonis (CA) 1, CA2-3, CA4-dentate gyrus (DG), subiculum, presubiculum, fimbria and hippocampal fissure. Absolute errors across MRI sites were comparable to those found for total hippocampus and in the range 1.5–5.0% for CA1, CA2-3, CA4-DG, subiculum, presubiculum and 15-25% for fimbria and hippocampal fissure. The ICC results were in line with the absolute error analysis (from 0.94 to 0.99 except for fimbria and hippocampal fissure where was in the range 0.79-0.95).

Conclusions: Despite the differences of the 13 MRI scanner configurations we found consistent hippocampal subfields reproducibility across sites. Test-retest reproducibility was lower in smaller relative to higher volumes. The poor reproducibility of fimbria and hippocampal fissure should be considered in studies involving subfield volumes to differentiate MCI from AD or to predict the conversion from MCI to AD. Pharmacog is funded by the EU-FP7 for the Innovative Medicine Initiative (grant n°115009).

A NOVEL IMMUNOASSAY FOR LONGITUDINAL MEASUREMENTS OF AMYLOID-BETA OLIGOMERS IN HUMAN CSF WITH POTENTIAL TO ASSESS THERAPEUTIC RESPONSE TO IMMUNOTHERAPY

M. Matijevic[1], F. Bernier[1], J. Kaplow[2], H. Desmond[1], J. Chow[1], Y. Oda[1], T. Lawton[3], V. Logovinsky[2]

[1]Eisai Product Creation Systems, Eisai Inc., Andover, USA

[2]Neuroscience and General Medicine, Eisai Inc., Woodcliff Lake, USA

[3]Biotechnology, Aliquot LLC, Gorham, USA

Objectives: Develop an ELISA to: 1) quantify amyloid beta (Abeta) oligomers in CSF of Alzheimer dementia (AD) and cognitively normal age-matched controls (CN), 2) examine longitudinal analyte stability and 3) correlate levels with MMSE.

Methods: In the ELISA, a mAb that preferentially binds multimeric Abeta species was used for capture (1g5 mAb, Aliquot LLC.). For detection, an Abeta N-terminal mAb, biotiniylated-82E1 (Covance) was used. The Meso Scale Discovery platform was used to establish the ELISA, synthetic Abeta protofibrils were used to generate the standard curve. Both inter- and intra- assay variability was <10%. Commercial longitudinal CSF samples (PrecisionMed Inc.) from the same subjects were tested.

Results: The assay detected Abeta oligomers in both AD and CN CSF, with AD demonstrating significantly higher levels compared with CN (p=0.0025). In this sample set of 10 AD patients, longitudinal Abeta oligomer and MMSE levels were relatively stable over 1 year. AD patients with lower average MMSE scores had higher average CSF Abeta oligomer levels.

Conclusions: Quantification of Abeta oligomers in CSF was achieved. Endogenous Abeta oligomers in CSF exhibited relative stability over the course of one year which suggests potential utility for assessing pharmacodynamic effects of treatments that target oligomers. There appears to be a moderate correlation (r^2=0.4149, p=0.0001) between MMSE scores and CSF Abeta oligomer levels in this subset of AD patient CSF samples that warrants testing of additional longitudinal CSF samples collected over a longer period of time.

[4]Pharmacology Department, Universidad de Navarra, Pamplona, Spain
[5]Biochemestry Department, Universidad de Barcelona, Barcelona, Spain

Objectives: Levels or the cyclic nucleotides cGMP or cAMP that play important roles in memory processes are not characterized in Alzheimer´s disease (AD). The aim of this study was to analyze the levels of these nucleotides in cerebrospinal fluid (CSF) samples from patients diagnosed with clinical and prodromal stages of AD and study the expression level in the brain of the enzymes that hydrolized them (phosphodiesterases: PDEs).
Methods: For cGMP and cAMP CSF analysis the cohort (n=79) included cognitively normal participants (SCI), individuals with mild cognitive impairment stable or AD converters (sMCI and cMCI) and mild AD patients. A high throughput LC-MS/MS method was used. Interactions between CSF cGMP or cAMP with MMSE score, CSF Aβ(1-42), and CSF p-tau were analyzed. For PDE expression analysis, brains of AD patients *vs* controls (n=7 and n=8) were used.
Results: cGMP, and not cAMP levels, were significantly lower in the CSF of patients diagnosed with mild-AD when compared to non-demented controls. cGMP reduction in CSF compartment showed a strong association to MMSE-diagnosed clinical dementia and to CSF biomarker Aβ42 within AD patients. Significant increase in PDE5 expression was detected in temporal-cortex of AD patients compared to that of age-matched healthy control subjects. No changes in the expression of others PDEs were detected.
Conclusions: These results support the potential involvement of cGMP in the pathological and clinical development of AD. The cGMP reduction in early stages of AD might participate in the aggravation of amyloid pathology and cognitive decline.

EVALUATION OF RETINAL CHANGES IN MILD COGNITIVE IMPAIRMENT, ALZHEIMER DEMENTIA, NON-ALZHEIMER DEMENTIA AND PD

J. Pillai[1], R. Bermel[1], A. Bonner-Jackson[1], H. Fernandez[1], A. Rae-Grant[1], J. Bena[2]
[1]Neurology, Cleveland Clinic, Cleveland, USA
[2]Quantitative Health Sciences, Cleveland Clinic, Cleveland, USA

Background
Retinal nerve fiber layer (RNFL) thickness has been reported as a biomarker of Alzheimer's (AD) and PD. Previous studies had lacked detailed clinical characterization of the patients with MRI volumetric analysis and neuropsychology evaluation to corroborate diagnosis. In this study we evaluate if retinal biomarkers relate to the degree of cognitive impairment in amnestic MCI, AD dementia, non-AD dementias, PD and differentiate them from age and sex matched controls in a well characterized cohort.
Methods
20 patients each of amnestic MCI, AD dementia, non-AD dementia and PD diagnosed after comprehensive neurological, neuropsychology evaluation and MRI volumetry were studied with 40 age and sex matched controls.Iin vivo cross-sectional RNFL thickness, macular volume and ganglion cell layer thickness (GCL) were measured by Optical coherence tomography (OCT) using Zeiss Cirrus 4000 spectral domain machine. Analysis of variance models were used to compare groups on MRI measures, cognitive test results and OCT measures. Associations between OCT measures and other measures were performed using mixed effect models.
Results
None of the groups differed from controls on RNFL thickness, macular volume and GCL thickness. Mean and Std Dev of Optic Disc average RNFL thickness OD: Controls (85.1±8.1), MCI (90.1±6.8), AD (88.5±8.0) Non-AD (89.4±15.5), PD(90.9±10.8). OS: Controls (86.1±8.8), MCI (89.6±7.0),AD(89.1±9.2),non-AD dementia(90.1±8.6), PD(87.9±14.0). No correlation between cognitive scores and OCT measures were noted.
Conclusions
OCT analysis of retinal biomarkers did not differentiate between the amnestic MCI, AD dementia, PD and non-AD dementia from age and sex matched controls in a well characterized patient cohort.

SPEECH DISORDERS IN ALZHEIMER´S DISEASE
P. Walecki[1], E.J. Gorzelanczyk[2], M. Kunc[3]
[1]Department of Bioinformatics and Telemedicine,
Jagiellonian University Medical College, Krakow, Poland
[2]Department of Theoretical Basis of Bio-Medical Sciences and Medical Informatics,
Nicolaus Copernicus University Medical College, Bydgoszcz, Poland
[3]Airedale NHS Trust Steeton, University of Leeds, Leeds, United Kingdom
Aims
Aim of the study is to evaluate the oral-motor speech disorders in Alzheimer´s disease as compared to the speech disorders occurring in the physiological process of aging.
Materials and methods
We examined 22 patients with Alzheimer´s disease (AD) at the age of 68 to 90 years. In all subjects with AD were diagnosed the initial stage of the disease with preserved speech processing and communication ability. The control group (C) consisted of 22 people. The test has 5 parts: dialogic speech, descriptive speech, naming, repeating simple & complex sentences, and repeating monosyllabic (easy) & polysyllabic (difficult)) words & nonsense words, and speaking automated verbal sequences. All studies were recorded in order to supplement the quantitative information on a sheet of observation, and a detailed analysis of the structure of speech.
Results
Statistically significant differences between AD and C groups in the number of correct and incorrect answers were found. The greatest difference was found between AD and C groups in the descriptive speech. During the repetition of monosyllabic and polysyllabic words in AD occurred significantly more often the articulation errors on repeated speech productions of the same utterance.
Conclusion
The results confirmed the presence of oral-motor speech disorders in Alzheimer´s disease. It was stated articulation errors, periphrases and jams. These errors occur in the structure of lexical-semantic and phonological system of the language. No abnormalities were noted in the area of grammar.

THE LYMPRO® ASSAY: A BIOMARKER FOR ALZHEIMER'S DISEASE USING BLOOD SAMPLES FROM CLINICALLY DIAGNOSED ALZHEIMER'S DISEASE AND COGNITIVELY INTACT SUBJECTS

L. Kirby[1], P. Jorgensen[2], M. Sarno[3], C. Bier[4]
[1]Medical Director, Amarantus Bioscience Holdings, San Francisco, USA
[2]Laboratory Development Director, Amarantus Bioscience Holdings, San Francisco, USA
[3]Statistical analysis, Vision Biotechnology Consulting, San Diego, USA
[4]Diagnostics Lead, Amarantus Bioscience Holdings, San Francisco, USA

Objective A blood biomarker would be advantageous for early identification of Alzheimer's disease (AD). Multiple reports have identified Cell Cycle Dysregulation as a key pathology in AD. Furthermore, it appears likely that this dysfunction is systemic, affecting peripheral blood lymphocytes as well as neurons. This study measures lymphocyte proliferation in response to a mitogenic stimulus to quantify the extent to which lymphocytes have entered the cell division cycle. It potentially represents a blood-based biomarker for AD.

Methods Whole blood samples obtained from 72 subjects (36 AD and 36 age matched controls) were shipped to a reference laboratory (Becton Dickinson) for flow cytometry analysis. Statistical analysis methods included uni- and multivariate receiver-operating curve (ROC) and logistic regression analysis, and calculation of diagnostic performance parameters.

Results Interim analysis demonstrated significant areas under the ROC curve for univariate measures including CD19, CD3+4, CD3+8, CD14, and CD45. These markers were also highly correlated to MMSE scores. On univariate analysis, sensitivity of 66.7% at 83.3% specificity was achieved by the CD3+8 marker. Multivariate model building yielded maximal AUC of 0.871 (odds ratio=24.0) and sensitivity and specificity of 80% and 85.7% at the optimal cutpoint.

Conclusions In this interim analysis, the LymPro assay provides multiple univariate indicators and multivariate combinations, which discriminate AD from controls. The assay appears to be a robust and reproducible measure of a key pathology of AD and the findings corroborate previously published LymPro findings. Final data from the current study will be completed by the time this abstract is presented.

PLASMA IL-6 AND TRAIL IDENTIFIED AS BIOMARKERS OF ALZHEIMER'S DISEASE

Y. Wu[1], J. Hsu[2], I. Cheng[3]
[1]Neurology, Show-Chwan Memorial Hospital, Chunghua, Taiwan
[2]Dementia Center, Linkou Chang-Gung Memorial Hospital, Taoyuan, Taiwan
[3]Institute of Brain Science, National Yang-Ming University, Taipei, Taiwan

Objectives
Several biomarkers including inflammatory biomarkers of Alzheimer's disease (AD) were reported inconsistently. We aim to identify biomarkers of AD to improve diagnostic accuracy at mild stage.
Methods
Patients with age older than 50 years and being diagnosed as AD fulfilled revised NINCDS criteria of year 2007 were included to the disease group. For subjects enrolled in normal control group, no memory problem was complained, and the score of AD8 below 2 or Montreal Cognitive Assessment (MoCA) score above 26. We evaluated the relationship between potential blood and CSF inflammatory biomarkers, cognitive status, and disease severity. Inflammatory biomarkers including IL-6 and TRAIL levels were measured.
Results
We enrolled 45 subjects in the disease group and 40 subjects in normal control group. The majority of subjects in the disease group were mild AD. Elevated levels of plasma IL-6 and decreased levels of plasma TRAIL in the disease group were noted compared to control group. In small number of subjects (n=6), plasma levels of IL-6 and TRAIL were highly correlated with each of their CSF levels ($p<0.05$ and $p<0.01$, respectively). Plasma levels of IL-6 and TRAIL were significantly correlated with each of their CSF levels.
Conclusions
Plasma IL-6, and TRAIL are identified as biomarkers of AD at early stage. Highly correlated plasma and CSF biomarkers levels found in IL-6 and TRAIL might implicate in the strong connection between peripheral and central inflammatory cytokines.

ADPD5-1722

CSF BIOMARKER VARIABILITY IN THE ALZHEIMER´S ASSOCIATION QUALITY CONTROL PROGRAM

S. Persson[1], U. Andreasson[1], K. Blennow[1], H. Zetterberg[1]
[1]Psychiatry and Neurochemistry, University of Gothenburg, Mölndal, Sweden

Background

The Alzheimer's Association quality control (QC) program for biomarkers in cerebrospinal fluid (CSF) enables participating labs to monitor their performance of measuring tau and Beta-Amyloid proteins using enzyme-linked immunosorbent assays (ELISA). The goal is to reduce site-to-site variation, harmonize levels and pave the way for uniform cut-off levels.

Methods

The Alzheimer's Association QC program consist of three rounds each year and at each round, three samples of pooled CSF prepared at the Clinical Neurochemistry Laboratory at the University of Gothenburg, Sweden, are analyzed byparticipating laboratories for tau and Beta-Amyloid proteins by ELISA based assays.

Results

The coefficients of variation (CV) between the laboratories using Fujirebio ELISA kits have so far been around 15-29% for Beta-Amyloid1-42, 12-28% for Total-tau, and 12-28% for Phospho-tau, while the between laboratories CV in the newly introduced ELISAs with ready to use calibrators this far is 6-11% for Beta-Amyloid 1-42, 6-13% for Total-tau and 7-17% for Phospho-tau.

For the Meso Scale Discovery new validated V-Plex kit results of the latest round the between laboratories CV% for Beta-Amyloidx-42, Beta-Amyloidx-40 and Beta-Amyloidx-38 were between 7-20%.

Conclusions

The overall variability of CSF biomarker measurements are still too high (target variability may be below 10-15%) to allow assignment of universal cut-off values for a specific intended use. But with the introduction of validated and ready to use kits it looks like steps in the right direction is made and with introduction of new assays in coming rounds exiting efforts from the industry is made.

ADPD5-1799
PLASMA CHOLINE ACETYLTRANSFERASE IN PATIENTS WITH COGNITIVE IMPAIRMENT AND AD
A. Karami[1], H. Eyjolfsdottir[1], E. Jodlowska[2], A. Nordberg[1], M. Eriksdotter[1], T. Darreh-Shori[1]
[1]Department of Neurobiology Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden
[2]Department of organic chemistry, Poznan University of Medical Sciences, Warsaw, Poland
Objectives: Decrease in cholinergic neurotransmission is observed in AD and cholinesterase inhibitors (ChEI) treatment can only delay its progression. The acetylcholine synthesizing enzyme, choline acetyltransferase (ChAT) is recently shown to exist in CSF and plasma. We have hypothesized that it regulates the extracellular ACh levels, which may in turn have an impact on the patients' prognosis and cognitive performance. The aim of this study was to measure activity and protein levels of ChAT in plasma, and to investigate the influence of different ChEI treatment on levels of plasma ChAT in AD patients.
Methods: Plasma samples were taken from ChEI-naïve subjects with AD (32), MCI (30) and SCI (22). Plasma samples at baseline, 3 and 12 monhts were also taken from AD patients treated with rivastigmine (11) or tacrine (17).
Results: The plasma ChAT activity and protein concentration were higher in AD patients compared to MCI and SCI patients (*p<0.0001*). Plasma ChAT activity correlated with the patients' cognitive test scores in MMSE after 12 months of treatment with tacrine. In the rivastigmine group, changes in the plasma ChAT protein showed 146% significant increase in patients with less annual cognitive decline.
Conclusions: This study shows for the first time that plasma ChAT differs between AD, MCI and SCI patients, which might allow to distinguish patients in different stages of dementia. The correlation between plasma ChAT and MMSE scores, suggests ChAT as a potential plasma biomarker for monitoring treatment effect.

ADPD5-2243

BINDING IN VISUAL WORKING MEMORY: A COGNITIVE BIOMARKER FOR EARLY ALZHEIMER'S DISEASE?

M. Heider[1], M. Betts[2], Y. Pertzov[3], E. Düzel[1], M. Husain[4]
[1]University of Magdeburg, Institute of Cognitive Neurology and Dementia Research, Magdeburg, Germany
[2]University of Magdeburg, German Centre for Neurodegenerative Diseases, Magdeburg, Germany
[3]The Hebrew University of Jerusalem, Psychology Department, Jerusalem, Israel
[4]University of Oxford, Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom

Introduction:
Binding single features to coherent objects in visual working memory (VWM) is impaired in early Alzheimer's dementia (AD) and asymptomatic individuals with familial AD, suggesting this may be an important cognitive biomarker for early detection and monitoring of individuals at risk of AD. We investigated healthy elderly people with impaired binding, comparing them to elderly and young individuals with intact binding.

Methods:
We tested 39 healthy elderly (69.2±4.9y) and 19 young (24.4±2.4y) participants on an object-location VWM task and performed structural brain MRI on them. On each trial, participants had to remember the identity and location of 1 or 3 objects. We analyzed memory for object identity and localization as well as identity-location binding performance. A median split was performed on the elderly according to binding ability. Imaging data were analyzed using voxel-based morphometry (VBM).

Results:
There was an age-related impairment in memory for object identity and localization. The low binding group was significantly impaired in object localization memory for 3 items compared to the high binding group. Crucially, their deficit in location memory could be fully explained by decreased binding performance. VBM showed structural alterations associated with a binding deficit in medial prefrontal cortex and left anterior cingulate cortex.

Conclusions:
Binding ability varied in elderly individuals who performed alike on all other measures. Its potential as a screening tool in AD will be evaluated in follow-up studies examining cognitive decline in individuals with impaired versus intact binding ability.

PARKINSON'S DISEASE BIOMARKER DISCOVERY USING SOMASCAN PROTEOMIC TECHNOLOGY

J. Ash[1], B. Liu[1], M. Lawton[2], Y. Ben-Shlomo[2], M. Hu[3], D. Grosset[4], S. Lovestone[1]
[1]Psychiatry, University of Oxford, Oxford, United Kingdom
[2]School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom
[3]Division of Clinical Neurology, University of Oxford, Oxford, United Kingdom
[4]Institute of Neuroscience and Psychology, University of Glasgow, Glasgow, United Kingdom

Objectives: Discovery of a blood-based biomarker that detects pre-clinical neurodegenerative disease could greatly accelerate the development of targeted therapeutics aimed at prevention. Such an approach is proving to be promising for Alzheimer's and may also be successful for Parkinson's disease (PD). Mapping Proteomics to Parkinson's Disease (MAP2PD) is a multi-phase programme funded by Parkinson's UK, aimed at the discovery and validation of a protein signature in the blood to detect and track progression in early PD.

Methods: In the discovery phase, we used an apatmer-based technology (SomaLogic ,Inc.), that quantified 1129 plasma proteins from 161 PD subjects (disease duration < 3 yrs) and 66 controls, age- and gender-matched. In addition to a case-control design, an endophenotype approach was used to define PD subgroups by cognitive and motor severity. Both regression and machine-learning models were then employed to analyse proteins associated with PD outcomes.

Results: A total of 55 proteins were differentially expressed in PD versus controls at $p < 0.05$. Multivariate analyses revealed a subset of 22 proteins that differentiated PD from controls with an area under the curve of 0.91, after controlling for covariates. Some of the proteins identified showed clinical and biological significance, which will be explored further in larger samples.

Conclusions: The discovery phase revealed a preliminary but promising set of biomarkers that will be tested for replication in larger samples in Phase 2, with subsequent biological validation. These data point to the potential for blood-based biomarkers to be used for early diagnosis of PD.
